MR. RECORD: We make no penalty, only in so far as costs are concerned. The only "no lost time" accidents that are taken into consideration are those where a medical expense is involved.

ERNEST AUGUSTUS (Mead Pulp and Paper Co., Chillicothe, Ohio): In our plant where an injury may be simply a case of sickness, we make a record of it and try to estimate what that cost is. Or, where an injured man may come in five or six times for redressing an estimate is made of that cost.

JOHN LUNDRIGAN (International Paper Company, N. Y.): We have a chart that unfortunately isn't quite ready, a very simple one, and in it we show the information for each individual mill—not only the cost per ton, but the cost per individual employee on account of accidents. The cost includes everything that has to do with the accident. The administration or routine of industrial accidents and the paying out of pocket are entirely separate, being carried on by two different departments.

Without giving the exact figures, our insurance premium in Massachusetts, the only state where we are compelled to hire out insurance, on our small mill in that state, is between \$3,000 and \$4,000. This premium is supposed to be better than others. The actual money paid by the insurance company is around \$500.

Someone has said that there is a difference in relative hazards in the new mills and the old ones, but note what is happening in our Three Rivers Mill in the Province of Quebec, which is supposed to be the last word, as against Record's mill, which is a very old one. On account of the unusual requirements with respect to the Compensation Law, the costs in the Canadian mill are much more in proportion. There are no boards and no commissions; we have to go directly to the courts. To go about a legal settlement of a case, when a man is incapacitated for a single day, we have to have our document signed by the judges of two separate courts. You can't go to the courts without a lawyer, and that usually incurs an expense of \$40 to \$50 before you are through with one of them.

A Duty to Study and Correct All Accidents

As to the cost of insurance, we are confronted with this in seven states and in the Province of Quebec. I do not have the exact figures with me but I think you will agree that about \$3.25 on each \$100 of the payroll is about the average paper mill cost. Our office carries the item of insurance at seventy cents. We have individual mills that carry their insurance at forty-five cents. Mr. Record's mill is one of them. That account is carried by the department of insurance and taxes. Allowing ourselves the difference between average premiums and our actual costs we have as a result a surplus running pretty well into two million dollars.

In our General Instructions No. 75 it is one of the duties of the mill to study and correct any cases of near-accidents. Our safety organization takes the same steps in bringing these things to the attention of the management as though a man had been killed.

In accidents that do occur involving no lost time, that 339 form which you just saw must always be made out. When the question arises, "What can be done to remedy such accidents?" we say, "What have you done to carry out your own recommendations?" If those questions aren't answered, we shoot the report right back to the mill. We want to know, and to be in a position to let other mills know, what ideas some of the other mills have developed.

As far as literature is concerned, we have had several inquiries as to whether or not these instructions issued by the International Paper Company were available for distribution. This subject of accident prevention is covered so completely, that we probably have 100 pages of instructions in these different pamphlets. The International Paper Company does not have the printing facilities to supply them, as everybody at the convention would want one, the trade journals would want them; and

I tell you frankly that the principal reluctance we have is that we're afraid these people won't use them when they get them. We have a long way to go—probably farther than we'll ever reach, but we have done a great deal in the cutting down of preventable accidents in our ten years of experience in this work.

B. D. ROGERS (Bird & Son Inc., E. Walpole, Mass): In the first record that was shown, was it the medical department that made out that report?

MR. RECORD: It originates in the first aid department. It is filled out there to the extent of the injury, and states how the injury occurred.

MR. ROGERS: My point in bringing this up is that we have made a very complete form, and we put it entirely up to the foreman. In that way, the foreman has to know about everything that happens. Do your foremen enter into it?

MR. RECORD: Only in so far as an accident or near-accident is concerned. The safety supervisor is supposed to interview the man personally and find out all about it.

MR. ROGERS: Our method is to put it up to the foremen and they are responsible more or less for the accident. I believe that since we have instituted this very complete form, we have gotten the foremen to realize the very valuable function of this report.

MR. RECORD: We have a small foreman's report which is turned into the first aid room. It does not go into the detail, but just shows they were notified of the accident.

MR. ROSEBUSH: May I state our own experience in that line? We will not accept an accident report unless the foreman's name is signed to the report. There is another report made by the nurse, so we have a double check.

MR. LUNDRIGAN: We say to the mill manager, "This safety supervisor is your safety department, and part of our staff, and he is responsible for seeing that this information is put together. The foreman is on record, the nurse and doctor and witnesses are on record, but we must pin it down to some individual to see that the report is complete. This report is not complete until it is signed personally by the mill manager himself.

CHAIRMAN GLEASON: I think that is covered in our mill too. She (the nurse) makes out the report and then turns it over to me. I then send it out to the foreman to get his comments.

The next speaker on the program is Mr. B. D. Rogers, manager, Labor Bureau, Bird and Son, E. Walpole, Mass. Mr. Rogers is supervising some 2,700 or 2,800 employees, and anyone with that to do has a program on his hands.

Plant Inspection and Safety Committees

B. D. Rogers, Manager, Labor Bureau, Bird & Son, East Walpole, Mass.

This paper on Plant Inspection and Safety Committees will center around the methods which we feel have proved fairly successful in our plants.

The first point, and one that I believe everyone interested in the safety movement agrees upon, is that the best, or even satisfactory, results can be obtained only when every member of the working organization is heart and soul in safety work. By that I mean the owners, the management, the supervisors and the workers. Everyone in the organization is jointly responsible for the success and promotion of safety as an integral part of any mill.

In our company the safety organization consists of a central safety committee, five local plant safety committees and the safety inspector.

The function of the central safety committee is to direct and keep alive all matters pertaining to safety. Its membership consists of the general manufacturing manager, assistant manufacturing manager, plant engineer,

superintendents of all plants, chief engineer, safety inspector and manager of labor bureau.

Our local plant safety committees consist of from ten to fifteen members depending upon the number of departments or workers in those plants. The superintendent of each plant is the permanent chairman of the committee. The other members include both foremen and workers. Appointments are made every six months by the central safety committee upon recommendation by the superintendent. Usually a member continues on the committee for a year so that only one half of the committee changes at one time.

Our safety inspector is directly responsible to our general manufacturing manager and, hence, his work is directive and official. His inspections are regular and continuous, and deal with:

Points Covered by Inspections of Safety Inspector

1. *The elimination of accident hazards through unsafe conditions and careless practices.* This means the recommendation of safeguards, safe working conditions, repairs to dangerous equipment, etc., and the correction of working habits of men and women who do not follow safe practices.

2. *The maintenance of safe working by cooperation with the foreman.* The inspector should see that the safety idea is always kept before the men. If a machine has a guard, he should see that it is used or kept in place. If a safety rule is established, he should see that the rule is followed at all times. If he condemns any equipment, he should see that it is repaired or destroyed. Every new employee is interviewed by the inspector during his first week of employment.

3. *The follow-up and investigation of accidents that do happen.* He receives a report of every accident that occurs and he should follow up these reports with a thorough investigation of the accident, which means inspection of the place where the accident occurred, talk with injured man, with the foreman and further interviewing of many others who might give light on where, how, or why the accident happened. His report covers his own views regarding the accident and he should make recommendations as to how its recurrence can be prevented.

4. *Co-operation with insurance and other outside agencies.* The safety inspector should at all times accompany representatives from the state departments and insurance companies who come to inspect the plant. By doing this he can not only point out to the inspector the work done in the plant, but he can receive from him many ideas and anecdotes from other plants that will help him in his work.

5. *Fire prevention.* In some plants the same man handles fire inspection who handles safety. Except in a small plant, this is not the best arrangement. The safety inspector should have enough to do in working on all the phases of safety unless, of course, he works in an industrial Utopia where all hazards are guarded, no one is careless, and there are never any accidents. Safety work in plants employing 1,000 workers or more is a one man job. It is not a job for a man who must devote part of his time in trying out fire extinguishers, testing fire alarms, or filling in on other odd jobs. If he is to be heart and soul with safety, he must do safety work and nothing else.

As I have said before, the safety inspector should report to a high official in the company, the higher in authority the better for him and for safety. He should not be forced to argue with a foreman of a department as to whether a guard is needed on some machine or not. If he, the inspector, after thorough investigation believes that there should be a guard, his word should be backed up solidly by his superior.

Everyone in the plant down to the lowest worker should know that what the inspector says goes—not that he should be feared, but he should above all things be respected.

The work of the plant safety committees, on the other hand, is of utmost importance in selling the safety idea to the workers throughout the organization. The suggestions made by the members of the plant committees should and do receive careful consideration. If a safety committeeman makes a suggestion that is adopted, it so appears in the records, and when possible is given sufficient publicity so that all workers will know that the committeemen are on the job and that their work is backed up and appreciated by those in authority. To bring up a good suggestion, have it receive only grudging attention, and then see the same idea later adopted as coming, say, from a foreman is discouraging to any safety committeeman and may result in it being the last suggestion that he ever makes.

Plant Safety Committees Meet at Least Once Each Month

Plant safety committees should meet regularly at least once a month, oftener if necessary. In our plants the names of committeemen are posted in the departments in which they work so that all employees know who the safety man is in their section. We also publish pictures and names of all committees in our plant paper so that they are known to everyone and we encourage their fellow-workers to go to them with their safety suggestions.

The method of plant inspections by the safety committees vary in our different plants and from time to time. In some committees two or three members are delegated to act as unofficial inspectors for that month, while in others all members of the committee are delegated to inspection tours. These men are released from their jobs for as long a period as is necessary to make the inspections and a report of their findings and recommendations is made at the meetings. I believe that our most thorough investigations and best recommendations are received when we ask for an inspection on special things such as cranes and chain falls, tractors, trucks and trailers, elevators, dangerous pulleys and belts, etc. In that way the committeemen are looking for specific things instead of everything in general and better results are obtained.

We feel that our plant is well taken care of so far as mechanical safeguards are concerned. The plant committeemen know this very well and are told that it is not the number of guards and other changes that a man suggests that determines his value as a safety man, but rather the example he sets by his own actions and the advice he gives his fellow-workers every day as he goes about his work.

When a new member is appointed he is sent a personal letter from the central safety committee reading something like this:

We are very glad indeed to notify you that at the last meeting of the central safety committee you were appointed a member of the _____ safety committee.

We ask that you assist in every way possible to make our plant as safe a place to work in as there is anywhere, that you caution any employee at any time who is doing an unsafe thing or working in a manner that may endanger himself or others.

Your committee holds regular meetings each month, notifications will be sent to you, and it is part of your job to attend every one of these meetings.

There are many ways in which you can assist in keeping your fellow-workmen from getting injured. Many of them you know, and others will be taken up at your committee meetings. Remember that over 90 per cent

of our accidents, in fact of all accidents, are caused by carelessness of the individual. Very few are caused by machines. Therefore, it is necessary to continually keep the safety viewpoint in everyone's mind.

We are enclosing a safety button which is the badge of the safety committee and we hope that you will wear it at all times.

When a workman is serving on the committee, we try and interest him in safety work so that when his term is up he becomes a true disciple of safety. Consequently, when the membership is changed, another personal letter is sent to the member which reads somewhat as follows:

As is customary at this time, we are changing some of the members of our safety committee and appointing several new members. Your place on the committee has been taken by one of your fellow-workmen.

You know, from your activities on the committee, that it is by getting every one's interest in safety that we can accomplish the most good. Consequently, we want you to continue to do everything in your power to help make our plant the safest place in the world to work in.

We know that from your experience on the committee you realize what a tremendous loss accidents are and how easily they can be prevented, if we can only keep the men thinking about being careful. We believe we can depend on you for your continued interest in this very important subject which effects every single man and woman that works for Bird & Son.

The Safety Committee Sometimes A Court

At the plant committees all accidents are carefully gone over and discussed. We have at times had the safety committee sit as a court of judgment on workers who have been injured. The injured man, his foreman and others concerned with the accident are brought before the committee. All sides of the case are heard. The committee discusses any questions and finally passes judgment on the cause and responsibility of the accident. This decision is sometimes posted on the bulletin board or otherwise given publicity. Allowing the committee authority to set any real punishment is questionable, but it is certain that by bringing this before the committee it impresses the worker with the idea that his fellow-workers and the company are taking it as a serious matter.

The safety committeemen can be of invaluable aid in general everyday co-operation in safety work. If horse-play starts in the absence of the foreman, it is the safety committeemen who can tactfully say, "Easy, boys, or somebody will get hurt," or if he sees an unsafe practice being carried on he can easily bring it to the attention of the worker or the company and have it stopped. Further the committeemen have good ideas on safety publicity. If you are having a "no-accident" week or month, form a publicity committee of local safety committeemen. They will often bring forth excellent ideas for publicity on such occasions. It is also a good idea in such cases and even in the general run of safety publicity to give the safety committees credit by signing notices, posters, etc., as coming from them.

At our plant we have designed a safety seal showing our safety button, a man representative of our safety committees and the words "The Sign of Vigilance." This sign appears on monthly record sheets of accidents, on a little safety newspaper published during the month and in the corner of a series of safety posters that we are issuing.

In general, while the foreman is frequently the authoritative link between the officials of the company including the safety inspector and the men in the

mill, the plant safety committees are the cooperative links invaluable when used in the right way.

K. L. FAIST (Champion Coated Paper Co., Hamilton, Ohio): Is there any remuneration given the Safety Committee?

MR. ROGERS: No, we don't pay them for the time spent in the committee work. It is part of the work, and they are taken off their regular jobs to do it. We do have a great many safety meetings, say in Boston. There is a series of 10 or 12 meetings. The safety committees are taken to those meetings. Busses are chartered to take them in, and a very large number go. In that way, we try to give them a good time as well as the safety influence.

MR. FAIST: This committee man who makes a tour of inspection—is that arranged at such a time as is convenient, or at some special time?

MR. ROGERS: They are told to make an inspection by the chairman of the committee.

J. J. PLZAK (Consolidated Water Power & Paper Co., Wisconsin Rapids, Wis.): What type of inspection do you make for example, on a hoist or shaft?

MR. ROGERS: The safety inspectors do not make a thorough inspection, but they do see that the cables and guards are O. K., and that the safeguards are being used, and the like of that.

MR. PLZAK: Do you have any such inspection that is practically a general overhauling of the machine?

Reasons for the Regular Inspection Plan

MR. ROGERS: Well, the reason that we make the inspection is this: In one of our factories, we handle paper rolls weighing something over five thousand pounds. On the drum of one of the cranes where the cable was installed, just a little solder was used, and one of these rolls went down, narrowly missing three or four men. Since that time, we have made a regular inspection on cranes, hoists, and so on. We have an outside elevator inspector and a regular mechanical inspection probably three or four times a year.

CHAIRMAN GLEASON: Do you concede that point that the safety committee takes the place of the regular inspection by people who are qualified to make inspection?

MR. ROGERS: Don't ever give up special inspections. I am glad you brought that out. We certainly can't hold the safety committee responsible for a bad cable on an elevator or crane or anything of that sort.

MR. PLZAK: I brought that up because we have quite a bit of vibration continuously, and those of you who know that this metal becomes crystallized, know that it is a very dangerous thing. An inspection once a week cannot reveal that crystallization. How do you go about finding that out?

MR. ROGERS: I don't know just what is done on line shafting and so on. We have a master mechanic to look after such things.

MR. SHERMAN (Titanium Pigment Co., Carondelet, Mo.): The practice in some mills and railroads is to anneal or use a heat treatment for certain pieces of equipment subject to crystallization. I don't know how you would go about that.

CHAIRMAN GLEASON: I think Mr. Rogers' point was a good one: Never release the men entirely from the safety committee. Make them feel even after their time is up that they are a part of it.

An idea that came to Hammermill, following the Cleveland meeting, might be mentioned. We had some five or six superintendents at the Cleveland meeting. When they went back, each one gathered all the foremen around him—a force of about 25 or 50 people. He made them go through the entire department, and the results were very good. They got something from each department. As a result the departments were cleaned up, and the safety record improved to just that extent.

Mr. C. K. Boyer, Interlake Pulp & Paper Company, Appleton, Wis., will speak on "Standard Guarding and the Papermill Safety Code."

Standard Guarding and the Papermill Safety Code

C. K. Boyer, Interlake Paper and Pulp Company, Appleton, Wis.

If you will turn to almost the first page in this Code, Rule No. 11, you will read, "The purpose of this code is to provide reasonable safety for life, limb, and health." If that code had nothing in it except that statement, I think the work placed on the code and the expense put in it would be fully justified. Its purpose is to protect healthy people from industrial diseases, to save sound bodies from becoming peg-legged and empty sleeved, and to reduce bills for flowers which too well depict the widow's faded interest in life as they wither away on top of a newly made "mill accident" grave.

Of course, the Code doesn't suit all of us. I don't think all of the Code would suit any of us. No single code can meet all of our ideas or individual experiences with industrial hazards. How many of you have read this Code?

(The majority had read it.)

Good. There are some mills in the United States and Canada that do not know yet that the Code was brought into existence a year ago, after working upon it for two, three or four years. But you have the Code, and it is your business to read it. Don't criticize the Code without reading it, at least. Let's be honest with ourselves. Let's comply with the rules we cannot criticize fairly to ourselves. Do this much, and before long our mills will be veritable show places of safety guards and safety methods. Let's pay for our privilege of criticizing by coming across with the safety measures which we must admit to ourselves are fully justified.

Standard guarding, as described in various state and Federal Codes, is no longer mere guess work nor a mere pretext to give state inspectors or sentimental safety enthusiasts a job. Rather, the matter of industrial and public safety has become so large and vital that it requires big men to do the safety job. Nor is standard guarding any longer a fancy luxury designed to catch the eye of a visiting welfare worker or social uplifter. Rather, standard guarding is a positive method of cutting production costs by eliminating medical bills.

Our modern high speed world of industry demands fool-proof working conditions as near as possible. A modern paper mill means taking a sheet of newsprint 20 feet wide through a series of press rolls, over four dozen hot dryers, through a 300-ton calender stack and on to a reel that never stops, at a speed of 18 feet per second.

It demands that chlorine gas, the poisonous terror of the World War, be handled in 15-ton carload lots in the very midst of a large city. Catch the full significance of that. It means the generation of steam in modern high pressure boiler plants, steam at 450 pounds pressure and *so highly superheated* as to endanger ordinary pipe metal and set fire to exposed woodwork with a tiny invisible jet of leaking water vapor.

Such hazards as these are actual consequents of modern speed, efficiency, economy and progressive paper mill engineering. Paper must be made thus to keep up with the competitive march with other industries. Hence, we cannot remove the basic causes of these hazards, but must safeguard them with the best engineering brains and practical experience obtainable. Safeguarding such hazards must be accomplished by tried and proven methods, set forth in standard systematic codes made available for all to read. Without such codes, which are simply the up-to-date records of results of practical past experience, each of us, when faced with industrial hazards new to us as individuals, would be compelled to repeat experiments already tried by other mills. Doubtless we would reach our solution after maiming or killing some one of our workers.

Hazards so great can no longer be dealt with in ways that are haphazard. Experienced industrial workers, executives and genuine welfare workers who have faced this responsibility for human life in the spirit of the Golden Rule, produced such codes. Such men have learned from experience that railings of a certain height and construction will best protect elevated passage ways. They have observed that a simple toe-board placed along the edge of such an elevated structure will prevent a stray bolt or nut from breaking an unsuspecting head beneath. They have recorded the rather simple fact that any belt nip or gear pinch point that can be reached by a man's fingers at the end of his arm should be shut up too tightly for those fingers to slip through. They have observed that any sharp projection on a revolving shaft will catch clothing and hence they banished the murderous set screw of Noah's day in favor of the countersunk set screw.

In short, "There's a reason" for every rule in these standard guarding codes. They are not arbitrary statements designed to arouse antagonism, but are common sense analyses of typical danger points with practical ways of eliminating the hazard. Therefore, don't condemn any coded safety rules without first analyzing the possible reason for its creation. Generally, your own study will reveal that the safeguard suggested will mean not only added safety, but greater production and lower production costs.

Standard Guarding Codes Are Simplified Common Sense

The standard guarding codes were common sense applied to all industries. Industries are becoming specialized and hazards are becoming specific and peculiar in their nature. Hand barkers whittle off the fingers of wood room men only, so a specialized code suggests mechanical means to turn the blocks of wood. Chip bins are peculiar to pulp mills, so our special code prescribes safety belts and chains to prevent the digester helper from being buried under tons of chips or boiled to pieces in a hell of steam and sulphurous acid.

The chemical industry, from its recent war experience, suggests gas masks to protect the acid makers and bleach plant operators from brimstone and chlorine gases. Medical skill points out that personal cleanliness and fresh air will help prevent lead poisoning from use of litharge in lining digesters. The code might add that careful periodic medical examinations and blood tests will generally give sufficient warning, so that workers may be treated in time and changed to other work, if necessary.

The whole Pulp and Paper Code could be analyzed, but this would be a useless task. The fact is, we have standard codes and a special code that contain an immense amount of safety information and based upon actual experience. It is for every foreman, every safety man, every mill executive to know the contents of these codes. It is for these men to realize their personal and moral responsibility to use these coded safeguards intelligently to protect the worker and the community life. Such responsibility accomplished means lower production costs, fewer hospital bills, and a friendlier feeling of the community toward the industry. It also adds many genuine safety workers to the honored list of those who help make real the Constitutional guarantee of "Life, liberty and the pursuit of happiness to all."

MR. PEACOCK: Mr. Altman just the other day wrote a letter emphasizing the statement I gave you earlier in the meeting, that the American Engineering Standards Committee is now ready, if they have the full approval of the Section, to issue this Code as an approved standard.

CHAIRMAN GLEASON: Is there anyone else who has a question?

MR. ROSEBUSH: I think that the years of study that have been put on the Code, and the use to which it has been made show that we are ready to back it up. I move this Section give their approval to its use as suggested by Mr. Peacock.

CHAIRMAN GLEASON: It is properly moved that this Section give their approval to its use as presented. Do I hear a second?

(The motion was seconded by Mr. A. S. Wilson.)

CHAIRMAN GLEASON: Are there any remarks?

C. M. GREEN (Wausau Sulphate Fibre Co., Mosinee, Wis.): I don't see why we don't have time to read it.

MR. BOYER: As chairman, Mr. Peacock arranged to have in the room today a copy available for everybody who wished to have one. Perhaps those of you who did not know the Code was in existence are to be criticized for not knowing about it. It was the hope that we could get the consensus of opinion of the paper and pulp mills in the United States and Canada—we wanted to get their reactions before adopting this Code as a National Code.

A Careful Reading of the Code Recommended

Just by way of establishing my criticism, one rule says that a grating with mesh not larger than eight by eight inches should be installed at the outlet of the chip bin to the digester. You try to fill a 17-ton digester through an opening of this size and you will find that it can't be done. The Code should be pretty nearly fool-proof before turned over to production men. It is better not to have any law than to have a law and see it broken.

JOHN LUNDEGREN (International Paper Co., N. Y.): I have not read the Code in some time, but I have read it, as I had something to do with the original preparation. If we haven't already done that, it might be wise to have a practical committee to separate this Code into what might be termed "arbitrary" and "advisory" requirements.

To fill a digester in the manner set forth in the Code seems to us to be ridiculous. There are several provisions having to do with incunning nips in different places on reels and winders that we don't consider practical, and we believe they can be improved upon.

CHAIRMAN GLEASON: I remember at the time we were working on this Code, we asked for suggestions and asked members to go over this thing, and we did incorporate all these things as far as possible. We had a meeting with the Bureau of Standards man and thoroughly discussed all phases of the Code.

MR. LUNDEGREN: Do you know whether this tentative Code is ready for adoption by the Government?

MR. PEACOCK: Mr. Altman has a letter from the American Engineering Standards Committee saying that they are ready to accept this form as an approved standard providing we will sign the thing as representing our Section. Mr. Altman doesn't want to take that risk. He was aware of such criticisms as Mr. Boyer has brought up.

CHAIRMAN GLEASON: Let's push this thing through under efficient criticism. Are there any further recommendations?

N. H. BERGSTROM (Bergstrom Paper Company, Neenah, Wis.): Would there be any objection to submitting this to the Superintendents' Association to get their sanction?

CHAIRMAN GLEASON: Did I understand you to make that a motion?

MR. BERGSTROM: I suggested that, but I will make it a motion. It could be presented to this Superintendents' and Technical Association for their approval or criticism.

CHAIRMAN GLEASON: Gentlemen, before you entertain that motion, we have another motion moved and seconded that we give our approval to the Code in its present form. Is the maker of that motion willing to withdraw it?

MR. ROSEBUSH: I withdraw it suggesting that we turn it over to the Superintendents' Association.

CHAIRMAN GLEASON: If we are not ready to adopt this code, let's appoint our own committee and get to work on it before we turn it over to anybody.

MR. BOYER: I didn't mean to be severe in my criticism, or I wouldn't have talked for it with all my heart and soul and mind. It is simply this: We must keep in mind the fact that the code can never become fixed. Even the Ten Commandments have passed through a long period of reconstruction. We are even trying to tamper with them today. We ought not to try to make a fixed code. Progress is made through criticism and reconstruction. We should have some provision for changing or revising the Code, and adding to it. Whatever action we take now, we ought to keep in mind that we can recommend other rules and changes.

MR. ROSEBUSH: You gentlemen will notice on the front page of this printed booklet that the Washington Government Printing Office has sent this out through the Department of Labor, I presume to all the paper mills in the United States. Would it not be wise for us to carry this discussion into our next session and talk it over in the meantime. It seems to me that it is going to involve more than we can settle here. Before the Congress is over, we may be able to get together between sessions and come to some definite point in the matter.

CHAIRMAN GLEASON: There has come a request that we vacate this room as soon as possible.

MR. BERGSTROM: I make a motion that this matter be laid on the table until tomorrow.

(The motion was seconded and carried.)

ADJOURNMENT

Wednesday, September 28, 1927

The second session was called to order at nine-forty o'clock by the chairman, W. J. Peacock.

CHAIRMAN PEACOCK: There is a matter of business left over from yesterday, and I want to suggest, gentlemen, before we go into this matter that today's program must begin at ten o'clock. This is the matter of the Code. Is anyone ready with a resolution?

F. H. ROSEBUSH (Nekoosa Edwards Paper Co., Port Edwards, Wis.): I suppose that the gentlemen who raised objections to the Code yesterday have read it since the meeting and are ready to make comments upon it. I think that we should allow this Code to go through. Like any text-book, it is open to revision. No one expects that this Code is going to be final. It is a guide by which the safety engineers can learn to guard their machinery. Five years of work have been put on this Code by a competent committee, and it has been printed by the Government. I make a motion that we allow this Code to be accepted as our standard, with the understanding that within 60 days any criticism sent in that is designated as proper criticism shall be accepted.

JOHN LUNDRIGAN (International Paper Co., N. Y.): I second that motion.

CHAIRMAN PEACOCK: Are there any remarks?

(The question was called for.)

CHAIRMAN PEACOCK: All those in favor will signify by saying "aye"; those opposed "no." The motion is carried.

I designate Mr. R. H. Altman, chairman of the original committee, as the man to whom you are to send any suggestions or criticisms. In the meantime, remember, gentlemen, we have a half dozen engineers representing the section. Mr. Costigane, Mr. Gleason, Mr. Rosebush, Mr. Hoyman, and other members of the Engineering Section are here and you can interview them if you have any suggestions to make. Is Mr. Dowd present?

We had an informal discussion yesterday afternoon regarding the Contest. We were very sweet about it, but we spent two hours in our sweetness. We asked Mr. Dowd to sit up all night and think things out for us.

A. SCOTT DOWD ("The Paper Industry," Chicago): I am reminded of the story of the old colored preacher who went to the Internal Revenue agent to get a permit for the use of "sacrilegious" wines. The agent asked, "what kind of wine do you want, Rastus?"

"Well, the members of the congregation at the meeting last Sunday night decided it would be gin!" was Rastus' reply.

I couldn't get a unanimous opinion from the members last night in regard to this unfortunate situation in the inability to give a cup to the "C" group. After sitting up all night and conferring with the publisher of "*The Paper Industry*" and talking with the members in the "C" Group last night and this morning, I cannot present anything contrary to the resolution that I am going to ask permission to present:

Whereas, Rule 3 of *The Paper Industry* Annual Safety Contest for 1927 reads as follows:

"Contest shall start January 1, 1927, and end June 30, 1927. However, should two or more mills in any one group be tied for first place, as of June 30, the contest for all contestants in said group shall be extended until the tie is broken," and,

Whereas, Rule 4 of the same Contest reads as follows:

"The winner of each group shall be the mill having the lowest accident severity

rate (days lost per 1,000 man-hours worked), in accordance with the rules and the 'Scale of Time Charges for Deaths and Permanent Injuries,' as listed on page 4"; and

Whereas, There were six mills in Group C (mills having 20 to 200 employees) which operated without an accident for six months, each attaining thereby a severity rate of zero, and the contest for all contestants in that group was extended according to Rule 3, and to date has not been broken; and

Whereas, An interpretation of Rule 4 has been expressed by certain contestants to mean that group winners shall be determined on the basis of man hours worked, which in the event of a tie would give prior rank to that mill working the greatest number of hours; and

Whereas, It is the desire of many to award all cups for the 1927 Contest at this annual meeting, and the desire that the aforesaid interpretation be accepted in order that all awards can be made; and

Whereas, Rule 4 specifically states that the "winner of each group shall be the mill having the lowest accident severity rate," and that this rate is defined therein in parenthesis as ("days lost per 1,000 man-hours worked") and that a zero number of accidents divided by any number of hours worked makes a quotient *rate* of zero, and that nothing can be less than zero, and that by this rule as specified, it is *impossible* to declare a winner until such tie is broken; be it

RESOLVED, That the rules governing *The Paper Industry* Contest for 1928 be formed to include the provision in the event of a tie that the mill in such tie working the greatest number of man-hours for the period of the Contest shall be declared the winner.

Respectfully submitted,

A. SCOTT DOWD.

Editor, *THE PAPER INDUSTRY*.

Resolution on Contests is Adopted

JOHN LUNDRIGAN (The International Paper Co., N. Y.): That is for the 1928 Contest?

MR. DOWD: Yes.

MR. LUNDRIGAN: I move its adoption.

CHAIRMAN PEACOCK: Are you ready for the vote?

All those in favor, kindly signify by saying "aye," those opposed "no." It is unanimous.

MR. DOWD: I haven't anything to say at this time regarding the 1927 Contest awards. I think the time set for that is the Luncheon. I imagine our anticipations are rated high for that which is to come.

CHAIRMAN PEACOCK: You all want to be there when this matter comes up. Mr. Hoyman is designated chairman for the program, and he will please take the chair.

M. G. HOYMAN (Kimberly-Clark Co., Neenah, Wis.): Having such an interesting event at twelve-thirty, and not knowing any more about the results than we know now, we do not want to do anything to prevent being here at that time. We have four speakers on the program this morning, which means we should get down to business at once.

We know that the greatest thing about safety is the business of selling it. In fact, everything we do is trying to sell something, whether it is service or goods. This idea of selling safety is the only way safety can be gotten across. These men will tell you in their own way just how it is done.

The first topic is "To Employees." We have some one who is well able to tell us about that—Mr. D. D. Thirkield, Sorg-Oglesby-Smith Paper Co. Middleton, Ohio.

Selling Safety to Employees

D. D. Thirkield, Sorg-Oglesby-Smith Paper Company, Middleton Ohio

My talk is short. I hope you will understand that I feel fairly humble in appearing before such a group of safety men. Some of you may remember that I was present last year, and I would like to say now that the information I received at Detroit has been the mainstay of my work during the past year as safety director of my company. When I started, I didn't have the slightest idea of what the job would be. The general attitude of the foremen seemed to be, "We have so many accidents anyway, we might as well have them and get them over with." I went back with the idea that we could reduce accidents.

The first of January we opened up a new department for this work, and I was placed at the head of it. When I started in at Middleton, I was very enthusiastic about what I had heard up here in the way of the safety contest, with cups for the winners, with dinners for the safety committees and all that.

I had a number of very definite plans, with two safety committees, one for the foremen and one for the workers. Then I was also going to buy three or four cups and have monthly dinners for the safety committee, and start off with a great big hullabaloo, and make 400 employees accident proof in thirty days.

Fortunately, I was so busy the first thirty days getting organized, that I didn't have time to put any of these plans into effect. I was very fortunate, for had I started off the way I had planned, it would have slid off into the river.

Many of the employees had been working 10 years or more, a couple of them 25 years, and they had never had safety talked to them. It appeared foolish to try to sell safety by the circus method. I decided that the thing to do was to go quietly about the safety work and sell them slowly but surely, and then when I got through they were all sold, because when such a point is reached it will stick. We didn't have any dinners, and have never secured a safety committee. I was fearful that with my ignorance coupled with theirs, any organized attempt for safety work would be disastrous.

I remembered that everyone who spoke about safety declared that anywhere from 75 to 85 per cent of all accidents were caused by carelessness. With that in mind, I went over the mill very carefully, and in spite of the age of various departments and the age of the machinery, found that we have lived up to that Code pretty well. The dangerous points were pretty well covered up, and I made up my mind that if this great percentage of accidents was caused by carelessness, I certainly ought to reduce accidents by making the men careful. That is the way I have been going along all this year. I have used the National Safety Council posters, and I couldn't have done very much without them. I had 25 bulletin boards made, and had them placed at strategic points all around the mill, after which these fine posters were put up. That was the starting point. Then I started mimeographing bulletins, of which I have a few samples here.

This is a green telephone book cover that we make, and I used that. (Indicating) I also used yellow posters like that. I make them fairly interesting, and they are always before the men. Also, there is always one of these either green or yellow bulletins indicating the safety progress in the work for that month.

After talking to several safety men down at my end of the valley, I was somewhat doubtful as to whether we would be able to reduce accidents the first year. Some of them thought it would take a year for the idea to sink in deep enough to make the men careful. They were right to a certain extent. The figures for the first nine months, January to October 1st, 1926, showed 73 lost time accidents. There

is no question about this being terrible. Anybody can improve on that 2,201 days of lost time among 400-odd employees.

Our method of selling safety isn't mine or our company's. It is really yours, gained through the National Safety Council. The results for the first nine months of 1927 have been: 29 lost time accidents, 391 days lost.

I have here the "*Sosco News*." Mr. Peacock suggested that I print up some extra copies to have at the meeting, and I believe he meant that, so I did print up a couple of hundred more of them. That is, in my estimation, the most important method of selling safety to our employees. As you glance over it, you will find it is practically all devoted to safety.

If you will take notice, you will find that January, February and March did not show any decrease in our accident prevention. March was the worst month. It took three months for the idea to seep through that accident prevention was possible. The second three months show a decided improvement.

When a man gets hurt, that is the best time to sell safety. When some one is injured, he reports to my office. I send him to any doctor he wants to go to, as we haven't a company doctor. Then he comes back to my office and makes out a report. Before he leaves, he is absolutely sold on the idea of safety. I don't give him a rough talking to. When he gets out of there, he is a mighty good disciple of safety work. He spreads it to his fellow workers, spreading the gospel of safety all the time, and that is very important.

Accident Prevention Has Been Justified

Our men are enthusiastic now about safety. They have had proven to them that you can reduce accidents. I have pumped the fact into them that they derive the greater benefit from fewer accidents in the mill, because they not only work the additional time but get the extra money. I feel confident that by pursuing the same methods without any safety committee and without any hurrah every day, and every hour of the day, keeping the idea of safety before them, I feel confident as I say, that next year we will reduce accidents in about the same proportion as we have this year, and in two, three or four years our four hundred men will feel about the same as you do.

So far, the response has been wonderful. Some men, some foremen and executives have told me, "Those fellows don't give a damn about safety—they don't care." But they do. They are just like the rest of us. I feel sure that as we go on in that quiet method, we will have at least a running chance at the Safety Cup to be presented next year.

CHAIRMAN HOYMAN: That just shows you what can be done. It may not be new to some of us, but it may be to others, and is at least an inspiration. As we are going to make the discussion very brief, if you have any question to ask, you have four or five minutes to do it in. Who is the first one?

STUART H. BROWN (Union Bag & Paper Corp., N. Y.): I would like to ask something more about these yellow and green sheets.

MR. THIRKIELD: The first one is dated May 1st, and reads:

"Lost Time Accident Record for April.

- | | |
|--|--------|
| 1. Lowell DeBolt, Oglesby Beater Room..... | 9 Days |
| 2. John White, Sorg Yard Gang..... | 3 Days |
| 3. Lester Dennis, Sorg Beater Room..... | 1 Day |

Total Time Lost	13 Days
The loss in wages for these three men was.....	\$42.69
Less Compensation paid by State.....	8.04

Net Loss	\$34.65
----------------	---------

Lost Time Accidents, First 4 Months 1927

January	6	57 Days
February	3	41 Days
March	7	135 Days
April	3	13 Days
	19	246 Days
Loss in Wages		\$868.39
Less Compensation		231.82
Net Loss		\$636.57

The Cost of Accidents is greater to the Insured than to the Company.
Make May a No Accident Month."

This green folder has the departmental standing which I get out every quarter. This shows the mill, department standing, average number employed, total hours worked, number of days lost, severity rate and frequency rate. We have a lot of discussion about the severity and frequency rates. By the way, never until last year was a record kept of the number of accidents.

GEORGE HEESAKER (Kimberly-Clark Co., Kimberly, Wis.): I would like to ask in selling safety whether it would not be a good idea to talk to them before they are hurt instead of waiting until after they have been injured. Why not call them together once a week instead of talking to them after they are hurt?

MR. THIRKELD: I don't believe the spirit is there yet where they can all come together in a big group and get very much out of a safety talk. I do not think it would be wise to call them together and address them through the executives of the company or by outsiders. I am not claiming that I am right, I may be wrong, but that is my opinion.

CHAIRMAN HOYMAN: I think we will have to go on with the next topic, because if we have time at the end, we can discuss and argue any of these points that we won't have time to talk about now. I think Mr. Thirkield made a great showing for the first year. I want to congratulate him. The next subject will be handled by Mr. W. E. Walker, Kalamazoo Vegetable Parchment Company, Kalamazoo, Mich.

Selling Safety to Foremen

W. E. Walker, Kalamazoo Vegetable Parchment Company, Kalamazoo, Mich.

When I was coming down on the train this morning, I wondered if I could do as well as a preacher I heard a week ago Sunday night. I think it was the best sermon I ever heard, and he did not exceed six minutes in delivering it.

Yesterday there came to my desk a paper gotten out by the American Management Association, on accidents usually classed as unavoidable. It says that Mr. Heinrichs brought out the fact that noncompensable accidents cost our plants four times as much as our compensable accidents.

I wonder if any of the foremen here are not sold on safety. If there are, I would like to have them stand up. I would like to meet the executive or the employer who is not interested in the folks that work under the foreman. I would like to know how they selected such a man for such an important job and just what they think the duties of a foreman are. My contention is, that a foreman who cannot see or pays no attention to the possible hazards of occupations under his supervision does not know whether his employees are doing a good day's work or not.

We'll grant, for argument's sake, that he does know that his men are producers and he is conscious of the fact that hazards or probabilities for accidents do exist, and yet he does nothing about it. Isn't he the man who sees many wastes, many

places where improvements could be made, many places where the company's interests could be better served, and yet does nothing about it?

The next gentleman on our program I believe, has the job of selling safety to superintendents or higher executives. He is the boy with the big job. And on the other hand, why does any live, wide-awake foreman, if he knows that something should be done, wait for the superintendent or executive to tell him to do it? He was evidently picked because he showed an interest in getting the proper things done without having to be told, as far as production is concerned and the best interests of the employer. Why does he remain ignorant of the possibility of loss of life or limb to an associate? Would he tolerate a machine that wouldn't produce goods accurately? I believe he would holler his head off?

What I mean by that is: A foreman is more apt to show an interest in the producing machinery than in the employee, who is really the higher cost of producing. I wonder if a foreman always thinks of what it costs his department and his prestige as a foreman when an accident occurs to one of the men under his supervision. I wonder if he knows this costs his employer many dollars in many ways.

The Accident Cost in Terms of Dollars and Cents

I know of a plant where in 1925, with 750 employees, the combined medical, hospital and compensation bills paid were \$5,730. This covered a total for 204 accidents in one year, besides which there were 1,501 days lost. Figuring labor at a very conservative estimate, say \$4 a day, that makes \$6,000 lost in wages to employees to say nothing of mental anguish, physical suffering and the privations endured by the families affected. That means quite a lot that might be avoided.

To get back to the costs of accidents in terms of production, in our plant we figure twice the amount in loss of production that a man loses in wages every day he is off. That means that when the employees' loss is \$6,000, the plant loss is \$12,000. This amount added to the compensation, medical and hospital costs, makes a total of \$17,730 for one year.

Would you say that was a lack of supervision on the part of the foreman? I would ask you that question and let you answer it to suit yourselves. But, anyway, the people who are most in touch with the people to whom these accidents occur are the foremen.

These figures may seem extreme, but they are compiled in a plant that has a safety organization, a poster or bulletin plan of placing warnings, and a safety engineer. What does it mean? I will tell you what I think it means. We all know what we ought to do all the time, but we need some one to constantly remind us of our duty every day to the fellow who works under us.

I think what we need more is the spirit of fair play in all of us, and above all things, all the time, the sense or responsibility that we as foremen ought to have to the wives and children, fathers and mothers of the men who are working for us.

CHAIRMAN HOYMAN: Does anyone care to ask a question?

MR. SELLHOFFER (Milwaukee, Wis.): I was very much interested in the speaker's remarks relative to the fact that a present day management didn't want to hire a foreman who is not interested in the welfare of those under him. What are you going to do with the fellow who has been with the company before safety became a real part of his responsibilities?

MR. WALKER: There is only way for a foreman to be today, and that is to keep pretty well posted on everything. He is not a good foreman today unless he is interested in the safety movement. It should be definitely realized that an increase in accidents causes a loss of production, and a decrease in accidents causes an increase in production. I would say that fellow was not keeping up to date with his job as a foreman.

W. A. GLEASON (Hammermill Paper Co., Erie, Pa.): I can answer that in another way. In this case, it took an accident to put these things into effect. After a very severe accident had occurred, in investigation the safety man said that he had experienced difficulty in getting safety devices installed in this particular department. The chief executive put the responsibility for that accident directly up to the superintendent who had been in the plant some 27 years. He in turn put the responsibility up to one of the foremen under him, and since that time there has been an entire reversal of policy. They are now leaders in the safety movement.

L. W. RHODES (Kimberly Clark Co., Niagara Falls, N. Y.): Is it possible for the foreman to be partly sold on safety?

MR. WALKER: I don't know where you would draw the line.

MR. RHODES: It seems to me that in selling safety to the foreman, you never can sell him 100 per cent on safety as you can on production.

MR. WALKER: The foreman may not figure it out that one way to increase production would be to decrease accidents. He may not be smart enough to know that a decrease in accidents would help production, but when a foreman gets that into his head, production is going to increase.

MR. RHODES: I have worked with a number of good men, yet they do not become half as excited about an unsafe practice as they do about bad machinery.

JOHN H. CRIST (West Virginia Pulp & Paper Co., Piedmont, W. Va.): I think most foremen are really sold on safety. Foremen are all human, and safety engineers and safety people aren't always as diplomatic as they might be. I believe when a man has the calibre and enough executive ability to get their respect, he can get results.

JOS. H. SLATER (Escanaba Paper Co., Escanaba, Mich.): I think it is wholly the attitude of mind of the old foreman who perhaps had his early training prior to the time the safety movement came into prominence. His mind is very much a one track mind. His mind doesn't include safety. He feels that it is one of the frills put on business and gives it as little attention as he can.

You must get after the foreman and change his attitude of mind. I had an experience of that kind in the past, where I called one of the old foremen in and told him that he didn't seem to pay much attention to safety in his department. I said that we would have to get someone else in there unless he adapted himself to the realization that accident prevention was as much a part of the business as the business itself.

Usually the man changes. It may not be as much of a change as you wish, but he changes. Then by treating him with some kind of friendly interest thereafter, he will presently become a pretty good safety man. The old type of foreman was a rather belligerent sort of fellow, having very little sympathy for the other fellow who got hurt. It is a matter of education for the superintendent and the foremen in seeing that the safety idea be observed and carried out.

CHAIRMAN HOYMAN: I am afraid we will have to go on to the next subject, which is the report of the Nominating Committee. Mr. Nat. Bartlett!

Report of the Nominating Committee

NAT. F. BARTLETT (Hollingsworth & Vose Co., Boston, Mass.): I want to thank you for this privilege of serving as Chairman of the Nominating Committee, and also for the absolute cooperation of the other members.

The Nominating Committee respectfully submit the following names to serve the Paper and Pulp Section of the National Safety Council for the coming year:

Chairman: W. J. Peacock, Northern Paper Mills, Green Bay, Wis.

Secretary: N. H. Bergstrom, Bergstrom Paper Co., Neenah, Wis.

Sixteenth Safety Congress

Vice Chairman for Canada: A. P. Costigane, Ontario Pulp and Paper Makers Safety Association, Toronto, Ont.

Vice Chairman for South: G. W. Phillips, Champion Fibre Co., Canton, N. C.

Vice Chairman for Middle West: M. G. Hoyman, Kimberly-Clark Co., Neenah, Wis.

Vice Chairman for East: W. A. Gleason, Hammermill Paper Co., Erie, Pa.

Vice Chairman for Paper Box Manufacturers: H. C. Sackett, Alton Box Board & Paper Co., Alton, Ill.

Engineering Representative: R. M. Altman, Marathon Paper Co., Rothschild, Wis.

Regional Directors

For Maine: Alvin F. Record, International Paper Co., Chisholm, Me.

For Massachusetts: Nat. F. Bartlett, Hollingsworth & Vose Co., Boston, Mass.

For Michigan: C. E. Torrance, Bryant Paper Co., Kalamazoo, Mich.

For Ohio: Kenneth L. Faist, Champion Coated Paper Co., Hamilton, Ohio.

For Pennsylvania: E. J. Gayner, Scott Paper Co., Chester, Pa.

For Wisconsin Valley: F. H. Rosebush, Nekoosa-Edwards Paper Co., Port Edwards, Wis.

For Fox River Valley: W. F. Ashe, Thilmany Paper Co., Kaukauna, Wis.

For New York: C. H. O'Connell, International Paper Co., New York City.

Committees

Chairman Statistical Comm.: E. E. Grant, The Crystal Tissue Company, Middletown, Ohio.

Chairman Poster Comm.: Ameil Umberham, Ft. Howard Paper Co., Green Bay, Wis.

Chairman Membership Comm.: J. H. Slater, Escanaba Paper Co., Escanaba, Mich.

Chairman Publicity Comm.: D. D. Thirkield, Sorg-Oglesby-Smith Paper Company, Middleton, Ohio.

Chairman Contest Comm.: A. Scott Dowd, Editor, "The Paper Industry," Chicago, Ill.

Chairman Health Research Comm.: J. J. Plzak, Consolidated Water Power and Paper Company, Wisconsin Rapids, Wis.

Respectfully submitted,

R. S. TURNER

W. A. GLEASON

E. A. KENNEDY

N. F. BARTLETT.

A Token of Appreciation to the Chairmen

CHAIRMAN HOYMAN: You have heard the report of the Nominating Committee, gentlemen, what is your pleasure?

JOHN LUNDGREN (International Paper Co., N. Y.): I move that the Secretary be instructed to cast one vote for the officers named by the chairman of the Nominating Committee.

CHAIRMAN HOYMAN: It is moved and seconded that the Secretary be instructed to cast one ballot. Are you ready for the question? All those in favor please stand up. It is unanimous.

I believe this will be a very appropriate time for Mr. Bartlett to say something to the past chairman and secretary, before he gets entirely surrounded.

MR. BARTLETT: There is nothing in this world like appreciation. I believe that one of the most unpardonable sins we have is forgetfulness or ingratitude. For the past three years, a gentleman by the name of Peacock from Wisconsin has given his services unstintingly to this Section.

On behalf of the Paper and Pulp Section of the National Safety Council, in

appreciation of the value of his services I wish to present a little token to Mr. Peacock, and I know he will accept it with equal pleasure to himself and to the Paper and Pulp Section.

Mr. Umberham, it also gives me great pleasure on behalf of the Paper and Pulp Section and those present to hand to you a token of appreciation and our esteem for your services as Secretary of this Section. Mr. Umberham, please come up and get it!

W. J. PEACOCK: Before you pass on to the next subject, I want to express my appreciation for these good words of Nat's and this beautiful wallet. I also want to express my appreciation of the unanimity of the vote on the report of the Nominating Committee. I am not certain that Mr. Slater was consulted, but the rest of you were, and I believe we are going to show the entire National Safety Council some speed next year.

CHAIRMAN HOYMAN: The next speaker is Mr. J. H. Slater of the Escanaba Paper Company, Escanaba, Mich.

Selling Safety to Superintendents

J. H. Slater, Manager, Escanaba Paper Company, Escanaba, Mich.

The fact that we should want to discuss the selling of safety to paper and pulp mill superintendents, indicates that there has probably been some disappointment or failure in having superintendents become interested to the extent they should in maintaining safety in the plants over which they have control. I think there is little doubt that this is so. I am tempted to believe that we have all had experience with superintendents which has been disappointing in connection with safety work, and we probably all have some idea as to the reason for not getting better results, better cooperation and more satisfactory safety conditions, because of laxness on the part of mill superintendents.

Personally, I am a believer in the old proverb that "the eye of the master makes the house thrive," and in this case the meaning of the proverb is that in the final analysis the management, including all executives who occupy a position over the superintendents, are perhaps as much to blame, or more to blame, for lack of energy or enthusiasm than the superintendents, themselves. Even the best of superintendents are much disposed to take their cue from the attitude of the management above them, and if there is an atmosphere of indifference, or perhaps more correctly an attitude of weak interest, on the part of the management, then the superintendents very easily and quickly senses this condition and falls into the same attitude. Particularly is this true since the superintendent has usually been trained and early on to give his first attention to quantity of production, in quality and then to the economy of production; and it is not easy for him to realize that a vital part safety plays in these matters of quality, quantity and economy.

While it is true that practically all men who subscribe to the doctrine of a safe mill and realize a profit in doing so, a great many treat the matter of safety as a small detail to be passed over with as little consideration and trouble for themselves as possible, neglecting the matter of following up nearly everything that has to do with safety and better working conditions to a superintendent of production.

Perhaps a safety organization has been formed, but all too frequently it exists as a weak, ineffective force. The recommendations for safer conditions and the recommendations of factory inspectors from the insurance companies are ignored or delayed for weeks and months and then too frequently carried

out reluctantly with much complaint about the cost, or the stupidity of the working force that makes them necessary. In other cases safety measures and safety work are attacked spasmodically, the result being that the whole subject finally comes to be regarded as a necessary evil hardly worth the effort.

The state of mind arising from a condition of this kind permeates the whole force and is a cause of much failure to obtain the large percentage of success in safety work which should be the aim of all effort in this direction. There is a species of insincerity, or at least a weak belief in safety work, and this quickly affects the superintendent unless he has been completely convinced on safety work previously; and, even if he has, when he finds a lack of vital interest and energy in this matter emanating from the head executive, he is almost sure to let down in his interest and effort. To attain success there must be a constant, aggressive demand for a betterment of safety conditions on the part of the executive management. There must be earnest encouragement and proper financial support given to all problems of safety, so that the superintendent and all his men may realize that safety in the operation of the plant is in a measure just as vital as production and quality—in fact we strongly believe it is one of the principal factors and production is lowered and quality impaired by an undue number of accidents, and quality is sustained and improved by a small number of accidents.

Safety a Part of the Executive's Plan of Management

The up-to-date executive will not fully delegate safety and improved working conditions to his superintendent but will make it an important part of his whole scheme of operation. He will want to fight the battle of meeting the needs of his fellow men in his particular line of manufacture with as few wounded and killed as possible. Why? Because it is the humane thing to do and particularly is it the economical way to operate. It pays in dollars and cents. It pays in the reaction of the employees—in the feeling that their comfort and safety is a matter of real concern—and the management recognizes its obligation.

Every superintendent is continually and profoundly influenced by the executive management above him. His thoughts are colored, his actions are influenced, his decisions are made almost invariably with the thought of what the executive wishes. Of course, this means that when strong influence is exerted in favor of certain action (as, for instance, safety) this will receive the support of the superintendent to a much greater extent than if certain desires are weakly expressed or indifferently sustained.

Therefore, if you have difficulty or think you have difficulty in selling safety to your superintendent, look to yourself and frankly analyze your own attitude. Judge if you have given him the proper moral and financial backing. Judge if you have by your actions created an atmosphere of sincerity regarding your interest in safety, your determination to demand safe operation as you will demand production, quality, economy and all the other features you believe necessary in successful manufacture. Then if you are really satisfied that you have done your part, I think there will be little difficulty in having your desires carried out, in selling more completely the safety idea to your superintendent. If perchance you do not have success, then your superintendent is evidently not the man for the place he occupies.

The extraordinary interest and vigorous effort accorded safety measures is of comparatively recent origin and yet it has been given recognition to a still greater degree each year, so that every superintendent today is more or

less interested in it, but just needs to have his interest stimulated constantly by insistence on measures and methods for the reduction of accidents.

Life is constantly being modified and adapted to meet the demands which are being made upon it, so we merely have to insist sternly that safe manufacturing operation be given adequate consideration and the superintendent is pretty certain to deliver what is required from him. However, there are many different minds and superintendents vary greatly in their opinions as to the value of safety. Thus it is strictly up to the management to impress on the superintendent the need for his leadership in safety work and in all the other functions of his position. The management can easily show the superintendent the outstanding value of safe working conditions in their actual reduction of cost per ton of production. Ordinarily this cost changes from month to month and is at its lowest when there are no accidents. This is convincing evidence and should spur the superintendent to redouble his efforts in educating his foremen and other employees to greater care. Once the superintendent is made to feel through the management the full responsibility of his position in this regard, he is almost certain to awaken and presently the whole organization will be permeated with a consciousness of danger and the need and power to prevent it by putting up a line of defence.

The progressive superintendent—and they all want to be numbered in this class—can be shown that to take more and more interest in safety work will enormously raise him in value to his employer for he will then more vividly comprehend the need for quiet but firm discipline because confusion and lack of order breed accidents. He will note more keenly the dangers about his plant from lack of cleanliness, from the disorderly arrangement of everything that has to do with the work, from the absence of proper lighting, unsafe tools, dirty corners, obstructed avenues, slippery floors, accumulated debris, dangerous, risky methods of working and the thousand and one features open to criticism which he perhaps never fully realized before.

Bad Housekeeping An Indication of Inefficiency

He is almost certain to see deficiencies and dangerous conditions in his mill with a new outlook—sloppy, wet floors in the grinder room, rickety trucks, grinders obscured in vapor and covered with stock and useless appendages, and all the other features that go with such conditions. These loom up as a danger. In a sulphite or sulphate mill, leaky pipes, a mill smelly with escaping gas and wood room and repair shop room confused and dirty and totally lacking in order, a mill yard without system—all these will present themselves as menaces to safety. A boiler house and power plant dirty and disorderly, creating a sense of insecurity and impermanence; a machine room perchance greatly overheated, improperly ventilated; employees exhausted from working in such conditions—all will emphasize in the superintendent's mind the need for better organization and better direction so that he may reduce accidents; and of course in doing this he will improve running conditions in his whole mill.

If he is the right sort of superintendent, he will be rather appalled at the imminence of the dangers arising from just a few of the conditions I have touched upon and he will probably want to begin at once to put his house in order. As a matter of fact, there is a vast amount of poor housekeeping in mills and it is a source of numerous accidents; but the superintendent who insists upon a clean, orderly mill with a place for everything and everything in its place will automatically reduce the accident record, also reduce waste,

cut costs, increase production and make all manufacturing conditions more definitely reliable.

Safety is an essential factor of operation, and failure to secure it is failure to fill the job satisfactorily. Every superintendent should realize this. He is called upon to play a difficult part. He is, to a large extent, "his brother's keeper."

Although we emphatically believe that safety should be observed and carried out on a strictly business-like basis, a friendly, sympathetic attitude on the part of the superintendent in his intercourse with his men will do a great deal toward avoiding accidents. The formation of safety committees should by all means be made and continued, and as time goes on it has been our experience that it is surprising how many men on committees show special aptitude for the work in suggesting dangerous places and dangerous practices. This is an excellent means of giving to a considerable number of your men possibility for self-expression. Many men will show real leadership in heading groups of workers. The wise superintendent will be quick to recognize such men and use their talent in various ways to cut down accidents and it will be a means of getting a more accurate knowledge of their fitness for promotion.

Great Losses Arise from a Small Injury

Our experience has shown that our greatest losses, our most severe cases, have usually come from a small injury—a small cut, a scratch, an abrasion that was not given attention and protection, so that presently it was a bad case of blood poisoning. An educated accident committee group will do much to reduce such cases by warning the injured man of his danger and by assisting the foreman to note such injuries.

Then a modern, intelligent superintendent hardly needs to have it impressed upon him that continued reiteration of warnings and cautionings and still more repetition is of infinite value in educating his men. It is the way we gain most of our knowledge and have it stick in the mind. Safety education advances through cycles. First one method is employed to impress the need of caution; then other means are taken to keep the mind fresh and active in the matter of accidents, the most recent one being the posting of highly colored posters—display pictures with pertinent and humorous quotations. We think this way of driving home the truth of wonderful value. It keeps interest alive and in a pungent manner shows the absurdity of many practices that make for accidents. Men talk about what is shown, getting a laugh out of it, but the truth gets over and remains in their minds.

The superintendent's duty is to direct the making of pulp and paper. With almost equal care he must direct the organization of safety or eventually his company and himself will be beaten; and, while committees, cautioning signs, placards, mechanical protections and the whole array of safety measures are needed, the superintendent must be the building force, he must take the initiative, he must reach out and keep himself thoroughly acquainted with what others have done and are doing and adopt as much of it as will fit into his particular mill. We may say with the poet, "If it were as easy to do as it is to tell what to do, then poor men's cottages would be princes' palaces." The superintendent's task in warding off accidents is everlasting and it is not as easy to do as it is to tell him what to do, and while he can not make poor men's cottages princes' palaces, he can do, if properly supported by his company, a world of good in keeping sickness, pain, disaster and death from many a poor man's cottage and while doing so make his mill more highly profitable.

CHAIRMAN HOYMAN: We are now ready for the discussion.

MR. HEILIG: Mr. Slater has hit the question right on the head. I have always asked the "how" and he has asked the "why." In my contact with mills, this fits the whole problem of safety. When you have safety as a part of your program of production, when you realize the synchronization of safety and production in its relation to cost and the increase of efficiency and quality because of this, you have found the answer to the problem. When you tie safety into production—tie it on the men's pay envelope making definite responsibilities, then you have a safety program in your mill. Mr. Slater is to be commended for the splendid paper in which he has put the problem as part of production.

CHAIRMAN HOYMAN: I agree with you that Mr. Slater has covered the subject so clearly and emphatically that there isn't much left to be said. I want to remind the newly elected officers that tomorrow morning in the room adjoining us, there is to be a meeting of all officers. Please be there at nine-thirty if you can for the discussion of the coming year's plans.

MR. PEACOCK: That includes the committeemen. I would like to make the suggestion that Mr. Slater is in good position to make a point of contact with the Superintendents' Association.

A. S. WILSON (American Writing Paper Co., Inc., Holyoke, Mass.): I am very much impressed with our meetings. It seems to me that this is the best one I have ever attended. We are getting higher up in the safety work all the time. Is it possible in any way to have Mr. Slater's paper come directly to the superintendents and other divisional supervisors through our Section? Is it not possible to get these words in a letter or some other manner to the various companies?

MR. PEACOCK: That will be part of the work of the Publicity Committee. Mr. Dowd will be glad to get this address in full into the paper.

CHAIRMAN HOYMAN: Is there anyone else?

J. N. FREEMAN (River Raisin Paper Company, Monroe, Mich.): I have a little record here that I think is pretty good, for our corrugated department. We had a superintendent who was not very much sold on safety last year. The record was very poor. With 250 men in his employ there were 52 accidents for 1926, 600 lost days and a medical expense of \$600. The net compensation paid was \$500. Medical supplies furnished by the company amounted to \$275. This year, so far, he has had five accidents with one and a half lost days.

CHAIRMAN HOYMAN: That makes a remarkable record, a very remarkable record indeed.

Our next speaker is one of the pioneers in this movement, and he will talk to us out of his experience. He is not tied down to any subject and can talk on anything he pleases.

Practical Experience in Accident Prevention

**John Lundrigan, Industrial Superintendent, International Paper Company,
New York City**

The prevention and care of accidental injuries in industry may be summarized as a policy and an education in what constitutes safe conditions and safe conduct, and seeing to it that the policy is maintained and the education actually carried on as an integral part of the operation of industry applied to every individual occupation. A good part of this program is the direct duty and responsibility of owners and executive managers of industrial enterprises. So far as policy is concerned, the sole responsibility rests here.

Where owners and management are in favor of such policy, a tremendous responsibility and continuous duty devolve on supervision and administration,

that is, on the men and women paid to supervise, direct and control individual employees. Because, particularly in large enterprises, individual owners and high executives cannot be expected to have more than a general knowledge of how to go about the job, and even if equipped with special training they have not the time required, as the business of maintaining safe conditions and practices runs current with every moment that industry contains a human tenant.

So, when we speak of administration and supervision, we mean the man in charge "where the wheels go round." He may or may not be an owner or executive. To this group falls the responsibility of creating and maintaining a system for securing the safety and promoting the health of every human over whom they exercise supervisory control. Such a system must be very much more than a perfunctory set of rules or even arbitrary rules. Its application must go infinitely further than posting of the printed word on bulletin boards or even the distribution of individual booklets to each employee. As a matter of fact, many high grade practical rules amount to nothing more than an alibi for putting the blame on the injured person after the accident has occurred, because such a rule was not obeyed.

Good Intentions Defeated by Ignorance

We all know that the Golden Rule, Ten Commandments, eight Beatitudes and many similar exhortations provide for an exemplary line of conduct. The unfortunate thing about them is, most people have only a vague or imperfect knowledge of their text or meaning and little or no feeling of personal responsibility for their observance, as well as a lack of human authority behind their enforcement.

We are becoming almost submerged in an ocean of laws and codes intended presumably to correct the ills of industry by government fiat. Nearly all of them create positive added costs in construction, alteration, equipment, compensation and medical care of injuries, and not by any means the least is added taxation to support government enforcement. We do not question the need of many such laws; because the attitude of some groups of employers is like the manager whose alibi is, "the injured person did not obey the rule, therefore he was to blame"; and they take the position, "I live up to the law, therefore the accident was no fault of mine." This leaves the legislator with no other remedy than to make the law more drastic; thus another bill is passed and while costs are increased the business of killing and maiming human beings not only goes on but increases in both numbers and proportion.

While a lot more could be said, we will call this enough in the way of glittering generalities, because you have a right to ask what we have done about all this and what, if anything, do we propose the rest should do. The best way I know of to meet that situation is to give you a rough outline of what our company has accomplished and how it was brought about, omitting of necessity details because time does not permit.

Up to the year 1917, in common with most other industrial concerns, while we did not intend to kill or injure employees and did what we could with the help of insurance carriers to prevent accidents, no intensive effort was made in that direction. Our experience had become so bad we decided it must be remedied if it was humanly possible to do so. What we have accomplished in the ten year period, 1917 to 1926 inclusive, is best illustrated in the following table dealing with the more important items.

	1917	1926	Decrease
Lost Time Accidents.....	1,399	451	948
Fatal Accidents	12	4	8
Total Days Lost.....	18,194	7,046	11,148

We might add that the first half of the current year 1927 shows an improvement of approximately 25 per cent over 1926 experience.

While we are none too proud of our current experience, it must be admitted we did "go some" compared with 1917, particularly when the best available information indicates that there has been a general increase, instead of a decrease, in industrial accidents as a whole.

Now, I know you want to know how we did it, which is the easiest and simplest part of the story. In the first place, there not only was no difficulty in securing the wholehearted support of our owners and executives, but we have known from the start they were solidly behind any effort made to improve existing conditions. Next, we were fully aware that the only place where accidents can be prevented is on the job. We made up our minds the men on the job were going to be the ones who "did the trick"; they were not only to have all the credit for any improvement shown, but were in fact to be the authors of the plan or conditions under which it was to be accomplished. Therefore, instead of taking them into our confidence, we asked to be taken into theirs.

All of us realized that with twenty-odd plants scattered over 1,500 miles of territory, system and regulations would be vitally important, so we collaborated on working out what amounts to a Magna Charta, or Constitution, intended to be not our maximum but our minimum of requirements, with each unit free to go as much further as local conditions and their resources permitted. This document when put into effect could honestly be said to have been created by the employees and local management of all of our plants, because they had either proposed or approved of every feature in it. Its foundation, (or perhaps keystone is better), lies in the fact it became officially and positively a part of the manufacturing policy of our company. I am leaving a copy of it with your chairman, so will only refer to its main features.

The Plant Manager Personally Responsible for Safety

We make the plant manager, who is our company so far as his locality is concerned, personally responsible for its everyday application as a part of his manufacturing operation. He is even personally the active chairman of his plant committee and does actually preside at all committee meetings unless he is absent from the plant. The committee includes all department heads, resident engineer, plant nurse and physician, where one is employed, together with one or more workmen selected by their fellows from each department. Should there be failure to make such selection, substitutes are appointed by the manager or department superintendent. Then comes the local supervisor of safety and sanitation who devotes all his time to the study of accident causes and their prevention, which includes supervision of the local plant employment service. At large plants he has such assistants as are needed. He is personally responsible to the local manager and in the matter of interchanging information, making required reports, etc., to the general management as well. The general office end serves as a clearing house and distributor of information, not only on accidents within the company, but from all available sources such as the National Safety Council, The National Industrial Conference Board, Government Departments, etc.

One of the things we give special attention to is seeing that all plants get full information relating to serious or unusual types of accidents that occur at any of our plants, so that each is at all times getting the benefit of the experience of the others, enabling all of them to guard against the conditions causing an accident at one. This type of information is sent out without delay, supple-

mented every three months by a detailed report of experience at all plants rated according to efficiency. In order that large and small plants may be on an equal footing, this rating is on the basis of "lost time per 100 employees" which includes all time lost during the report period without reference to when the disability began. Our system and reports provide positive information and a complete check on all lost time accidents including current cost. In the case of fatal accidents a penalty of 1,000 days is added and for total disability after one calendar year of lost time has been charged, a penalty of 500 days is added. So you see our separate plants are practically engaged in a continuous accident prevention contest each with the other.

Some time ago, we added to our manufacturing cost sheet a separate item showing the cost of industrial accidents. We know this has a direct influence on accident prevention because it is a positive and frequent reminder of cost variation for this item, the same as is the case of stock, power, etc.

I want to add that every report or form that is made up at a mill (and there are a great many that accompany these instructions) is forbidden to leave the mill without being sure of a journey back in the next mail unless signed by some one acting in the capacity of mill manager.

Now we don't wait for these quarterly reports in the case of any unusual accidents. As soon as we can get enough information that will be of some benefit to the other mills, the history and the remedy of the particular accident is dispatched in the next mail. In this way, they don't have to hurt a man at each mill to find out what can be done.

Physical Examinations of the Employee

Five years ago we established what we term an "employment service," to which we later added a system of physical examination of all future employees, which has been and is of practical value in accident prevention. This service is in charge of our safety supervisor, thereby coupling it with our safety organization. It provides a positive contact with every new employee providing opportunity to start them right by posting them as to our safety and health program, as well as seeing to it they are properly instructed in the work they are to do. This part of our system is a long story by itself; therefore, it cannot be gone into here any further than to point out what is already known, that accidents and health are closely identified, for which reason we take a real interest in the health features of this service. No one is rejected for employment on account of any physical disability that will yield to treatment, provided the person concerned is willing to cooperate in being restored to health. The system provides for financing this procedure so as not to be a burden on the employee concerned. We also undertake to transfer men who are not fitted for the particular job in which they have been placed, but may be properly placed at other work.

The foregoing provides a somewhat rough and very condensed outline of what we are doing and how it is brought about. But, after all, while we feel sure we have good practical rules and regulations, we find the big thing is personal contact plus instruction, advice and encouragement to the men on the job by the department superintendent, foreman, gang boss or whatever you may call him. To his crew this "Boss" on the job is the company and that is as it should be, because in actual practice management looks to him for quality, quantity and cost of production. As a matter of fact, he is the "Top Sergeant" of industry and the real point of contact between employer and employed; which, as we see it, means that if safety is to be "put across" he is the largest single factor in doing it.

Thus it naturally follows we must see to it that this important man has the needed equipment. It is more than likely he became a boss because of long and efficient service in one plant. In most instances he has had very little outside time or opportunity to learn of many things needed to combat successfully the hazards of industry. Often he may not even realize the existence of a real hazard or know a practical way to avoid it or how to instruct others to do so. This is one of the situations we try to meet by securing this information for him and then giving him all of the assistance and encouragement we can in its practical everyday application. This is perhaps the most important part of our safety supervisor's job, and in turn our job at the general office, to see that the information reaches the plant organization.

We have studied and tried many and various forms and methods of providing information and securing interest. We have no quarrel with any of them. In fact, we have and will probably continue to use many devices and services that may or may not help in this work.

The Safe Practices Pamphlets of the Council

We do, however, want to testify to what I consider not only a real help, but a practical necessity in this work of preventing accidents. That is, the Safe Practices Pamphlets issued by the National Safety Council. Not only on account of the technical and practical knowledge and experience utilized in their preparation, but on account of the form in which they are provided, treating each subdivision or separate hazard by itself in a comparatively small and well illustrated pamphlet, using such language as the men in the street may understand. We believe they are not only the best sources of information, but the best reference data for the everyday use of the man on the job.

Engineering associations and individual engineers have done and are doing a great deal to improve safety of structures and equipment by the elimination of hazards in plans and specifications for construction, equipment and machinery. It is not only safer and more sightly to build safety requirements as an original part of structures equipment and machinery, but less costly than to be compelled to install them later. We should encourage this character of service.

Beyond machinery and power transmission hazards, there is still a larger field not often fully realized. Our experiences show 85 per cent of lost time and costs result from accidents in the most ordinary occupations and operations, largely owing to lack of knowledge on the part of the injured how to do his job safely (which nearly always means efficiently). Just because it is an ordinary or common job, management and supervision seem to take it for granted persons so engaged need little or no instruction other than to keep moving. We are convinced it is just as important to teach employees safe methods of loading and unloading, piling or taking down piled material, digging ditches, taking care of tools, etc., and in any of the hazards of industry, and having done this we must exercise constant vigilance to see that safe practice continues.

One of the most expensive accidents we ever had occurred one cold night in February, when a night watchman went out to call somebody. In doing so, he froze his big toe. He fussed around with it, and did not use the first aid treatment, as he didn't know much about those things. He went home and soaked it in cold water. When the doctor started in, he first cut off the big toe, then the ankle, finally cutting the leg off above the knee. The old man then died. According to some of the methods of recording accidents, we would have had no lost time at all.

If a man is discharged for the accident in which he was injured, he is losing time. That should be charged as a penalty, because the company is losing time until he can be replaced. His family is suffering and he surely is. The lost time must go on and on until there is a final conclusion. We think we have done the fair thing, but we are still looking for light.

We have no quarrel with insurance companies; in fact, know they render considerable service in developing and carrying on safety education and practice. At the same time, we are convinced our policy of carrying our own compensation insurance risk is one of our most valuable helps and incentives in centering constant attention on not only the prevention of accidents, but seeing to it that every available assistance is given to hasten speedy and complete recovery of those who are injured.

Time and space permit only a brief reference to what can, and we believe must, be done along the lines of safety education for the future. It must begin in the school and be made an integral part of our educational system in order that the children may secure fundamental training in safety and health that must have a large influence in their adult life. Our company is doing something along this line usually by cooperation with local school authorities in the way of providing material for study and to some extent personal attendance of members of our safety and nursing system.

Lastly, we believe there is a positive need for better information in the form of what is commonly termed statistical data, in order that all of us may have a better and larger knowledge of what is actually going on. In our opinion, the existing basis on which such data are computed is neither practical nor fair and does not lend encouragement to employers to voluntarily provide necessary information.

The First Move is Consultation of the N. S. C.

I want to say that nearly every time we have anything that appears to be an unusual accident and sometimes what appears to be an ordinary accident, before I do anything about it, I usually reach for my file of National Safety Council pamphlets on that subject and I get something that is of real, positive help to me in seeing that situation and it also helps the man at the mill.

Believe me, we should do more than simply listen to a paper giving us encouragement in that character of service. I don't think a good many of us who are inclined to pat ourselves on the back realize what the engineering talent of this country has done to cut down the volume of accidents, even though they did have the question of economy and production before them.

For instance, in the International Paper Company, they have done away with the old hand-fired boilers, substituting stokers in their place. In the modern paper mill, it is practically impossible to find the beater room. Up on the mezzanine floor they have a little box of steam where they have a system for mixing the stock. They have almost entirely gotten over the idea of putting sulphite and groundwood together, pressing it, looping it and then beating it up again. The engineering talent of this country has moved this man out of the way.

Another thing, if the Paper and Pulp Section would have representatives from the various manufacturers of pulp and paper machinery present to discuss these matters, they could help you in solving your problems.

I also believe if we could have that sort of contact at these meetings in order to learn more about the electrical devices and other machinery it would be a lot cheaper in the end, because we would know how to do away with lost production caused by interruptions in service when something goes wrong, and at the same time a lot could be accomplished in the prevention of many serious accidents.

We are hopeful this Council or some equally reputable body will promote a proper basis of statistical data and develop a scheme or system for its compilation and distribution. We believe it would be a misfortune to continue the present system which does not furnish any real information and has a distorted basis. Unless something is done we may find the whole subject taken out of the hands of the direct representatives of industry and added to the hoard of governmental duties and supervision already existing.

Summed up, we must provide individual responsibility for capable study of our own accident and health hazards and experience as well as similar information from all available sources. We must make such information available and provide for the facilities for its application in the case of all employees, particularly the "Gang Boss." We must assist him in educating the individual workman as well as providing him with the authority and resources to establish safe operating conditions and safe practice. We must see that injured persons have competent medical care which often means help beyond what the physician may give. All of which, we believe, we have proven can be done in large industrial organizations with little or no added costs per unit of production and a large saving in accident costs. We believe the same thing may be accomplished on a community basis where groups or numbers of small plants or industries are willing to cooperate. Our principal slogan is good housekeeping which means cleanliness and order. This automatically compels safe places in which to work and requires teaching employees safe and orderly practices, which combined spell efficiency, safety and health.

ADJOURNMENT

Wednesday Luncheon, September 28, 1927

The luncheon session was called to order at twelve forty-five o'clock by the chairman, W. J. Peacock.

CHAIRMAN PEACOCK: Don't disturb the looks of tables just yet, gentlemen, we are going to have our picture taken.

(Luncheon was served immediately following the photographing of the group.)

CHAIRMAN PEACOCK: Our program is long enough to give attention to conserving time, but for the purpose of good-will and efficiency, I want you to know the new officers and committeemen whom you have elected. Certainly you will want to know them if they happen to be in your region.

(Chairman Peacock read the list of nominations voted upon at the Wednesday Morning Session and introduced each officer, the Section applauding meanwhile.)

CHAIRMAN PEACOCK: We are not unmindful of the past history of this Section. We have with us the gentleman who served as the first chairman of the Section. He modestly denied this, but I have the goods on him in print. His name is S. F. Shattuck, of the Kimberly-Clark Company. Do you want to hear from him?

S. F. SHATTUCK (Treasurer, Kimberly-Clark Company): Mr. Chairman, Gentlemen: That had grown very faint in my mind. I haven't forgotten though, the burning desire to get on top of that terrific accident record we were having a few years ago. It has been my bad fortune all my life to find people who do things so much better than myself that I lose my place to them. Mr. Peacock, Mr. Hoyman and others have proven this. But, comparing the impression one gets from this gathering with the impression one received 10 or 12 years ago, I confess that those first gatherings were very discouraging. There was a small sprinkling of paper and pulp men, and the room was filled up with insurance men and machinery salesmen. Our seed was sown outside of our territory a great deal. I rather think that it is pretty solidly a paper and pulp gathering this afternoon, and a very substantial one. Through Mr. Peacock and other members of the Section, it has become quite the envy of the National Safety Council. We are to be congratulated upon the officers you have selected to carry on the work of this Section.

CHAIRMAN PEACOCK: My reply to Mr. Shattuck is somewhat like the story of the little Negro on the wrong end of the street fight. After the other fellow had called him all kinds of names, he said, "Is you 'fru?"

The other fellow said "no," and added a few remarks.

Pretty soon the meek one said, "Now is you through?"

The reply was "yes," so he said, "All right, all dem things you done said about me, you is!"

Frankly, Mr. Shattuck has been an inspiration, and a tutor for a lot of us. In experience and vision he has had much to do with the making of the present Section.

Proceeding with our program, George Burns is the darndest little czar I have had anything to do with in years. After I build the program up, he unbuilds it. But, thanks to numbers, we have built it again, and George is first speaker in spite of his intentions.

GEORGE E. BURNS (National Safety Council): I am merely going to tell you at this time who won the contest in the "A" and "B" groups, and leave the details until other speakers have finished. What I have to say so interlocks with some of the other speakers, I don't want to take any advantage of them.

The winner of the group "A" cup is the Nekoosa Edwards Paper Company, of Port Edwards, Wisconsin, with the following: Number of employees, 948; hours

worked, 1,345,455; number of accidents, 7; days lost, 56; frequency rate, 5.21; severity rate, .041.

The winner of the group "B" cup (and this is a good one, because we had to fight like the very devil to get them to come in), is the International Paper Company, Niagara Falls, N. Y. Their record is as follows: Number of employees, 497; hours worked, 674,956; number of accidents, 2; days lost, 66; frequency rate, 2.96; severity rate, .10.

Unfortunately, or fortunately, I should say, because we are primarily interested in accident prevention, group "C" is still tied, with six companies tied for first place.

We have the pleasure of having Mr. C. E. Pettibone, Vice-President for Industrial Safety, National Safety Council, with us today, and I will turn the cups over to him.

C. E. PETTIBONE: It is a pleasure for me to be here. It is more than that. For a good many years I have watched the accident game, and have always been very much interested in the National Safety Council. The Paper and Pulp Section, as I have watched through the years, has passed beyond anything we ever dreamed of years ago in the Council. It seems to me today we have a National Council in the Paper and Pulp Section. There are more people in one meeting now than we had in a dozen sections during whole meetings years ago.

As one of the past chairmen said, in those days a few insurance men would sit around, and they made poor ground for this work. The thing I see here today, and it is most gratifying, is that you have actual owners and operators of organizations at these meetings. Safety work has grown beyond the point where a man was given the job just because he had nothing else to do. People are recognizing the fact that it is absolutely a part of production.

The Reaction of the Section to the N. S. C.

I think that I should say a word as to what the relation of your Section is to the National Safety Council. In talking with men, I not infrequently find the assertion that the Executive Committee runs everything. What are your respective relations? Your Section can run itself just as it pleases, with one exception: that it does nothing to interfere with the general policy of the National Council, or other Sections. It is your Executive Committee, made up by people you elect. They are not the holy of holies, and they probably don't know half as much about your problems as you do. The Council is absolutely dependent upon the Sections.

The Paper and Pulp Section, I can say without fear of contradiction from my friends in other Sections, is one of the most, if not the most interesting, active, earnest Section in the whole Council.

I don't want to make a speech, but, there is one fundamental thing about the American people—one fundamental trait—and that is the love of contest. Here in Chicago after the Tunney-Dempsey contest, I think it is a poor time to talk about it, but we do love contests, and this is one we can all enter in, can play fair and all win. Another fundamental trait of the American people, although it is kept hidden under cover and very seldom allowed to get out, is a love of humanity.

It seems to me in this contest that has taken place, you have both of these characteristics—you have the love of contest and the great good you have done for humanity, for the people in your employ. Those of you who haven't won have still accomplished a great deal, not for this year perhaps, but for years to come. So, it is a great pleasure for me to award these cups.

Is there a representative of the Nekoosa Edwards Paper Company here? Will he come forward, please?

(F. H. Rosebush came forward.)

MR. PETTIBONE: The inscription on this cup reads:

very much desire to have some representative from that mill here to express their appreciation which I too feel, not only for that mill but for the whole company.

I want to say at the same time, as was said here last year, while our Niagara Falls Mill was one of the most efficient or lucky or combination of both, I believe in encouragement to all of them. I believe that the Niagara Mill will have closer contestants among our own mills in the next contest. I thank you.

MR. PETTIBONE: Gentlemen, there are a great many contestants who will not receive cups. Without detracting in any way from what has just passed, this is one place where you can lose and win. One contestant reduced accidents two-thirds. Certainly, there is a wonderful record when you think of what that means, not only to that mill but to the paper industry as a whole in the National Safety Council and everybody in the United States.

I hope that those who have not won cups will not be discouraged and will not feel that the race has been in vain. The work is worth while; the contest purely a stimulation, and I hope you will work harder next year and we will always continue these contests for the good that they do through the industry.

CHAIRMAN PEACOCK: I am just as new to this information as all the rest of you. I didn't know until just a few minutes ago who were the winners of the cups. I am appreciative of the last words Mr. Pettibone gave you. We are all winning in a contest of this kind.

From my mill it looks like a hopeless contest, out in a city where labor turnover is something terrific, promoted by agencies which we can't control, and with manufacturing problems which we think are extraordinary, when we compare ourselves with my good friend, Franz' town, where the babies are all named after John Alexander, and where the preacher and school teachers are practically all in the official family; we seem to be out of the running.

But, I am still thankful to you, Franz, and to you, John Lundrigan, for the pace you are setting. As chairman of this Section, it is my anxiety to appreciate this fact: That we are all winning by the efforts we make in these contests. We are winning for the comfort of our men; we are winning for our mills cutting insurance rates, cutting costs, promoting efficiency, doing our part in promoting new spirit of achievement in the entire paper industry.

The next speaker on the program was to have presented the Grand Cup awarded by *The Paper Industry*, of which Mr. Edward B. Fritz is the publisher. Mr. A. Scott Dowd, of Chicago, is editor of the paper.

(At this time Mr. E. B. Fritz, publisher of *The Paper Industry*, was introduced.)

Presentation of Certificates of Merit

A Scott Dowd, Editor "The Paper Industry," Chicago, Ill.

I appreciate the honor you have shown me and the kindness of the publisher of *The Paper Industry* who has offered the Grand Cup for the 1927 Contest, in allowing me to make this presentation. That you may know him better, I want to introduce my dad—or "our dad," as he is affectionately called by us boys and girls in his employ—Mr. Edward B. Fritz.

I wish now to congratulate the two winners of group cups. It is gratifying indeed to observe their records. That of the Nekoosa-Edwards Paper Company is a long jump better than they made last year, and the International Paper Company's splendid achievement accompanies their first participation in *The Paper Industry* Contests.

Fifteen states of this country and three Canadian provinces have been represented in the contest this year; and the numbers entered have increased

from 41 mills that took part in 1925 and 72 that were registered in 1926, to the pleasing total of 119 that started off on January 1, 1927. The 107 mills that stayed through to the finish on June 30 made a safety record so far below the marks made in previous years that convincing proof is thus shown that safety contests are wonderful and excellent mediums through which to reduce industrial accidents.

The average severity rate for the Pulp and Paper section for the past seven years was 2.36, and frequency 42.03. The average severity rate for the six months of this year's contest was .63 and frequency 33.01, this severity rate being far below the splendid contest record last year of 1.746.

We are inclined to take as a sort of bogey the mark made in 1925, namely that in the 30 day contest in August of that year there were 16 out of the 41 mills that operated without a lost time accident. Perfect scores (no accidents) in the first month of the 1927 contest were 16; and the average for the eight months thus far recorded was 37 perfect scores per month, or 37 mills each month without an accident.

The 1927 Contest Was Among Four Groups

The contest this year, as you know, has been divided into three groups as follows: Those mills having 500 or more employees are classed as Group A; those having 201 to 500 employees are in Group B; and mills employing between 20 and 200 people are in Group C. This classification has made it more fair for the small mill to compete with the big one, and cups having been donated by the National Safety Council for the winners of each group, the opportunity to win a trophy has thus been tripled. Then the customary Grand Prize Loving Cup donated by *The Paper Industry* is to be awarded to the mill which, in the opinion of the group of judges, has made the most outstanding record in the contest.

The rules provide that on the basis of the lowest severity rate if two or more mills in any group are tied for first place, the contest for all contestants in said group shall be extended until the tie is broken.

There are six mills in Group C that have thus far had no accidents and their severity rate is therefore zero. Under the rules of the contest, this group as a whole must continue until there is one mill that has a lower severity rate than all the others.

The awarding of the major cup must therefore be held up pending the result of this C Group contest.

It is unfortunate in many ways that this large handsome silver cup which you see before you cannot be awarded at this time. However, I ask why you should fail to rejoice in the possibility that one of the mills in this open group which does not have a perfect score at present might even yet be declared a winner, and the spread of opportunities to win the major cup becomes wider as the contest lengthens.

I feel rather keenly the disappointment to be on the program to award this grand prize cup, and arrive at this time to find that I am unable to do so. Undaunted, however, in the desire to be of some service in this respect, *The Paper Industry* has given me certificates of merit to award to a few of those mills in Groups A and B, whose good records deserve some form of recognition.

Constructive activity in the Pulp and Paper Section is causing the gospel of safety to be spread over larger areas and into the minds of workers everywhere, and the results are becoming more and more gratifying.

I am therefore going to award a few of these certificates of merit to those mills who have won them.

The Champion Coated Paper Co., Number Two Mill, of Hamilton, Ohio, is the first to receive the Certificate of Merit, ranking Number 2 in the Group A contest. This is the first time they have been registered in the contest, and they have made an exceptionally low frequency rate.

I will ask Mr. Faist to approach the front of the room and receive the Certificate of Merit.

The Champion Coated Paper Company, Number Two Mill, has an average number of employees of 547; days lost, 28; hours worked, 663,050; number of accidents, 5; frequency rate, 7.54 and a severity rate of .042.

This company had more than one mill entered in the contest, there being 3 mills at Hamilton, Ohio, with 2,200 people entered in the contest. They made a combination severity rate of .609 and a frequency rate of 16.07.

K. L. FAIST (Champion Coated Paper Co., Hamilton, O.): As Mr. Dowd has just said, this is our first experience in a contest. However, from this time on, we are going to show the Nekoosa Edwards and some of the other mills what we can do.

At the start of the contest we almost lost out altogether. We were hardly on the second week when we had a fatality, but the rest of the mills pulled through and carried us on. Our Palmer Mill No. 2 had a wonderful record, and another of our mills came along mighty fine. All three mills will be in rank next time.

MR. DOWD: The Chillicothe Mill of the Mead Pulp & Paper Company of Chillicothe, Ohio, ranks third in the Group A contest. Will Mr. Ernest Augustus please approach the front to receive this Certificate of Merit.

This mill had an average number of employees, 674; severity rate, .044; days lost, 42 in 937,070 hours work; number of accidents, 7; frequency rate, 7.47.

During the eight months they were in the previous contest, the 1926 contest, their rank was 16, with a severity rate of .194. In the August, 1925, contest their severity rate was .064. Their lowest severity and frequency rates have been in 1927.

Confidence in Eventual Winning of a Cup

ERNEST AUGUSTUS (Mead Pulp & Paper Co., Chillicothe, O.): I just want to say to Mr. Fritz and the rest of you that we are going to be in it next year, and one of these days we are going to win the cup.

MR. DOWD: Rank Number 4 of this group is a repeater—the sun shines brightly on some of the contestants in this year's contest. The Hudson River Mill of the International Paper Company, at Palmer, New York, is the winner.

Mr. Lundrigan, is there a representative of that mill here? Mr. George J. Adams is the man we have been corresponding with.

MR. LUNDRIGAN: No, there is no representative here.

MR. DOWD: This mill had an average number of employees of 738; severity rate, .10; days lost, 91; hours worked, 951,626; number of accidents, 11; frequency rate, 11.56.

This is the largest paper mill in New York, and the fourth largest in the United States. The International Paper Company entered 15 of their 32 mills in the contest. The figures for these are as follows:

4,132 employees in 13 of the above 14 mills (155 accidents in 6 months); severity rate for 12 mills (6 months), .48; frequency rate for 12 mills (6 months), 20.99.

MR. LUNDRIGAN: I would just like to make one remark. There *must be something* in this safety contest business. This mill during 1926 and for several years past has not done as good work in this direction as might be expected. I did not expect to hear that they had won a certificate, and I surely will see that they get it.

MR. DOWD: The next rank is 5, and there are two mills tied for this position. We do not give one any priority over the other. The first one is Dill & Collins

Company, of Philadelphia. Is Miss Raub or any representative present? That is too bad. We will have to see that the certificate is mailed there.

This mill has had an average number of employees of 619; severity rate of .16; days lost, 146 during 885,755 hours worked. Number of accidents, 15; frequency rate, 16.94.

Their record for the previous contest during the eight months in 1926 in which they were entered was: rank, 13; severity, .193. The severity rate was lower in 1927 than in the 1926 contest. This company was one of the organizers of the Paper and Pulp Section.

The Laurentide Company, Ltd., of Grand Mere, Quebec, was also tied for Rank 5. This is a groundwood, sulphite, newsprint and board mill. Their average number of employees was 1,047; severity rate, .16; days lost, 205 in 1,255,295 hours worked; number of accidents, 17; frequency rate, 13.55.

In the previous contest during 1926 (8 months) their standing was: rank, 10; severity, .173, and in 1925 (1 month), a severity rate of .06.

The last mill receiving certificates ranking Number 6 in this A group are our old friends, the Marathon Paper Mills Company, of Rothschild, Wisconsin.

This groundwood, sulphite, paper and board mill with an average number of employees totaling 587, had a severity rate of .19. The days lost were 155 out of 814,270 hours worked; number of accidents, 20; frequency rate, 21.56. In the previous contest (1926—8 months), their rank was 44; severity rate of .706.

Mr. Altman was a former chairman of the Section, and an early participant in Safety Contests, winning a safety flag in 1916 in 3 months contest among Wisconsin mills.

An Old Contestant Victorious in Group B

As an official of that company, I will ask Mr. Everest if he will accept this Certificate of Award from *The Paper Industry* with their congratulations. We know that the message of inspiration will be brought back to the employees of that mill.

D. C. EVEREST (Marathon Paper Mills Co., Rothschild, Wis.): I regret that Bob Altman, the pioneer in this work, is not here to receive it.

MR. DOWN: Mr. Everest gives the credit for this safety record to the safety director, but without the inspiration and without the support of the mill management, where could the safety director get? Surely, without the complete endorsement and support of the Marathon Paper Mills, they could not have made this record.

In Group B the first Certificate is awarded to a mill that has been in former contests, but never has received any awards in them. We are very greatly pleased that this mill has been recognized this year—the East Walpole Mill of Bird & Son, Inc., of East Walpole, Mass.

This is a paper and board mill, with an average number of employees, 394; severity rate, .12; days lost, 67 in 557,916 hours worked; number of accidents, 12; frequency rate, 21.50.

In the previous contest during 8 months in 1926, their rank was 21, with a severity rate of .228. Will Mr. Rogers come forward, please?

B. D. ROGERS (Bird & Son, Inc., East Walpole, Mass.): It is certainly very gratifying to receive this Certificate. It is as much a pleasure as it is a surprise, as I had no idea we were in it with our 12 accidents. It is going to be a great pleasure to present this to the men at the mill, and it will be an incentive to do even more.

I want to pay tribute to the winners of the cups presented, but serve notice on them right now that seeing we have won a certificate, perhaps we can get a cup next year.

MR. DOWD: The next ranking mill is a repeater. This is a regular pump gun contest. I see John Lundrigan getting out his handkerchief to wipe his eyes, and it is true—The Glen Mill Number 5, at Berlin, New Hampshire, of the International Paper Company ranks Number 3 in Group B. As you know, this is a groundwood and sulphite mill. This mill had an average number of employees at 454; with a severity rate of .15. Days lost were 83 in 557,203 hours worked. Number of accidents, 10; frequency rate, 17.95.

MR. DOWD: The next ranking order is a mill which made a much lower record in 1927 than previously. The Mittineague No. 1 Mill of the Strathmore Paper Company, Mittineague, Mass., ranks Number 3 in this group. Is Mr. Wyman or any other representative of that company present? This mill had an average number of employees of 256; severity rate, .15; days lost, 46 in 306,716 hours worked; number of accidents, 7; frequency rate, 22.83.

The next mill is one which has never yet participated in any of these contests. Gentlemen, just notice that all down the line every mill has been improving its record. This mill is the Rhinelander Paper Company, of Rhinelander, Wisconsin. Is Mr. Bertels present? Mr. Roller? Will you kindly step forward, please?

MR. ROLLER's mill, the Rhinelander Paper Company, a sulphite mill, with an average number of employees of 382, had a severity rate of .19; days lost were 91 in 485,526 hours worked; number of accidents, 12; frequency rate, 24.72. It gives me great pleasure to present this certificate to you.

Speaking for the Boys Back Home

GEORGE ROLLER (Rhinelander Paper Co., Rhinelander, Wis.): This is indeed gratifying, and I know the boys back home will feel just as proud as I do. I would also like to express my appreciation of the assistance given by the inspectors of the Employers' Mutual Liability Insurance Company of Wausau, who were always interested in the promotion of safety in this mill.

MR. DOWD: The mill ranking fourth is the Mead Fibre Co., Kingsport, Tenn., with an average number of employees of 310; severity rate, .19; days lost, 79; hours worked, 423,494; number of accidents, 3; frequency rate, 7.05.

H. R. LADY (Mead Fibre Co., Kingsport, Tenn.): Gentlemen, you will hear from us again next year, I am sure.

MR. DOWD: The next mill is the Falls Manufacturing Company, Oconto Falls, Wis., a groundwood sulphite and sulphate mill. Average number of employees, 324; severity rate, .19; days lost, 88 in 464,274 hours worked; number of accidents, 10; frequency rate, 21.54. Their record in 1926 (8 months) was: rank, 12; severity, .188.

Mr. Bolt, will you just step to the front and receive this certificate?

MR. DOWD: The next mill, ranking Number 5, is the Beebe & Holbrook Mill of the American Writing Paper Company, Holyoke, Mass.

Mr. Wilson, will you represent the mill and accept this certificate?

A. S. WILSON (American Writing Paper Co., Holyoke, Mass.): I am proud to do so.

MR. DOWD: Their record is as follows: Average number of employees, 222; severity rate, .20; days lost, 56 in 278,752 hours worked; number of accidents, 4; frequency rate, 14.35. Mr. Wilson, kindly accept our Certificate of Merit for this splendid achievement.

A. S. WILSON: I feel elated inasmuch as we haven't been in this contest before. At that, we didn't do as well as we hoped to. Perhaps this is because we are situated a little differently from some of you, with twelve mills scattered all over the city. This makes it very hard to get results, although we have been working hard to prevent accidents. However, we have an incentive to do better another year. Thank you.

MR. DOWD: The last certificate in this group is to be awarded to the Port Huron Sulphite & Paper Company, Port Huron, Mich. Is there a representative of that mill present? If not, we will see that the certificate is mailed out with a letter of congratulation. This mill had an average number of employees totalling 238; severity rate, .27; days lost, 85 in 318,706 hours worked; number of accidents, 10; frequency, 31.38.

It is a personal sense of gratification to see a Regional Director of this Section in the State of Michigan and we feel that Michigan has an opportunity to do valuable regional work. We hope to give you publicity in order to build up some real enthusiasm in the State of Michigan.

The certificate that I have awarded to a Canadian mill, I am unable to give to anyone, as no one from the Laurentide Co. seems to be present. It seems necessary this year to resort to the pleasure of requesting our good friend, Mr. A. P. Costigane to serve as bearer.

A Final Group of the Severity Rates

A. P. COSTIGANE (Ontario Pulp & Paper Makers' Safety Association, Toronto, Ont.): It would be the greatest pleasure for me to do so, but I think they might value this Certificate more if it were accompanied by a letter of congratulation from you.

MR. DOWD: That shall be done.

Just in closing, I would like to quote these severity rates:

Average Severity Rate for 41 mills during 1 month, August, 1925.....	.276
Average Severity Rate for 63 mills during 7 months, January 1 to August 31, 1926	1.746
Group A—23 mills during 6 months, 1927—Frequency.....	28.22 Sev. .56
Group B—23 mills during 6 months, 1927—Frequency.....	44.00 Sev. .81
Group C—36 mills during 6 months, 1927—Frequency.....	34.82 Sev. .70
Average severity rate for Section for 7 years.....	2.36
Average frequency rate for Section for 7 years.....	42.03
Perfect scores (no accidents) in the first month of 1927 Contest were 16, and the average for 8 months of this year was 37 perfect scores per month (37 mills each month without accident).	
Average severity rate for leading 10 mills in 1926 contest.....	.125
Average severity rate for leading 14 mills in Groups "A" and "B" in 1927 contest	.126
"A" Group (7 leading mills), Severity.....	.105
"B" Group (9 leading mills), Severity.....	.162

In Group "C" the following six mills have had no accidents, and were therefore tied. There has been no winner to date:

Provincial Paper Mills, Ltd., Montrose Div.
 Kimberly-Clark Co., Neenah.
 International Paper Co., Riley.
 U. S. Gypsum Co., Gypsum, Ohio.
 Lincoln Pulp & Paper Co., Ltd., Lincoln.
 U. S. Gypsum Co., Lancaster, Ohio.

The next contest can perhaps simply be touched upon by me at this moment. The services of *The Paper Industry* are offered to carry on a contest in 1928 with your acceptance. We are enthused in this work as well as you are. Our work as publishers of an educational magazine is to enlighten our industry and bring those engaged in it up to higher levels of achievements. Safety is one of the greatest departments that there is in the industry.

We had been taking an active interest in the value of safety in the paper industry as early as 1910. It is gratifying to this magazine that the work has progressed as well as it has. You boys have responded to the inspiration of the thought of the contest that has linked Canada and the United States together in this safety work. This year has been greater than the preceding years. We are now looking forward to next year, to January, 1928, to terminate this contest at a definite time.

Learning as we do, getting nearer and nearer to perfection, and getting more enlightenment, I can say that we will not again have a repetition of the cup going over a meeting. Let me state the fact that this cup is to be awarded at a subsequent meeting, and the inspiration is there for the "C" group to go on and win their Group Cup, thereby building up regional contests. Perhaps one of the little mills will get the cup. In this way, the gospel of the Paper and Pulp Section will be spread over large areas as the results become more and more gratifying.

CHAIRMAN PEACOCK: The next speaker is Mr. D. C. Everest, President, American Paper and Pulp Association. We are indeed honored to have him present.;

Why Safety Is Worth While

D. C. Everest, President, American Paper and Pulp Association, New York City

It is a pleasure for me to meet with you today and discuss the subject "Why Safety Is Worth While." You are all familiar with the whole safety movement and many of you, from the earliest time of organized effort along that line. You know why safety is worth while, and you have helped to increase its value to your fellow men and the concerns which you represent. You know the game and you do not need figures to prove it. I have been asked to discuss it from the viewpoint of management; and as one who has watched the work of the National Safety Council, and particularly of the Paper and Pulp Section, and individuals in this section who were lending their efforts to this work before the formation of this section, I desire to extend my sincere congratulations on the good you have accomplished for the paper industry.

To my mind you represent the Technical Association of Safe Practice for the Paper Industry. You represent one of the pioneer sections of the Council and that seems but natural, since the paper industry itself is one of the pioneer industries of this country. With the rapid development of the business, it was recognized over fifty years ago that there was need for association work in the industry and consequently there was formed at Saratoga Springs, N. Y., the present American Paper and Pulp Association, which I have the honor to represent. I believe there is only one other trade association which has been in continuous existence for a longer time. Fifty years, or perhaps we may say seventy-five years, at the most, represents the development of the so-called industrial age in this country. People engaged in the industry were among the first to take up cooperative work as an association and this section of the National Safety Council was one of the first to vigorously enter into safety work and apply it to its business. It has paid the industry to do it, and the best evidence of that fact is that those who first started in the work have been the most enthusiastic for its continuance.

In considering whether it is worth while, I have always separated the subject into the two groups of tangible and intangible benefits and I am sure that if it were possible to satisfactorily measure the intangible benefits, they would far outweigh those which we are able to compute in figures. For instance, we know that we are making definite savings in the matter of premiums on compensation insurance. But I think too many were slow in taking up intensive safety work because they were not able to see in this one feature sufficient saving to warrant

any great expenditure along safety lines. It is the same class who attempt to operate plants with out-of-date machinery, limited personnel in both operating and accounting departments and boast of the fact that they do all their office work with one or two men and a stenographer. They only come to realize the necessity of safety work, of adequate machinery and ample personnel when the economic urge of business competition forces them to either get in line or get out of business. In our industry I think there has been greatest advancement in the art of manufacturing since the formation of the Technical Association ten or twelve years ago than there had been in any previous forty or fifty year period.

It may be interesting to note that expansion in output per person in all industry has been particularly large during recent years, amounting to 11 per cent in the two years from 1923 to 1925, and to 41 per cent in the six years from 1919 to 1925. Practically the same increases were recorded for the paper industry. The increasing of speed, the addition of new and complicated machinery has revolutionized the productive capacity of mills and yet with this continual "speeding up" one would naturally expect increased hazards and increased accidents, but such has not been the case. There have been fewer accidents in relation to productive output and to the number of men employed than ever before. It is the work of the men engaged in safety work, both in our own industry and in the machine building industry, who have made such a condition possible. You have in your line kept pace with the development of speed. If we had not received the benefit of your efforts, I can easily conceive of a highly hazardous manufacturing business instead of the comparatively safe and increasingly safe operation which we have today. It has been the cooperative work of the so-called practical men, the technical staff and the safety organizations which have made these things possible.

Continuity of Employment a Result of Safety

It must be evident to every one that with less accidents there has been greater continuity of employment for skilled men and labor familiar with the operating conditions in every plant. Labor turnover, which is one of the most expensive things in plant operation has been reduced. Safety organizations in plants have awakened everyone to the necessity of seeing what is going on about them, and in consequence many of the leaks and wasteful practices which have been going on for years have been stopped. From my own experience I know that there has been added interest on the part of every employee to stop waste, improve plant conditions and contribute to the general welfare of both employee and employer.

One of the outstanding things which I think has done more to benefit the management and therefore the business itself, is the fact that safety work has brought the management, the operating staff and the employees together in conference. This has built up a better understanding, a better situation generally than could have been done in any other way. It has provided a meeting place for the discussion of all plant and personnel problems. I think every manager knows his men better and the men have a better understanding of the management and its policies.

Safety work in a plant must be seriously considered. The management and all concerned with it must show real personal interest. The safety and health of men are at stake and despite the criticism made several years ago, that industry was not concerned with the sacrifice of life or limb and were only interested in what a man might produce, I am convinced that present day

operators are deeply interested in their employees and that they recognize that their highest duty is to expend every effort for their protection from accident or disease. If there are today selfish men in charge of plants, even they, as well as those who have a deep human interest in their men, must realize that from an economic standpoint they cannot afford to sacrifice men either through accident or illness. Take the situation from any angle you may view it, you cannot afford to provide anything except the best in the way of protection.

Safety work and the discussion of its various phases has opened up a new era in plant management and every factor which it has developed has been worth while. It has made for closer relationship, allayed suspicion, provided a healthy and wholesome atmosphere in which to work, eliminated the suffering of the employee and the consequent worry and mental distress on the part of himself and family. It has educated those who have come in contact with the work in health and sanitation, encouraged the provision of nursing service, brought about the adoption of group insurance, both life and health and accident. It has brought home to each man the necessity of further protection in the way of life insurance other than that provided under group policies. It has been the means of contact, and, through discussion, the point of origin of some of the finest things which we have in our industrial life today. It has, in fact, accentuated every good thing for the benefit of those who, through their daily work, contribute to welfare and upbuilding of the industrial and social life of this country.

The Council Has Made People Think

I am pleased with the fact that as the industry which we represent, has been a pioneer in the development of business relations in so many ways, that it has also taken such an active part in the work of the National Safety Council and has shown other industries the way in many of the things which go to make up a safe and efficient manufacturing business in this great industrial age of hustle and bustle, which, if left to its old policies might have resulted in much suffering and misery.

You have made people think. You have made them think about themselves, their families and their fellow men. No one can think and think seriously of the program as outlined by such an organization as this, without having a kindlier feeling for those about him. Any program which includes the idea of protection to others and watchfulness and care in your own doings, cannot help but make for better relationship with one's associates and a happier and better world in which to live.

In conclusion, I wish to again congratulate you, who have made this condition possible. You have made management and operating force both understand that the safety program is worth while and that the greatest thing in industry today is the elimination of suffering and waste of human life.

CHAIRMAN PEACOCK: Thank you, Mr. Everest, both for your presence and for your very interesting address. I can see a very useful continuation of these addresses in print.

F. H. ROSEBUSH (Nekoosa Edwards Paper Co., Port Edwards, Wis.): May I interrupt for just a moment.

I think one motion should come before us. *The Paper Industry*, as you all know, has been very active in forwarding the interests of the Section. In fact, we feel as though *The Paper Industry* belongs to us. I would like to make a motion that this Section accept the offer that Mr. A. Scott Dowd made as to the 1928 Contest, and also that we express our thanks to the Editor and Publisher of *The Paper Industry* for the efforts extended in our behalf in this Paper and Pulp Section.

(The motion was seconded by Mr. B. D. Rogers of Bird & Son, East Walpole, Mass., and unanimously carried.)

EDWARD B. FRITZ (*The Paper Industry*, Chicago): I don't think we need to have any further words. I think it is more blessed to give than it is to receive. At least, the Good Book says so. There is more pleasure in giving this cup and in saving the little finger of some employe than in receiving something.

CHAIRMAN PEACOCK: From now on a name has been coined for you—"Dad."

MR. FRITZ: It is a familiar one.

CHAIRMAN PEACOCK: We shall hear next from Mr. George E. Burns.

Paper and Pulp Contest Achievements

George E. Burns, National Safety Council, Chicago, Ill.

When Mr. Peacock asked me to speak on "Contest Achievements" I was panic stricken and even now I am somewhat in the same frame of mind. To answer this or rather to point out all the good that is accomplished, cannot, I believe, be done by merely studying the reports as they are received. As you know, this is the only resource at my command and I therefore have resorted to this graph (indicating) in order that you may follow the thought I have in mind.

The greatest good, to my mind, is to the individual, whether he be president, superintendent, trucker, or what not. Unfortunately, however, the reports that I receive for tabulation do not reveal the salient points. I can only hope to interpret for your approval, facts as I personally have noted them when handling the monthly and yearly accident statistical records.

Let us, if you please, consider for the moment the experience of the Paper and Pulp Section since 1920, the first year that an attempt was made to compile this data.

In 1920, 45 plants reported for an average severity rate of 2.60 and a frequency rate of 46.34

1921—	55 mills averaged	2.83 severity and	41.67 frequency
1922—	55 mills averaged	2.36 severity and	47.77 frequency
1923—	66 mills averaged	2.73 severity and	43.50 frequency
1924—	62 mills averaged	2.07 severity and	41.58 frequency
1925—	99 mills averaged	2.15 severity and	38.43 frequency
1926—	133 mills averaged	1.95 severity and	36.77 frequency

This brings us up to the start of the present contest. During this seven-year period the average severity was 2.36 and the frequency rate 42.03.

As can be noted on this curve (indicating) the averages are higher than those established during the 1926 contest, at which time the severity was 1.75 and the frequency 34.00. I am at a loss to understand why, during the first two months of the present contest, both the frequency and severity were subject to sudden rises and falls. It may be that many, never having entered previous contests or kept their accident records on this basis, failed to note all lost time cases until after the first month or two of the contest. Some believe that unless an accident is compensable, it should not be considered as a lost time accident, and this also may have had a tendency to overload the first few periods. Then again, it may be that some contestants reported cases which really should have been charged to December of the preceding year. Of course, upon learning of this condition, I immediately made every effort to correct our records as well as to give the misinformed member more detailed information.

Perhaps you can see that the severity rates outlined on this curve do not correspond with those quoted by Messrs. Pettibone and Dowd in awarding the

cups and certificates. Please do not misunderstand for I do not wish to distract in any way, shape or manner from the excellent showing made by these mills, but I think it is only fair that your attention should be called to the fact that these rates were not figured on the so called "standard 6000 day penalty" basis. You will recall that when the contest rules were discussed last year, we adopted for 1927 a 1000 day penalty for death and permanent total disability instead of the 6000 day penalty. Therefore, all severity rates will naturally be lower. All other charges were in proportion (6 to 1) to the old plan. Where 300 days were charged for the loss of the little finger, under the new plan 50 days are charged. Consequently, in preparing this chart, it was necessary that I revamp all records and put them on the standard 6000 day charge so that they might be compared with previous years' records. Of course, this change has no effect on the frequency rate. You can get some idea of what effect it had on the severity rate when I tell you that under the present plan the accumulative rate for the first six months is .63, which when revised becomes 1.97.

You may be interested to know that up to June 30 there were 11 fatal accidents reported. This is slightly above the average for the section which is 21 per year. During the same period 18 permanent and 1,603 temporary disability cases were also reported. The total days lost for all cases amounted to 31,488 days. This is the record compiled by 111 mills working 50,211,176 man hours, and employing over 38,000 workers.

The accumulative severity rate of 1.97 for the present contest is somewhat higher than that of 1.76 for the 1926 contest. However, the 1927 average is not really as bad as it first appears. It is quite a bit under the rate of 2.36, the average severity for the past seven years of the section.

Records of Short Duration Not Dependable

One should not be too hasty in forming opinions based on records of such short duration. Even five or ten years are hardly sufficient to visualize clearly the results of safety efforts in industry. Accident fluctuation during short periods bears too heavily upon the average. Year to year, or five year to five year, trend downwards will go far to furnish evidence why safety efforts should be expanded and made more directly responsible for management efficiency.

It is not difficult to reduce a high accident rate to one of modest proportions. But to reduce the rate below this would involve ten times the effort necessary to reduce it in the first place.

For example, take the drilling operation for oil or water. The first 50 or 100 feet is easy or it may not require much more effort to reach 1,000 feet. But after that every additional foot may cost as much as the 100 feet preceding. While finally, an irreducible resistance is reached, making further progress hopeless, at least with the tools in use.

So it is when accident records reach the average of many, many years' experience.

In all industrial accidents, we are, of course, always concerned with two elements. The first and easily controllable is the mechanical equipment, which may be defective.

The second is the human element influenced by age, customs and usage, while lacking in training or disposition. These can be brought under control by years of patient influence in educational directions. I believe this second factor is brought out quite forcibly by the fact that in all contests conducted by the Paper and Pulp section, the winners have been mills actively engaged in accident prevention for several years past. It is this patient influence in educating employees in safe practices which really brings about a healthy reduction from year to year.

The mills that have just been awarded the cups in Groups A and B will, like the example just mentioned, be called upon to exert extra effort. For them the race is by no means over. You will recall that in the contest rules, the grand prize cup is awarded to the mill, which in the opinion of the judges, makes the best record. This means that the Nekoosa Edwards Mill and the International Paper Company Mill at Niagara Falls, N. Y., must keep going every day or the winner of Group C might run away with that big cup. All the judges will have to go by is what we put on paper, or what can be explained to them should a conference be called prior to awarding the cup. We are planning to give the judges the history, as near as we can get it, of the accident prevention activities, both past and present, of the three group winners. Also, some idea of the manufacturing processes involved so that they can compare the so called "inherent hazards."

There has been some question why certain mills have withdrawn from the Contest. This is just a little family gathering, and I don't want anyone to feel that we haven't explained everything. I have had mimeographed the standing of all mills to date. I have a number of copies of this, and will be glad to give each and every one of you a copy.

A Regrettable Misunderstanding in the Contest

On the last page, you will find listed the mills withdrawn from the Contest, due to shut downs or one thing or another that prevented them from continuing. There are one or two mills in this group that I think might be referred to without mentioning any names. I think there was a little misunderstanding in the rules for this year's Contest. I hope the Contest Committee, for next year, will keep this in mind and not leave any "Stumbling Blocks."

When Bill Peacock said "George, you do it," I knew nothing about paper mills and nothing about the difference between mills. So, I said, "The Contest is open to all members of the Paper and Pulp Section of the National Safety Council, employing more than 20 employees and manufacturing pulp, paper, container board, strawboard, plasterboard," and after I got as far as strawboard and plasterboard, I just said, "and so forth."

I think that got us into a lot of trouble. Later we drafted a little pink slip and sent it out to each and every mill. We did not believe that anybody was prevaricating, but thought that it would be nice to have them state whether or not they were actually engaged in the manufacture of paper and pulp. Some of the replies we received weren't any too polite. Some of them called our attention to the fact that we did not have "actually engaged in the manufacture of paper and pulp" in the instructions that were originally sent out. Nevertheless, those mills were withdrawn from the Contest. With this one mill in particular, it was really unfortunate, because we had one of the national officers visit this mill and they were doing a real bang-up job. They were right on the jump every minute. They had posters throughout the place, and every man was keyed right up, having a wonderful time until we had to tell them they were out of the Contest.

I expected, after that, to meet someone at this meeting with a shot gun, waiting for me. I think that was true with one or two other mills. Mr. Hoyman had a mill or two that wrote in and said it was the same way with them—they hadn't taken time to read the original instructions, and just said "We are in the Contest." Mr. Hoyman very graciously withdrew those mills.

I want to clear up that question for those who thought it might not be fair.

CHAIRMAN PEACOCK: George, name the six mills for us that are still tied in the "C" Class.

MR. BURNS: The Provincial Paper Mills, Ltd., Montrose Division, Kimberly-Clark Co., Neenah; International Paper Co.; Riley, U. S. Gypsum Co., Gypsum, Ohio; Lincoln Pulp & Paper Co., Ltd., Lincoln; U. S. Gypsum Co., Lancaster, Ohio.

These are all in first place at the present time, and I wish you would please note in this report that I have listed all as Number 1. Never again will I list according to man-hours worked. I made that mistake in April and unthinkingly left the plant with the greatest number of man-hours first and let it go at that. This time they are all down as Number 1, and may the best one win.

C. E. TORRANCE (Bryant Paper Co., Kalamazoo, Mich.): You mention the fact that a contestant has to be a bona fide manufacturer of paper. What about our case? We have five mills, and three of them are paper mills. Wouldn't the three paper mills be eligible?

MR. BURNS: I think that promotes a little bit the argument we had last night. When *The Paper Industry* originally started this Contest in 1925, I believe it was the idea to award the Cup only to those actually engaged in the manufacture of paper. I feel this way: If you have separate divisions (this is my personal feeling in it, because Mr. Dowd is now chairman of the Contest Committee) if you wish to penalize yourself by putting in the power and repair division with one of your other mills, you can.

MR. TORRANCE: In a great many paper mills where they have several mills, each one has a power and maintenance division. About five or six years ago they were separated. The three paper mills have a total of 11 machines. The coating mill buys the paper from our own paper mills. It would seem to me, in view of that, only the three paper mills would be eligible to enter the Contest.

MR. BURNS: Somebody got up in the discussion last night and asked the same question. I don't know, but I believe everyone felt as you do, that the coating mill should not be included. I don't know how you keep the pay roll record. How do you charge maintenance?

Adjusting the Circumstances to the Contest

MR. TORRANCE: It is pro-rated over the mills. We have a system where that is charged to the mills issuing them.

MR. BURNS: If you have men working a day or two in mill No. 2, why not charge those hours to the mill if the men suffer injury?

MR. TORRANCE: No man working in another division except on a definite order is charged to that division when he has an accident.

MR. BURNS: We had that come up from one of the Eastern companies. They had an electric railway, and owned the entire town. They claimed that all their employees were engaged in the manufacture of paper, but at that time I just arbitrarily said that these men doing other work should not be counted. That is the way I had to do in my office, not knowing anything about it.

STUART H. BROWN (Union Bag & Paper Corp., N. Y. C.): I imagine there must be a similar condition in all the paper companies where they run more than one plant. We had a great deal of difficulty in determining for ourselves how to take care of this situation. We have electric railway, power and maintenance plants and the other departments that have nothing to do with the actual paper making. Still, they are more or less coincident to paper making, and I think that is a question that ought to be very closely defined for the future, because I have no doubt that there are many cases where an unfair advantage might be taken. There is lots of leeway there for things that do not exist. I would recommend or urge rather, that for next year's contest that very question be very closely defined.

JOHN LUNDRIGAN (International Paper Co., N. Y.): It seems to me the simplest and easiest question to decide since I have been in Chicago. If one of those main-

tenance or repair men was injured in the coating mill, it wouldn't count of course, any more than the hours he worked would count. But, if that same man was injured in part of the maintenance of the pulp and paper mill, it would count. If your truck driver went to the freight station for a gear to be used on a pulp and paper machine and was injured on the truck, it would positively be a part of the business of manufacturing pulp and paper. But, if this happened to be a gear for some other department in that company having nothing to do with the business of manufacturing paper and pulp, this accident could not be counted. I can't see how it would be understood otherwise.

As I said this morning, one of the most expensive accidents we had, occurred one cold winter's night in February when the night watchman of one of our mills was calling out a man. He froze his feet and later died. However, he was engaged in the business of manufacturing pulp and paper, but if he had been out on one of the several auxiliary or subsidiary interests of the International Paper Company which we operate and control, we couldn't consider charging this to anything but the department to which the accident would be chargeable.

How to Charge the Accidents

We have a door mill construction company, covering large jobs in our mills. While we inject the spirit of our safety organization into this door mill construction company, we absolutely separate them from the accident costs and charge them with whatever is directly up to them.

If in any way it has to do with the manufacturing of paper and pulp, that division is charged with it. After it is manufactured, it goes into a thousand and one interests. Our own company happens to operate several such interests. We have our own woodland operations. We have a great many accidents there, but it is kept as completely separated as a separate corporation, because we do not consider that it enters into the process of manufacturing paper and pulp until we begin to unload it out of a boat or a car at a plant. The moment we start to do that, it becomes an essential part of the business of manufacturing paper and pulp.

B. D. ROGERS (Bird & Son, Inc., E. Walpole, Mass.): I dislike to disagree with Mr. Lundrigan, but I want to say this: We have a paper mill and two box factories, and the only way we could decide this thing was, that we felt certain maintenance and engineering should be entered into the paper mill contest. We couldn't enter the box factories, although they were by far the largest and the maintenance crew work under the same work order system. We arbitrarily said the maintenance crew is part of the paper mill, and if the maintenance crew happens to be working in the box factory, and an accident occurs, the accident goes into the manufacture of paper and pulp.

The truck driver goes to the freight station for machine parts, a motor for the box factory and a gear for the paper mill. They were both on the same load. Then suppose an accident occurred. Who will you charge that to? One department will try to put it over on the other.

I say you should decide what departments and what mills will be in the contest and let it go at that. We have a definite number of men then in the contest, and those departments are in it. Otherwise if you try to separate these things after the accidents happen, you will find that you don't know where lots of them occurred.

MR. BROWN: The way we disposed of such accidents was to have the maintenance and engineering departments entirely separate, making them separate units from paper making or bag making or whatever it may be. We tried to get it down to the personnel as finely as possible—to what part of that department the repair crew belonged, for instance in paper making, and we decided after much research that 25 per cent belonged to the paper mill. Then, every month we took 15 or 25 per cent of the maintenance and engineering payroll and added it into the paper mill.

Whether that is satisfactory is a question, because conditions may occur which will make the results entirely wrong. We can't get very much closer, though.

A. SCOTT DOWD: Mr. Rogers covered the point I wanted to bring out. This company having paper and converting plants, with a maintenance crew working in both plants, the question would come in where to distribute the time when the men are engaged at the same time in service for both plants. I can't help feeling as we felt last night, that a maintenance crew would perhaps be included in the paper mill man-hours if the paper mill would be charged up with them. The paper mill would get the credit and not the power and repair mill.

MR. LUNDRIGAN: Let's get this clear. The maintenance and repair crew of a paper mill covers about 10 per cent of the payroll. They are not there waiting for something to happen. They are all over the mill, keeping the mill running. They are a part of the business of manufacturing pulp and paper. It is a mere matter of bookkeeping from time to time when you call one of those men into another industry, possibly joined to the same building. To my mind, that doesn't leave any doubt when the man gets hurt where the accident should be charged.

Now, if it could be determined as closely as our friend from the Union Bag & Paper Corporation says, where the average percentage of time of the repair crew is distributed to some certain mill, that is a good way to do it. For instance, in the town of Pittsfield, Massachusetts, our company owns every mill in the town but two. We have to maintain them. Oftentimes we may have to build a house. We could find many cases if one of the repair crew fell off the roof of a house, to charge that to the business of manufacturing paper and pulp, because the technical fellow will say, "You have to have the town there." Another brother put up a technical question also that would kill a thousand per cent batting average when he asks where to charge an accident when the truck driver goes to the freight house to get machinery for both plants.

Points in the Contest Referred to Committee

If we will be fair with ourselves, we can honestly determine every time an accident occurs whether it has to do directly and is a part of the necessary operation and process of manufacturing pulp and paper. If it can't be directly connected with that business, it surely has to do with some other industry. That is the way I see it.

MR. ROSEBUSH: Who are the other members of this Prize Committee besides Mr. Dowd?

CHAIRMAN PEACOCK: It hasn't been completed yet. All we know is that we have a chairman.

MR. ROSEBUSH: I move the question we are discussing and the questions relative to the next contest be turned over to Mr. Dowd to consider.

MR. LUNDRIGAN: I second the motion.

MR. ROSEBUSH: I move that the committee shall consist of Mr. Dowd and the vice-presidents of the different regions of the United States.

CHAIRMAN PEACOCK: That sounds pretty good. Is there a second.

(The motion was seconded.)

CHAIRMAN PEACOCK: All those agreeable say "aye." contrary "no." The motion is carried.

MR. ROSEBUSH: There is one other motion I would like to make if I may have just a moment: That the Nominating Committee put on the name of Mr. Robert Altman with the Engineering Committee. Mr. Altman is entirely competent to act on that committee, but I happen to know that Mr. Altman has been engaged in other work. If it meets with the approval of the Section and the Nominating Committee, I would suggest that we add another name, Mr. F. W. Braun, of the Employers Mutual Insurance Company of Wisconsin.

(The motion was carried.)

NAT. BARTLETT (Hollingsworth & Vose Co., Boston, Mass.): Before I go home, I want to say this: To these men here present, my heartfelt appreciation for the loyalty and kindness extended to me, and also for the correspondence and various posters and so forth to assist me in the safety work in Massachusetts. I also want to thank Ben Rogers who is adjacent to me, in fact just across the street, in opening up the archives of their safety records to me for my benefit.

ED. H. VALLIERE (Michigan Mutual Liability Co., Detroit, Mich.): I happen to be one of the insurance representatives at the meeting today, and I heard the reference made in regard to the great expectations from Michigan in the next contest. I want to assure this body that I will do all in my power to cooperate with Mr. Torrance to put Michigan on the map in a safety way.

CHAIRMAN PEACOCK: I have a suggestion which appeals to my sense of fitness: that "Dad" stand on his feet and say something.

EDWARD B. FRITZ (*The Paper Industry*, Chicago): I haven't anything on my mind. I came down to get something to eat, and am rather like the colored man, "At peace with the world—Ah just done et."

I am mighty glad to be here. We will be particularly happy to present this bigger cup to the winner sometime in the future. I believe the fight for the cup has, in a sense, helped to prevent many accidents in paper mills. And if it has done that, we are very happy. As I said before, the giving of this cup gives us a great deal more pleasure than anything we possibly could receive, because we are trying to help every section of the paper industry, and we consider this one of the very important ones. We are mighty glad to be a part of this organization.

CHAIRMAN PEACOCK: I wish Mr. H. G. Noyes would stand on his feet. He is engaged in educational work with the Vocational System in Wisconsin. He knows a lot about this safety game; in fact he teaches it to foremen.

B. D. ROGERS (Bird & Son, Inc., E. Walpole, Mass.): Do you want anything in the record in regard to the roofing situation?

CHAIRMAN PEACOCK: Go ahead, let's have whatever is on your mind.

Discussion of the Roofing Situation

MR. ROGERS: The first day I was here, I talked with Mr. Peacock about this matter. The National Container Association has recently joined the Council. The roofing manufacturers in many cases throughout the country, are not represented in the Council except in an auxiliary way. I thought a great deal of interest could be aroused in the roofing industry if we could get the safety idea to them. I also thought that the Paper and Pulp Section was the closest connection that could be made.

There is a National Roofing Association the same as the Container Association, and it would seem to me that through that way, the Executive Committee might interest them further in this Section. It would make it a larger Section if we could get them in. The machinery used in that work is about the same as the paper machinery, and the hazards are about the same.

Mr. Bickford is the representative of the Flintkote Company. They have paper mills, and incidentally I want to mention that they are probably the largest roofing, having one or two paper mills. They are not in the Association. Mr. Bickford is very keen on it, and he expects to become a member shortly, and I assure you that our people will also get back of it.

CHAIRMAN PEACOCK: We will ask you gentlemen to nominate someone who would get up interest in your Section.

MR. ROGERS: I think we can do that.

CHAIRMAN PEACOCK: Before we leave tomorrow we will try to appoint whoever you name as a chairman.

GEORGE BURNS: I want to take this opportunity to say something if I may. This

being the only opportunity I have of seeing you all together, I want to thank each and every man for the real and truly wonderful cooperation I have received during the handling of the contest for this year. You have most graciously sent in the reports, and I want to thank you for the the various little courtesies extended, and for the very kind way you have taken what we have attempted to give.

CHAIRMAN PEACOCK: I have just made the suggestion to Mr. Scott that he see that George's picture in connection with a write-up be placed in *The Paper Industry*, so that all of our friends may be acquainted with him face-to-face.

MR. DOWD: I was just hoping that that would be a little surprise. That is a very unusual thing for *The Paper Industry* to do; they are not in the habit of publishing the pictures of individuals. I was looking forward to this opportunity, and I think his picture really has a place in the magazine.

MR. FRITZ: The first time we published the picture of an individual was last March, and that was our good friend Mr. D. C. Everest.

ADJOURNMENT

Thursday, September 29, 1927

One of the most important meetings of the Paper and Pulp Section from the viewpoint of constructive planning and accomplishment for the coming year was the special business session held Thursday morning at nine-thirty o'clock, with Chairman Peacock presiding.

Chairman Peacock opened this meeting with the following welcoming statement:

"We are to understand that this year's business is over, and that we are entering upon the first meeting for the year 1927-28. The purpose of this meeting is designated in your program as, 'a meeting for intensive study and discussion of the major problems of the section, held especially for new officers, regional directors and committeemen to acquaint them with their tasks and to adopt a unified program for the coming year.'

"Our objective in the Paper and Pulp Section is to have a section that functions all year round. Those of you who have followed the history of this section know that the problem has been to get an activity and a group feeling that will carry through the entire year.

National Safety Council Service. We must not forget the service that the National Safety Council can and does give us. Get our individual mills in touch with the National Safety Council, and their facilities. Posters, educational service, statistical compilation is all part of the service that the Council is anxious to give to the members of the Section.

Carrying Home the Spirit of the Congress. Carry the Congress kick back to each region, urged the Chairman in his message. We have learned how to do that in this Section. Get the inspiration to the last man in the mill in the farthest isolated region. Chairman Peacock then diagramed the coming year's activities into the following divisions: Commissions, Newsletters, Contest, Regional Conferences, Safe Practice Pamphlets and Reports and Membership Drive."

Commissions. Chairman Peacock told the group present that this year the Paper and Pulp Section will elect research men to fill commissions and study certain problems throughout the year. He also made the announcement that J. J. Plzak of Consolidated Water Power and Paper Co., Wisconsin Rapids, Wis., had been elected as one of these research men.

A suggestion made by one of the prominent members of the section to the chairman that consideration be given to the idea of employing a paid secretary to carry on the work and activities of the section was announced and the request made that the matter be given the benefit of careful thought.

Newsletters. George Burns, of the National Safety Council, urged all members who desired to receive newsletters for the coming year to cooperate with the council by sending one centrally named address, one designated person to receive these, and a group number of newsletters to be sent in one package.

He explained that in this way, 20 or more letters can be sent at once to a central place and to one particular person to be held responsible for their distribution, saving postage, and at the same time eliminating the possibility of loss of the newsletters and later complaints to the management of the mill or the council that the letters are not reaching the right persons.

In connection with the material available for newsletters, Mr. Burns urged all those present to promote the regional conference idea, renew membership activities, and promote committee activities throughout the year. Developing safe practice pamphlets will give something to the section through the medium of the newsletter by announcing it to other members. Food for the newsletters can be provided and developed through the above channels throughout the year.

1928 Contest. A. Scott Dowd, chairman of the Contest Committee, spoke on the coming contest, and asked for suggestions as to any way that several manufacturers now members of the section could be included in the coming year's contest. These included such manufacturers as converters, coating mills, and others.

George Burns suggested having a group designated as N. O. C., "Not Otherwise Classified," but J. H. Slater of Escanaba, Michigan, immediately took the floor and said as follows:

"This is a rather deep question. When you start differentiating, you open up a real problem. Hazards are less in book and fine paper mills than in newsprint mills. Roofing mills while handling large amounts of material have a comparatively simple handling operation. Converters buy by far the greater portion of their material and make the paper from this material. We might take and divide the industry in half and put into one group the book, tissue and wrapping mills and put into the other group the news mills. However, let us have the question open for debate, gentlemen."

A Contest Equalizing Factor is Discussed

Mr. Rosebush then took the floor, and his expression on the contest situation was as follows: "When we are in a contest, we want to be measured according to the hazards we have. I suggest that hazards be made a factor in the coming contest. However, we are in favor of the one cup idea, and would like to see all the mills entered in the contest for one cup as last year."

M. J. Steinman of the Indemnity Insurance Co., of North America, then suggested that some adjusting rate, such as that used by steel companies and General Motors Co., in bringing all plants down to one basis, be used in the Paper and Pulp Section.

Mr. Burns promptly took the floor and stated that the only difficulty is determining this so-called equalization factor, and getting some sort of a measurement to bring all the mills down to one level.

Mr. Slater then spoke again and said that one of the determining factors should be whether the concern actually makes paper or not. Just how far we want to allow the concerns to do other things is a question open for decision.

The question then came up as to the desire of mills handicapped with serious hazards having the same incentive to enter a so-called "losing race," but Gleason, of Hammermill, brought out the fact that his mill, having serious hazards, even though it had never yet won the cup, had been stimulated to greater activity by far since entering safety work, and had reduced accidents immeasurably.

Chairman Peacock then suggested that in the near future we should have some other basis of judging, such as an achievement of first year's results. This met with the approval of the group present.

A. P. Costigane, Ontario Pulp and Paper Makers' Safety Association, Toronto, Ont., Can., then asked if the rules for the 1928 Contest would be submitted to all members. Mr. Dowd, chairman of the Contest Committee said that all members would ultimately have a chance to see the rules for the coming contest and comment upon them.

Developing Safe Practice Pamphlets. W. Dean Keefer, Chief Engineer for the Industrial Division of the National Safety Council, told of a prepared folder that the council is working on, entitled "Organization of Activities in Industrial Sections." The exact duties and obligations of each committee and executive committees is told in this folder. He suggested that sub-committees be appointed geographically so that they can get together and have reports circulated among the executive committee, and eventually have these reports printed by the National Safety Council as a safe practice Pamphlet. He emphasized the fact that reports and work done in different regions must be made available to those who do not come to the meetings or the Congress.

Regional Conferences. The Paper and Pulp Section is planning to have the regional conference idea uppermost. Chairman Peacock inquired of Alvin Record as to the possibilities for the regional conference in Maine this year, and Mr. Record assured him that this year they would attempt their very best to have a conference. They plan to make a canvass of all the mills in Maine and find a central location, and hold the meeting there. Invitations will be extended to non-members as well as members in an effort to make the meeting thoroughly worthwhile.

Chairman Peacock then asked M. G. Hoyman of Kimberly-Clark Co., to report on the results of their regional conferences in the past. Everyone knows that Wisconsin has had signal success in their regional conferences. Mr. Hoyman suggested that more mills and geographical groups make use of the National Safety Council, and get speakers from them to help put the meeting across.

Mr. Gleason of Hammermill Paper Co., then told of Erie conferences which had been held in conjunction with other organizations, getting local organizations for sponsors.

Mr. Hoyman in telling the value of regional conferences stressed the fact that men going to regional conferences get so many practical ideas and meet men that they know and exchange ideas of value. He then spoke about the unusual success of the Sheboygan conference this past spring, and urged more meetings to stimulate safety growth in the mills.

Chairman Peacock concluded the discussion on regional conferences by stating and emphasizing the fact that we must tie up our paper and pulp meetings if possible with some other safety meeting. Then, too, he stated that as soon as a region is large enough we will have a regional director.

He then announced that C. H. O'Connell, International Paper Co., as regional director of New York, who stated that he would work out his plans for the coming year with Mr. Lundrigan, industrial superintendent for all of International's mills.

Membership Activities. Mr. Burns spoke on the plan of getting new members and bringing those who had cancelled membership back into the fold. He stated that the best plan so far was the one of making so many definite appointments with different mill officials, and a field man from the National Safety Council would come up and keep these appointments. With the introduction provided by the members in bringing this field man to the new official, the National Safety Council man had a very good entree, and a splendid opportunity to talk safety to the official.

Mr. Burns also reminded those present that the National Safety News is publishing several pages each month devoted to exchange ideas, or practical mill helps. He urged the members present to be generous in sending in little kinks and practical suggestions. Many times a little device that has been helping in many ways is operating in your mill, and forgotten because it is no longer new to you, but the other fellow would like to have the idea, so pass it along whenever you get a chance.

Conclusion. Mr. Dowd concluded the meeting by stating that contest ideas that had been expressed in this meeting would be put into some form of a questionnaire and first of all submitted to the vice-presidents, who constitute the Contest Committee. The results would then be submitted to the regional directors for their comments. Finally, the adopted rules would be submitted to all members of the section.

Chairman Peacock adjourned the meeting by stating that he felt this session had been one of the most important of the Congress, and hoped that each member would carry back the stimulus of the coming year's activities to each individual of his respective mill.

ADJOURNMENT

SIXTEENTH ANNUAL SAFETY CONGRESS
NATIONAL SAFETY COUNCIL

Petroleum Section

New Section Officers

Chairman, GEORGE F. PRUSSING, Union Oil Company of California, Los Angeles, Calif.

Vice-Chairman, DR. R. P. ANDERSON, American Petroleum Institute, New York City.

Chairman Atlantic Coast Division, S. W. CANDEE, Tide Water Oil Company, New York City.

Chairman Mid-Continent Division, T. N. SHAW, The Midwest Refining Company, Midwest, Wyo.

Chairman Pacific Coast Division, F. A. SCOFIELD, Associated Oil Company, San Francisco, Calif.

Secretary and News-Letter Editor, A. A. NICHOLSON, The Texas Company, New York City.

Poster and Slide Committee Chairman, O. W. HUMPHREY, Standard Oil Company (N. J.), Elizabeth, N. J.

Publicity Committee Chairman, RALPH E. MOTLEY, The Atlantic Refining Company, Philadelphia, Pa.

Program Committee Chairman, RAY E. MILLER, Marland Companies, Ponca City, Okla.

Statistics Committee Chairman, J. W. MYERS, Standard Oil Company (N. J.), New York City.

Field Representative, H. N. BLAKESLEE, National Safety Council, Chicago, Ill.

Engineering Committee:

Chairman, C. W. SMITH, Standard Oil Company (Ind.), Chicago, Ill.

F. L. NEWCOMB, Standard Oil Company (N. J.), Elizabeth, N. J.

C. L. HIGHTOWER, Texas Pacific Coal & Oil Company, Thurber, Texas.

R. E. DONOVAN, Standard Oil Company of California, San Francisco, Calif.

Executive Committee: THE OFFICERS AND

E. J. SENNE, Vacuum Oil Company, New York City.

R. S. BONSB, Standard Oil Company (N. J.), New York City.

C. C. BENEDICT, Standard Oil Company of New York, New York City.

A. L. BARTH, The Atlantic Refining Company, Philadelphia, Pa.

V. R. CURRIE, The Texas Company, Houston, Texas.

D. J. WALLACE, Mid-Continent Oil and Gas Association, Tulsa, Okla.

E. D. MURPHEY, Mid-Continent Petroleum Corporation, Tulsa, Okla.

R. B. ROAPER, Humble Oil and Refining Company, Houston, Texas.

H. L. EGGLESTON, Pan American Petroleum Company, Los Angeles, Calif.

C. P. ANDERSON, Richfield Oil Company, Los Angeles, Calif.

H. M. WOLFLIN, California Petroleum Company, Los Angeles, Calif.

W. C. LYNCH, General Petroleum Corporation of California, Los Angeles, Calif.

Retiring Officers

Chairman, V. R. CURRIE, The Texas Co., Houston, Texas; *General Vice-Chairman*, DR. R. P. ANDERSON, American Petroleum Institute, New York City; *Chairman, Pacific Division*, CHARLES M. BUTLER, General Petroleum Corporation, Los Angeles, Calif.; *Chairman, Mid-Continent*, RAY E. MILLER, Marland Refining Co., Ponca City, Okla.; *Chairman, Atlantic Division*, THOS. W. WADDINGTON, Standard Oil Co. (N. J.), Elizabeth, N. J.; *Secretary*, A. A. NICHOLSON, The Texas Company, New York City. *Committee Chairman: Program*, F. C. SINGLETON, Standard Oil Co. (Ind.), Chicago, Ill.; *News-Letter*, A. A. NICHOLSON, The Texas Co., New York City; *By-Laws*, DR. R. P. ANDERSON, American Petroleum Institute, New York City; *Poster*, D. J. WALLACE, Humble Oil & Refining Co., Houston, Texas; *Membership*, GEO. F. PRUSSING, Union Oil Co., Los Angeles, Calif.; *Statistical*, J. W. MYERS, Standard Oil Company (N. J.), New York City; *Engineering Representative*, E. J. SENNE, Vacuum Oil Co., New York City; *Executive Committee*, THE OFFICERS and ROY S. BONSBIB, Standard Oil Co. (N. J.), New York City; F. A. SCOTFIELD, Association Oil Co., San Francisco, Calif.; J. D. BRIGHT, Texahoma Oil & Refining Co., Wichita Falls, Texas; W. F. BURT, Standard Oil Co. (N. Y.), New York City.

Tuesday, September 27, 1927

V. R. CURRIE, Chairman

Manager, Employment and Service, The Texas Company, Houston, Texas

The first session of the Petroleum Section of the National Safety Council was called to order at nine-thirty o'clock by the chairman, V. R. Currie, manager, Employment and Service, The Texas Company, Houston, Texas.

CHAIRMAN CURRIE: We want first to extend a most hearty welcome to any representatives present of new members enrolled during the last year, also to any representatives or members who may be attending for the first time a Congress of the National Safety Council. We hope that you will enter into our discussions in a wholehearted manner in order that you may derive the greatest amount of benefit from your contact with these safety men during the next few days.

It might not be a bad idea at this time to have these new members and representatives rise for a brief moment and give their names, as well as the names of their firms, in order that we may all get acquainted.

(About twenty-five men rose to their feet and gave their names and the names of the firms employing them.)

CHAIRMAN CURRIE: It is customary at the start of meetings of this kind to make a few announcements, and then hear the reports of the various officers and committeemen.

Several months ago I appointed a Nominating Committee composed of Messrs. E. J. Senne, chairman, D. J. Wallace and R. S. Bonsib, in order that they might deliberate and decide on nominations for office for the next year. I believe that they have worked out a line-up, and we sincerely hope that you will be present tomorrow morning at the election of officers to help select our officers for the coming year.

I believe that I can safely report that some progress has been made in the acci-

dent prevention activities of the Petroleum Section during the past year. Much of the work of your chairman has been handled by correspondence, but I feel that the outstanding feature of the year's work has been the employment of a full time field representative for the section. This was brought about by a continuation of the efforts of my predecessor, Mr. E. J. Senne, and also through the interest, aid and cooperation of the American Petroleum Institute. This plan became effective during May of this year, and our section has the distinction of being the first section of the National Safety Council to have a full time representative in the field. Through a special committee authorized at our last meeting, a young man was selected for the post and this selection confirmed by a mail vote of the Executive Committee, and I feel that I can best cover this particular phase of my report by presenting an exhibit. It is my pleasure to present to you, as Exhibit A, the only sectional full time field representative in captivity, Mr. H. N. Blakeslee, field representative of the Petroleum Section of the National Safety Council. As he is on the program you will hear from him later, so I will not ask him to say anything to you just now.

An Appeal to the Membership and Founders

I want to make at this time a special appeal to the general membership, but more particularly to the founders of this section. I want to ask all of them to continue to give their full support for the maintenance and promotion of the present scheme for a field representative which the American Petroleum Institute has so kindly sponsored. We all owe it to them to see that the office and the duties of the representative are kept at the maximum of efficiency and that the time is divided equally so the industry in general receives the help and support that was promised and intended.

I think I will continue my scheme of presenting the different officers as exhibits, and so as Exhibit B, I will introduce General Vice-Chairman Dr. R. P. Anderson. Dr. Anderson, have you any report to make?

GENERAL VICE-CHAIRMAN ANDERSON: (American Petroleum Institute, New York City.) As a perfectly proper General Vice-Chairman, I have no report.

CHAIRMAN CURRIE: Mr. Butler, have you any report?

C. M. BUTLER: (General Petroleum Corporation, Los Angeles, Calif.) I have nothing to report.

CHAIRMAN CURRIE: Mr. Miller, have you anything to say?

RAY E. MILLER: (Manager Safety Department, Marland Refining Company, Ponca City, Okla.) I think I included all that I have done in my letter to Secretary Nicholson, and he probably has it in his report, and I do not think it necessary for me to say anything here. If you read the secretary's report you will find out what I have done.

CHAIRMAN CURRIE: Then I will call on Mr. Thomas Waddington, chairman of the Atlantic Division.

(Mr. Waddington, chairman of the General Safety Committee, Bayonne Refinery, Standard Oil Company, Elizabeth, N. J., presented a detailed report of activities of the Atlantic Division.)

CHAIRMAN CURRIE: Secretary Nicholson is not present, and we are not going to have his report read. His report is here and as we have about a hundred copies available, the members who would like to have a copy may get one. There may be some salient features that you would like to know about.

I would like to say that Secretary Nicholson has done wonderful work indeed in getting out our News Letters and other work in connection with his duties, and this becomes more wonderful when we remember that he has been flat on his back since February. His contributions have come practically from a hospital cot, and

I think that we owe him a vote of thanks for what he has done. He has kept up both his work as secretary and that in connection with the News Letters.

R. S. MURCH (The Texas Company, New York City): I should like to call attention to some points in that report.

On Page 29 our secretary has outlined some suggestions which you might want to consider. They are as follows:

1. That the field secretary arrange to hold at least one General Divisional Conference each year.
2. That copies of all proceedings be sent to the secretary of the section for file and record.
3. That definite assurance be secured from the NATIONAL SAFETY NEWS, that at least one page be granted in each issue to the Petroleum Section, and that the field secretary be held responsible for securing suitable material for such page.
4. That at each Congress, the field secretary will render his annual report separate and apart from the report rendered by the secretary of the section.

The News Letter to Be Continued Quarterly

5. That the publication of the News Letter be continued on a quarterly basis, and that there be secured from the representatives the name or names of the executives of each concern member, and that a copy of News Letter be sent them direct. This would seem in order, inasmuch as these concerns make our section possible and it is only reasonable to assume that they are interested in keeping in touch with the section throughout the year.

6. That the chairman of the section will interest each Regional Chairman to appoint, without delay, a News Letter representative of the division who shall be responsible for submitting News Letter data to the editor, per his submitted schedule.

CHAIRMAN CURRIE: I think that Secretary Nicholson has done a wonderful piece of work on this report, especially when we remember that it has practically come from a sick bed.

R. S. BONSB (Standard Oil Co., New Jersey): I think that we ought to express our appreciation of his work to him by a letter or telegram from the chairman. Many men would have used that as an excuse not to do anything at all, and he has gone on just the same and kept up not only his secretarial work, but the News Letters beside, and I think that we owe it to him to send him some word of appreciation.

CHAIRMAN CURRIE: I shall be very glad to send him a telegram.

R. S. BONSB: Is he still in the hospital?

CHAIRMAN CURRIE: I believe that he is now confined in his home.

(The following telegram was sent):

A. A. Nicholson,
c/o Overlook Hotel, Saranac, N. Y.

Members Petroleum Section in session today unanimously express hearty appreciation for splendid work performed by you during the past twelve months, and join in wishing you full, complete and speedy recovery.

(Signed) Members of the Petroleum Section.

CHAIRMAN CURRIE: Mr. Wallace is not present, and I have received no report from him.

We have no report from the Membership Committee, but in spite of the inactivity I feel that we have made considerable progress during the year in the prevention of accidents, and I want to express my appreciation at this time to the officers who

have served and cooperated with me during the last twelve months, as I may not have an opportunity later.

I am not going to introduce the next speaker with any flowery language. I am going to give Mr. H. N. Blakeslee, our field representative, the opportunity to say something, of which I deprived him a while ago.

H. N. BLAKESLEE (National Safety Council, Chicago, Ill.): I want to thank the safety men and the engineers with whom I have been dealing for their co-operation, and I take this occasion to thank the superintendents and officers who are not present, for their splendid cooperation.

The Accident Situation in the Petroleum Industry and the Progress Made Thus Far

H. N. Blakeslee, Field Representative, Petroleum Section,
National Safety Council, Chicago, Ill.

This is the sixth annual session of the Petroleum Section of the National Safety Council. The first session was held in Detroit in 1922. The proceedings of that meeting indicate that a group of petroleum men interested in accident prevention got together in a round table discussion of the accident problems of the petroleum industry. The next program in 1923 brought forth some well prepared talks on the hazards of acetylene welding and static electricity. Each year since then other hazards have been covered in a similar manner. Speakers have told those in attendance how they were reaching the accident situations within their organizations and how accidents were being prevented. The committee, in bringing to you the present program, has endeavored to produce a program that will show actual accomplishments in accident prevention. It is the hope of the committee that upon the completion of this program every person present will feel as never before that his work is not only humanitarian but that it also is essentially a part of the production program of his company.

Management in the old industry is interested in accident prevention as never before. The American Petroleum Institute has proved its interest by making it possible to employ a full time representative on the staff of the National Safety Council. Company managers have made accident prevention a part of the duties of certain departments and have in many cases employed full time safety engineers, established foremen and workmen's committee and are making working conditions as safe as possible.

First-aid training is being given to workmen wherever possible. Instead of depending upon the United States Bureau of Mines for an instructor, employers are having one or more of their employees specially trained by the Bureau for the purpose of giving instructions to all company employees. First aid has proved its value in developing the accident prevention thought which causes employees to avoid injury. Artificial respiration alone is saving the petroleum industry thousands of dollars in death compensation claims by reviving workmen who have been overcome by petroleum vapors or gas. First-aid kits are being provided so the small injuries will not be neglected and cause unnecessary lost time.

Physical examination of new employees is almost a general practice. Old employees have been examined and are occasionally placed on work for which they are physically better suited. This works for general efficiency and is a help in preventing accidents. Employees were skeptical of the physical examination at first but they now realize it is for their own protection and are for it. In some localities where living conditions are not the best, typhoid inoculations have been given to employees free.

Free and group life insurance have been provided to create an estate for the

employee's family and also pay benefit in case of total disability. This insurance serves as an inducement for permanency and eliminates to a certain extent the worries upon the mind of the workman regarding the future of his family.

By these acts progressive management is manifesting its interest in employees' welfare and protection.

In contrast with this situation there are companies which have not yet realized the value of accident prevention. Occasionally I find a company which has a beautiful organization on paper for the purpose of securing insurance credits and is actually doing very little accident prevention work. I have talked with company officials who know their accident costs are high and would like to reduce these costs, but to use their own words "we would like to do something but we don't want to spend any money." Boards bristling with protruding nails are every place on some properties. There are no rules prohibiting smoking and no-smoking signs are not used. Boilers are set up with no thought of safety in operation. Keys protrude from engine shafts. Rotary draw works are unguarded. Cat heads are badly grooved and the cat head keys protrude. This may sound exaggerated to some but others know it is true. Insurance rates are very high and some insurance companies are simply refusing to carry these risks. The refusal of insurance companies to renew contracts has caused some of the companies to undertake accident prevention. These small companies usually have been able to make money under flush production but as production falls off become a losing proposition until one of the larger companies takes them over and by good management with improved and safe operating methods makes them pay.

State Legislation Sometimes Works a Hardship

These situations where management fails entirely to protect the workmen cause state legislation which sometimes works a hardship upon the conscientious operator and the entire industry. It would be far better to prevent the accidents and obviate the necessity for legislation.

Many of the safety engineers are new in the producing end of the petroleum industry and are learning the hazards of production. The Executive Committee of the Petroleum Section feels that accident prevention in refineries has been much better cared for than in the producing fields. For that reason I have devoted practically all my time to a study of producing department problems and I will try to express to you my thoughts in preventing accidents in the producing department.

The National Safety Council now has a Petroleum Section membership of 100 companies and in 1926 only 20 firms reported their accident experience. This report is not at all complex and if you have kept your records so that you are in a position to make a report of your progress to your Executive Board it is an easy matter to make your report to the National Safety Council. Only eight companies reported their experience for producing operations. Make a definite study of your experience for 1927 for your own information and then send it to the National Safety Council and in return you will receive our statistical report which will list your own record as compared with the records of other oil companies. No doubt your President will be interested in knowing where you stand in relation to others. The safety engineers who do report are always anxious to get the National Safety Council statistical summary. It will be indeed gratifying to the National Safety Council to receive the 1927 experience of the entire Petroleum Section membership. In sending in your experience you are helping build up interesting and useful information.

A close study and investigation of every accident makes possible the effective use of a cause classification which discloses the real hazards. Many accident reports are incomplete and even incorrect and give no clue to the real cause of the injury. No doubt you are all familiar with reports which read like this: "Stepped on

like to have Mr. Blakeslee give us some of his own experiences, that is, places where he has been and what he has found, something about his own work.

MR. BLAKESLEE: During the summer I made a trip through the Seminole, along the border line of Texas, to Fort Worth, Houston and Beaumont, and everywhere I went I was welcomed, and I came in close touch with a number of engineers and managers.

I am going to tell you of one situation. One Sunday morning I was scouting around, and I went into a drilling station. Everything was in good order. The drilling rig was well set up and everything looked good.

From that location I stepped to another location. The set-up was very bad. I said, "Whose rig is this?" and the operator replied, "I have only been on this job a few days, and I don't just know who I am working for."

The cathead was badly broken, the cat line was hanging down over the cat-head, and things were about as bad as you could find. Quite a story could be told right there. A good competent workman would not stay on that job any longer than it would take him to find another. Which one of those wells would get production first? What does efficiency in the set-up of the drilling rig mean to the owner of the well?

I am satisfied that it was a losing proposition for the owner of that poorly set-up rig.

C. L. CANFIELD (The Sinclair Oil Co., Kansas City, Mo.): I should like to ask Mr. Blakeslee if he has ever inspected water wells, I mean the portable type of derrick?

MR. BLAKESLEE: I do not remember that I ever did.

MR. CANFIELD: I was just going to call your attention to the fact that the derricks sometimes blow down.

CHAIRMAN CURRIE: If there are no further questions we will listen to our next speaker. I have made a change in the program here, and instead of calling on Dr. R. E. Humphreys at this time, I am going to call on Mr. Boyd V. Osborn, safety director, Standard Oil Company of Indiana, Casper, Wyo.

Our Reasons For and Methods of Departmental and Plant Inspection Committees

**Boyd V. Osborn, Safety Director, Standard Oil Company of Indiana,
Casper, Wyo.**

Success in any phase of safety work depends entirely upon the ability to secure cooperation from every department, and the wholehearted support of every employee, whether he be superintendent, foreman or laborer. I named them in that order for the reason that in my opinion the man at the top is the key to the ultimate success of the plan. Likewise the importance of their position in safety work and accident prevention depends greatly upon the importance of their regular position on the job.

Granted that one has the backing of the plant managers, superintendents and assistant superintendents, the next problem is that of educating the foremen and other employees to the idea that safety work is not something apart from their regular line of work, but is a phase which holds a very important position in their daily plans and should always be considered.

There are numerous methods of accomplishing this vast educational program and one of the best and most successful is that of establishing and organizing active safety committees. Some large organizations have these committees composed largely, if not entirely of foremen, sub-foremen and pushers, while other

companies select them from the entire staff of employees, making it a point to have at least as many men who are not foremen on them as they do of foremen. Some industries have one large committee composed of representatives from most of the various departments, this large committee to meet periodically and as frequently as experience teaches is wise. Others divide the plant into divisions either according to the number of men employed or according to the nature of the work or both and a committee is appointed from each of these divisions.

At any rate, these committees should have regular meeting dates, and the time should be set aside religiously so the meeting will be held without fail. Someone who is qualified should be selected as chairman and the meeting conducted according to a well organized plan. In spite of this plan, formalities should be almost entirely dispensed with. Many employees become embarrassed with formalities and red tape. They must feel perfectly at ease and free from restraint so that suggestions may be made without fear of adverse criticism or prejudice. It has been our experience that monthly meetings give better satisfaction than having them either quarterly or semi-annually, for the reason that they are kept more alert with frequent meetings.

Two Fallacious But Very Old Theories

I expect that the large majority of men present today have been brought up under the old teaching that it pays to take a chance and accidents are bound to happen. Isn't it strange that these two fallacious theories have lived so long and go so well together? Yet when you stop to think of it they are always found hand in hand. So when you think back over your years of experience and realize the change which has come over your own thoughts, you can easily realize that many of our best employees who have not had the advantage of close contact with accident prevention work, will need a lot of good, sound preaching of the doctrine which we champion today: "Safety—at work—on the street—and in the home."

In addition to the need of education, I believe the other main factor to justify the existence of the committees is the correction of dangerous conditions. I name this as secondary in importance to education because I believe that proper teaching will bring about the correction of these bad conditions, while the mere fact of making safe these things which are unsafe will not alone build a solid foundation upon which the Safety structure can be built. Our problem today is to have such a thorough knowledge of human nature and such a keen insight into physical and mental dangers that the work we do will be of lasting benefit to posterity.

So far you will see that we have touched upon two reasons for the use of safety committees: (1) For the advancement of safety education; (2) for correcting dangerous physical or mechanical conditions.

The next phase of my topic deals with methods, which means a more detailed explanation of the organization of the committees, where and how often they meet, and what they accomplish.

In our case, the safety committees are selected semi-annually, having one meeting a month for each committee. Thus you will see that each committee member should attend six meetings in a term and will learn the aims of the safety division and have a broader and better vision of our ambitions and goal.

For the purposes of our industrial relations department, of which the safety division is a part, our plant is divided into nine main divisions. For each of these nine divisions a safety committee is selected composed of two employees who are not rated as foremen, and one man who is a foreman or department head. The safety director is also a member of each committee. These employee

representatives on the safety committees are selected through the channels provided by the industrial relations department and the foreman is appointed by the plant management.

At the first meeting of each committee the safety director goes into considerable detail to explain the duties of a safety committeeman. He emphasizes the fact that regardless of how a man was appointed on this committee his duties are exactly the same. He also explains the plan much as outlined in the introduction of this paper. At each succeeding meeting some subject is prepared and discussed which will keep up the interest of the work and articles are cited from the NATIONAL SAFETY NEWS and other safety magazines to show that safety is not merely a local fad, but is a nation-wide program among nearly all industries.

It is pointed out to these committees that accidents are an economic loss. There is no gain, nor are dividends declared on money lost through accidents. The employee is drilled over and over that he is the big loser when it comes to accidents. Loss of life, impairment of health and earning capacity, suffering to loved ones at home through interruption of earning ability, discouragement due to worry when recuperating from injury, and, in fact, many of the ills to which humanity falls heir are either directly or indirectly due to accidental injury.

The foremen who are members of the safety committees as well as the foremen on the plant generally are impressed with the idea that they will be held personally responsible for the safe working conditions of their men. Thus, if you have 100 foremen on the plant, you will have 100 safety inspectors who are responsible for seeing that the work is completed with as few hazards as possible. I never lose an opportunity to tell the foremen that one of the nicest ways they have of saving money for the company is by reducing accidents. In doing this they are not only reducing the expense to the company but are also increasing the pay checks of the men.

They Know the Foreman Is In Earnest

The outstanding result of this procedure is that the employees soon learn that the foreman seriously emphasizes safety work and instead of considering it a joke they, too, take it seriously. If, on the other hand, a foreman considers it a joke, his men reflect perfectly his attitude and very little can be done until the foreman is brought to see the light. Experience has proven conclusively that the general attitude of any gang of men is almost entirely governed by the attitude of the foreman.

I have digressed slightly from the subject of safety committees, but you can readily see the connection when you stop to think that after a period of four or five years you will have had a chance to come in contact with from 200 to 400 employees, and they will have gone out on the plant as active safety men although they are not active safety committeemen.

It is the hope of the safety division to keep at this program and almost every employee will have had an opportunity to serve on one of these committees. In doing this we find we are able to smooth off the rough corners that appear to exist between men of different thoughts and ideas. Every new safety committeeman is looked upon as an opportunity to enlarge our own knowledge and experience. It has been my experience that every man who has served on one of these committees has taught me some new angle from which it may be viewed. Through contact with these men I have learned how frequently they have been right and I have been wrong. A deep-seated sympathy has developed for their views, and a respect for their opinions.

Of course, over a period of years one comes in contact with many different

types of men and each man must be handled in just a little different manner. Some men wonder why they were appointed in this capacity and think ~~someone~~ who had served on one of these committees before should be appointed. They are told that we are attempting to give every man a chance to act on the committees and inasmuch as they had never been on before they were chosen.

The success of a safety committee depends largely upon the ability of the safety director to keep the interest of each man aroused. Some of our employees become discouraged if their suggestions are not accepted immediately and in the same form they are submitted. This, however, is not always possible nor practical. Some suggestions might have merit to a certain extent but it would not be possible to shut down operations until an entire unit could be remodeled to suit some of the ideas advanced. Other suggestions may also have merit, but conditions may have existed for years and it is occasionally difficult to bring out these merits to the point where they will be recognized and accepted.

The Qualities of a Good Committeeman

So, in order to overcome these tendencies toward discouragement, the safety committeeman must learn just what are the qualities which will improve his work in this line and enable the safety division to profit most. The qualities which make a good committeeman are: tact or diplomacy, perseverance, patience, and a respect for the opinions of others.

Tact or diplomacy is named first because it is essential to have the good will of the large majority of your associates if you expect to succeed as you should. Perseverance comes next because no man can hope to get results in safety work unless he is willing to stick to his propositions even though they do not always meet with success at the first attempt. Perseverance implies a desire to defend your opinions with proper arguments. Patience is third for the reason that the world cannot be made over in a day and the teachings of carelessness which have been imbedded deeply into our thoughts cannot be changed merely for the asking. Repetition and reiteration of our ideals and thoughts will eventually leave an impression in the mind, but we must be patient if we desire to succeed. Last, but not least, comes that wholesome quality, respect for the opinions of others. Without this, we are liable to make many errors and with it we will frequently find that the other fellow did have some good thoughts after all.

Both Methods Used With Success

Some safety committees are in the habit of making weekly or monthly plant inspections and others are taught to keep on the alert always to learn of dangerous conditions or unsafe practices. In our organization both methods are used with success. Safety committeemen see conditions that need attention and they are corrected frequently before the safety director learns of their existence. Most of the small jobs of safety work are nothing more nor less than regular repairs that should be made anyway regardless of the safety factor, and are treated as such. As I stated before, we are attempting to educate our men and foremen to the point where they will recognize safety work as a part of their regular daily duties.

Once in a while a great deal of good can be accomplished both for the plant in general and the safety committee in particular if they have a plant inspection of about a half hour. Taking them over the plant gives them a better idea of what is wanted and also develops dangerous conditions that have never before

been noticed. It also serves to keep the foreman a little more on his toes if he knows that a safety committee may make an occasional inspection trip through his department.

Safety committees, if properly trained and prepared, are always of inestimable benefit to the cause for the reason that they are able to reach almost every employee and pass on information which could not be successfully disseminated otherwise. They can be of great educational value when they are handled rightly. Employees out on the plant who have no direct touch with the safety division are given a means of advancing suggestions through their representatives. It is the nature of some men to hesitate in offering suggestions to their foremen and the fact that divisional safety committeemen are available makes them feel more free to advance their ideas.

In conclusion I wish to say that in order to maintain the success that any safety movement deserves, it is necessary to keep everlastingly at it. After a goal has been reached it is very easy to slip back into the old rut and lose the value of what has been accomplished. It is very essential to keep aroused the interest which was shown during the campaign. We must keep in the minds of the safety committeemen that they are to look at their work with the deliberate intention of finding unsafe conditions, should they exist, rather than viewing their work with the idea that everything is safe.

Keeping Everlastingly After Safety

CHAIRMAN CURRIE: This paper is now open for discussion. If there are any questions you would like to ask Mr. Osborn concerning this matter he will be glad to answer them.

L. C. HOWARD (Standard Oil Co., Ind., Sugar Creek, Mo.): I think we should give Mr. Osborn a vote of thanks for his modesty in his report. He has not said one word about how efficient his methods have proven. I work in the same company and I know something of what he has done, and I want to say that his company has a record of working an average of 1,420 employees for 108 days without one loss of time due to accident. That is the best record that has ever been made, so far as I know.

C. L. CANFIELD: I would like to ask Mr. Osborn how he gets his safety suggestions. Do you solicit them and pay for them, and if so, how much do you pay for them?

MR. OSBORN: We once tried having a suggestion box, and I think we got everything in it but suggestions. We were not able to get much out of it. We have rarely solicited our suggestions, but we encourage the men to come to us with them, and many of them are brought to us that way.

MR. CANFIELD: Do you pay for them?

MR. OSBORN: We do not try to find out who gives them. Sometimes, someone will say, "Who put in that suggestion?" and I say, "I did." We can tell by the tone how the suggestion is received, and we try to protect the men in every way, as sometimes the suggestions are not received in a good manner, and the men would not send them in if they thought we would find out who gave them. We never pay for them.

In 1921 we had 14 lost time accidents per thousand employees; in 1922 we had 10 accidents per thousand; in 1923, eight; 1924, six; 1925, five; 1926, four and one-half; and in 1927 we cut it down to about one and one-half.

From February to May was a clean slate, or a total of 108 days without a loss of time due to accident, 130,000 man hours worked.

CHAIRMAN CURRIE: Our secretary could not be here in person to read his paper, but he has sent it in, and I am going to ask Mr. R. S. Mutch of the Texas Company to read Capt. Nicholson's paper.

What We Consider Our Chief Means of Instilling Safety into the Hearts and Minds of Our Employees

A. A. Nicholson, The Texas Company, New York City

To the above title, I should like to take the liberty of adding "hands" as well as the heart and mind, for, after all, the hands are the servants of the mind, and out in the midst of industry the hands do the major part of human operations. To really cover the title question specifically is more or less of a problem, because we are, in a measure, passing through the experimental stage of plant safety. We are trying this and that; we are exchanging safety ideas and notions; some of us are working toward foolproof plants and operations, and some of us, with new employees coming into our services, are failing to pick up where the former employer left off. In a measure we are all trying to instill safety in our workers through a conglomeration of ideas—all of which are really in practical sequence so far as the worker is concerned, though they may be from the standpoint of the safety department. So, I am going to simply state that we are trying to instill safety in the hearts, minds and hands of our employees through a building up of safety individuality.

Personally, I do not believe that we can ever hope to reach or approach the Utopia of industrial safety until we not only are able to get all of the industries, large and small, interested in this problem of human economies, but until we secure and adopt a standard code and conduct of safety in all plants, irrespective of the nature of the business. This is a gigantic task, but a big start has been made and with some further concentrating and boosting, I am sure it could be put over. Safety is safety—you can't make anything else out of it. There are certain fundamental safety principles that are just as applicable to a small town garage as they are to a great railroad system. In each plant, of course, there would have to be certain modifications to cope with the particular situation at hand, but in general, the basic fundamentals of safety are just as applicable to a rolling mill as they are to an oil refinery.

In The Texas Company, as in other concerns of a like nature, there are great departments which correspond to other and separate industries. For instance, the refining department, the sales department, the producing department, the marine department and so on. For a long time we worked under the theory that a different kind of safety was required for each of these particular departments. We had the cart in front of the horse, and so we didn't get very far. Now, we are putting over a general program of safety for the company as a whole and then developing the modifications to meet peculiar situations as they arise. But we do not consider that safety is a mass proposition, and herein we have erred in the past.

You will recall that I said we were trying to get safety into the heads, the hearts and the hands of our employees through the development of individuality. I believe we all agree that very few accidents just happen—they are caused; and with all due respect to the sixteen principal causes or any other sort of classification, I am sure that you'll agree with me that the real cause of accidents rests with the workers. A thing is caused when two opposite forces form contact. To every man there are two forces at work—one is negative, the other is positive. When the man on the job attempts to combine positive and negative forces, an accident is the inevitable result. Our problem then is to eliminate, as far as possible, the negative complex in our workers. Assuming then that we are able to remove the negative forces, only the positive forces, or those which are for good, will be left, and these will cause our accidents to decrease and our production to increase. The ratio of production and destruction is always in proportion.

Man is the most peculiar species of the animal kingdom because he possesses the power of forming ideas, and this power united with other human characteristics and particular environments causes him to form negative ideas. If you want to see an example of this, just take any gang in any plant, give each worker a raise except one, and see the negative idea come to the surface. That's human nature and it's also an example of negative ideas, and though no two men are exactly alike, you will find that in the forming of negative ideas more than 99 per cent of them stand on common ground. What works with money works with safety, or with time, or with any of the other factors that cast an influence on human happiness.

Safety, in an organization where the plants are widely scattered and of, perhaps, a different nature, will take on the appearance of a local epidemic. In other words, there will be found existing safety in spots here and there, and these will be pronounced;—in other localities will come to the surface a sort of half-hearted safety: while in some places it will look as though the game of production had turned into a game of slaughter. In making an analysis of our situation, we found, in a measure, that such a condition existed. Like the folks who eat grapenuts—"There must be a reason." And so, we set about to discover that reason which would furnish the clue to the remedy.

Kalamazoo and Halifax Are Similar

It was felt that what would work in safety lines at Kalamazoo would work the same way in Halifax. If plant A could operate with 500 men for 200 days without an accident, there was no logical reason why plant B, with half that number of men, should not operate for at least the same length of time without an accident. For a long time we sugar-coated and swallowed the bunk that the plants in the North were having the greater number of accidents because of the great slipping hazards during the winter months. As a matter of fact, the larger number of slipping accidents were taking place in plants that were located below the frost line. Surely there was a nigger in the wood pile somewhere. We sought that colored gentleman and he was located in the plants that were turning out all products and no cripples. The secret of safety is the man, and therein lies the mainspring of industrial safety, from the time that the new worker knocks at the gates of industry as an apprentice boy, until the mutual benefit association takes him to the last stop this side of the Jordan after he has died of ripe old age.

It is rather difficult for me to adhere to the text of this paper. I should like to say something about bulletins, mechanical safeguards, community safety, and other important and influencing factors, but again I repeat that we consider our chief means of impressing safety through the development of individuality. Safety to be effective can't be luke warm. It's got to be hot stuff, kept at a high temperature, and it's got to start from the top of an organization and come down. You can never start safety at the bottom and go up with it and get any kind of results. I don't know whether our concern has an edge in this respect on other concerns or not, but I do know that we have always been extremely fortunate in having the thought of the physical welfare of our workers foremost in the minds of our executives and subordinate leaders. So the safety organization in our concern has not had to plod for greater support at the headwaters of the program. Rather it has been that our executives have made constant inquiry as to how they might be of greater assistance to the movement.

So, in attacking this problem we have used simple mathematics. We have taken man, our greatest asset, and have divided him three ways. We have divided him according to production and under the general assumption that "Wild Bill" in the bull gang was doing work proportionately as important as the most skilled mechanic. The class of work he was doing did not lessen his importance to the organization.

right up. Workers don't require bossing nearly as much as they require friendship and fellowship. A job should be a place of happiness and not a semblance of a chain gang, and this is made one or the other by the foreman. It doesn't require a prophet to gauge the accident standing of a gang when every man would go to hell for his foreman, but the gang that is trying to "get" their foreman generally gets hurt. And so, this high temperature safety which was fired with human interest at headquarters must be kept hot by the foreman. He does this in a number of ways; going over the job, tools and materials; pointing out special and hazardous conditions together with the remedial rules covering them; and by making safety gang meetings a regular part of his production program.

The foreman can't spend all of his time with each individual worker. He wins him, gets him on the right track, and then turns him over to the other workers in the gang, who carry besides the other tools in their kit the never-failing and accurate measure of safety—the Golden Rule. The workers in the gang must make him feel "at home," not only that he is one of the gang, but that he is one of the most important ones in the gang. The guardianship of the other workers supplements the efforts of the foreman, and their combined safety fellowship sinks the wedge a bit deeper into the heart, which reacts to the mind, and which reflects itself in the hands and makes and keeps the job safe.

Safety Individuality is the Keynote

I am sure that safety individuality is doing more to build up a healthy and permanent safety organization than anything we have done thus far. Of course, we hold safety schools, safety rallies, use safety posters and all other kinds of safety stimulation, but aside from administering these safety stimulants, we want something that will inoculate the entire organization against inherent carelessness. We are endeavoring to forge a great chain of safety that will hold together an organization which spans the world. The great safety hook has been forged by our executives, and each link attached thereto is the individual worker. There must be no weak links in the chain if it is to securely anchor human happiness and preserve it against the rust of "let down" and indifference which breed accidents; it must be kept constantly painted with a thick mixture of sincerity and human interest.

We are amassing here in America the greatest army that the world has ever known—the army of production—which is daily becoming more and more engaged in the war of busy industry. We possess the men—we possess the arms—both are essentials to victory. If our ranks are properly trained in the school of the worker, if they are led by real leaders who know what leadership consists of, and if they can be inspired by the spirit of safety, there need be no casualties. So, from the standpoint of safety in our concern, we have turned our thoughts to the individual worker, telling him, teaching him, and taking him through the busy avenues of industry—training his fingers, developing his mind, and winning his heart—bringing him out as an individual, rather than leaving him a part of the great mass—and showing him, not the horrors of the careless, but the happiness of home and safety.

"Home" and "Safe"—

That is what we strive to teach,
Two little words of four letters each.
Just two simple words—no more, no less—
But which, entwined, spell happiness;
Which bring to workers joys untold,
And life grows sweet as yours unfold.
These words, it seems, were coined above;
They breathe of things we dearly love—
Home and Safe!

Home and Safe!
 In industry those words you'll meet;
 They sift the bitter from the sweet,
 And put real spirit into work
 That never tempts to slack and shirk.
 Half naked men who toil in sweat
 Live out their lives without regret;
 Their smile bespeaks an open heart
 As on they struggle with their part—
 Home and Safe!

Home and Safe!
 When din and noise and hissing steam
 Are left behind at night, it seems
 The sweetest path of life still waits—
 A dimpled baby at the gate,
 Who waits for daddy's loving arms—
 All grease and dirt—yet full of charms;
 For angels knot the tie that holds
 A baby's love and a worker's soul.
 Home and Safe!

CHAIRMAN CURRIE: That was a wonderful paper and it is now open for discussion. Has anyone any questions to ask concerning this?

Some questions have been presented to me on the question cards which were distributed among you, and we will take up these questions now.

C. L. HIGHTOWER (Texas Pacific Coal & Oil Co., Thurber, Texas): Gentlemen, I think we are forgetting something. I think that we owe Capt. Nicholson a rising vote of thanks for his wonderful paper, and I move that we do that.

(The motion was seconded, the question put and the motion carried by rising vote of thanks.)

Discussion of the Question List

CHAIRMAN CURRIE: Now I will read these questions, and I am quite sure somebody will answer them. Here is the first one:

What methods are used by workers (welders, lead burners) repairing tanks, agitators, and other vessels in regard to disconnecting lines or blind gasketing them?

A. TIMM (Standard Oil Co., Bayonne, N. J.): The lines are all disconnected, and the air of the tank is tested to see if there is any combustible gas in it, and the men are not permitted to go into the tank until we are sure that the lines are disconnected and a good test has been made of the air in the tank.

CHAIRMAN CURRIE: I have another question here:

What type of hose is most feasible for steaming of tank cars and other equipment for elimination of static electricity?

H. E. DISCHINGER (Roxanna Petroleum Corporation, St. Louis, Mo.): That was my question, but I find that it will be answered in the report of the Research Committee, so I will withdraw it now.

CHAIRMAN CURRIE: I might say that we will be glad to hear from Mr. H. C. Fowler, United States Bureau of Mines, Washington, D. C. I know that Mr. Fowler will have something interesting to say to us.

MR. FOWLER: Gentlemen: Even though I cannot be with you longer than today, I am glad to have had this one brief session with you.

I wish I could stay with you for the rest of the sessions, but, as all of you know,

the hand has written on the wall, and I am no longer a safety man. Mr. Miller and I leave this afternoon for Washington.

In common with all safety men, there is one line of safety which is my hobby, and that, as you know, is hydrogen sulphide. It was a long time before I could make the managers hear the rattle of the snake, and during that time the snake was taking its toll, but finally they took hold of the situation, and we found the snake. I do not mean to say that we have exterminated the snake, but I do feel that we have gone a long way toward doing so, and I am sure that the time will come when we will be able to avoid accidents caused by hydrogen sulphide gas, just as we have been able to avoid accidents from other causes.

OWEN HUMPHREY (Standard Oil Co., Bayonne, N. J.): This morning at breakfast I had a long talk with Mr. Fowler, and he told me that he had written a book dealing with hydrogen sulphide, and that it would soon be off the press, and I should like to have him tell us something about it.

MR. FOWLER: I have been studying this subject for a long time in an endeavor to find some way of preventing accidents due to hydrogen sulphide gas, and I feel as though I was just beginning to know something about it.

Just as we think we have it under control there is an accident and we have to go over the ground again, and this book is written from the experiments I have made and what I have learned from studying situations in an endeavor to find out whether or not a man can enter an atmosphere containing hydrogen sulphide gas with safety.

This book, "The Prevention of Accidents Due to Sulphide Hydrogen in Handling Sulphur Petroleum," gives the results of some of my experiences in that line, and as Mr. Humphrey said, will soon be off the press.

ADJOURNMENT

Wednesday, September 28, 1927

The second session was called to order at ten o'clock by the chairman, V. R. Currie.

CHAIRMAN CURRIE: We are going to make a little change in the program.

Mr. R. E. Donovan, Standard Oil Company of California, is the first speaker. He will illustrate his talk with moving pictures and the moving picture machine is not here now, so while we are waiting I am going to call on the next speaker on the program, Mr. Ralph E. Motley, director, plant personnel and employment, Atlantic Refining Company, Philadelphia, Pa.

How We Locate and Correct Unsafe Practices

Ralph E. Motley, Director Plant Personnel and Employment, The Atlantic Refining Company, Philadelphia, Pa.

It is written that "when the mountain wouldn't come to Mohammed, the sagacious prophet went to the mountain."

And so it is with all phases of safety. When results won't come to you (which is the rule, rather than the exception) you must "go out after them," and after you have exhausted all your bag of tricks, pray that you will harvest a good no-accident crop.

"How We Locate and Correct Unsafe Practices" is really a word picture of what we do when we "go out after them." It is not a new story. But it is a subject which bears repetition and one which usually offers a few choice morsels for those who are really interested in improving their methods of locating and correcting unsafe practices. A detailed account of the procedure we follow would be imposing on good nature, so I have subjected it to a "cracking" process and trust that the picture I will paint may be of some interest and value to you.

There are two chief bodies around which the safety activities of our plant are centered: the Safety Committees, and the Safety Department, each contributing in its own way to the locating and correcting of unsafe practices.

Ten sub-safety committees, composed of four or five persons each (usually foremen) and representing the various departments of the plant, make regular weekly inspections of all portions of the plant according to a predetermined schedule. These inspections are made on Monday or Tuesday of each week so that the reports will be in the hands of the general safety committee on Thursday morning. The reports, in addition to covering the entire results of the inspections along with the seemingly desirable recommendations, also include any other safety items of importance which come to the attention of the committee while on the particular inspection. Once a month each of the sub-committees meet with the safety engineer and discusses such things as: how to make more efficiently the assigned inspection; what to look for; ways of gaining the desired end without antagonizing foremen or men in the particular department being inspected, and other pertinent subjects of general interest to the committee. Each committeeman wears a company safety badge which identifies him as a bona fide safety committeeman.

The general safety committee, which is composed of the safety engineer as chairman, a representative from each of the main divisions of the plant, mechanical, operating, sales, package, miscellaneous, marine, engineering, and myself, meets each Thursday morning. At this meeting the reports sent in by the sub-committees are thoroughly discussed, digested and then forwarded

subsequent test shows the gas content to be below the required point. If the work is urgent, men are supplied with hose masks and are allowed to clean the tank if it does not pass the test. In all cases, a member of the safety department stands by to make sure that all necessary precautions are taken, and to lend intelligent assistance if necessary.

In high sulphur tanks such as storage tanks or distillate tanks of Crane Upton Crude, a preliminary test is made for hydrogen sulphide. To determine whether there is hydrogen sulphide present in the particular tank, a member of the safety department makes a test for this poisonous gas with a Tutweiler Burette. If the Burette does not indicate the presence of H_2S , the Burrell gas test is then made. The tank must be free of H_2S as well as below 25 per cent for gas before anyone is allowed to enter. In order to protect those persons who have occasion to work on the top of high sulphur tanks, a sign warning everyone to stay off the tank is placed in the middle of the stairway so persons attempting to reach the top of the tank will be warned of the danger involved. On any vent work on top of tanks or in taking samples or gauges from the thief hole, gas masks must be worn on all tanks containing hydrogen sulphide gas.

The Employee Must Be Thoroughly Trained

Before the inception of the tests for gas content of tanks and other containers ready to be repaired, the company had several unfortunate experiences, but since these precautions have been followed, there have been no fatalities due to these causes.

Before being allowed to operate a fuel oil burner independently, the employee must be trained by a competent instructor and then examined by a member of the safety department, in order that the safety of the individual operator as well as his companion employees may be assured. Gaseous repair work, still burning, elevator inspection, guard design, building inspection and special inspections are also functions of the safety department.

Anything can be done safely, even fighting. The story is told of a safe fight in which Henry Clay and John Calhoun were the chief combatants. The argument waxed hot. The contenders were nearly at blows.

"You are an old loafer, John," said Henry Clay.

"Say that again and I will knock your jaw off," replied Calhoun.

"Consider it said again," retorted Clay.

"Consider your jaw knocked off," diplomatically responded Calhoun.

Virtually all of the 350 foremen and many of the men at the Philadelphia plant have been instructed in, and are now capable of intelligently performing, first aid and artificial respiration. This instruction is given by the safety department under the supervision of the safety engineer. In addition to holding "refresher courses" for these foremen, it is planned to extend this course to all the employees at all the plants in order that everyone will be competent to lend such assistance should the occasion arise.

The safety department is held responsible for the strict observance, by the employees affected, of a set of rules known as "Plant Regulations." These regulations have been formulated by the superintendents, foremen and the safety department, are issued by the plant manager's office, and include such subjects as:

Precautions to be taken in ridding of vapors, stamping, welding and repairing of steel packages.

Method of work and attire of men working on acid lines and tanks.

The placing of planking where men must work on tank roofs.

The carrying of water in, and the stretching of nets outside, tanks being constructed.

The cleaning and loading of tanks and tank cars, and the use of masks. Precautions to be taken when repairing stills, agitator and ships, and many others where it seems advisable to issue such regulations.

The kind of bulletin board that demands attention.

As another step in our endeavors to make sure the regulations are being strictly adhered to, we are now drawing up rules and regulations for each individual craft. For example, the pipe fitters' rules would include such things as: when goggles should be worn, methods of working with various tools, precautions to be taken on different lines, kinds of pipe to use for different

installations, and many other essential safety precautions peculiar to that particular craft. These regulations are really nothing more than just what applies to the particular craft, as taken from all the existing rules and regulations and supplemented by other essential precautions which have not as yet been issued in regulation form. The advantage of individual regulations such as these is that the employee is not forced to digest several hundred rules which might not be at all applicable to his particular work.

Every accident report is thoroughly investigated by the safety department in an endeavor to determine whether the employee was personally responsible, and if so, to make sure that the relative chances for a similar accident to another employee is practically negligible.

The method we employ in keeping accident statistics enables us to analyze them individually and collectively by causes, character of injury, part involved, foreman, time of day, day of week, department, nationality, sex, color, education and marital state. All this information is contained on the accident report form which is made up by the dispensary, and which is subsequently punched on Hollerith statistical cards by the use of a proper set of codes. Then by the use of an electric sorting machine, any desired combination of contributing causes or factors can be determined for the entire plant or for the individual department. For example, we might wish to determine the number of married Italian laborers receiving contusions of the head by falling objects at 2:00 a. m. on Fridays. A monthly analysis is made for causes of accidents and the respective foremen involved. The former analysis points out the chief factors to be considered during the following month, and the latter analysis enables us to administer the necessary remedial ointment to the chief offenders. Each year a complete analysis is made of all the information contained on the card, for each department and for the entire plant. Analyses such as these afford some very illuminating facts, and are well worth looking into. A detailed account of the facts brought out in this yearly analysis is contained in the March issue of *Manufacturing Industries*.

Many Accidents Caused by the Tool Slipping

Many accidents attended by severe injuries have been caused by the simple slipping of a tool. The danger of injury is greater when men are working in elevated places, because if a tool slips at that time, the man may lose his balance and fall; and it is seldom brought out in the inquest that someone has been sufficiently instilled with the spirit of safety to go around placing feather mattresses in the several places scheduled for the receiving end of the man's anatomy. This hazard may be minimized by, (1) making sure the worker has in his possession good tools with which to work, and (2) by making sure that the worker uses his tools properly. A temporary lay-off for the first offense and dismissal for the second offense has practically eliminated the giving out of bad tools by the tool house employees. In addition to a monthly check up of tools by the safety department, one tool house man devotes his entire time to inspecting tools which are out in the plant on holdout orders, and instructing the workers in the proper use of them. The tool house contains adequate equipment for testing the capacity and strength of various equipment such as chain blocks, pneumatic hammers, gauges, hoisting machines and air compressors. Regular tests on these are made every two months. A monthly inspection is made of all acetylene equipment by submerging the torches under full pressure in water, in order that leaks which might cause a serious accident may be located and made safe.

Numerous manufacturers and retailers have justly complained that compe-

tion has forced them out of business, but in safety work, "competition is the life of the party." Posters, rallies and many other forms of creating interest all have their places, but if the spirit of competition has not been aroused, the

A safety trophy for which competition is keen.

fullest results will not, in most cases, be obtained. In an endeavor to create competition and arouse additional interest among our four plants, a special 1927 safety campaign was launched, the key-note of which was competition. All kinds of advertising media were prepared, including a distinct safety paper.

Immediate interest was aroused by allowing the employees to suggest names for this safety paper. Out of the numerous names submitted, *The Siren of Safety* was selected as the one most applicable to the proposed magazine. A silver safety plaque was then purchased to be awarded quarterly to the plant having the fewest lost time accidents per thousand hours worked during the respective three month periods, and to become the permanent property of the plant having the best record over the entire year. Space is provided for engraving the names of the winners by quarters and also for the entire year. The Pittsburgh plant was the winner for the first three months, and, incidentally, succeeded in going through the two months of February and March without a single lost time accident. In view of the fact that an extensive construction program was in progress during that time, this record was exceedingly encouraging. Because of its perfect no-accident record during the months of April, May, and June, the Brunswick, Ga., plant was awarded the trophy for the second three months. A keen spirit of rivalry exists among the four plants, and is entirely due to the fact that whole-hearted competition has been aroused. As an indication of this competitive spirit, the following telegram was received from the plant manager at Brunswick, Ga., when it was determined that his plant had won the coveted trophy for the second three months. "Please tell the Pittsburgh plant to send us that trophy P. D. Q. and kiss it good-bye, as it is coming to Dixie to remain forevermore."

An Interdepartment Competitive Race

At the Philadelphia plant, we are holding an inter-department competitive safety race in an endeavor to get our hooks on that trophy, which we have, so far, been unsuccessful in obtaining. To start the ball rolling, the superintendent of the mechanical department challenged all other departments to a contest for fewer lost time accidents for the remainder of the year. The large bulletin boards at the main gates of the plant were changed in such a manner that any employee could easily determine which team was leading for the month, and also which departments were responsible for any accidents which might have occurred. The accident experience over the past few years at the Philadelphia refinery has shown the mechanical department to be the chief offender. Since the challenge in March, the mechanical department has had several no-accident months, is leading in the inter-department contest, and accidents in all other departments have been greatly reduced.

Over the past five years, an average of 17 lost time accidents have occurred each month at the Philadelphia plant. While a great number of these involved the loss of only a day or two, nevertheless, they were considered as lost time accidents. In October, last year, by a special safety campaign, we succeeded in going through the entire month without a single lost time accident. Instead of having from 10 to 25 accidents per month this year, we are having only three or four, and all indications point to an even greater reduction.

The mechanical department has a special safety inspector who devotes his entire time to accident investigation and prevention. The fact that he insists that the company rule of reporting to the dispensary for even the slightest injury be strictly followed, has led to some very amusing incidents. One day he was down around the pipe stills, when, looking up into the air where riggers were placing beams, he noticed one man rubbing his finger, which to all appearances, he had recently bumped or scratched against the beam. Not a word was said. The mechanical inspector merely pointed his thumb toward the dispensary and the meaning was communicated to the rigger just as effectively as though the command had been spoken directly into his ear. The

rigger immediately slid down from his lofty perch and was last seen hot-footing it in the direction of the first aid emporium.

Before the medical sciences reached the stage where various kinds of vaccines and antitoxins could be successfully used in warding off many kinds of contagious diseases, literally thousands and thousands of persons in all parts of the world died because of the lack of these preventives. But now, through the wondrous advance of these sciences, there is in existence vaccine for warding off almost any kind of contagious disease. In view of this degree of perfection of the medical profession, perhaps some day someone will concoct a potion, which, if injected into the arms of all new employees, will render them totally immune from all kinds of accidents. But until that time, we will have to be satisfied to keep everlastingly plugging at accidents with the methods we have at hand, and those we borrow from our neighbor.

The chief thing to keep in mind in "locating and correcting unsafe practices," or in any one of the many phases of safety, is to locate and correct that unsafe practice before that unsafe practice takes its toll.

CHAIRMAN CURRIE: I want to thank Mr. Motley for his wonderful paper, which is now open for discussion.

It has been a recognized fact that very little can be accomplished without the support and cooperation of the men higher up, and I think that we are fortunate in having some of these men with us today.

I want to present to the members of the Petroleum Section one man who, perhaps, more than any other, has been responsible for the promotion of accident prevention work in the oil industry, and if Mr. C. J. Hicks of the Standard Oil Company, New Jersey, will please rise, I will be glad to introduce him to you.

(Mr. C. J. Hicks acknowledged the introduction by rising.)

CHAIRMAN CURRIE: The next speaker will be Mr. H. J. Tobin, Standard Oil Company, Indiana, Chicago, Ill.

What We Consider Our Most Successful Method of Promoting Safety In The Sales Division

H. J. Tobin, Standard Oil Co. (Indiana), Chicago, Ill.

So that you may understand our method of promoting safety in the Sales Division of the Standard Oil Company, it is necessary that you first comprehend our problem, the type of accidents we must cope with, their cause and the means at our disposal to eliminate that cause. To be sure, accidents are no respectors of persons and we sustain, as most of you do, accidents of all the various kinds and degrees that are known to the marketing end of the petroleum industry, from the tragedy of death to the showing of a profit in the business—which nowadays is indeed an accident.

But the particular accidents we suffer most frequently are automobile accidents. The Chicago division of the Standard Oil Company is located in a heavily populated metropolitan district, very congested, where the automobile accident rate is great, and the power to combat this problem not entirely in our own hands.

Now in dealing with accident prevention problems I believe you will find that in the main they may be dealt with in three different ways.

First: Where it is possible you may often remove the hazard of eliminating the cause of the accident. To illustrate, simply; around your plants where the danger of personal injury to an employee exists from use of a defective piece of equipment. You may eliminate the hazard of removing the defective equipment without injuring your operations.

Second: Where the hazard exists and it can not be removed, use measures to forestall the occurrence of an accident.

To illustrate: In the marketing of petroleum products there is always the fire hazard to combat. Protect yourself with modern fire fighting equipment and instruct your employees as to its use.

Third: Educate your men through all the devices at your disposal that safety is part of their job; that it pays them dividends and is a great power for doing good. And it is through this last method that we accomplish most, although it is the most difficult and intangible method of promoting safety that we have at our disposal. We believe we accomplish this end through the operation of our local safety committee. In our educational program we use the devices familiar to all of you. Lectures by the safety man at the meeting of salesmen, tank wagon drivers, and service station men, safety posters furnished by the National Safety Council displayed at all plants and service stations, competition in safety records between various plants and service station divisions. But in our safety committee we believe we have the most effective weapon to combat accidents.

The safety committee for the Chicago division is composed of the manager, the superintendent of equipment, the shop foreman, two tank drivers, a service station man and the safety man. The personnel changes from time to time so that as many as possible may have an opportunity to serve on the committee. The committee meets each Tuesday at 5:00 p. m. at the main office. Its purpose is to recommend methods of eliminating and preventing accidents. So far we operate about as all of you do; many, if not all, of you are familiar with the safety committee, its organization and operation. But here I believe we differ.

Men Involved in Accident Are Interrogated

Our safety committee brings before it each accident considered of importance, by calling in the man or men involved in that accident and having them explain in detail, with diagrams, charts and miniature equipment, the conditions under which the accident took place. With the man involved in the accident is his immediate superior, his foreman, or superintendent, whose duty it has been to investigate the accident immediately after its occurrence and who is before the committee to substantiate or contradict the man's explanation of the accident. After the man has explained his accident he leaves the room while the committee discusses the accident. They then vote on whether or not in their opinion the employee has been at fault. The man is then again called before the committee and is informed of their decision. If the committee believes the accident inexcusable the man is perhaps informed that the committee will recommend his discharge or demotion. If the accident was unavoidable and the man's conduct excellent, the committee does not hesitate to praise him. Now do not misunderstand me. The committee is not a court trying a man. It does not deal out punishment like a court of law. It is a committee of the man's fellow employees sitting to review the accident and to do all in their power to help that man avoid similar occurrences.

Now as to the effect on the man. Without doubt you can well see that a man would not care to come in before the committee and explain his accident. In the first place, he comes in on his own time, after working hours, and gets no pay for it. Secondly, no one cares to "go on the carpet" and explain the reason for an accident, whether he is right or wrong in the case. There is always the chance that the committee will not see the man's side of the story. In fact, most times they do not and no one cares to be "bawled out."

Now as to results. Five years ago, before the committee was created, operating about 350 cars and trucks and perhaps 100 service stations in the Chicago field we suffered about 90 accidents per month. Today, with 600 cars and trucks and about 400 service stations, we have on an average 30 accidents per month. This includes all types and kinds of accidents, from a spill of furnace oil on a lawn to a severe automobile collision. Now we are proud of our record and we attribute any improvement we have made to the fact that we have instilled into the minds of our men the fact that they will personally be held accountable for every accident in which they are involved. We have placed the burden of accident prevention on them and consider it as important a part of their job as making their sales quota.

The secret of our success, if you believe we are successful, lies in the fact that figuratively we take off our coats and go after each individual accident. We pick it apart to see what caused it and how we can prevent it in the future. We are earnest and sincere in our work and we try to instill in others that sincerity for accident prevention work.

Furnace Oil is the Cause of Much Worry

CHAIRMAN CURRIE: Are there any questions that you would like to ask Mr. Tobin? His paper is open for discussion.

C. L. CANFIELD (Sinclair Oil Co., Kansas City, Mo.): I should like to inquire the type of hose that you use for the delivery of furnace oil.

MR. TOBIN: Furnace oil is the bane of my existence. As you refinery men know, furnace oil is usually used by people who have nice lawns and are very particular about them, and in delivering oil it is almost impossible not to spill a few drops, and if you spill a few drops on these lawns it ruins them in the eyes of the owners; so when our men spill any oil it means that we have to send someone out there to dig up about 50 rods of ground and fix the lawn up, and this takes time, and we have never found any good way of delivering this oil.

We use the ordinary gasoline type of hose, but it is not very satisfactory for furnace oil. Sometimes we carry a tarpaulin to spread under the hose, and that helps. Perhaps you have a more effective way of handling this.

MR. CANFIELD: Our method is not very satisfactory, either.

R. J. LAUDER (Roxanna Oil Co., St. Louis, Mo.): What kind of fire equipment service do you think is best for service stations?

MR. TOBIN: We have not found fire extinguishers particularly effective. We have found the soda and acid combination not very useful, nor has Pyrene equipment been very satisfactory. We have had pretty good results by using the Pyrene with the one quart Foamite extinguisher. Of course, if there is much wind the fire is harder to control, but we like the Foamite very well, and used with the Pyrene we get pretty good results.

MR. BONSB: Do you ever use sand?

MR. TOBIN: We have not found fire extinguishers particularly effective. We nearly always the shovel is missing, because, as one of the men said, they make good coal shovels, and it is hard to keep them there. Then when you need it there is nothing to get it up with. The most effective way of using sand is to keep it in buckets, but it takes a great deal of it to put out a fire.

CHAIRMAN CURRIE: We will now listen to the report of the Nominating Committee.

R. S. BONSB (Standard Oil Co. of New Jersey, New York City): As Mr. E. J. Senne, the chairman of this committee is unable to be present, I was asked to read his report. He asked me to take his place, but I am unable to do that, so I will just pinch hit for him.

Report of the Nominating Committee

Chairman, George F. Prussing, Union Oil Company of California, Los Angeles, Calif.

Vice-Chairman, Dr. R. P. Anderson, American Petroleum Institute, New York City.

Chairman Atlantic Coast Division, S. W. Candee, Tide Water Oil Company, New York City.

Chairman Mid-Continent Division, T. N. Shaw, The Midwest Refining Company, Midwest, Wyo.

Chairman Pacific Coast Division, F. A. Scofield, Associated Oil Company, San Francisco, Calif.

Secretary and News-Letter Editor, A. A. Nicholson, The Texas Company, New York City.

Poster and Slide Committee Chairman, O. W. Humphrey, Standard Oil Company, (N. J.), Elizabeth, N. J.

Publicity Committee Chairman, Ralph E. Motley, The Atlantic Refining Company, Philadelphia, Pa.

Program Committee Chairman, Ray E. Miller, Marland Companies, Ponca City, Okla.

Statistics Committee Chairman, J. W. Myers, Standard Oil Company, (N. J.), New York City.

Field Representative, H. N. Blakeslee, National Safety Council, Chicago, Ill.

Engineering Committee Chairman, C. W. Smith, Standard Oil Company, (Ind.), Chicago, Ill.

Executive Committee, The Officers and—

E. J. Senne, Vacuum Oil Company, New York City.

R. S. Bonsib, Standard Oil Company, (N. J.), New York City.

C. C. Benedict, Standard Oil Company of New York, New York City.

A. L. Barth, The Atlantic Refining Company, Philadelphia, Pa.

V. R. Currie, The Texas Company, Houston, Texas.

D. J. Wallace, Mid-Continent Oil and Gas Association, Tulsa, Okla.

E. D. Murphey, Mid-Continent Petroleum Corporation, Tulsa, Okla.

R. B. Roaper, Humble Oil and Refining Company, Houston, Texas.

H. L. Eggleston, Pan American Petroleum Company, Los Angeles, Calif.

C. F. Anderson, Richfield Oil Company, Los Angeles, Calif.

H. M. Wolfkin, California Petroleum Company, Los Angeles, Calif.

W. C. Lynch, General Petroleum Corporation of California, Los Angeles, Calif.

CHAIRMAN CURRIE: Are there any other nominations?

THOMAS W. WADDINGTON (Standard Oil Company, Elizabeth, N. J.): I move that nominations be closed.

H. D. KETTELL (Standard Oil Company, Baltimore, Md.): I second that motion.

CHAIRMAN CURRIE: All those in favor of the list of officers submitted by your Nominating Committee please signify by saying "Aye."

The motion is carried unanimously.

I do not know of any better time for me to get out from under than just at this moment, and in turning the chair over to your new chairman, I want to express at this time my appreciation of the honor which has been accorded me, and the splendid cooperation, not only of the members of this section, but also by the officers and the various committees.

I want to compliment the officers upon their section, and compliment the section upon the officers it has selected. Mr. Prussing, come up and make your bow.

(Mr. George F. Prussing, Union Oil Company of Los Angeles, California, then came forward and received the badge from Mr. Currie.)

CHAIRMAN PRUSSING: As the newly elected chairman of your section, I wish to express my thanks to the members for the honor conferred.

I am not going to burden you with a speech. It is a pleasure to be able to act as your chairman, although I feel that the chairman of your Nominating Committee gave me more credit than I deserve.

The next speaker for this morning's session is well known on the Pacific Coast, especially to the Standard Oil men, for his wonderful work in the Safety Department. He has raised the standard of safety in California, and reports of his work have spread until everybody in the Southwest is looking to the Standard of California.

The work of R. E. Donovan is well known all over the country because of his work in preventing loss and accidents by fire.

In California they have been fighting fire by the use of a smoke screen or foam. This system was developed at tremendous expense, both as to the cost of the equipment and as the loss of oil due to its becoming mixed with the foam and being run out of the tank, sometimes on top of the foam.

Tank Fire Tests

R. E. Donovan, Standard Oil Company of California, San Francisco, Cal.

Just three days before the last meeting of the American Petroleum Institute, which was held in Los Angeles in January, 1926, a 115x35 foot storage tank containing 17 feet of engine distillate, burned at Standard Oil Company's refinery at El Segundo, a few miles out of the city. We did not have very much to say on the subject at the time, because we were somewhat disappointed by the fact that in spite of being equipped with what we considered a first class foam system, we were unable to extinguish the fire.

Perhaps I should say right at the start that this foam system was not put in by the Foamite company, though some Foamite equipment was used, and our Chief Fire Protection Engineer is an ex-employee of the Foamite company. I might add also that we had foam protection systems in operation before any company specializing in this form of fire protection was organized.

As a large number of pictures are available, both of this fire and of our experiments since, the whole story can probably best be told graphically.

The origin of the fire is not definitely known. The tank was modern in every respect, having a gas tight steel roof, vacuum and pressure valves, and an emergency liquid seal hatch. It was one of the few around the refinery which contained a distillate with vapor pressure likely to produce a combustible mixture within the tank. It was being gauged at the time with a steel tape, and the resulting explosion blew the roof from the tank and caused the death of the gauger. The fire started at 8:52 a. m., and by eight minutes later, the refinery operators had the foam system in operation.

The tank had been equipped with two type LA Foamite mixing boxes. These are the large size late design. They were supplemented by the addition of special deflectors designed to insure that the foam would be guided against the shell in its downward journey. Immediately after the foam was turned on, it was observed that the box upon which the roof had fallen was discharging most, if not all, of its foam outside of the tank. The foam was therefore turned off from this box and the entire capacity of the system was put through the

remaining box. A test immediately after the fire showed that the rate of delivery was about 510 gallons each solution per minute. A picture taken about seven minutes after foam had been turned on shows plainly that progress was being made; but that the progress was extremely slow and unsatisfactory is evidenced by the fact that pumping was continued into this box for 1 hour and 15 minutes, at the end of which time enough of the foam to cover the tank approximately 6 feet deep had been used (assuming a net expansion of 6), and the fire was still burning extremely fierce with no indication of further progress being made. Under the circumstances the management decided that either the mixing box had been damaged or that some other unknown cause was affecting the efficiency of the foam. They therefore decided to abandon foam application until such time as they could bring up some of our portable foam mixers and make an entirely new try at extinguishment.

Portables An Individual Type of Equipment

For various reasons this new attempt was delayed for several hours; but eventually portables were brought up. These portables are a type of equipment developed by our own forces, and it is perfectly feasible to erect and operate them after a fire has begun. With this new equipment in place foam was again applied at the rate of 730 gallons per minute, and pumping was kept up for 31 minutes. Again indications of progress were observed at times, but they were far from pronounced and did not continue. This time enough foam was pumped on to make a blanket three and one-half feet deep. As the foam stock was being seriously depleted and no further progress appeared to be made, it was decided to abandon further efforts to extinguish the tank and to allow it to burn itself out.

A review of the equipment and methods used in fighting the fire revealed no apparent fault. It was realized that the conditions prevailing at this fire might occur again at any time, and that unless some method of successfully coping with them could be developed, the value of our foam protective systems would be seriously lessened. Our directors accordingly decided to make some large-scale experiments to determine why the tank had not been extinguished. The old shell was moved to a more convenient location. The best sheets were straightened up until throughout most of the circumference of the tank it was 20 feet high and on two opposite sides it was raised to 25 feet high. In addition to that, a great deal of test equipment was out in place. Independent lines were run to each piece of apparatus, with an orifice meter on each line so that information on the rate of flow was always available. Eighty foot towers were erected to permit observation of the progress of extinguishment inside the tank, and thermocouples were located in about 15 places inside the tank.

It was attempted in the first test practically to duplicate the conditions of the actual fire. The Foamite mixing box therefore put in place cocked over just as it was in the original fire, and the distance from the box to oil surface was made approximately 20 feet—just as it had been.

Before putting any oil in the tank, foam was run through this box, and it was observed that the crooked position of the box did not affect the quality or the flow of the foam.

The test fire was allowed to burn for ten minutes, after which foam was applied at an average rate of 585 gallons per minute for 58 minutes—and much higher rates toward the last. At the end of this time the fire was out, but it had been a terrible struggle, and the method of extinguishment was not considered satisfactory from a practical standpoint. It should be borne in mind that at this test fire we had ever advantage of complete preparation and observa-

Aerial view of the tank fire in full career.

tion, as well as the benefit of the experience of most of the experts of various kinds available in the corporation. These are conditions which cannot be expected to exist at the time of the ordinary fire; and, even with these advantages, enough foam was used to put a blanket 5.2 feet deep over the tank before extinguishment was accomplished—some 33,000 gallons of each solution having been used.

Observation from both the towers and the ground indicated that foam which is allowed to drop any considerable distance into a fire undergoes the following losses.

A little is dried up as it falls through the heated atmosphere.

A considerably greater quantity is lost due to the up-draft of the fire swirling it out of the tank.

Placing the portable in position.

It should be borne in mind that this heat and swirling is the fiercest at the point where the foam is applied, because the falling foam splashes a great deal of oil into the air at that point. When the remaining foam with its high-falling velocity hits the oil surface, it is submerged. This submergence itself no doubt crushes some of the foam bubbles. Part of what remains then comes up into the turbulent and fierce-burning area immediately adjacent to where it went under. Most of this is probably consumed by the fire. Another part is forced some distance out under the oil before it comes to the surface. When it does come up, it is covered with an oil film, which has to burn off before an effective foam blanket is formed. It is easy to see that only a very small part of the original foam applied in this fashion ever does effective work.

In order to see whether this matter of the drop was the only serious difficulty, or whether there were other more important factors handicapping us, it

was decided to run a second test in which the foam would be applied close to the oil surface.

A hole was accordingly cut in the tank about three feet above the oil level and the mixing chamber was lowered so as to discharge through that hole. Additional holes were cut at about the same elevation so that our portables could be given the same opportunity to operate with only a few feet of drop. In a later test we demonstrated that these holes can be readily cut after the tank is on fire.

As in the previous test, the fire was allowed to burn ten minutes before any move was made to extinguish it. At the end of that time, two portables were put in place through the side of the tank and about 400 g.p.m. of each solution were applied through them, and an additional 400 g.p.m. through the permanent

The manifold and test equipment.

box. As was expected the foam applied in this way proved far more efficient—although even with this small drop the velocity was sufficient to splash the oil at the point of application and make it the hardest burning part of the tank and the last to go out. About 8,400 gallons were used, enough to make a 1.2 foot blanket.

These two tests had definitely indicated that a long drop from the mixing box to the oil surface severely damages the foam, and may be so serious that it will be impossible to control the fire. We were all convinced that to be in a position where we could confidently expect to extinguish all kinds of tank fires with our foam equipment, we must devise some means of applying the foam in a comparatively gentle fashion and from near the oil surface. We accordingly spent about a month studying various possible schemes for accomplishing such a change in the method of foam application. A great many plans were considered; but the one which appeared to be most feasible was to attach an asbestos tube to our portable mixers, on the bottom of which we proposed to hang something in the general shape of a dishpan either made of metal or asbestos. We figured that such an arrangement would protect the foam during

its drop, would kill the velocity at the bottom and then release it at slow velocity and around a big periphery very close to the oil surface.

We accordingly built several of these tubes, and some six weeks after our first tests, ran a new series. In this series our first fire was used to check the previous results. A permanent mixing box was set 10 feet above the oil and tried as a check on the two previous tests. It agreed remarkably well, requiring a total of some 11,000 gallons of each solution, or enough to make a blanket 1.7 feet deep over the tank.

A new fire was then started, and an attempt made to extinguish it with the new type of portables. After the fire had gotten a good start, the portables were brought up and put in place without serious difficulty by the fire crew. The asbestos tubes released just as anticipated, but the results were entirely unsatisfactory, as the tubes broke almost immediately when the full load was put on. Altogether, three portables were erected and every one gave way somewhere. Of course, they had been tried ahead of time for strength, but enough allowance had not been made for the weakening effect of the heat and the difficulty of getting both solutions started at once, etc.

After the new portables had failed, the fire was put out with the permanent mixing box set 10 feet above the surface which had been used in the first of this series of tests.

Another Test of the Asbestos Tubes

We still had two of the asbestos extension tubes which had not been attached to our portable mixers. As the indications were that, made up as they were, they were of no value anyway, we decided to try them at the beginning of the next test. They were accordingly brought up and erected; and while one of them broke at a seam part way down almost immediately, the other stayed intact and worked perfectly. For the first time in any of these tests the fire went out under the mixer almost immediately, and the foam spread from there, crowding the fire ahead of it. Some damage was done by allowing foam to flow through the broken mixer, which was located close to the effective one, this damage being caused by the splashing of the oil due to falling foam. The final result was extinguishment in a generally smooth and orderly fashion, using a total of 6,000 gallons of each solution—by far the least used in any of these experiments up to that time.

We were now entirely satisfied that the tube extensions would accomplish what we thought they would, that they were perfectly feasible to erect after a fire was started, and that the only defect in our plans was the mechanical strength of the tubes. The original tubes had been built of wire-inserted asbestos cloth with no additional reinforcing of any kind. We accordingly designed some new tubes well reinforced with wire and tried them.

The results were entirely satisfactory. Two fires just like the previous ones were extinguished with a single portable lowering the foam 20 feet through the asbestos tubes. The rate of application was only about 200 g.p.m. of each solution and the first fire was put out with a total of about 3,300 gallons of each. In the second fire the tube was damaged a little and 3,700 gallons were used.

In this case the mixer was erected over a frame, the top of which was 20 feet above the oil surface. This spot was chosen rather than the high side of the tank, merely because of more favorable wind conditions.

We believe this method of foam application marks a distinct advance in the art. You will note the tests show that the basket method of delivery is not only far more efficient when there is a big drop for the foam, but is also considerably more efficient than the permanent box, even with little drop. Imme-

View of test fire when nearly out.

After the test fire was out.

diately this brings up visions of possible future foam systems consisting of mains and hydrants only with possibly smaller solution storage and smaller pumps and a more positive assurance of extinguishing the fire. Bear in mind also that the portables will be stored in a safe place and that they will escape the risk of being damaged by the falling roof, etc.

Quantities of Foam Required

115 Foot Tank

Method of Application	Total Gals. Each Sol.
Dropping 20 feet from permanent box.....	34,000
Dropping 10 feet from permanent box.....	11,000
Dropping 3 feet from portables without asbestos tube.....	11,000
Dropping 3 feet from permanent box and portables.....	8,000
Dropping 20 feet from portable with asbestos tube.....	4,000

From many angles, therefore, this latest development in foam fire-fighting equipment is perhaps as much of a contribution to the fire-protection activities of the oil industry as were our pioneer tests conducted back in 1909. And since protection against fires is a matter in which this company has always been glad to cooperate with other members of the industry, this description of our newest development can close with the same words that were used in the article published in 1914—"The Standard Oil Company allows other oil companies to use this process free of charge."

A set of drawings and permission to build the equipment described will be furnished upon application to H. H. Hall, Chief Engineer. If more than one set of drawings is required, these will be furnished at a nominal charge. Any well-equipped sheet-metal fabricating shop can build the portable mixers; the asbestos tubes (or material for making them) can be obtained from suppliers of wire-inserted asbestos cloth.

CHAIRMAN PRUSSING: The subject is now open for discussion.

W. F. ROONEY (Tide Water Oil Co., New York City): What kind of roof construction do you use?

MR. DONOVAN: There are some questions I can not answer. Perhaps Mr. Prussing can tell you about that.

CHAIRMAN PRUSSING: We have been using a lot of gas tank roofing. We do not use the standard combination tubing. The Foamite chamber is fastened at the roof. If the roof goes it takes the chamber with it.

MR. ROONEY: Do you use just one mixing box with the portable tubes?

CHAIRMAN PRUSSING: One mixing box alone will not take care of the fire. That was proven.

MR. ROONEY: When I examined the drawers of the portable chamber I noticed that in the inflow pipes near the bottom of the chamber you have set glass.

CHAIRMAN PRUSSING: Those are the windows in the bottom of the chamber.

MR. ROONEY: I presume the only purpose of those windows is to show when the hose has reached the connection.

CHAIRMAN PRUSSING: That is all. The mixing chamber is attached to the asbestos tubing, and on the bottom of the tubing is a sort of a dishpan made of metal or asbestos, and the windows are for the purpose of watching the mixing chamber.

Starting with these metal baskets, there is a water connection, on top of that there is a goose neck, which is a standard, from that there is an asbestos tube, and at the bottom of that is a basket or a reflector, so that the entire apparatus can be made up for any particular occasion without any loss of time.

MR. ROONEY: Do you have to adjust these to suit the tank at the time of the fire?

MR. DONOVAN: These tubes are carried in stock, made up in various heights or lengths.

MR. ROONEY: Then does the tubing have to be cut at the time of fire?

MR. DONOVAN: It is either cut at the time of the fire, or kept in stock in certain lengths.

R. J. LAUDER (Roxanna Oil Company, St. Louis, Mo.): I would like to know just the number of men required to operate the portable mixer and carry the powder.

CHAIRMAN PRUSSING: We have found that the portable mixers can be erected by four or five men.

In order to train the men to handle these portables, the Standard Oil Company of California cooperated with the other companies in the training of regular

Asbestos tube contracted.

fire fighting forces. In some towns foam is being used and 100 men are being trained in the use of these portables.

W. T. FILMER (Sheet & Tube Company, Youngstown, Ohio): Has anything ever been done about the distribution lines? Could they be carried under the surface and forced up through the oil? Sometimes when the foam is used on the surface of the oil, it splashes the oil, and causes the fire to spread.

CHAIRMAN PRUSSING: At a fire test some experiments of that kind were made. One of the permanent mixer tubes was let down on the inside of the shell and submerged. This formed a sort of a slide, and the foam slid down the tube under the surface of the oil and then came up through the oil. This was not very satisfactory.

Another test was a floater made of metal and buoyant, which was attached to the mixing box. This thing was shaped something like an automobile disk wheel with a hole in it, and placed across the center of the tube, giving an impact for the foam as it descended. Being placed in a vertical position, naturally it would take the impact of the foam, and it would strike the surface of the oil with less velocity.

Another device was a 25-inch casing attached to the inner shell of the tank under the mixing chamber, the tube descending to the bottom of the tank. This was perforated at various points with two-inch holes. This was under the theory that the flow would go down under the oil and build up and discharge with less violence to the oil surface.

We are hopeful that this type of apparatus will be successful.

S. L. NEWCOMB (Standard Oil Co., New Jersey, Elizabeth, N. J.): In reading these articles, we rather thought that it was the idea to do away with all permanent mixers and use the portable mixers. Is this right?

MR. DONOVAN: I think you are right. I think that was Mr. Hall's idea, that the use of the portable mixers in fighting fire would result in less loss of time and oil.

MR. NEWCOMB: We have been using the portables, and in using the center column in fighting fire we found that before we could bring the column to the side of the tank the tank would boil over, and we had to use it through the Siamese connection.

I do not think we should do away with the use of the permanent mixers altogether, as it has been my experience that if one of the lines on the portable mixers does not work right the rest of them are usually affected.

And when we have fires that boil over before the men can reach the tank to get the portables set up, we need the permanent mixers. I know that we would have had considerable loss if we had not been able to use the permanent mixers. Of course, in this case, there was not much of a boil over, but it does not take much of a boil over to make the men run.

The Experiments Not Made With Crude Oil

MR. DONOVAN: The fire prevention work in the company does not come under me; it comes under the fire chief, Mr. Hall, and I am not entirely familiar with all situations; but ordinarily a tank does not boil over that quickly. That would not be true of refined oil. What kind of oil was in the tank?

MR. NEWCOMB: I think it was crude oil.

MR. DONOVAN: These experiments were not made with crude oil. Crude oil boils over very quickly. Where we are using these portable tubes is where there is refined oil, in storage houses or bulk stations.

MR. ROONEY: In connection with permanent types of mixers, I doubt if we would agree to do away with them entirely. We have a number of 24-foot tanks located pretty close together. If a fire breaks out in one of these tanks we can cover the surrounding tanks with the permanent type of mixer while we are using the portables on the fire, and if we did not have the permanent I do not know how we could take care of a large fire.

Have any of you gentlemen ever had any experience with foam generators? We have four of them, and we find that there are some places where they are successful in protecting the slope, and we find them quicker to hook up than our permanent.

S. L. NEWCOMB (Standard Oil Co., Elizabeth, N. J.): I would like to know how many men it requires to carry the powder to your generators?

MR. ROONEY: I do not know exactly. We have always used them in our refineries, where we have plenty of men to carry the powder. I do not think it takes more than five or six.

W. T. FILMER (Sheet Metal & Tube Company, Youngstown, Ohio): In conducting experiments with your foam generator, how do you handle a broken tank?

MR. DONOVAN: We have made some tests on that. We have let the fire go until the whole ground was on fire, and then have had men ready to carry the tanks and other men to carry the powder and we put that fire out in 12 minutes.

We used four cans, and had one man to open the can and another to mix the powder.

MR. FILMER: How do you transport the generators?

MR. DONOVAN: We carry the generators mounted on trucks, which can be handled by one man. I believe there are five cans to our truck.

CHAIRMAN PRUSSING: It has been my observation that these generators have been bought more for use at marketing stations and places where there is a chance of small fires. They are purchased with the thought of their usefulness and not as to the number of men required. A number of them have been sold, but their usefulness is limited.

MR. NEWCOMB: We considered purchasing a number of them to use as in emergencies. Our central pumping stations are located on the outskirts of the refinery and we considered the advisability of purchasing them to keep out there so in case of fire we could use them immediately.

We found, as far as protection was concerned, that if we had enough to protect our 15-foot tanks we could not load them fast enough to take care of the fire.

We had a large tank which we tried to protect by three generators, and it took two men to each generator, one to feed the powder and another to open the cans.

ADJOURNMENT

Thursday, September 29, 1927

GEORGE F. PRUSSING, Chairman
Union Oil Company of California, Los Angeles, Calif.

The third session was called to order at nine-thirty o'clock by the ~~chairman~~ George F. Prussing.

CHAIRMAN PRUSSING: The first speaker on the program, I am going to ~~present~~ without any further introduction, Mr. C. L. Swim, Skelly Oil Company, Tulsa, Oklahoma.

The Promotion of Safety in a Producing Department

**C. L. Swim, Skelly Oil Company,
Tulsa, Okla.**

The principles of safety are identical wherever you may consider them but the application may vary somewhat depending upon the phase of industry considered. This is true in a producing department of an oil company, because there are some factors peculiar to these operations that make them at once different from most if not all others. To mention one or two, there is, first, the scattered personnel which may be made up of small groups located in as many places throughout several states; and second, the inherent hazards which go with every effort to deal with natural forces, especially in drilling operations where the character, location or extent of the force is unknown.

Every effort which seeks to change the habit or attitude of a man must, to be successful, proceed along a line of interest to that man. This is true of any plan to promote safety and in this connection we should always remember that, true to the nature of the human race, self interest is one of the greatest actuating forces. The application of this to safety I shall try to demonstrate.

Safety must come from the top of your organization down and never the reverse. If your executives are sold on safety you are fortunate even as I am. If they are not, their interest lies in your demonstration to them that safety and the prevention of accidents is good business; that accidents are one of the very real wastes of industry for which no one can show a gain or an advantage; that a decrease of accidents reduces confusion, lost time, and costs with a direct and unmistakable increase in profits. Then, too, the executive more than the other classes we shall discuss, is more susceptible to the humanitarian appeal.

The next to consider in your safety program are your superintendents and foremen. These are your key men. Safety comes from the top down and I am fully persuaded that unless and until you have these superintendents and foremen sold on safety you are in a large measure wasting your time in going to the men with your safety program. Concentrate on these and let the process be continuous.

Where does the self interest of these men lie? Each one of them holds his position because of his indicated or demonstrated ability to work with men and to accomplish desired results. His personal success and his chance for promotion depend upon his ability in this direction and this being true his self interest lies in anything that will help him attain this objective. Sell him safety and your program for securing it, not only upon humanitarian grounds, but upon the basis that accidents are one of the costs of doing business and that you can

help him accomplish results with less accidents, and hence less cost so that the profit side of the operations, of which he has charge, is increased; and that this puts him in a favorable light compared to the man in a similar position who disregards safety and as a consequence has higher costs due to accidents. Sell him the proposition that his value to his company depends upon his ability to accomplish results at a profit; that his organization has only one pocket book; that into this goes all income and out of it comes all expense; and that it matters little how many barrels of oil he produces if he does it at the cost of preventable accidents with resulting decreased profits or a loss. In other words convince him that his personal fortune is involved in safety.

There is a third group in a consideration of the personal elements involved in the development of a program of safety. The workman—the man on the firing line where the accidents happen—is, of course, the one who has the most to gain and yet who sometimes seems the hardest to reach. To him an accident is a personal matter and it would seem easy to find his interest, yet experience has taught some of us that some workmen do not, apparently, see the necessity of giving special thought to this and base their lack of interest on the fact that they have never suffered an accident and by a curious line of reasoning assume they never will. To reach the various types of individuals making up any group of workmen, a continuous program of education, involving every known method of appeal, is needed. Some can be reached by being made to realize that they may be injured by the careless act of a fellow workman so that they do have an interest in the broad idea of preventing injuries. Examples of this from your own organization can usually be brought to their attention, such as a recent case in my own company where the careless act of one man caused the death of himself, another and the serious injury of three more.

Outlining the Lines of Action

Now that we have considered the groundwork necessary for a successful furtherance of safety, let us briefly outline the lines of action. In the first place there must be a clear placing of responsibility for accidents and this should be upon the superintendents and foremen. The obligation of a man in one of these key positions is to obtain results without accidents and every accident sustained by a man under his supervision should be charged to him. Workmen try to please their foremen and superintendents so that the opportunity of indicating his belief in safety first is accorded such a key man every day.

One company has been using the plan of its safety director sending a report each three months to the executive officer in charge of the producing department, which report is a summary of the number of lost time injuries for the quarter year just preceding for the men under each superintendent, with a rating on the basis of the ratio of such accidents to the average number of men employed. With this report goes a letter pointing out significant records and which shows that each superintendent receives a copy of the report and letter. The effect from this has been marked in that it is at once apparent to such executive that although two groups are similar as to number of men and character of work and working conditions, yet one group is having a considerably more serious accident experience than the other. This results in the superintendent hearing from the man who gives the pay check and in turn a determined effort on his part to locate and remedy the trouble.

You will note that by this plan every key man is criticized or praised to his superiors in a completely above board fashion. This is important, for to accomplish results the man who keeps the safety motor wound must be on terms of

frank friendliness with the superintendents and foremen, and in addition to this with the men as well.

Carry your message of safety to the men in the field and do not make the mistake of thinking your work as safety director is an office job. Get acquainted with the men and go to them to do it; get more than a speaking acquaintance with your superintendents and foremen, ride with them all day, learn their problems and sell them your proposition that when accidents are reduced lives and losses will be saved and their personal value increased. Get your key men to arrange safety meetings for a discussion of their own problems. Encourage good housekeeping and arrange for first-aid instruction and training of first-aid teams such as is given and sponsored by the Bureau of Mines, for accidents decrease in the presence of these two.

As all of you know the Bureau of Mines is willing and anxious to give first-aid training wherever as many as 15 can be brought into one group. You can supplement this, however, by getting the Bureau to train some of your own men who can then go from one plant or district to another, and by fitting their time to your operating schedule almost every man can be reached. My company has by this means given the complete course to about 600 men this year, and the Bureau has been kind enough to examine those trained and has awarded certificates to a large number.

Few Accidents Due to Improper Equipment

It has been demonstrated by carefully kept statistics that about ten per cent of all accidents are the result of improper equipment or the failure to have the most safe working conditions. May I earnestly suggest to you that your company adopt a standard of safety equipment and standard for working conditions and do this as thoroughly as the American Petroleum Institute has covered the matter of standard operating equipment. When you have adopted such standards you will display to your employees additional evidence of your intention to reduce accidents and you will largely eliminate the most costly ten per cent of your accidents, for the injuries resulting from this cause are, considering the number, some of the most serious ones sustained.

Another successful plan used by a producing organization to reduce accidents is an inspection, from time to time, by a safety man having a practical viewpoint, of the physical equipment in use and the working conditions. If you know your key men as you ought, this can be handled without there being any feeling on their part that you are on their properties to criticize, for you will be able to sell them on the proposition that you are there to help them reduce their accidents which is one of the yardsticks by which they are measured at headquarters. To be sure, this plan cannot be effective unless your executives are ready to approve the changing of the conditions or equipment that appears to be an invitation for an accident to happen.

Keep accident statistics so that you are able to know currently the experience of each group. This will show you where to devote your major effort and make it possible for you to commend the district showing a good record and to do it while the record is being made, also, you can go to a superintendent with an unfavorable record to help him correct it before his year's standing is ruined.

In this connection I recently had an interesting experience. A few years ago when we first began on safety one of our old producing districts was found to have a bad record that was outstanding. With an average working force of about 100 men during all the time in question their record for lost time injuries has been: 1923, 57 injuries; 1924, 40 injuries; 1925, 12 injuries, and 1926, 9 injuries. In the early part of this year the number started to increase. I called the super-

intendent's attention to this and received from him an immediate letter of thanks. He told me he had not realized there was an increase and promised to find the trouble. That was three months ago and they have not had an injury since. I know that superintendent and all of his foremen and when I go there I feel I am among friends.

In the beginning I said that you must organize for safety from the top down and I should like to stress that now. With your executives ready to look at working conditions, equipment and the records of men from the safety standpoint; with your key men feeling that management is in earnest and that you are a fair, honest and frank friend who is trying by all reasonable means to save lives and losses and to help them make a better record; with the adoption of a safety standard for working conditions and equipment and with periodic inspections to keep these up to standard, you are well on the way to reduce your accident frequency.

Courage and Incentive to the Workers

When you have done these things you have provided encouragement and an incentive to your workmen to do their work the safest way for they will see it is the popular way. There are, however, some men who are already so steeped in carelessness or have a don't care attitude and a few of these may have reached key positions. Let us consider these for a moment. The superintendent or foreman who after full opportunity does not seem willing or able to realize that safety pays by any test, is, in my opinion, a liability to your organization and needs consideration by the executive department. There are some workmen whose records show they sustain or cause frequent injuries by their carelessness and if these can not be changed to safe workmen by a frank friendly talk from their chief, they should be required to labor in a field less dangerous than the producing department of an oil company and this for their own good as well as that of the industry.

A case in point happened in our refining division. At the end of 1924 it was found that a certain boilermaker had suffered ten injuries to his eyes in the preceding twelve months. Investigation disclosed that he wore his goggles around his neck. The superintendent called him into his office where he was reminded of this and told his work was entirely satisfactory but that the next time he was seen at work without his goggles in the proper place he would be separated from the payroll. He is still with us and has not had an injury since.

The development of safety to a satisfactory degree is not the work of a day or a year and efforts to reach this standard, to be successful, must be continuous. I have restricted myself to a discussion of methods that have proven successful and I am confident the adoption of these suggestions varied to suit your conditions, will, if seasoned with frankness, friendliness and earnestness, enable us to come nearer our goal of less accidents in the petroleum industry.

CHAIRMAN PRUSSING: The producing end of the oil industry is a large part of the work of the safety man. A safety man working for a company that does not produce does not work very long for that company, and Mr. Swim has read a splendid paper on that subject.

I know that in our company when we made our first analysis we had to see where our accidents were happening, and we found that out of 1,000 drilling men and 500 producing men, 55 percent of our accidents came from the thousand men.

The most hazards are in the producing end of the business.

Mr. Swim's paper is now open for discussion. Who is going to be first?

R. S. BONSB (Standard Oil Company, New Jersey, New York City): Just to

start the discussion, I will say that I do not think the accidents are due so much to the natural hazards as to the type of man that you have to deal with. The type of man that you find in the fields where there is the greatest difficulty is a difficult type to handle, and that is what makes it so hard for the safety man. He will rush pell mell into things, not take time to consider, get into impossible situations, does not read very much, and is a real problem.

I want to emphasize the need of standards in safety. I think that is the greatest need. Due to the lack of a standard way of meeting situations, one man will do one thing in one field under certain conditions, and another man will do something different.

I think that if every local had a set of standards telling what to do in certain cases and certain kinds of accidents, it would be of great value, and I think one of the things we should do is to work out some standards to be sent out in this way.

The greatest thing is the drawing up of a set of standards, and this step has been made, and the first set was issued in the "Clean-Up."

The second point is this bird that is always having accidents. I think that if a man has had the same type of accident two or three times he is a good man to replace, because there must be something wrong with the man or the job.

We want to do what we can to make the job safer, but after we have done that and he keeps on getting hurt he is unfitted for that job and should be transferred.

Sometimes a man is kept on a job because the foreman or manager thinks that he is a good man, and they could not get along without him. I had a case of that kind once.

The Good Worker Was Laid on the Shelf

A certain workman kept getting things in his eye. I spoke to the manager about it and he said, "Yes, but he does very good work."

Then I spoke to the manager of the plant about it, and he said, "Oh, he is a very good man. We could not get along without him."

About two weeks later this man got something in his eye that put him on the shelf permanently, and the man that the company could not get along without is unable to work at all, and the company that could not get along without him is still running without his help.

Would it not have been kinder to have let him go when he would have been able to find something else, instead of keeping him on until he had an accident which disabled him? He was unfitted for that job.

MR. SWIM: I agree with everything Mr. Bonsib has said, but I want to say that I have just a little different angle on this thing. Probably I should have embodied this in my speech, but I did not, so I am going to say it now.

I feel that the producing end, and particularly the producing end of the oil industry, has, and is, overlooking a bet in not standardizing upon safety equipment and safety working conditions. My company has been just as lax as anybody, but we have started on the right track at last. Day before yesterday I sat in conference with every superintendent in my company discussing that situation.

In the accident that I mentioned where one man was burned to death and three were injured, the wind was blowing from the south and blew into the engine house disturbing the air hose on one of the engines. This engine, a new type of construction, began pulling gas into the engine from one of the intake pipes. One of the boys got excited and jerked the spark plug wire off the engine. The engine died down and he started to put the spark plug back, and there was too much gas in the engine and it exploded.

When I started digging into the thing I found one thing which I wish to point out to you—the air intake pipe on the engine is on the outside of the engine house.

We have come to the conclusion that the manufacturers must fix that engine, or we will quit buying them.

MR. BONSB: It strikes me that the proper person to look into these things and carry out these suggestions is Mr. Blakeslee. Is he here? He is missing some good things if he is not.

Let's get safety equipment. Impress it upon the purchasing agents that it pays to buy safe equipment. Sometimes purchasing agents can not see that quality pays, because they feel that they want to save money for the company, but maybe we can impress it upon them that they can save money for the company that way.

H. A. MATIER (Union Oil Company, Los Angeles, Calif.): When we started in California a number of years ago to make them see the necessity of safe equipment in the prevention of accidents, we practically had to go out and dig in new earth. Every company had its own idea of the matter.

One man would go to a company where he was unfamiliar with the conditions and try something that he had used somewhere else, and which would not do at all for this particular case, and it was a terrible state of affairs.

Unsafe Equipment Scrapped After a Conference

Finally a meeting was called of the oil company representatives. The labor representatives and the oil company representatives were at this meeting and talked the situation over, and we had a real house-cleaning and got rid of our unsafe equipment.

I think all of us should have a house-cleaning of this sort and get rid of the unsafe equipment and practices.

Then let us get after the manufacturing companies and see that they put safe guards on the equipment that we buy, and have a standard about that. If we get together on that we can get results, and that is what we are here for.

My other idea is the training of the men who have been in accidents, and are unable to continue on the job as safety men. These men make the best safety men because they can tell the others what to do, they have had experience.

We have a case of a driller who was hurt, and Mr. Prussing got a job for that man as a safety worker, and he is doing good work.

CHAIRMAN PRUSSING: The thing that Mr. Matier means is the training of the man who, first of all, is familiar with the job.

There are two ways of putting men into the safety work, not only in the oil industry, but in the other lines as well.

One is to take men into the safety work and teach them everything there is to know about it, and the other way is to take a man who is competent to hold a drilling job, or a job in the producing end, who has been injured, and place him in the safety work. This man is not only qualified as a driller or worker, and therefore familiar with the work, but he is also qualified by his experience to help prevent accidents.

We were fortunate in being able to use a man who was a first-class driller, but who had become incapacitated for that job. That man was turned over to the safety department and put in the work in the drilling gang. He became the "father confessor," as it were, of the entire gang and did good work in that department. He was looked up to by every man as a person to whom to go for advice.

I think that the high priced men should be used in the safety work. The safety man has a hard enough job as it is, with most of the men thinking that he does not know what he is talking about, but they will listen to one from their own gang. He goes into this work with a real knowledge of the job.

I would like to hear from Mr. Currie about a little book which is being prepared.

V. R. CURRIE (The Texas Company, Houston, Tex.): I felt for a number of years that we lacked a little book or pamphlet of some kind that would have in it

some new general or model speeches on safety, a book that you could put in the hands of your foreman and to give him ideas for talks.

While Mr. Nicholson was laid up this summer I asked him if he would not write me a few such talks, and we have published in pamphlet form 50 short talks on safety. I have 100 copies of these on hand this morning, and if any of you want some we will be glad to give them to you.

MR. BONSB: I am not going to discuss Mr. Currie's book, but to get back to the standardization of safety methods, to be effective these standards must be 15 per cent mechanical and 85 per cent human. We want to be careful not to forget the human side of it.

The other big thing is for you safety men to impress it upon your purchasing agents that quality is what counts. He may think he is saving money for the company by buying something without regard to quality, but in the long run he is not.

You, of course, can not tell your purchasing agent where he shall place his order, but you can help a lot by drawing up specifications that will show him what you want. Then ask him to place the order where these things can be obtained; let him decide where, and if he has the specifications he can see just what you mean.

One thing that we are specially interested in is welder's gloves. We could not tell our purchasing agent what particular kind of gloves to buy, but we could make a drawing of what we wanted.

Brief Discussion of Safety Kinks

S. L. NEWCOMB (Standard Oil Company, New Jersey, Elizabeth, N. J.): I think that those who were here last year will remember that I presented a paper in which I spoke of the work of the safety men as a whole, and stated in that paper that I felt we were covering too much surface.

I think that Mr. Swim's paper has gone a long way to getting back to the fundamental point. I did not rise to discuss Mr. Swim's paper, but I would like to say that I appreciated and enjoyed it very much.

I had a few minutes' talk with Mr. Blakeslee concerning the staging of accidents and near accidents for the purpose of taking pictures, and I would like to ask that Mr. Blakeslee tell us something about it.

CHAIRMAN PRUSSING: I think that Mr. Blakeslee will have an opportunity of telling us about some of the scandalous places he has found in his investigations a little later. (Of course, he found none of these conditions on our properties).

Our next speaker, Mr. H. W. Boggess, of the Sinclair Oil & Gas Company, Tulsa, Oklahoma, is not present, so I am going to ask some of our friends to give us a few words, and the first man I am going to call on is Mr. E. D. Murphy, Mid-Continental Petroleum Corporation, Tulsa, Oklahoma.

MR. MURPHY: I believe they asked us if we would not say a few words on the safety "kinks." I am not full of "kinks," I have tried to keep straight.

I was out with Mr. Blakeslee when he was taking those pictures. One thing I learned from the taking of those pictures was the interest aroused in the hazards in accidents. When those pictures were taken the accident was staged so that the points he wanted to bring out could be obtained, and the men all gathered around us, and discussed it and showed a great deal of interest in it.

Now I am using pictures in the field and in the refinery and explaining it so as to arouse the men so that they will be on the lookout for hazards. I think this is a good way to do, as it impresses it on their minds.

CHAIRMAN PRUSSING: We also have had that experience in showing the pictures, and have found it to be quite effective.

We have also found it effective to post up on the bulletin board where all the men can see them, pictures or notices of the accidents which occur in the plant under some such caption as "This bonehead stunt was pulled today."

All the men see them, and it makes the other men careful so that their picture or name will not be put there.

One man conceived the idea of placing photographs on the bulletin board of accidents each day, under the caption of "The prize bonehead stunt of yesterday."

These are nine by ten pictures, and they illustrate the little things that can happen in a plant. Sometimes it is just a tool left in a dangerous position, sometimes it is a posed photograph of something he happened to catch on the move, and had it staged so as to get it in the camera; and these things are very effective.

The men always go to the bulletin board first to see whether they are photographed or not.

Activities of An Organization With 1,200 Men

I am going to call on Mr. C. L. Hightower, of the Texas Pacific Coal & Oil Company, Thurber, Texas.

MR. HIGHTOWER: Some of the things I am going to say to you have been related here this morning and some in the past, but perhaps one or two of the ideas may be new to you.

In the first place our organization is a small one, about 1,200 men, and it is not so hard for our safety organization to work with them as it might be with a larger force, and we feel that our safety department has produced results.

The first question that we asked was as to the best way to get results, and we worked under the assumption that educating the men was the most efficient. Working under that assumption we decided that direct contact with the men in the field was necessary. Then we began holding meetings every month in each district, and the safety director and representative from my office meet each month with the foremen, superintendents, managers and the men in the field.

In order to assure a program for the meeting we always send out a list of suggestive subjects for discussion. These suggestions are made up from reviews of accidents. Then, if our program committee has failed, and program committees composed of workmen often do fail, we have something to talk about.

We hold these meetings on the company's time, and pay the men for the time spent attending the meetings.

In some of the more isolated districts we hold the meetings in the evenings because we have found that the men in those districts, not having much entertainment, will attend, and when such meetings are held it is our policy to provide some special entertainment to show the men that we appreciate their interest. We supplement this work with our bulletin service.

We have a suggestion system which is very successful. We started this system in April, and since that time 50 suggestions have been submitted, 45 of which were accepted and awards paid.

We are planning to have a six months campaign, and offer prizes for the best suggestions. We include suggestions for the improvement of apparatus, and we have received suggestions that have saved the company hundreds of dollars.

We have attempted occasionally to have efficiency talks given by the superintendents and foremen, and at this time we are arranging for one of the executives to attend the meetings and give the men a talk.

On the first of each month we give what we call a field report. This report is a record of the work of the man. If it is a good report he is complimented, if it is bad he is criticised and his errors pointed out.

Another thing that we have accomplished is a little pamphlet. This was made up by the foreman and superintendents. It includes the company's policy pertaining to safety, and then outlines the life insurance for employees, and then presents written instructions for each and every employee of the company, such as "Hand tools should be kept in good order at all times. Burrs and metal slivers from punches, chisels

and hammers have caused many eye injuries. There is a tool for every job. Use the right tool at the right time."

These and many others are for the carpenter, but we have a set of such rules for all employees.

We appreciate that in presenting these rules we did not include all the things that could happen and that should have been included, but we do feel that this has been a step.

When this book first came out I was a little skeptical as to how it would be received, so I talked it over with each superintendent and they took the matter up with the foreman, and it was discussed with each representative, and practically all of the men approved of it and said it would be a good thing, and we keep them on hand to give to the men.

It is not my purpose to hold up our organization as a flaring example. I appreciate that there are many rough spots, but we do feel that we are making headway.

We have had a reduction in the number of accidents, and in 127 days we have had only 15 absences due to accident. I cannot give the record for the year, as during the last twelve months our company has been undergoing a period of reorganization and the records are incomplete.

Three Things That Should Be Stressed

Three things I would like to stress; from my experience I know that the management must be sold on the safety idea, or they will not see that the recommendations of the safety man are carried out.

I know of a case that happened recently. A recommendation was made by one of the men that the tool rack be repaired. The foreman agreed that the tool rack in the field needed repairing, but that was as far as it went. Incompetence on the part of the company is one of the greatest detriments to the advancement of the safety work. The workman's tools are what we should look to first.

Make a personal contact with your men. Mr. Swim stressed that. Get in touch with your men. Let them call you by your first name—I mean the men in the field, not your office associates—get to know them, and let them know you.

Third. Understand the work that your own organization is doing. Encourage your men to come to you with suggestions and then investigate them yourself. Get the men to make up a list of the hazards on the job and you will find this will be a benefit to you.

Five or six months ago I did not know much about the Petroleum Section, and I attempted to give a plan for the prevention of accidents, and fell short because I did not know the operation. I do not think that can be too strongly stressed—learn the operation.

MR. BONSB: I would like to ask you, Mr. Hightower, what methods you use to get the field men to read the instructions in your hand book.

MR. HIGHTOWER: Sometimes we hand a book of instructions to the field men, and sometimes the foreman or the man who employs them gives them a book when they are hired, with instructions to read and study it.

MR. BONSB: It is nice to hand out those instructions, and it is all right to have the foreman and gang leaders have them, they will read them; but how do you know that the field man will read that book?

MR. HIGHTOWER: We give all new employees a book of instructions, and then a week or so later the superintendent, or somebody, quizzes them to be sure that they have read it.

We see to it that our men are given personal instruction, and the safety department has, each month, a sort of a questionnaire, by which the men are tested as to their knowledge of the subjects outlined in this pamphlet, and I

think that we are getting good results. It has been brought out that the men read these instructions.

We had one instance where a man was working in the field and picked up a wrench to do some hammering, and one of his fellow-workmen stopped him, telling him that he had better see if that was the right thing to do, and pulling one of these pamphlets out of his pocket to see what it said, found, "Don't use a wrench for a hammer; use a hammer."

H. A. MATIER (Union Oil Co., Los Angeles, Calif.): This matter of handing a book to the new workman is one that I have thought over for the last ten years.

I thought that perhaps the National Safety Council could prepare a set of rules that would apply to most of the situations that come up, but the question arises as to the good they could get out of it. If we publish a book of this kind we should put in it a rule like this, "Be yourself. Use your common sense."

Common sense rules should be the nucleus of such a book.

R. E. DONOVAN (Standard Oil Co. of California, San Francisco, Calif.): I want to tell you some of our experiences along that line.

We have a book which we put out in California telling of the employees' benefit plans, stock investments and so forth, and not over 25 per cent of the men in the company know what those things are. How are you going to get them to read a hand book?

I think it was suggested in one of the papers that we try to put out rules applying to the general safety of the men. This might not work out, as we are operating in different states and under different laws.

In California there are certain state laws that we are required to live up to, and you might make safety suggestions that would conflict with these laws. That is true in other states.

We have had experience with hand books, but have never had good results.

The Safety Department Got Out a Questionnaire

RALPH E. MOTLEY (Atlantic Refining Co., Philadelphia, Pa.): I am going to do as they suggested at the banquet last night, start an argument.

You remember yesterday you heard me say something about certain rules being issued by the firm, and also that we were rather dubious as to whether or not they were read?

We decided to have the safety department construct a sort of questionnaire consisting of about 25 questions. These questionnaires were distributed by the foremen and each man got one with instructions that they be returned within 15 days.

Within 15 days 45 of these had been returned, and nine per cent of the questions were correctly answered, showing that the men had read the instructions.

MR. BONSB: How do you know that these questions were answered by the men on the job?

MR. MOTLEY: The answers were turned in by the men on the job. We have not tried to make sure that they really answered them. It shows that they must have read them or they could not have answered them at all, and if some one else did answer them, the men wrote the answers and would get the benefit that way.

We are getting up a special set of rules for each of the different crafts.

MR. BONSB: May I ask if you ever talked with the men to see whether or not

they were getting anything out of these instructions, or if they just read them to follow the instruction to read them?

MR. MOTLEY: I do not think that it makes much difference how they read them, so long as they read them. If we gave them the instructions and they do not read them it is not up to us. Of course we do everything we can get them read. I have not talked with any of the men concerning the handbook.

CHAIRMAN PRUSSING: Before we listen to Mr. Eggleston's paper, I am going to call on Mr. Owen Humphrey of the Standard Oil Company of New Jersey, Elizabeth, N. J., to speak to us.

An Outline of Three Safety Kinks

MR. HUMPHREY: I am just going to talk a few minutes on three so-called safety "kinks."

The first one has to do with the subject that we are talking about, and that is the handing of a hand book to the new employee.

When new employees are taken on they are given a hand book with instructions as to the proper procedure, and we emphasize the importance of following out these instructions and studying this book.

They are also given a safety talk by a prominent man in the company who has had a great deal of experience, and then he is given a card stating that he has received instructions from the foreman. This is a safety registration card, and after he has received instructions in safety from the foreman he signs it, and the foreman also signs it to show that he has instructed the man, and then the foreman returns it to the safety department.

This plan has been in practice for about five months and I can not say yet whether we can put our finger on any definite results. We are following it up and feel that it is efficient.

The reason we have the man sign this card is so that he can not say that he was not instructed by the foreman. Sometimes, after an accident occurs, the man will say that he was not instructed, but if we have his signature he cannot say that. Then sometimes the foreman is busy and does not take the time to properly instruct the man, and this card guards against that.

The second kink is the wearing of gas masks. We have been up against it here.

At the Bayway Refinery they decided on the canister type of mask, but we were not always able to know when the mask had broken down. So a committee was appointed to figure out a way by which we could tell when the man had used the canister for a certain number of hours, and to find out how many hours the canister could be used before breaking down. The committee devised this card which is attached to every canister.

After the man has finished using the mask he takes a pencil and checks off squares on the opposite side of the card the exact number of hours he has used the mask, then the next man to use it knows how long it has been used, and will not run the risk of wearing the mask when the life has gone.

We did not want to risk depending upon the ability of the man to detect the odor of the gas when the mask begins to break down, and so we have decided that the limit should be a ten-hour period, and we use this card to keep track of the time.

Third, we believe in selling the men safety shoes, and for some time we have been selling these shoes at cost. In the middle of the summer the sales lagged. We tried to think of some method to bring up the sales, and we finally decided to give a cap with the shoes; so with every pair of safety shoes that were sold we gave a

cap as an inducement to wear the shoes. It would also advertise the fact that the man was actually wearing safety shoes.

We first ordered some of these caps through our purchasing department, and they finally were successful in getting one of the manufacturers to make some of these caps, which we gave with every sale of shoes.

C. L. SWIM (Skelly Oil Co., Tulsa, Okla.): I would like to ask a question. I presume you hire a number of men directly into your laboring gang. What sort of instructions do you give those fellows?

MR. HUMPHREY: When a man is hired into the laboring gang he is first given preliminary instructions by the employment manager, which consist of directions concerning all hazards he is likely to come up against. Then when he comes on the job he is given a book of instructions by the foreman.

RAY E. MILLER (Marland Refining Co., Ponca City, Okla.): I might say that new employees just coming onto a job are always ready to receive instructions, and that is the time to get them; and in the plant the safety department gives them instructions after they have passed the physical medical examination.

MR. BONSB: Referring back to the beginning of your talk, Mr. Humphrey, just what is the idea of having the men sign the card saying that they have received instructions?

A Man Can't Go Back on His Signature

MR. HUMPHREY: Sometimes when a man gets hurt he says he never was told. If we have his signature that he has been instructed, he can not spring that. Then sometimes the foreman is busy and neglects to properly instruct the man, and if we have the signature of the foreman too then the foreman cannot say that he instructed him when he did not, so it acts as a double guard.

E. A. TIMM (Standard Oil Company, New Jersey, Bayonne, N. J.): At Bayway Refineries the men must come up to the safety department and sign a statement to the effect that they have been instructed in the use of the gas mask.

I had had cases where the men have stated that they had never received a gas mask instructions. That was before we started having the Canister Data Time cards.

CHAIRMAN PRUSSING: Has anyone ever tried the chemical devices? We have such a device at our plant.

MR. TIMM: I might say there is such a device under consideration.

CHAIRMAN PRUSSING: We are using a little tube through which the gas passes, and when the gas passes through this free of compounds it shows white, and when it is not free, it shows colored, and it depends upon the wearer to know when the change takes place. So far it has been successful.

S. L. NEWCOMB (Standard Oil Co., New Jersey, Elizabeth, N. J.): I happened to be a member of that committee that was organized for the handling of gas masks.

When we first took this matter up with our companies they insisted that the masks would break down slowly, and the men could detect the odor, and it was perfectly safe. We contended that the man might have a bad cold, and we did not want to take any chances of a man with a bad cold wearing a gas mask.

Another thing, the odor of the gas is considerably different there than it is in the laboratories. It does not have that rotten-egg smell that you are all familiar with, and the man might not recognize it.

The canister was used for a longer period of time than ten hours before it broke down, but when it does break down it goes rapidly, and we thought it better to be on the safe side and limit it to ten hours. They did not believe it, but agreed to run experiments, and they found that, as we had said, when this mask was used for a longer period of time than ten hours the break down was rapid.

For that reason we decided on this ten hour period, and we are working on a detector that will show when the mask begins to break, but even if the detector does not show a breakdown, the gas mask is not to be used for a period longer than ten hours.

V. R. CURRIE (The Texas Company, Houston, Texas): After the session started this morning there came to my mind a plan, which might be of interest to the members. I might say in the first place that for the last 15 years our central committee of safety has consisted of a committee composed of one man from each plant.

Our plant fire organizations, on the other hand, consist, naturally, of a fire chief, several assistants, lieutenants, captains and five men for each company.

At this particular plant they started to experiment in accident prevention along the same lines as they did for fire prevention, and have had very good results with this new organization, in fact have had only one loss of time due to accident since this new organization was formed.

They are now extending that same plan of organization to the different departments in the plant, and if they continue on the same basis, they will be able to show a reduction of 60 per cent in accidents this year.

Origin of an Interesting Resolution

While I am on my feet, there is another matter that I would like to bring up at this time.

During the week, while talking with the various delegates and National Council officers, the thought has come up that probably it would be to the advantage of all concerned if this Congress were held at one point every year, and I would like to present the following resolution at this time:—

"Whereas, the National Safety Council is more efficiently and economically held in its headquarters city, and

"Whereas, the cost of sending delegates is as low if not lower when the Congress is held in Chicago, and

"Whereas, the city favored by the Congress when moved from point to point gains only at the expense of the delegates and their employers,

"Be it therefore received that this Section is in favor of holding the Congress in Chicago regularly during the last week of September in each year.

"Respectfully submitted,

(Signed) Geo. F. Prussing,
Union Oil Co. of Calif.,
Chairman-Elect,
Petroleum Section."

CHAIRMAN PRUSSING: You have heard the resolution read. Are there any suggestions?

RAY E. MILLER (Marland Refining Company, Ponca City, Okla.): I move that we adopt this resolution.

MR. BONSB: I second that motion. Our section is getting larger every year and I think we ought to have a larger hall to hold our meetings in. Every year we have one of these small halls, and you know how uncomfortable it is. I think we ought to do something about this now, while we are all here. There are other sections smaller than ours that have larger meeting places than we have.

If we come to the same place each year there will not be so much that is new to see, and we may attend to business better. Most of us are familiar with Chicago and we do not want to see the stockyards, we have all seen them, and I think it would be better to have Congress held here every year. Of course it is nice to go sight-seeing, but your main purpose in being here is to get something accomplished.

I am strongly in favor of having the Congress at this place next year.

CHAIRMAN PRUSSING: It is a fact that this is the first Congress that we have held in which all the meetings were held in one building, and while there are lots of improvements that could be made, yet I think that it would be better to hold it here.

I am not touting for the Hotel Stevens, but in another year these boys and girls may have learned how to run a hotel and the accommodations may be better, and the service better. Are you ready for the question?

. . . (The question was put and the motion carried.) . . .

CHAIRMAN PRUSSING: As our time is getting short, I am going to call on Mr. H. L. Eggleston, Superintendent, Pan American Petroleum Company, Los Angeles, Calif., who will now speak to you.

How We Promote Safety in Our Natural Gasoline Plants

W. L. Eggleston, Superintendent, Pan-American Petroleum Company,
Los Angeles, Cal.

I am not a safety engineer, and am only involved in safety and accident prevention in so far as it has a bearing on the efficient performance of the work pertaining to the construction and operation of natural gas-gasoline plants. I have preferred to approach the safety problem from the standpoint of a practical manager of a department seeking to secure safe, satisfactory and efficient results from his department, and I have found that I frequently differ with bona-fide safety engineers in my beliefs and this is possibly due to the fact that I try to promote safety by attempting to analyze the *fundamentals of correct procedure* rather than to specifically encourage *safety*. I have much to learn from the safety engineer, but believe efficient performance will be more satisfactory than merely safe performance. I hope to describe the specific method we use—which we believe to be quite satisfactory as a means of promoting safety.

The natural gasoline problem is a serious one. The gas from producing oil and gas wells in an oil field contains natural gasoline. This gasoline can be profitably extracted in an absorption plant and a sale may be effected for both the gasoline produced and the resultant dry natural gas. The function of the natural gasoline manufacturer is usually to collect rich natural gas from the traps of producing wells, to transport this gas through pipe lines to a central plant where the gas is compressed to a suitable pressure for gasoline extraction; the gasoline is then extracted, and thereafter the gas is sold or disposed of for fuel purposes with or without further compression. Some plants make a practice of delivering the discharge gas at high pressures, either to public utility companies or to distant fields or refineries, and in some cases, dry discharge gas is supplied direct to gas lift installations at pressures ranging between 400 and 1,000 pounds.

There are two very dangerous commodities to take care of. The first is a very volatile gasoline—much more volatile than any product of the ordinary refinery—and the other is a flammable gas occasionally handled through a plant at varying pressures and at varying temperatures. Heat is necessary as steam must be produced by boilers for distillation, and there are other ignition sources that must be considered. Generally speaking, even in a properly designed plant, there are combustibles that present a serious hazard because of their volatility or the conditions under which they must be handled, and there are also ignition sources present which cannot, under ordinary conditions, be entirely isolated. The matter of safety and fire prevention, then, is highly important, and while, fundamentally, one might say that if combustibles and ignition sources are separated and kept apart, there would be little danger of fire, there are other angles to be considered. Usually, natural gas-gasoline plants must be erected in a crowded oil field with a very small ground space allotment, and must be erected quickly to take care of flush production, and frequently

must be in partial operation before the entire construction job is finished. There are several different problems that must be faced, usually in the following order: (1) design, (2) construction, (3) operation.

Design: If a plant is properly designed, the equipment will be suitable for the work and hazards will not be created due to excessive pressures on vessels containing combustible liquids or gasses. The equipment will be located properly so that combustibles and ignition sources will be segregated as much as possible. Other factors such as adequate water supply, fire protection, mechanical guards, railings, and so forth, will be provided, so that the plant will function properly with the minimum of potential hazard if it is properly handled.

Construction: During the construction, accidents will happen if the utmost efficiency is not preserved throughout; there is heavy equipment to be located quickly; there is necessity for welding sometimes in the presence of combustible vapors; and there is of necessity a constant pressure on the construction crew to make time in order to save the tremendous losses experienced owing to lack of facilities for handling gas which is being blown into the air. Accidents will happen if the construction crews throughout are not thoroughly familiar with their work, and if they do not exercise the greatest measure of precaution.

Operation: After a plant is erected the operators must proceed with utmost caution in the performance of their work to prevent fires and accidents; fires being the more serious because they result in most cases in fatal accidents. An accident or a fire is not efficient handling, so the secret of safe operation is efficient workmanship at all times.

Safety Synonymous With More Efficient Workmanship

Sooner or later, in a growing organization, the matter of safety must be considered from the angle of an actual campaign to produce *more efficient workmanship* on the part of the individual employee. About two years ago the Pan American Petroleum Company arrived at the point where it recognized the need for some control over the thought and action of employees while at work, and various methods in use by other companies to promote safety and prevent accidents were discussed at meetings held for the purpose. It was thought that by considering the schemes of other companies, and by discussing the problem in relation to the practices of other companies, that we would evolve a system of our own which would take care of our problems satisfactorily. At the outset, it was recognized that safety is *part and parcel* of the job of designing, building and operating natural gasoline plants, and that only when there is the utmost degree of safety can a job be carried on efficiently. We felt that if all our men thoroughly understood the work they were called upon to do, and that if they did this work efficiently and capably, we would have no fires, and no accidents. It was also at this time established as a law that sphere of accident and fire prevention in the natural gas-gasoline industry came under four classifications, in the following order:

- (1) Fire Prevention.
- (2) Accident Prevention.
- (3) Ability and equipment to fight fire.
- (4) First Aid.

We assumed that the first aid training and the ability and equipment to fight fire would not be needed at all if no accidents and no fires occurred, but that they would have to be provided and would have to be in readiness for instant use in case of an emergency, so as to take care of accidents and fires which might occur. We believed, then, that if we thoroughly educated our men by outlining carefully the work to be done, and by insisting on higher standards of workmanship, that we would save ourselves a lot of trouble, and we went after the problem from this angle. Naturally, our first step in education was to disseminate specific information, and

we considered employing an instructor who would make a specific study of our operations and hold classes for instruction. This idea we discarded because we felt it would be hard to retain the interest by class room work, and that it would be hard to arrange to reach every individual at a time when he was in a receptive state of mind, and when he could give undivided attention to the task of learning what there was to know about his work; also, we felt that the men best suited to give actual instruction in the work we were doing were the men who had charge over that work—namely, the manager, the superintendents, the foremen, and in certain cases, the men themselves. All of our men who had risen to responsible positions had been with the company for some time and had started at the bottom and knew, thoroughly, practically every angle of the work that was being done, so they were the men best fitted to instruct the others. We decided, then, that *we* would instruct, and that if our instructions were put into print and given to each individual monthly in the form of a bulletin, that every employee would permanently have a copy of all instructions to which he could refer at any time, and which he could study during his spare moments when he was able to give undivided attention to the study of the instructions.

The reason for putting our instructions in print and in placing them before every employee, we believe is well grounded. A man will readily forget lectures and information given verbally in instruction classes. He will soon tire of class room lectures, particularly on Safety and first aid, and the matter of class room instruction we believe should be eliminated at the start. Another means of instruction open to us was in furnishing on the bulletin boards of the company, posters, instructions and letters cautioning employees, but we believed that the benefit to be derived from bulletin boards was, of necessity, limited, although we do furnish posters supplied by the National Safety Council on the bulletin boards periodically. We felt at the start that if our bulletin placed proper stress on the correct procedure in the matter of design, construction and operation, we could reach every man with the desired information at any time that it was convenient for him to study the instructions given, and that he would retain those instructions and the information given to much better effect than if it were presented in any other way.

A Bulletin That Has Proved Effective

We came to the conclusion some two years ago that this bulletin, edited and issued along the lines indicated, would be the most satisfactory method of—

- (1) Preventing fire.
- (2) Preventing accidents.
- (3) Providing education in the best methods of fire fighting.
- (4) Providing education in best methods of first aid.
- (5) Elevating the morale of the entire organization.
- (6) Increasing the operating efficiency of the organization.
- (7) Lowering construction and operating costs.
- (8) Lowering the cost, visible and intangible, of accidents.
- (9) Stimulating the individual employee to direct his best thought and effort on his particular task.

We believe that we have made excellent progress along these lines, and we believe that it is largely due to the fact that we put all our instructions in printed form and place them in the hands of every man.

This was the first step, but immediately we had to consider the sphere of the ordinary house organ, and we decided that our bulletin had a definite object—namely, the training and education of our men in efficient practices, and that if we were to accomplish the desired end we would have to concentrate definitely on training and education, and would not have room for items of a comic, social, or athletic nature. Our first attempt was in January, 1926, and consisted of a ten-page mimeographed

letter size bulletin which contained a description of the flow of gas from the producing wells to the intake of our plants, outlining the proper operation, the proper equipment to use, and the proper way to take care of that equipment; also, in this first issue was an article on compressor room operation, dealing with the hazards to be expected, and indicating steps that should be immediately taken to prevent fire and accident. Questions were asked about these articles that would encourage a study of the subject matter presented, and announcement was made that in order to stimulate greater interests, these questions would be graded and a record kept of the grades, so that the interest taken by different men would be a matter of record. A blank sheet of paper addressed to the head of the department was also furnished, on which employees were encouraged to send in requests for information about any phase of the work with which they were not familiar. Succeeding issues of this bulletin dealt with various problems. At first, the articles given dealt with the most essential details of plant operation, and stressed always the fact that a gasoline plant was at best a concoction of the devil that must be handled with extreme caution if fire and accidents were to be prevented.

Actual instruction in proper design, proper ways of handling construction problems, and proper ways of operating, has throughout been the most important function of our bulletin, but, at the same time, the bulletin is an ideal medium for encouraging the men to more conscientious effort; is an ideal medium for creating a more active interest in the work they are doing; is ideal for transmitting definite instructions and orders for the conduct of the work. Commendation of good work can be stressed easily in such a publication and such commendation, if properly given, is an inspiration to those commended and to others who always have the good will of the management to strive for. Company, plant and department traditions may easily and conveniently be established by the proper wording in a publication that reaches every employee, and the old method of hit or miss endeavor is supplanted by one of specific instruction which reaches every man.

The Work Handled From the Manager's Office

At the outset, the work of writing, compiling, editing, printing, binding and distributing this bulletin was handled direct from the manager's office by several of the men most vitally interested in the matter of more efficient operation. The articles were written by foremen, clerks, laboratory men, roustabouts, and occasionally by outsiders, and the whole composition was directed and edited by the manager of the department. The actual work of printing was done initially on a ditto machine and later on a mimeograph which we stayed up nights to crank. Later, as our activities grew, we found someone who was willing to contract to do this work cheaply and in better shape than we were doing it, and we were thus relieved of the routine work of printing. As time went on, we found the time we had to devote to this important work was gradually growing less, and occasionally we had to resort to using re-prints from other publications which were suitable for use in our bulletin. We also found that if we were to get the best result we would have to detail a man who would specifically look after the selection of material and the editing of the bulletin. We selected a man in the department for this purpose, and without giving him any title whatsoever, sent him out to study the work of our various plants, and then to study the work produced by all the men of the department with a view to later recommending better practice, and to helping individuals in producing better work. This man might well be called a combination safety engineer, personnel manager, efficiency man, and editor, and he was selected because of his knowledge of the work of the department, his familiarity with the men employed in the department, and because he had a personality which gave assurance that he would be able to produce a result with everyone in the department without creating the slightest measure of dissatisfaction.

This description may seem somewhat detached from the specific matter of safety and fire prevention, but if you will bear in mind that, consistently, in every issue of our bulletin, we stressed the matter of efficient workmanship, safe practice, prevention of fires by a reduction of hazards due to better and more efficient workmanship, you will realize that these objects were always foremost in our minds, and that every man in the department had continually before him every encouragement to strive for fewer accidents and fewer fires. We were going further, in other words, than mere accident and fire prevention, and further by far than applying first aid to injured men, or by fighting fires that had attained disastrous proportions before they were extinguished. We believed that we could absolutely prevent fires and accidents, and that if we prevented them we would not require first aid nor fire fighting equipment, but we recognized that we would have to educate the men in first aid, and in the use of fire fighting equipment, and that we would have to supply the best of first aid and fire fighting equipment so as to be well prepared for any fires or accidents that might occur. They have occurred, but at astonishingly rare intervals, and in a very small way. We have not bothered much with statistics and we have only tackled the problem from an extremely practical angle, hitting where we felt we could do the most good. The fact that our accidents and fires have been far below normal, speaks for itself, and we feel that after 21 months of work along this line, we have accomplished a very good result, and have actually gone further than we would have if we had worked along conventional lines usually followed by safety engineers.

Prevention Ranks Higher Than Cure

We believe, in other words, in prevention more than in cure, and we have tried to prevent, but have always been in readiness to provide a remedy for any failure to prevent that might exist. Our fire fighting equipment is of the best and is standardized along practical lines, as is our first aid equipment, but we have found little use for either, and believe this is due to an intensive campaign that we have waged to educate every man in the best way to do his work with safety and fire prevention always in the foreground. I once heard a comment by a prominent safety engineer after a gasoline plant fire had resulted fatally for several men. The comment was that the first aid team had done very commendable work, and that it had established a record at this particular fire. The thought occurred to me that while the first aid team had made a record and had done commendable work, no amount of first aid would help a dead man, and that a better way to promote safety would have been to deliberately educate those men in the conduct of their work, and in the hazards they faced before they committed acts which resulted in their being burned to death. This, I believe, is true in every major gasoline plant fire; if the men had been previously carefully instructed, and if they had observed the details of their instructions, disastrous consequences would not have followed.

A picture of the make-up of the bulletins we have issued can only be had by a study of the bulletin itself, but the ground we have covered may be illustrated briefly by a summary and description of the articles that have been most important in the issues that have been sent out. To start with, we had a series of articles on compression and absorption plant operating, and had a very accurate description of the correct method of operating each plant. This description was usually written by a plant foreman and was shaped along standard lines that would give uniformity to all the descriptions. We then went into the matter of definitely classifying the combustibles and ignition sources. In one of our articles we very painstakingly classified all combustibles showing where those combustibles normally should be kept, and showing what precautions would be necessary in most of our plants to keep them confined where they belonged, and then we carefully classified all ignition sources and decided to eliminate a great number of these as not essential to plant

operation, and laid down definite instructions as to the confinement or the isolation of those that were necessary to plant operation. These classifications of both combustibles and ignition sources were very beneficial in fixing in the minds of the men exactly what hazards existed, and suggesting various remedies that would relieve them. The method of definitely taking steps to correct faulty practices was left for a period of about two months to the initiative of the men themselves, in order to stimulate thought on their part rather than to say definitely what should and should not be done. After we felt that these hazards had been fairly well covered, we went into the matter of first aid and we reprinted the best information that we had on the proper method of applying first aid for the more common injuries. In addition to our regular mimeograph bulletin, we distributed certain pamphlets that were available, giving definite instruction on first aid. We felt that this would quite possibly be better than holding first aid demonstrations that would possibly not serve the purpose, due to inability of most of the operators to attend these classes without interfering with their work.

A Code of Duties for the Various Employees

After the first aid, we concerned ourselves definitely with the duties of the different classes of employees and obtained from the men themselves an expression of opinion as to what their duties consisted of, and then co-ordinated these expressions of opinion so as to definitely formulate a code of duties for engineers, oilers, boiler firemen, absorption operators, mechanics, roustabouts, etc. Then, later, we took up matters pertaining to proper plant design, in order to stimulate thought on the part of the men in the plants, and requested them to submit criticisms of existing designs and to remedy, as far as they were able, faulty conditions. We derived considerable benefit, from a design standpoint, from the suggestions rendered by the employees.

In conjunction with the work we were doing in the matter of specific instruction, we endeavored by every means at our disposal, to encourage a study of the subject matter presented, and periodically tested the knowledge of the employees by asking direct questions in the form of examinations. These were carefully graded and certain benefits were given to the men whose grades indicated the most thorough study of our instructions. Also, we had, from time to time, articles on routine matters, such as the care of leather belting, the proper care of boiler tubes, the proper manner of operating gas engines, the importance of indicator diagrams in the utilization of horse-power, the relation of tests to operating efficiency, and such other matters that would encourage a more efficient result in the operation of our plants. These matters that were covered were carefully explained to be of prime importance to every man, and the fact was emphasized that the greatest benefit would be derived by those men who spent the most time in study and practice of these instructions because their knowledge of operating conditions and design would be enhanced by a study of our instructions, inasmuch as these instructions constituted perhaps the most complete single course in natural gas and gasoline practice available, and that they could not secure from any other known source information about the natural gas-gasoline industry that was as complete and reliable as the information we were furnishing.

One very important result was foreseen, and that was the matter of a definite increase in the morale of the entire organization. The men took a greater pride in the proper performance of their work and tried to outdo each other in doing their work carefully, safely and efficiently. There was evident from the start a more consistent effort to do good work than we had ever noticed before we made the start on this work.

This result has been maintained over a period of about two years, and we

still believe that we are securing exactly the benefits we expected to secure when we first started, and that we are really going farther than we ever hoped we would. The operations of our department are far more efficiently carried on. We believe we are getting better results in the matter of fire prevention and accident prevention, and we believe that the individual employee has been encouraged and stimulated to doing work of a higher character than would have been possible under any other condition.

Our methods and our results may be criticised by bona-fide safety engineers, and we may be neglecting a good many angles of the Safety situation that are important to them, but we firmly believe that we are pursuing the proper course, that we have definitely accomplished a decrease in our accidents and fires, and that we have obtained a more efficient condition within our department.

We believe, in short, that safety may be best promoted by attacking the fundamentals of *correct* and *efficient* operation because if any operation is performed correctly and efficiently, safety is a prerequisite. A thoroughly safe operation, on the other hand, may not be efficient.

Not a Handbook—But a Training Course

CHAIRMAN PRUSSING: Are there any natural gas gasoline men present who have any questions they would like to ask Mr. Eggleston?

C. L. CANFIELD (Sinclair Oil Co., Kansas City, Mo.): It seems to emphasize very clearly Mr. Swim's statement that the safety work must come from the management end, that it cannot start from the bottom.

R. E. DONOVAN (Standard Oil Co. of California, San Francisco, Calif.): I want to tell Mr. Eggleston that what he has classed as a hand book is not a hand book at all. It is a very fine training course. We have used something on the same line. A hand book is just a little book that you hand out to the men, and this is a course of instruction and we need it. It shows that Mr. Eggleston has gone into the matter thoroughly.

THOS. W. WADDINGTON (Standard Oil Co., Elizabeth, N. J.): It was my privilege and honor to be the first man employed by his father at the old Bayonne Works in New Jersey.

I think his paper was admirably rendered and his suggestions can be followed by others in the field. With certain limitations, something of that character would be a wonderful thing to follow out and use as an example. We know at Bayonne that certain lines of printed instructions have been used effectively.

MR. BONSB: I have had the pleasure of reading that paper, and I wish it were possible for all natural gas operators to have similar instructions.

I agree with Mr. Donovan that it is not a hand book. It is the finest set of instructions that I ever saw. The men are going to read that and study it. The natural gas operators are a pretty good type of men, but I do not believe it would work well with the average field man.

H. A. MATIER (Union Oil Co., Los Angeles, Calif.): I want to say a few words for the despised hand book. We have found new employees pathetically eager to learn something about the work and the company when they first come on the job, and that is the time to give them instructions and the time when they will learn the most, and if you have a printed copy of instructions to give them, they are going to read it when they are first hired.

This wonderful paper is not intended for new men, and my plea is for consolidation of thoughts that can be put into some kind of book or printed form for the new man, something that will make him feel that the company has his welfare at heart and will make him want to work for the company. That is what the new man needs. The time was that when a man first went on a job he was given tools and told to go to work and God help you. Mr. Burgess, the gen-

eral manager of the company I work for, sent me such a pamphlet. In it were instructions like "Don't couple your wagon that way, do it this way," and this was illustrated; and that was the kind of a hand book I was suggesting.

CHAIRMAN PRUSSING: The spellbinder is right. A new man coming on the job is pathetically eager to learn about the job, and all of us know it. There is no period during which he is so susceptible to suggestion as when he first comes on the job, and if printed or written instructions have any value they certainly are of value to the man when he comes on the job.

It has been our plan to give the men definite instructions during that period, and not to expect them to earn anything for the company for the first few days. One of the activities which I hope to see carried out in the future is the promotion of this idea.

I had in mind, when Mr. Blakeslee sent in his first set of pictures, that something in the way of a code could be made from each little item, and could be used as a poster for this section. In the past the oil industry has not received posters because they have not contributed anything on which posters could be made. Are there any further suggestions?

Several Questions Are Discussed

CHAIRMAN PRUSSING: Several questions have been handed to me. Here is the first one: Are trees close to storage tanks a fire hazard, and why?

S. L. NEWCOMB (Standard Oil Company, New Jersey, Elizabeth, N. J.): They are to a limited degree. Ordinarily your tree is higher than your tank. Moreover, attacks of lightning have influence over a given radius. On the other hand, if lightning strikes a tree that is close by a tank, the tank may be ignited. I know of one case where lightning struck a tree and four tanks standing 25 feet away were ignited simultaneously.

CHAIRMAN PRUSSING: It is not practical to leave trees standing in some of the fields. It is always an expense. We have incurred much expense where lightning has struck the tree and large tanks have become ignited.

MR. NEWCOMB: In the case I referred to, the four tanks were the old wooden tanks. We had the Johns-Mansville roofs put on.

CHAIRMAN PRUSSING: Here is the next question: "What results have been obtained with the question and suggestion box?"

H. L. EGGLESTON (Pan-American Petroleum Co., Los Angeles, Calif.): In connection with our question box we have a question sheet, and you can get the men to ask the questions and then give them instructions on those. The men will usually read the questions asked, but having them write the questions for the sheets is a little harder. Let them read the questions asked and then put in requests for the sheets.

RAY E. MILLER (Marland Refining Company, Ponca City, Okla.): This spring our central safety committee sent out questions which ultimately reached every man in the plant asking him to analyze the hazards of his work, and we got a mass of replies. There was a lot of chaff in it, but there was also some pretty good stuff. Then men brought up ideas that we had passed time and again and overlooked.

I do not like the straight question box idea. I have tried it from time to time, but I would say that it is far better to make the employees point out the hazards and ask questions.

C. L. HIGHTOWER (Texas Pacific Coal & Oil Co., Thurber, Texas): I might enlarge a little on our suggestion and question box idea. We pay two dollars for each accepted suggestion, and we encourage the making of suggestions, and encourage the men to turn in reports of the hazards, and that consists of anything that comes in as a hazard. Anything that comes in in the way of main-

tenance work we would not consider worthy of a reward. But for anything that is instructive, if we think the suggested plan is a good one, we give the reward. This, of course, requires constant following up, but you will find that many of the suggestions are good.

RALPH E. MOTLEY (Atlantic Refining Co., Philadelphia, Pa.): We have suggestion boxes at five main entrances, and from time to time we have received valuable suggestions. I feel that we will not have good results until we place the rewards for the suggestions on a monetary basis.

Last winter I tried a different method. We sent out pictures of accidents and asked the men to tell us what was wrong, and I got some of the best replies I ever read. They must have put a lot of thought on this. At different times I offered prizes for suggestions and ideas to put in a safety moving picture.

CHAIRMAN PRUSSING: Mr. Matier asked me just now about the cleaning of tanks. The technique of cleaning tanks was suggested as a subject for our safety committee to develop. That was developed by asking for suggestions from the superintendents that had anything to do with storage tanks. Out of what we received we evolved a simple code for cleaning tanks, and this was sent out to superintendents and foremen, and after several passages back and forth it was used and sent out by the manager of department to his own men with definite instructions.

MR. HUMPHREY: I might say that the process of getting suggestions was as follows:

We had what was called a "Coiner Idea Committee" and at each refinery this committee had suggestion boxes, and on these boxes were forms that could be filled out and deposited in the boxes. These were collected and considered by the committee, and if the local refinery agreed it was sent to the other refinery and then sent to the "Coiner Idea Committee" for its O. K.; and if the committee thought well of the suggestion, it gave a reward.

ADJOURNMENT

Friday, September 30, 1927

V. R. CURRIE, Chairman

Manager, Employment and Service, The Texas Company, Houston, Texas.

The meeting was called to order at nine-thirty o'clock by Mr. V. R. Currie, past chairman.

MR. CURRIE: I regret to advise this morning that our chairman, Mr. Prussing, is somewhat under the weather and not able to be here, and the general vice-chairman, Dr. Anderson, has left for his home. I am therefore pinch-hitter for both of them.

The first paper on our program this morning will be given by Mr. T. N. Shaw, Midwest Refining Co., Casper, Wyoming.

How We Take Care of Injured Employees

T. N. Shaw, Assistant Director of Industrial Relations, The Midwest Refining Company, Midwest, Wyo.

The subject which has been assigned to me in its relation to Safety reminds me of that old story of the soap and perfume manufacturer's ad, "If you don't use our soap, for God's sake use our perfume." And so I say, "if you don't practice safety, for God's sake practice first aid." If you can't keep your men from getting injured, take the best possible care of them after they are injured.

Care of the injured employee logically begins with first aid, and so in dealing with my subject I am going to tell first how we are organized and equipped to handle First Aid.

Training—For a number of years we had most of our locations fairly well supplied with first aid materials, but it was not until the fall of 1922 that we started our first systematic training in first aid. The Bureau of Mines system of training was adopted as our standard and representatives of the Bureau came into our field to give the training. We have had them each year since and in each of our locations the training has been given. Last year at the close of the training period, we had nearly 100 per cent of our employees trained. First aid teams were formed in nearly all of our departments and a big contest conducted by the Bureau of Mines was held last fall.

Equipment—Our equipment consists of three types of containers. First we have a cabinet calculated to be fastened on the wall. It is about 8x16x22 inches inside measurement, is supposed to have a considerable quantity of each of the articles specified and is a supply base for the smaller kits of that particular location. It is usually located either in office or warehouse and furnishes dressings for injuries that are brought in. When located at "wild cat" wells or isolated places this cabinet is supplied with several remedies as well as first aid. We have 44 of this type in use.

A second type of container is a portable outfit and is carried on trucks accompanying large gangs. It is a box 5½x11x19 inches and is filled with an assortment of supplies suitable to the needs of a gang of a dozen or more men. We have 72 of this type in use.

One of these containers filled especially for severe burns or injuries is located in each of our 22 booster stations, which are fairly evenly divided throughout the field. These kits are sealed and marked "for use in severe cases only." At these booster stations we also have a stretcher and roll of blankets, so with each of our

field offices having equipment supplies are quickly available at most any place about the field.

A third type of container measures 3x6x9 inches and is equipped with a variety of articles for first aid but of necessity a small quantity of each. About 400 of this type are scattered throughout the organization. Each truck and car has one; they are supplied to rod and tubing crews, connection crews, drilling crews, etc. Before the small kits were put out we had an average of about 10 infection cases per month; now they seldom occur.

Maintenance—It is one problem to properly locate first aid equipment, but to keep the containers filled with supplies is another problem. Depending on the other fellow is not successful, and after trying several other methods we adopted our present Postal Card System. Each month a postal card is sent to each cabinet, the card has a return coupon addressed and stamped for return to the supply base. On this return coupon are listed the supplies needed. Since installing this system of checking, we have had no trouble from our kits being without supplies. A few of the smaller kits in the hands of the pushers in the Salt Creek field are checked and replenished by our safety inspector at the monthly safety meetings.

Medical Department—After first aid comes the medical department. Our present hospital in the Salt Creek field has accommodations for about 40 patients, but in emergency can care for twice that many. A nurses' home is operated adjacent to the hospital and will accommodate about a dozen nurses. The regular staff consists of two doctors and of course the number of nurses varies with the number of patients. Besides caring for the company's injured employees, this hospital serves the general needs of the community.

In each of two other locations of the company, we operate a hospital and employ full-time physicians jointly with one of the other companies; but in all other locations local physicians and hospitals are used.

When located where it is possible to use public hospitals and employ regular practicing physicians, I would strongly recommend it in preference to operating your own. The cost would be much the same, but even if a saving could be made it does not offset the grief attached to operating your own. It is harder to satisfy people with a doctor than with a religion; it is better to let them do their own selecting or at least give them a choice of several, and when you have your own hospital you can't do it. We can handle almost any type of injury in our hospital, but when specialists are needed we either call them in or send the patient to them. We would rather spend money to repair a man than to settle with him; however, when a permanent disability is incurred the case is turned over to our legal department to be settled according to the law in the state where the accident occurred.

Advantages of Picric Acid in First Aid

MR. CURRIE: This is a very important subject and I am quite sure we can have a lively discussion on it. Are there any questions you wish to ask Mr. Shaw?

R. E. DONOVAN (Standard Oil Co. of California, San Francisco, Calif.): Mr. Shaw, do you use picric acid for the big burn package you spoke of?

MR. SHAW: We use picric acid as first aid, for two reasons. In the first place, fire or heat that is hot enough to burn the flesh sterilizes the wound. Picric acid is also an antiseptic solution to help keep it sterile and it has an anesthetizing effect which is the most important part in our minds for using picric acid. It takes the fire out of the burn, it is cooling. I have used it myself, and it gives the feeling of rubbing a piece of ice over the burn; it is actually soothing.

What our doctors use in the hospitals varies. We have some who use picric acid, some who use tannic acid, and some who use mercurochrome, but of course we are not dictating to the doctors what they should use.

R. S. BONSB (Standard Oil Co. of New Jersey, New York City.): There are three points in connection with first-aid kits. One is that it is very important that you have those kits properly located, another that you use a seal on them. It is rather a peculiar thing that most people will very rarely break a seal, although it is a simple thing to do. Perhaps they have been taught that because the railroad companies have been teaching people the penalty for, and the inadvisability of, breaking a seal. If you put a seal on a kit, then, it won't be used until there is a legitimate use for it. If it is unsealed, the temptation to take material out of it to take home is very great.

The third point is to place first-aid kits where their use will be understood by the foreman or gang leader. It is a great mistake to do otherwise. Lots of times you will find a first aid kit in the field and people don't know how to use it. If you have iodine in there, they will put a dip on a wound and then bandage it. Another thing, they will break a bandage, throw it back into the kit. They will later take that dirty bandage and use it on another wound, causing an infection. A lot of things happen like that unless people are told about it.

T. N. SHAW (Midwest Refining Co., Casper, Wyo.): Mr. Bonsib brought out one point that I should like to take up, that of using a bandage and putting the balance back into the kit. For that reason, along with others, we discontinued using rolled bandages. We use nothing now but bandage compresses, and that is an individual bandage and does away with any possibility of using part and putting the rest back where it becomes unsterile.

First Aid Work of the Bureau of Mines

As you know, the Bureau of Mines has that as one of its hobbies. And while I am on my feet, I want to emphasize the importance of the work the Bureau has done in first aid. They have certainly given our company wonderful service, and their system can't be beaten. I don't believe there is another system like it that is any better. It is similar, of course, to the Red Cross and the Boy Scouts; they are all founded on about the same basis.

There is still another point I want to emphasize, that I forgot when reading my paper; that is, in making the statement that every car and truck is supplied with a first-aid kit, I hope you caught all that that means. It means that if one or two or three men are working where a first-aid kit is not handy or where, because of a more serious accident, more supplies are needed, all the men need to do is to go out onto the road and flag the first company car that goes by; wherever there is a company car, you get additional supplies, and in an oil field that is a very important thing because cars and trucks are coming all the time.

MR. CURRIE: Any further questions?

V. B. CURL (Maryland Oil Company, Berger, Texas): I should like to ask Mr. Shaw what method he employs, what one he has found the most effective, in training and instructing his men in first aid?

MR. SHAW: My answer to that is that the Bureau of Mines system of training is the best. The supplies in our kits are based on that training. It is a definite course, has been studied and improved upon time and time again over a period of years, and these improvement have been worked out by doctors of the profession, although the training has been given by what we call laymen—that is, men who have been trained by doctors have trained the employees.

The system was first developed for use in mines, but it is just as applicable in an oil field or a refinery as anywhere else, and their manual is available through the Bureau's office in Pittsburgh.

They found laymen were better trainers than doctors, because doctors get too technical, use too many Latin phrases and talk over their listeners' heads.

MR. CURRIE: I feel wholly incapable of introducing the next speaker in the manner in which I feel he should be introduced.

From time to time we have stressed the fact that accident prevention work should begin at the top and that without the cooperation, interest and support of the executives higher up, very little could be accomplished.

Our program committee is to be complimented and we are indeed fortunate in having at this session an executive who will present to us the safety idea from the executive's standpoint. It is my privilege, and a great pleasure, to introduce to you at this time, Dr. R. E. Humphreys, assistant general manager of Manufacturing, and member of the Board of Directors, Standard Oil Company of Indiana, Chicago, Illinois.

Safety From the Executive's Point of View

Dr. R. E. Humphreys, Assistant General Manager of Manufacturing, and Member of Board of Directors, Standard Oil Company, (Indiana) Chicago, Ill.

You will probably say about my talk this morning, what was said of Green's *History of England* when it first appeared. The critic who had attended a banquet the evening before said of the book that it contained much that was new and interesting, but the trouble with it was, the part that was new was not interesting and the part that was interesting was not new.

I merely hope to present a point of view that will afford a different lighting on a familiar picture, emphasizing different features in a way to give them a new interest.

But I trust, however, you will bear with me, because of the fact that I am actively concerned in a great industry and was at the head of a large oil refinery during the period of installation of safety methods there.

We live in an age of development. During my long career, I have seen the beginning and the development of many wonderful inventions, such as the telephone, the bicycle, the ukelele, the typewriter, chiropractic, the cafeteria, and many other such things. Life is growing more and more complicated and involved. Birth control is making birth difficult, and the machine gun is making death easy, and the saxophone is making it welcome. Alimony is taking the place of matrimony and prohibition is making us good, or at least it is causing us to die young.

I suppose you have all heard of the whisk broom cocktail they are now serving down in Louisville; with every cocktail they give you a whisk broom with which to brush yourself off when you get up.

We are just now having overnight service to Europe and I presume prohibition should be given the greater part of the credit for that. We have the automobile and now the neighbors have one, too. Thanks to the radio, a man can make a speech in New York and we can listen to him in Chicago; and thanks also to the radio, we can turn him off whenever we so desire. I know you will agree with me that that is a very pleasing thing to be able to do, and you will probably agree with me much more enthusiastically before I get through.

But seriously, my friends, I have just passed through the early part of one of the most interesting and important parts of all our development. The growth of safety programs in industrial life, the influence upon the happiness of the world is destined to be important and far reaching. The maiming and accidental killing of workmen in building and manufacturing operations has hitherto, as you know, been accepted as inevitable, but I do not think it will be so very much longer.

One of the earliest recorded instances of the kind of which I have any knowledge occurred during the building of the tower of Babel, and that is quite early, you will agree. The people of that enterprising city had a wonderful vision of a tower that

would rise up into the heavens and they set about the erection of this structure in order to hobnob with the gods in their own ethereal domain. But their purpose was thwarted by an industrial calamity, when they lost the power of understandable speech. No one could tell what a workman was talking about, and those of you who have handled crews of Slovaks and Turks will not doubt their descendants are with us yet.

However, an understanding of languages is not everything. I know a professor who speaks seven languages fluently, but his wife speaks only one, and yet I bet on the woman every time.

The maiming of workmen in the olden times was taken as a matter of course. It is not difficult to visualize the tremendous loss of life that occurred during the building of the great pyramid at Gizeh. The fellow who built that pyramid was some "geezer." Its base covers an area of 15 acres, and it looms 150 feet higher than the dome of the great Cathedral of St. Paul, which ought to impress every man—except, perhaps, some fellow from Minneapolis. Its engineering was so nearly faultless that its four great sides have a mean area of only six-tenths of an inch in length and twelve seconds in angle from a perfect square. A modern tailor can't cut out a vest nowadays and come as close.

Human Sacrifices Are Still Offered Up

What was it for? Only that the royal remains could be preserved until exhibited in a British museum or an American circus. I think every man should have a higher ambition than merely to be a success as a mummy.

But my admiration for the engineering is obscured by the realization that those ancient monarchs sacrificed thousands of their subjects merely that their carcasses might be preserved for all time from the ravages of decay.

We haven't been as careful of our workmen as we should have been. Human sacrifices in the building of bridges, the building of skyscrapers have all added a toll of death to the record of industrial progress. And why? Probably because engineers and manufacturers deemed these things inevitable and part of the press of civilization. But this idea could not persist forever. Aside from humanitarian considerations, the compensation statutes would sooner or later have made it too expensive, and I am of the opinion that if the idea of employees' safety had been effectively brought to their attention before, the manufacturers would have accepted it for their own sake. I am sure that was the case with my own company.

However, the idea and the necessity of employees' safety did not make much of a dent in the consciousness of the Standard Oil Company of Indiana until the year 1911, although accident prevention programs had been carried on as early as 1909. Even then the idea was accepted only with many reservations.

My company prides itself on being in the forefront in every movement that affects its business and yet it never rushes forward heedlessly and headlong. The safety campaign seemed an interesting experiment that might be worth trying once, and so in 1911 we put on a preliminary program at our largest plant, the Whiting, Indiana, plant.

In order that safety might have a fair chance of success, it seemed only right that we give it a department of its own and put it in the hands of a man who knew something about it. Industrial corporations are not like municipal corporations. They would not put a horse doctor in a hospital—and yet I am told that right here in Chicago at one time politicians tried to put a horse doctor at the head of the psychopathic hospital.

A new baby should not be trusted to the care of the cook and the chambermaid, the gardener and the chauffeur; it is a job for the mother, and no one else will do. Also, in the same way, safety should have proper leadership; it can't be left to the care of the foreman, no matter how capable he may be.

old type grease pits which were narrow and caused the operator to work in a cramped position. They were so short that a large car completely covered them, allotting no space for a hurried exit, and in some cases none at all, in case of emergency. To some it may appear that the hazard in the average small grease pit is of no consequence. True, it is seldom that anything serious has come from them, but the possibilities are great, for a large number of operators do not spend enough time and work on them to keep them clean. The pit having its floors and walls covered with oil, grease and crank case drainings is a very good setting for a serious accident if it is not so constructed as to allow the operator easy and rapid egress.

The Hazard of the Filling Station Pit

Just a short time ago one of our men was working in one of these short pits but, due to previous instructions, he had taken the precaution of moving the car forward far enough to allow for an emergency exit. While in the act of draining the crank case the wind blew a quantity of the drainings over the shoulder and side of his uniform, and when he had finished the job he requested the customer to wait until he could get out of the pit before starting the motor; but the customer failed to hear or heed the request. When the motor started, it backfired, and the flash, due to the gasoline dilution in the crank case drainings, ignited the man's clothing. He had presence of mind enough to lie down in the corner of the pit and smother out the flames, rather than to run out into the air where no doubt he would have been burned seriously. Now had the circumstances been just right—if the floor and walls of the pit had been covered with oil, grease and crankcase drainings, and the car had covered the pit entirely, this man might have been burned to death.

At the present time, when it is felt that a pit is the proper thing to install at a particular station, it is constructed wide enough to allow the free and unhampered movement of the operator, long enough for him to get out easily up stairways at either end, and all cars are drained directly into an underground tank through an adjustable pipeline. We are also trying out a number of the automobile lifts with a view to determining their merits as compared to those of grease pits.

Another important step was taken when an operating and fire prevention manual, containing a set of rules covering the operation of all equipment and the handling of petroleum products in a manner to conform with all state and national laws, was sent to all agencies.

No doubt these things are largely responsible for the scarcity of fires and explosions, and the reducing of the mechanical hazard to a minimum; but they have had only a small bearing on the more important safety angle—the human element. Therefore, the greater part of our work and this discussion, lies along the lines of safety education and sales; that is, the selling of safety to the men.

Periodical inspections of all stations and warehouses are made by the safety department, at which times the men are encouraged to discuss not only their safety problems, but their regular operating, sales, and service problems as well. It is felt that a great deal of importance should be attached to this policy, because it not only has a tendency to act as a sort of safety valve for their mental condition, enabling them to think along straighter lines, but gives us an opportunity to study their methods of thinking and working; and this, coupled with the general condition of the stations, gives us a very good foundation upon which to base our work with them. During the discussion after the inspection is made, the weak points discovered in either the equipment or methods of operation are pointed out to them with full explanations as to why they are

considered weak. The average man employed in our stations is capable of following instructions and rules better if he thoroughly understands the reasons for them. An inspection report is made to the general office with a copy to the manager of the division in which the inspection was made, outlining to them the things that were found and the suggestions offered to the man at that point, so that the divisional staff can follow up the recommendations and see that necessary changes are made and the suggestions put into effect.

Also periodical letters are written to the divisional staffs giving them a list of unsafe practices observed while making inspections, together with a list of the causes of all no-lost-time accidents; the lost time accidents are given in the formal monthly report, a copy of which goes to each divisional manager. This means is used in lieu of the regular foreman's meeting, as it is practically impossible to hold such meetings with the traveling personnel of the divisions; and it is felt that these letters will enable them to better organize the men and to make frequent inspections without the aid of the safety department. In addition to the periodical inspections by the safety department, which, due to the large territory covered, cannot be made as often as might be desired, the means of typewritten circulars and bulletins is employed in carrying on the campaign to the stations. This is for the purpose of getting to the men any information which might be of value in familiarizing them with thoughts or facts which will aid them in organizing safety at their agency. This method is also used for the following up and enforcing of the rules as outlined in the operating and fire prevention manual previously mentioned.

Influence of the Plant House Organ

Through the advertising department, the marketing department publishes a house organ, *The Marland Service Man*, which is a semi-monthly publication and was originated for the purpose of keeping the members of the various divisions posted on the operations, both business and social, of the other divisions, and to promote company spirit, sales and service. Due to the efficient manner in which this magazine has been published, it has become very popular with the entire personnel of the department. On account of its popularity practically every man in the organization reads it from cover to cover. This fact has caused a great deal of weight to be placed upon its effectiveness as a messenger of safety. In each issue at least one page, and more if necessary, is devoted entirely to safety. Ordinarily the safety page carries one or two short practical articles inspired either by accidents which have occurred in the past, or unsafe practices which have not yet resulted in injury. Then, too, a small amount of inspirational material is used along with a few safety slogans, and once each month a report of the divisional accident records is included in such a manner as to inspire friendly rivalry between the divisions. Each division is shown with the number of accidents occurring by month as well as the accumulation, with personal injuries and truck accidents separated.

In connection with marketing department safety, as is true in any other branch of the industry, I believe that the investigation of all accidents is important for the purpose of bringing out the true causes. However, we are handicapped with our investigations because it is impractical for the safety engineer to travel the required long distance to investigate them. The plan of following them up by letter was first attempted, but the results were not at all satisfactory. Later, it was decided to try the plan of having the men who are in closer contact with the stations do the investigating, and the traveling supervisor who works under the direction of the superintendent's office was given the responsibility of investigating all personal injuries with a view to determining the exact

cause and responsibility. The traveling truck inspectors, due to the fact that they are held, in a large way, responsible for the maintenance costs on the trucks and cars in their territory, were given the responsibility of investigating all truck and automobile accidents. As soon as an investigation is made a report is given to the division office with a copy to the safety department. So far, this plan has not been in effect long enough for us to judge it fairly; however, it is felt that it will be much more effective than the old method in that it will not only give us the correct cause, but will also impress the men with the importance of being careful and will help to jar them loose from the old idea that accidents are to be considered a regular part of everyday life.

We have not yet adopted a policy of discharging a man for his accident record, unless it is an extreme case, preferring rather to impress upon him the importance of safety and to try to make a better man of him. We believe that if a man gets off on the wrong foot it is better to spend some time and energy in trying to get him straightened out rather than to replace him with a new and inexperienced man. This policy has no doubt had a large part in the building of the spirit which exists in the department, and it is not desired to depart from it except in extreme cases where there is no alternative.

Regular Meetings Were Organized

Over the past few years a large percentage of the total number of accidents in the department occurred at the points where there was a number of men working and a fleet of trucks operating. When safety was introduced to the marketing department, one of the first thoughts was directed toward the elimination of accidents at these points. With that thought in mind, regular monthly meetings were organized in conjunction with local sales meetings. Our program covering safety as introduced in these meetings was outlined on a schedule plan.

The safety talks given are divided into two sections. The first section outlines the various departments of the company, and at the same time endeavors to familiarize the men with the company's policies and the attitude of the officials toward the employees through the industrial relations department and through other benefits given for the purpose of improving conditions generally. The second section is devoted entirely to safety discussions and the application of safety. In connection with safety discussions the showing of safety moving pictures has been adopted, which, no doubt, will be very effective and is to be improved upon in the future. I say improved upon for the reason that at present we are unable to show in the meetings anything other than general safety pictures. However, in the future, with the aid of a moving picture camera recently purchased, we expect to take the causes of past accidents and the unsafe practices as discovered through inspections, and work them out in pictures, possibly showing the right and the wrong ways of doing the various phases of work as applied to service stations, distributing stations, warehouses and trucks. This plan is an improvement in that the pictures will be the means of working out the details previously mentioned and will deal directly with the problems our men have to overcome. Also the fact that they are pictures in which our own men, our own stations and equipment, are the principals will tend to work up a greater interest in safety and in the company as a whole.

In these meetings all accidents which have occurred over the past month are brought up and discussed freely from all possible angles, the men themselves being encouraged to do the greater part of the talking. At some of the larger points, we are following the practice of having at each meeting some man in the local organization deliver a five or ten minute talk on some particular phase

of the work, in which it is suggested that the driver at angles, including safety, pertaining to that particular phase.

Out of seven of these ~~larger trucks~~ ~~which~~ ~~the~~ ~~last~~ ~~material~~ ~~to~~ ~~base~~ ~~com-~~
parative figures over the ~~last~~ ~~six~~ ~~months~~ ~~of~~ ~~1926~~ ~~as~~ ~~against~~ ~~the~~ ~~first~~ ~~six~~ ~~months~~
of the present year. ~~four~~ ~~showed~~ ~~a~~ ~~decrease~~ ~~in~~ ~~accidents~~ ~~and~~ ~~one~~ ~~of~~ ~~them~~ ~~being~~
perfect records for 1927. The ~~frequency~~ ~~rate~~ ~~of~~ ~~one~~ ~~of~~ ~~them~~ ~~increased~~ ~~and~~ ~~the~~
remaining one was the same for both years. The ~~total~~ ~~for~~ ~~the~~ ~~seven~~ ~~stations~~
shows in 1926 a frequency rate of ~~2.14~~ ~~and~~ ~~in~~ ~~1927~~ ~~of~~ ~~an~~ ~~improvement~~ ~~of~~
32 per cent.

The promotion of safety with ~~truck~~ ~~operation~~ ~~is~~ ~~different~~ ~~and~~ ~~more~~ ~~compli-~~
cated than it is among service station ~~attendants~~ ~~and~~ ~~warehouse~~ ~~men~~, in that in
most cases of truck accidents there are ~~different~~ ~~questions~~ ~~to~~ ~~be~~ ~~asked~~ ~~and~~ ~~an-~~
swered due to the fact that ~~instead~~ ~~of~~ ~~one~~ ~~thing~~ ~~there~~ ~~are~~ ~~two~~ ~~to~~ ~~be~~ ~~considered~~,
different local traffic rules and regulations, and a much more complicated piece
of equipment. The majority of truck accidents are of minor importance, but
still it is just as important that these minor accidents be eliminated because
usually the causes are practically the same as those of the more serious ones;
and if we eliminate permanently the cause of the slight accident we have done
a great deal toward the elimination of the other. About the same general plan
which is used in our safety program for the service station salesmen and ware-
house men is used in getting it over to the truck salesmen; that is, through the
above mentioned Marland Service Man, the traveling supervisors, truck inspec-
tors, and through circular letters and bulletins.

Effective Slogans Located on the Dash

Each division has one or more regular truck inspectors who inspect every
part of the truck as nearly once a month as possible, to insure the best condi-
tion of the equipment. As a result the accidents due to mechanical failure have
been practically eliminated.

In addition to this we have equipped each truck with two metal plates located
on the dash. One of these is for a driving slogan which is changed once each
month, and the other is a permanent plate cautioning all drivers against the
hauling of passengers other than company employees in the line of duty.

It may be that in the future we can establish some system wherein all drivers
with perfect yearly accident records will be rewarded, but at the present time
nothing along this line has been inaugurated.

There is one other thought on which we are working now and hope in the
near future to get action upon, and that is the distributing to every driver in the
department of a small card or pamphlet in the form of "instructions to drivers."
It will contain a list of suggestions which will not only tend toward the elimina-
tion of accidents but will help to promote courtesy on the road and the proper
care of rolling equipment, these suggestions to be worked out from, and based
upon past causes of accidents, unsafe practices, general courtesy which not only
prevents accidents but builds good will, and past experiences with maintenance
costs.

At the beginning of the year 1924, it was desired to work out some plan
whereby the highest type men among the agents and field men would be given
some special distinction and at the same time would act as an incentive for
others to build up and develop themselves. It was finally decided that each
year a number of men selected by a secret committee would be presented with
a small gold button bearing the Marland triangle trade mark and the words
"Honor Man." This badge was termed "The Merit Badge," and the men who
have so far received it consider it an invaluable possession. These men are
judged upon the following qualifications: loyalty, honesty, cheerfulness, sin-

and it would be foolish for a safety engineer to try to work out all of the details unless he had previously been through the mill in a similar manner.

There is one branch of the marketing department which has not previously been mentioned and that is the construction gangs. At the present time it appears to be the hardest branch in which to do any real safety work, and this is due to the fact that the personnel is continually changing. A job is completed in one location and the foreman moves on to the next job, which may be in an adjoining town or even in another state, and it is impossible for him to take with him the men he had employed on the former job. Therefore, it means that he is continually working with new men while the older men are no longer connected with the department. Due to this condition, our safety work has been handicapped, in that it is confined to the foremen who can do little more than direct the construction work in such a manner as to make it as safe as possible, and to talk safety to his men in a more or less general way, for it is impossible, due to their short time with us, to educate the men in all of the details pertaining to their work.

Inasmuch as organized safety in the marketing department might be classed as in the pioneering stage, it is not only new to the men on the firing line, but is also new to those in command; and as a result a large number of our methods are undergoing development through the experimental field. No doubt, there are a number of other ways and means in which marketing department safety can be successfully carried out, and as we progress in our work we hope and expect to develop some of them. Since our work has been largely along experimental lines the results have possibly not been as great as they would have been had the work been done altogether along established lines. However, the improvement for the first six months of the present year over the first six months of last year, has been very encouraging. The frequency rate on personal injuries for the first six months of 1926 was 48.20, while for the first six months of the present year it was 18.78, showing an improvement of 61 per cent. The severity rate for the first six months of 1926 was .29, as against .21 for 1927, showing an improvement of 27 per cent. The frequency rate of the truck accidents as based on the number of accidents per million miles traveled for the first six months of 1926 was 39.75, as against 24.78 for the first six months of 1927, showing an improvement of 38 per cent.

If such improvements can be shown through inspections and the talking of safety in general, it appears reasonable to believe that the teaching of safety in detail, which is planned for the coming year, will bring forth an additional substantial decrease in the frequency and severity rates for the year of 1928.

Staging the Accident for Motion Pictures

MR. CURRIE: The subject is now open for discussion. Any questions you wish to ask Mr. Hearne?

R. S. BONSB (Standard Oil Company of New Jersey, New York City): Mr. Mr. Hearne mentioned the taking of motion pictures as a part of their program. I am just wondering how you are going to stage these causes of accidents, or safety procedures.

MR. HEARNE: Our plan at the present time is to take the unsafe practices we have discovered and the causes of past accidents and reenact them, using our own men and equipment.

MR. BONSB: Isn't that rather an expensive way of getting it across? Wouldn't it be just as effective, and more flexible, to have slides?

MR. HEARNE: Possibly they might be, but movies make a bigger impression on a man's mind than slides.

MR. BONSTB: I question the efficiency of motion pictures because of the technique required. You take the average person being photographed, he knows it, he is so self-conscious that usually it is very glaring on the screen, and so many mistakes are made that often the pictures appear very funny to the people who see them. It kills the effect. But you can take a snapshot quickly, and anyway most people aren't shy of those.

In our company we use slides effectively. They are very flexible. We make a series and change the order of the slides to fit any situation we meet that is interesting when we go through the plant; in that way we can show up any particular condition we may run across.

The average motion picture is expensive to make, and a safety man has to realize that there is a certain limit beyond which we aren't justified in going.

RAY E. MILLER (Marland Companies, Ponca City, Okla.): I can't agree with Mr. Bonsib, chiefly because he believes one thing and I believe another.

We can make up motion pictures at a very slight cost. I happen to have had a little camera work, and have made a few pictures in the past, although I don't think I could get a job at Hollywood. I have been able to make a few pictures that serve our purpose, however, and I don't believe the men are camera shy to an extent to bother anybody. We have tried to use the regular man on the job and I feel safe in saying that the average man on the job is really highly superior to the paid actors whose unfamiliarity with the work and the job and the materials causes him to act unnaturally.

It is simply a matter of training the workmen to forget the camera is there and to do the work as they ordinarily would.

We get those pictures made without a great deal of expense. The only cost is the developing of the film, because pictures can be taken on regular inspection trips.

We feel the men are interested in seeing the pictures move, seeing the men in action rather than standing still, and we are very much interested in the motion picture idea.

Some Experience in Making Motion Pictures

H. L. EGGLESTON (Pan American Petroleum Co., Los Angeles, Calif.): We have monkeyed with motion picture quite a good deal; although the expense is high, they are of definite value in fire prevention. For accident prevention, we don't believe it wise to reenact accidents because then we are working from the wrong angle, we are impressing the man how to cause accidents rather than how to prevent them.

We find that a motion picture without suitable titles is valueless; some titles should be used with it.

The field we try to cover is the fire prevention field. For our pictures, we build a fire and show the correct procedure of putting that fire out, something similar to Mr. Donovan's pictures. We just try to indicate the correct procedure and never go to any spectacular lengths, our sole purpose being to show the men the proper method of extinguishing a fire. From that standpoint, I think the motion picture is of value.

R. E. DONOVAN (Standard Oil Company of California, San Francisco, Calif.): I don't want to take up too much time, but there is one more use of the motion picture camera that probably hasn't been brought out. I carry a portable motion picture camera with me on the field trips I make. It isn't very expensive.

The chief value of the motion picture is in helping in the standardization of safeguards, especially in the producing department where the equipment is changing all the time which means changing the types of safeguards. You will have one division superintendent who believes such and such a guard is the correct one to

use, and the other believes the other one is, and before you get through you have an awful conglomeration. When you transfer one equipment to another, this money spent on the first is wasted, for the superintendent will throw the old equipment out because it doesn't fit. Things aren't standardized as they should be, and we finally decided upon a safeguard or a certain type of safety device, and take photographs of the ones we use—that is, moving pictures—and show them in other divisions, for in order to put this over you have to sell the men who are going to put them in.

It is true we have a system in the company now whereby there is nothing but a standard type of safeguard used. The type is ordered by the committee.

If you show the men the utility of the device through the medium of motion pictures, they are more likely to be willing to adopt it.

The cost of the pictures is about eleven cents a foot for raw materials, including printing and developing, but if you have your own laboratory, you reduce that down to nine cents per foot; and the two cents you save will take care of all the editing and title making. A hundred feet of film will put over an idea.

We believe we will get success out of it. We put personnel matters in the films, photographing some man who has been with us for 25 or 30 years, for instance; someone who has an exceptionally good accident record. Those things are interesting to the men and are one way of creating interest in your safety meeting and help you along much faster than if you just went in and talked to the fellows.

The Small Picture Film Need Not Be Costly

H. A. MATTER (Union Oil Company, Los Angeles, Calif.): I think we might divide the motion picture into two headings, for there are two separate features suitable to two definite things.

One is the picture for public display. Mr. Donovan and I were connected with the making of a feature picture. Roughly speaking, it was about 2,400 feet in length—a four-reel film with the best actors we could get. The result wasn't as good as the acting we got from the men pulled directly from the shop, for the shop men were entirely unconcerned, while the men from Hollywood seemed very much embarrassed. And that big film was made by one of the best camera men in the world, and its cost was borne by a good many of the film companies.

But the small one you make is not costly; you could take a small film and bring out the safety practices around service stations, for instance. You can show it in the schools.

T. N. SHAW (Midwest Refining Co., Casper, Wyo.): You know we could argue on motion picture films from now until doomsday. Just refer to the picture industry itself. A company may spend a million to bring out a picture that may be a knockout or a financial failure, and so it is the same with the films. We might make one that goes over big, and then we might make another that would be a flop. It all depends on how it is made and how it is received. I believe it is entirely possible to make motion picture films that will do good, as well as those that will not, but so far as the picture film being superior to the slide, I want to say this: The slide is an old institution and most of us get sick of seeing it; it has no appeal to the average workman, whereas there is a little novelty in the motion picture. I know that in our field if we go out and take pictures of some of our fellows we are asked on every hand, "When are we going to see it?"

I took some of the children in a picture at some of the schoolhouses. They stuck their heads out from the windows and wanted to know if that picture would be shown down at the theater. It is just the novelty of seeing yourself and the other fellow moving.

R. S. BONSB (Standard Oil Company of New Jersey, New York): I probably make more illustrated talks than anybody else, for I make an average of 250 illus-

trated talks a year, and so I know that you certainly can hold a crowd with slides if the slides are handled correctly. I grant you the film is a great entertainer, but for real instruction, for really getting over your point, use the slide. You can concentrate on the point you want to make; there is no flickering, no breaking of films, nothing else to take the mind off of the subject at hand.

H. D. KETTEL (Standard Oil Company, Baltimore, Md.): I gathered from Mr. Hearne's paper that they have developed a manual for fire protection at their stations. I should like to know what protection is considered sufficient for the average service station, what type of equipment and what number of pieces of equipment are used at the service station?

MR. HEARNE: The fire protection equipment that we use at the average station consists of one Pyrene, carbon tetrachlorid and one Foamite, two and one-half gallon size. Of course it all depends upon the size of the station, the number of rooms and the ground plan of the station whether you have more, but that holds true in the service station and the average bulk station.

In our larger bulk stations we have two and one-half gallons of Foamite for every thousand feet, as well as Pyrene.

MR. CURRIE: I want to extend to all those who took part in our program, and to those who participated in the discussions, our hearty appreciation, before we adjourn to meet again at the Seventeenth Annual Safety Congress.

ADJOURNMENT.

SIXTEENTH ANNUAL SAFETY CONGRESS
NATIONAL SAFETY COUNCIL

Power Press Section

New Section Officers

- Chairman*, J. W. HENNING, Automatic Electric Company, Chicago, Ill.
Vice-Chairman in Charge of Program, J. B. GIBSON, Western Electric Company, Chicago, Ill.

Tuesday, September 27, 1927

THEO. O. MEISNER, Chairman
 Manager, Central District, Safety Division, American Can Company,
 Maywood, Ill.

The first session of the Power Press Section of the National Safety Council was called to order at nine-thirty o'clock by the chairman, Theo. O. Meisner, manager Central District, Safety Division, American Can Company, Maywood, Illinois.

CHAIRMAN MEISNER: Gentlemen, it gives me great pleasure to open the first session of our newly formed Power Press Section. There will be very little discussion at this morning's meeting. On each seat you will find a program announcing the slides that will be shown, the firm from which they came and a brief synopsis. The slides are numbered, and when a slide is shown that you are interested in, check that slide and call for it in the discussion Thursday morning in this room. Tomorrow will be devoted entirely to Drop Forge work.

The Nominating Committee to select new officers for the ensuing year are: C. H. Gerding, Western Electric Company, Chicago, chairman; Mark A. Kroger, Safety Engineer, Chevrolet Forge, Detroit, Michigan and A. L. Kaems, Safety Engineer, Simmons Company, Kenosha, Wisconsin. They will report tomorrow.

There are a number of mighty good reasons for our forming this Power Press Section, and our good friend George Thompson is going to tell us that story. George doesn't need any introduction to this bunch.

The Purpose of the Power Press Section

**G. S. Thompson, Manager, Casualty Department, Detroit Insurance Agency,
 Detroit, Mich.**

Many new ventures go wrong because they deviate from the path of their original intention. Success can only be obtained when we definitely determine what goal we are headed for and bend all of our efforts in that direction. We are opening our first sessions. We are the Baby Section and I am inclined to say: some baby!

Now, boys, what is our purpose? First, what are we and what have we? What is our product and what is our equipment? Well, let us answer these in turn.

First, what are we? (I have not said who are we, as who we are matters little, but what we are matters much.) We are human beings engaged in preventing others from suffering and injury in the regular daily duties they are called upon to perform.

Second, what have we? We have years of experience in actual performance of tried and proven processes and constructions.

Third, what is our product? Now, if I should attempt to state all of our products

represented here today, it would consume entirely too much time. I will say this, that if our product was taken from our markets, we would cause the human race to go back at least half a century. In fact, the automobile would not be in existence or in common use as it is today. Electricity would be a laboratory product instead of a daily necessity. You know, we would still be boiling and cooking on a coal stove instead of preparing breakfast on the table. Again, who would go back to the old cast iron bedstead, when we see the beautiful creations of sheet metal, another of our products, and the kitchen utensils instead of cumbersome heavy articles. We have wonderful creations of sheet metal, aluminum, copper, and the like, so you see our product is absolutely essential to the comfort and luxury of our well-being.

Fourth, what is our equipment? We deal with the power press, foot press, punch press, hammers, steam, board, belt, rope, etc., shears and commonly called metal tools, and these are fitted with metal jaws, dies or cutters. Our experience has taught us that these jaws injure people, and very seriously so sometimes. Now, is it not evident to you that our purpose can be only one, and that is to pool our experience and present suggestions to conserve our manpower from injury and maintain our position in industry?

Every Member Can Accomplish Good Work

Fifth, how are we to accomplish this purpose? This is a problem that remains entirely in your hands. Your officers have labored all this year in organizing and assisting in local meetings, and they have produced wonderful results and are to be complimented on their untiring efforts. Now, it is your turn, and here is the place. No questions asked here by anyone should be allowed to go unanswered, and the answer should leave nothing to be surmised. I believe we take too much for granted and are inclined to "yes" one another when we really should "no" one another more. That goes both ways K-N-O-W and N-O.

We must expect to give as well as receive, and keep in mind the fact that all present are not tool designers. Our answers must be in primary language so that the layman can understand; and yet let us be thorough and build a mountain of safe practices that will be a monument of credit. Confucius said, "If I were building a mountain, I would not consider it completed until the last basket of earth had been dumped and graded." This should be our guide, not to just touch on our subjects, but to complete our line of thought. Then again, all accidents are not caused by dies. The machine construction is a matter of issue; and still another, don't forget the foreman and the workers. This is the biggest problem of all. Oh! if we could only find a way to keep the state of mind in perfect accord with our intentions we would indeed be happy men.

In conclusion let our purpose be to make our class of machinery better, our tools safer, and to present plans to conserve our workers from injury from all causes. Let this section be the clearing house for the desired information, not in these sessions alone but all year round. When you are face to face with a problem don't stand alone, but call on the members of the section and let us create a family circle that will extend from coast to coast, and from north to south, just a big happy family ready to do a good turn at any time and solve the problem, for you know—

There is a fellow in your shop
Who complains and carps and whines,
Till you'd almost do a favor
To his heirs and his assigns;
But I'll tip you to a secret
(And this chap's involved),
He's no foeman to be fought with—
He's a problem to be solved.

There is a man in your department
 Whose cussedness is such,
 He has no pride nor manners,
 No, nor gumption overmuch.
 'Twould be great to up and tell him
 Where to go, but be resolved,
 He's no foeman to be fought with—
 He's just a problem to be solved.

This old earth's (I'm sometimes thinking)
 One menagerie of freaks;
 Folks invested with abnormal
 Lungs or brains or gall or beaks.
 But we're not just shrieking monkeys
 In a big vast cage revolved;
 We're not foeman to be fought with—
 We are problems to be solved.

SO, BOYS, LET'S GO!

CHAIRMAN MEISNER: Mr. Thompson has brought out two very important things in his talk. Let this Section be the clearing house for the desired information, not in these sessions alone, but all the year round. We have an Advisory Committee functioning the entire year; we advertised in all the magazines and papers that we could find, but people seem to be backward in sending in their problems. You will find a lot of men around here with yellow badges on, who are supposed to know something about punch process, there is an exhibit in the next room with a lot of models and new ideas in the practice, etc. Some of these men will be around here practically all the week, and will give you the desired information.

Many Interesting Slides Were Shown

We were a little disappointed in getting up our program this year, due to the fact that it was so hard to get in material. It is a very hard thing for a few men to take pictures in their own plants and bring them down here and show them to you. The slides we have, some of you have already seen; they are the collection we have been adding to year after year as we put them on this type of program. We have 84 of them here. I feel safe in saying that if they are properly discussed and explained at the meeting Thursday, we will all get something from them.

(The slides were then exhibited on screen.)

(A recess was then taken for a few minutes.)

CHAIRMAN MEISNER: Boys, let's take our seats and get started; we have some more on the program this morning. Before we start with that, however, Thursday morning we are going to have a discussion of the 84 slides just shown you on the screen: so, get one of these programs, and I would like to have all of you come here Thursday morning prepared to discuss Power Press problems.

Now, some of you probably know, and I wish all of you knew, that we have a Power Press code, sponsored by the National Safety Council, which has been revised and recently printed by the United States Department of Labor. Mr. Keefer, who is secretary of that Committee, and chief engineer, Industrial Division of the National Safety Council, has been good enough to come here and is going to give us a brief resume of that code. We will have a discussion after that, as no doubt some of you will want to ask Mr. Keefer some questions.

A Brief Resume of the National Safety Code for Power Presses

**W. Dean Keefer, Chief Engineer and Director, Industrial Division,
National Safety Council, Chicago, Ill.**

First of all, let me urge every company in whose plant one or more power presses are operated to secure at least one copy of the Power Press Safety Code. Copies can be secured from either the National Safety Council or from the Superintendent of Documents, Government Printing Office, Washington, D. C., at a cost of 20 cents each.

During the past three or four years I have had occasion to talk to various individuals about the Power Press Safety Code, and these men, if not already familiar with it, invariably wanted to know the answers to such questions as:

What is the Power Press Safety Code?

Why was it written?

Who wrote it?

How can it be used?

So perhaps I could not use the short time allotted to me on your program to better advantage than by trying to answer these questions in the order in which they have been presented.

What Is the Power Press Safety Code?

This code is a set of minimum standards providing for the safety of the persons who operate power presses. The most striking, and perhaps the most valuable feature of the code is the chart which appears on page 6 of the printed book. This chart classifies the various methods of feeding presses and specifies in preferential order the methods that can and should be used to safeguard each classification. Each classification is defined, and each safeguarding method is so described and illustrated that anyone—an engineer, foreman, or even the average workman—can understand just what is possible and what is required.

Why Was It Written?

This code was written for two reasons: To promote uniformity and to save lives and limbs.

Uniformity. For the past ten years or more various insurance companies and state labor departments have been very active in developing standards, orders and laws to prevent accidents. Naturally, some of these standards, orders and laws have been very good; others not so good, and a few absolutely worthless. Unfortunately, until the organization of the American Engineering Standards Committee, there has been no group or body to sift the good from the bad and there has been a great deal of confusion. The insurance companies may require one thing; the New York State Board something else; the Wisconsin Board may have still another requirement, etc. The result has been that the average employer, even though willing to do everything in his power to prevent accidents, has become confused by the conflicting requirements and has often thrown up his hands and done nothing.

This condition is being improved slowly but surely through the work that is being done by the American Engineering Standards Committee. This organization, comprising representatives of six different groups or special interests—insurance companies, state and governmental boards, employers, workers, machine and equipment manufacturers, and engineering societies—is now looked

The code, of course, can never take the place of this section. Here you have the opportunity of bringing sketches or models of your most difficult jobs and of getting the personal assistance of the best experts in the country who are only too glad to help you in safeguarding such jobs.

On the other hand, the section can never take the place of the code in securing uniformity in state and insurance company requirements, or in selling the safety idea to the hundreds of plants which are never represented at Safety Congresses or conferences like the one which we are privileged to attend this week.

CHAIRMAN MEISNER: Mr. Keefer has just told us that eventually each State Labor Department will endeavor to adopt a code for their particular state. There is already one in Ohio; that is, a committee has been tentatively appointed to compile such a code, but owing to their particular laws they can not adopt this code as it is, and will modify it somewhat. No doubt other states will follow.

Another thing Mr. Keefer mentioned that should not be forgotten is that all die setters, supervisors, etc., should operate with a copy of this code. I am going to make a statement now that probably some of you will not endorse. I believe that every punch press operation should be operated with a guard, and everyone of them can be guarded if you will get enough people together to help dope one out. A lot of these slides shown here today are already shown in that code. Some of them will be turned over to the committee so that the code can be kept up to date from time to time.

ADJOURNMENT.

Wednesday, September 28, 1927

The second session was called to order at nine-thirty o'clock by the chairman, Theo. O. Meisner.

CHAIRMAN MEISNER: As all of you gentlemen can see by the program, this meeting is devoted entirely to Drop Forge Work. Before we start that particular program, we have the report of the Nominating Committee and the election of officers. Mr. Kaems, will you read the report of the Nominating Committee.

Report of the Nominating Committee

Chairman, J. W. HENNING, Automatic Electric Company, Chicago, Ill.

Vice-Chairman in Charge of Program, J. B. GIBSON, Western Electric Company, Chicago, Ill.

Vice-Chairman in Charge of Publicity, W. F. DITTMER, Westinghouse Electric and Manufacturing Company, East Pittsburgh, Pa.

Vice-Chairman in Charge of News Letter, S. H. SLAYMAKER, Fairbanks, Morse and Company, Beloit, Wis.

Secretary, A. L. KAEMS, Simmons Company, Kenosha, Wis.

Exhibit Committee Chairman, W. J. LARSON, Clum Manufacturing Company, Milwaukee, Wis.

Statistics and Engineering Committees Chairman, T. O. MEISNER, American Can Company, Maywood, Ill.

Poster and Slide Committee Chairman, M. A. KROGER, Chevrolet Forge Division, General Motors Corporation, Detroit, Mich.

Membership Committee Chairman, W. J. GRAVES, Michigan Mutual Liability Co., Detroit, Mich.

CHAIRMAN MEISNER: Gentlemen, you have heard the report of the Nominating Committee; all those in favor of the adoption of that report will signify it by saying "aye."

All those opposed to the report of the Nominating Committee will signify it by saying "nay."

The report of the Nominating Committee is unanimously adopted.

I am now going to turn the meeting over to a man who has forgotten more about Drop Forge than I will ever know. I take great pleasure in introducing to you Mr. George Hodge, assistant manager, Industrial Relations, International Harvester Company, of Chicago. Mr. Hodge, will you kindly take the Chair?

GEORGE HODGE (Assistant Manager, Industrial Relations, International Harvester Company, Chicago, Illinois): Gentlemen, I have just come from a meeting and one thing the speaker pointed out was to be able to look the group, in fact, the individual, in the eye. I can't do that with you gentlemen in the back of the room. But I am sure any speaker would appreciate very much being able to look every man in the eye, and I think therefore we ought to fill up these front seats.

Don't forget to fill in the registration cards, which I presume you have all been supplied with, also the question card, and after the speaker finishes we can handle our questions by the written question, or we can handle them orally, whichever is your pleasure. However, if you have a very important question be sure to write it out.

I have had the pleasure in the last few years of discussing safety pretty much throughout the country, and in almost every group that I have attended I have been asked for an opinion on Mechanical Safeguards vs. Metal Safeguards, as they often put it; and, gentlemen, it seems to me that mechanical safeguarding is not only a part of the foundation of our safety organization but it is an essential part, and if a management expects cooperation of its employees in the prevention of accidents it must reasonably safeguard its machinery. That is the least it can do.

I am quite pleased in connection with this program to have a small part devoted to the mechanical end of safety. It is a very, very important part, and I know that the committee felt mighty happy when they secured the consent of Mr. R. T. Herdegen, president and general manager of the Dominion Forge & Stamping Company of Walkerville, Ontario, Canada, to present the subject of Drop Forge Safety to you this morning. I am happy at this time to present Mr. Herdegen.

Drop Forge Safety

**R. T. Herdegen, President, Dominion Forge & Stamping Company,
Walkerville, Ontario, Canada.**

About two months ago I had the pleasure of attending a meeting at Toronto composed of the Industrial Accident Prevention Societies, and as you probably know there has been a great deal of discussion about the word "industrial," but we will not go into that here this morning.

I was asked to talk at this meeting. I wrote a paper, and it looked to me like a pretty good paper. I went over it three times and put in some nice large words, and when the time came I went to Toronto and read this paper. After I was through I met a couple of fellows who said, "Well, it wasn't so bad, but why did you read it? It would have been much better if you had spoken." So, when the question came up this morning about talking, I said, "Well, I am not very successful with a written paper, so I will try to talk from some notes."

There is one thing that has always appealed to me, and that is the mathematical aspect of safety. I remember when I was in college we took a course known as "The Theory of Probabilities." I was very much pleased when, in about two or three weeks, the problem came up of what was the chance of getting two sixes to turn up when you shoot a pair of dice. I thought here was something that was going to be of actual value to me. So we found exactly what the chances were of getting double sixes; but the unfortunate part of it seemed to be that they seldom came at the right time.

That reminds me very much of a story they tell of a baron who found himself on the banks of a lake and in that lake there were 47 ducks. These ducks were swimming around and having a lovely time by themselves, while he sat on the bank with a gun, but the unfortunate part of it was that he had only one shell for his gun. As he sat there watching the ducks they swam about in a kind of line formation, and he figured that, mathematically, if he waited long enough he would be able eventually to get all of them with his single shot. And it turned out to be true. The baron watched his chance and he did get all 47 of the ducks.

Now, perhaps you wonder what in the dickens that story has to do with safety. I feel that it has a great deal to do with safety, because it shows that just as the theory about the ducks runs mathematically true, so the same rule applies to accidents. Many times in answer to some inquiry, we say, "We are getting along pretty well; we haven't had any serious accidents." The reason that man couldn't figure out about his accidents was because he didn't know the exact rule that applies to the particular type of accident to which his plant is subjected. At other times a lot of executives don't know they have accidents. That was exemplified to me

when we got out the pulley catcher. Do you know that in my inquiring around I was not able to find one single, solitary drop forge executive who had ever had a pulley come off? It seems to me that the Dominion Forge was the only plant that ever had that happen.

The management should realize that they are going to have accidents, and unless they inquire around they won't know whether they have had any accidents or not—unless they get into compensation difficulties, and that brings us to another distinct viewpoint on the matter.

I do not know whether the societies in the United States look after accident prevention and accident compensation, but in Ontario we have a compensation law and you can't keep your dirty linen in your own back yard. That was very well illustrated to me when I went before the Compensation Board some months ago in Toronto to discuss the question of methods of assessment. I got up before the Board and there were five members, each with a pad of paper on which he was making notes. After I had finished what I had to say, one of the members turned to the committee and said, "By the way, you have Mr. Herdegen's accident record here, haven't you?" He said, "Yes, we have it." He pulled out a sheet of paper and there was our accident record for the last six years. Now, if we hadn't been in a position to have our accident record examined, I would have found myself in a very embarrassing position. I wonder how many men in this group would care to have their accident records posted on the wall of this room.

Talking Is Not Preventing the Accidents

It seems to me that the fellows who do the largest amount of talking about drop forge safety are doing the least in their own plants. I know of several instances of that sort. When you come to the question of really doing something (and a lot has been done in this country for safety), there is something being done in drop forge shops also. But in many industries the most safety work is done by the larger organizations, and the smaller organizations seem to take the view that they cannot afford to do anything in the safety line; that it is an expensive proposition; it is all right, apparently, for the big companies to do something, but the smaller ones can't employ safety men or have visiting nurses.

Now, when you start out to do safety work you might just as well make up your mind that you have started out to spend some money. There isn't any kidding yourself on that point. There are too many managers whose idea of safety is to post notices of a big dinner. They get a room in a hotel and serve fancy food; then they pass around some cigars and they talk about safety. Then they go back to the plant. To do anything in safety, you have got to spend money. To convince anybody you really mean business you must start spending your own money. It is all right when you have a community drive for a fund to tell everybody else but unless you go ahead and spend your own money your interest isn't worth much to anybody.

The same thing is true with the safety requirements. Until a company gets busy and actually spends some money they are not in the safety movement at all; they are just running around, that is all they are doing. Now, it runs into rather large figures. I have been surprised sometimes at the amount of money we spend, but when you look at the total money spent and compare it with the accident record you can easily see that it has paid you in dollars and cents.

This year, unfortunately, we were not very busy; but when I left the plant our accident cost so far this year was only \$25, and I remember the time when that ran \$15,000. That, of course, is rather an extraordinary comparison, and we have been very lucky so far this year. Anyhow we have been shown very definitely,

and the way it started was, we got the superintendent, master mechanic and myself to make an inspection of the plant.

Now, for the small plant (and this is probably rank to you boys, but it is my opinion anyway), all of this talk is powder and shot in the air; it amounts to nothing. But if you get your superintendent and master mechanic, and they get your general manager and president to go through the plant and take a piece of paper and make a list, put down the things that have to be done, something has been started. Then let the president take that sheet of paper and put it on his desk, not in the desk. Then two weeks later let him call his superintendent in (not merely call up), and say, "Well, what has been done?" "Oh, done? Well, we made the list up." "Well, just exactly which things have been done? I have a few minutes spare time, and I would like to go out to the shop and see just exactly which of these things have been done." Well, as it turns out, the superintendent says it is a bad day, the master mechanic had a bad day, and it was getting along toward the end of the week, and so next Monday we will make our inspection. Next Monday, when you make that inspection, you will find some of those things have been done.

Now, that is my idea of tackling the mechanical end of safety work. In the final analysis, your foreman is not so much interested in the men who work for him, as he is deeply interested in the man whose name he sees on his pay check; he gives a great deal more attention and a great deal more interest to putting a guard on a certain hammer if he knows the man whose name is on his pay check is interested. You come out there tomorrow to see whether that thing has been done, and it is done.

Always a List of Things to Do for Safety

Well, we started this thing seven years ago, and I am telling you that I still have a list on my desk, and I don't expect, until I am six feet under, ever to part with that list on my desk. At first the list was long, and by the time that was pretty nearly done, I said, "Let's make out another list"; and in another few months we got two more. If you will keep that list with which the president of your company can check them up, he will learn a great deal more about his plant than he ever knew before. If the president of a company goes through, and you have a lot of guards out of place, and in a lot of instances you have flashings, he learns more about them.

Now, you don't want to take your president and show him a guard that is down in the corner somewhere, all covered up with a lot of junk; you are going to keep your shop cleaner and you are going to do better work.

On the question of guards, I think the average plant in the drop forge industry has got to spend a lot of money. A lot of them don't show any interest, but I hope in time to get some interested.

The first and most obvious thing to have in any forge shop is a scale guard in front of the hammer. You don't want to injure your customers, they are scarce enough without injuring them. Now, a scale guard means a scale guard in place. I have been through a plant where there wasn't a guard, and I said, "Where are the guards?" And the fellow says, "Well, we put them over in the shed." Of course, they didn't do anybody very much good. That is the first thing everybody should have.

The second thing everybody should have (and I don't think there is any excuse at all for not having it), if there are any board hammers, is to have some sort of an arrangement on top so that when those boards break, they don't break open and hit somebody. They should be in place, and that is a perfectly obvious thing.

Yet I have been in many plants where I have seen no guards at all for taking care of those boards.

Another thing there is no excuse for not having is treadle guards. I have been in plants with no treadle guards and I know instances of people tripping hammers accidentally, and the result was terrible. If a fellow isn't killed, he had better be lots of times. There is no excuse for not putting in treadle guards, and that comes back to the list again. You fellows, if you are in the accounting business, know the accountant comes around and figures depreciation on your plant. What does depreciation mean? Depreciation merely means that you are setting aside a reserve. The management expects its hammers to wear out; it expects its presses to wear out; but for some reason a lot of people don't seem to feel that guards are going to wear out. Those guards aren't going to last forever; they are going to wear at least as fast as the equipment. Treadle guards are going to wear, scale guards are going to wear, and the sooner we realize we have really got to do something of that sort continuously the better off we are—don't forget it—the better off our accident record will be, and the lower our accident cost will be. We will get the money back.

Two Buttons on Each Press Electrically Operated

Now, all hammers certainly ought to have scale guards. There are other things also that should be put on. We are much interested in pulley catchers' guards, but we are not talking about pulley catchers today.

In this Power Press Section I suppose a lot of you fellows are interested in presses. So far as I know, outside of ourselves, there is no other drop forge manufacturer that has its presses electrically operated. We have two buttons on each press, and we have those buttons arranged so that when a fellow runs that press he is going to block one of those buttons. We expect that. I have had friends of mine come through our plant and say, "Well, it is all right, but if they are going to block one of the buttons, what is the use in putting them on?"

Here is our answer. It seems in our education system that our two arms are better connected than the left arm and right foot; so that if you have two hands they work better than a single arm and single foot. I went through a plant about six months ago that didn't have any guards at all. Let us imagine there is a press right here, and there is an aisle coming down here. This press is here, and this finger gets here, and you have a complicated forge up. The fellow forging it was apparently living under the impression that it would never have to be trimmed. Right at this corner is a treadle lever, about two feet long. I said to the president, "Look at that"; he says, "Yes, it is very bad forging, isn't it?" I said, "Look at that;" he said, "Yes, it is complicated." I said, "Look at that treadle." I said, "Suppose you and I were walking by there and happened to trip that press and it cut a hand or a couple of fingers off." He said, "My God, that would be hell, wouldn't it?" I said, "Why don't you take that thing off?" He said, "We have had that thing there seven years and never had an accident." When I got back to the office I told him the story about the ducks. I said, "Now, here, you have been very lucky, but I am telling you that just about the time those 47 ducks are in line, you are going to lose a man's hand in that press." He said, "I guess that is so, I am going to fix it." If it wasn't so far away, I would like to hop on the train today and go to that fellow's plant and see if he has taken the treadle off.

We put those two buttons on our presses because some men handle some forgings better right-handed and some better left-handed. I used to imagine that about one person in every 10,000 was left-handed; but about one-third are, and a lot of people are left-footed, too, we found out. We put our treadle guards on, we started first with a certain foot and we found that a lot of fellows didn't want to use that

foot, so we put on a slide so they could use them with the right foot or with the left foot.

A lot of fellows in the press business do not feel like putting on these buttons because they feel that the workmen are going to block one of them. I think we have had one accident since we put those buttons on, and I don't care to tell you how many we had before that. It cost about \$100 a press; so, if you have got 20 presses you are going to spend \$2,000.

As the matter of goggles, I will just say that we believe in goggles and let it go at that.

On the question of material handling, all of us have our material handling troubles. I think that the material handling problems are rapidly being solved from an entirely different angle than you boys are working on, and that is this: In the drop forge business a lot of fellows found out their material handling was costing them a great deal of money, and that is a sort of thing every man can see very well. Most drop forge plants are increasing their facilities for handling material, and getting more trucks. Now, I don't understand this box loss, and I never did; it is a mystery. We have a place where we put our broken trucks and broken boxes and broken pieces of machinery, a kind of graveyard; I go by there every day and I can see what we are breaking up. I thought I could find a lot of portions of barrels and all that sort of thing, but I didn't. About every six months I buy a lot more boxes, barrels and that sort of thing, and where they go, I don't know; but I know this much: If you don't load those trucks, don't fill those boxes and those barrels so full, you don't have so much trouble. Here is 99 per cent of the material handling trouble. You attempt to put everything on one truck, while if you had two trucks you wouldn't pile them so high; but if there is just one truck and that is busy, you are going to pile everything you possibly can on that one truck, and you may have trouble. If you had two trucks and didn't pile them so high you might not have an accident.

The Problem of the Proper Floor Material

The next trouble in material handling is what the truck runs on. In the old days I know drop forge plants used just a sort of clay mud—I call it clay, of course, it had scale mixed with it, but even with that the trucks would stick and tip over and very often have serious trouble. The next idea that came along was concrete, and it looked fine at first, but as soon as somebody started to haul a dye block down that concrete, something happened. Anyhow it ended up on the pavement and there was a nice, big hole; and the next truck that came along made another hole; so pretty soon you have an accident. Now, for two years we repaired concrete, and it looked like—well, I don't know what Michigan avenue looks like, have done in the industries, in shops, in railroads and in street crossings, we have but it looks like Jefferson avenue in Detroit. Then we got a brilliant idea from the city, putting asphalt over this old concrete, and when it gets hard, provided the wheels of your truck are wide enough, and provided you don't overload your truck, it won't cause you any trouble. We have had that pavement down there two years and it hasn't given us a particle of trouble. That cost us \$2,500. I mention these things because I think they are big things that a lot of us ought to think about, but you are going to have to spend considerable money.

Now, I like this safety education fine, but I didn't exactly realize this outside safety business situation until a couple of days ago. It is funny sometimes how you go along; you think about it, but you don't realize exactly what it means, and I tell you that you can figure on it costing money to do that. I was talking with one of the officials of one of the six largest life insurance companies in this country. Their records show that for the last 50 years their death claims in seven per cent of the cases were due to casualties. For 50 years it stood practically the same,

without a change in the figures. Last year 40 per cent of those casualties were due to the automobile; in other words, with all the safety work which we have done in the industries, in shops, in railroads and in the streets, we have just been able to go fast enough to take care of the increase in automobile accidents. It is like a fellow who has a salary of \$200 and trying to save some of it. It doesn't make any difference whether he spends \$50 and his wife spend \$150, or the other way around; if the \$200 is spent, you are just where you started from. Now, as long as these casualties keep at seven per cent we haven't gained anything in the aggregate.

The final analysis of casualties in most instances is a question of loss of time in the shop. Now, you can talk about loss of time and the cost of training new men for half a day, and not get started, and a lot of companies have spent a lot of time and a lot of money on account of new men; but I take it that all their figures and all their computations do not show us what it cost to have a man out in the drop forge business. There a man is a much more important factor, I think, than in any other business. You boys probably know that I am very much interested in cost activities, and there is one thing we found in the drop forge business, we have discovered that the cost of running or the cost of making a forging is dependent to a very large extent upon the time that that forging occupies the hammer. In other words, it costs \$10 an hour to run a certain hammer. Now, it cost you the \$10, and also cost you \$10 to run the furnace; and unfortunately you burn just as much oil if you turn out 100 pieces in an hour as if you turn out 200 pieces, or if you turn out five pieces. The depreciation on that hammer is so much an hour. The auditor at the end of the year is going to chalk you up so much for depreciation. So, you come right back to the situation, that the big thing in the drop forge business is to turn out a large number of pieces per hour, and that brings us right back to this thing we are talking about. In other words, look at it carefully. You are interested in safety. This compensation that you talk about, that is interesting, but it is much more interesting to have a man go to work in the morning and turn out a large number of pieces, much more interesting than it is to have a new man try to run your hammer. And that isn't foolishness; that is facts.

Good Men on the Job Every Day

So that in your safety campaigns, when it comes to your education, when it comes to your guards and when it comes to your outside activities, your automobiles, your safety schools—it comes right back to the problem that what you want is the best men, and you want them there every day. Now, that is where safety means co-operative safety, cooperating together, to see to it that you have the best man for the job, and have him satisfied, and have him there. That also means the spending of money.

Now, I have talked quite a bit, and I am not going to talk any more. If there are any questions you wish to ask, I will be glad to answer them. But I just want to leave this thought with you, that your management can get large cash dividends by the expenditure of money in safety work, but they have got to spend the money, and they have got to realize it is a continuous expenditure. You have got to spend money on guards; you have got to spend money on public safety and you have got to contribute money to local safety work. But you will get your returns from two angles, more in the drop forge business than in any other business. I think the safety men in the drop forge business have got the best argument of any safety man in any business. In many shops the average press will just produce so many pieces, no matter who runs the press, but that most emphatically is not so in the

drop forge business. Why, I have seen shops where one fellow will turn out two or three times as many pieces as another man. It just so happens that that fellow has a certain action there, he doesn't seem to be hurrying, but he is there and he turns out the pieces; and the other fellow is running around with great apprehension, running here and there, but at the end of the day the number of pieces he turns out may be half the number of the other fellow. Business is mighty competitive. I don't suppose there is any business in which the production capacity isn't twice the demand, and the fellows who are going to survive in the drop forge business are going to be the fellows who have their plants well guarded, have good hammermen; and the fellows who have poor hammermen and unguarded plants, those are the fellows who are not going to survive. So it seems to me, if there is a safety man here that can't sell safety in the drop forge business, I think he is about the biggest dumbbell in Chicago today.

General Discussion of the Problems

CHAIRMAN HODGE: I don't think there is any question about the interest of the Dominion Forge & Stamping Company. I think one criticism on a lot of our programs at conventions is that we often get too many speakers on the program, do not allow sufficient time for the speakers and do not permit sufficient time for a discussion of the topics. I think the committee on arrangements is certainly to be congratulated in getting the speaker who presented this subject from A to Z. I think it was one of the finest talks on the subject I ever heard, and I am sure I express the opinion of the group here this morning in passing that along.

We have on the program some lantern slides, and as I understand these slides are presented from work at the Dominion Forge & Stamping Company, I think we will have those lantern slides at this time. It is possible that in your discussion there will be some points brought to your mind by these lantern slides, and then we can discuss them later on.

(Lantern slides were shown.)

CHAIRMAN HODGE: Now, gentlemen, we have a little time in which we can discuss the various phases of drop forge safety. Any question that you have in mind may now be put to the speaker.

WILLIAM SCHUELE (International Harvester Company, Milwaukee, Wisconsin): I would like to ask the speaker how they handle their materials from the car and get them to the hammer; and afterwards, whether they use boxes, trucks, steel or wooden boxes, or what they do use?

CHAIRMAN HODGE: The question is the delivery of materials to the machines and taking them away.

MR. HERDEGEN: I think the problem of handling steel is entirely a local problem, depending upon the relationship of your steel yard to your railroad and your shop. I think the installation is, of course, to have the railroad track come below the crane-way; the steel is then lifted from the gondolas in bundles and piled in the steel yard, being placed in such a manner that it can be picked up in bundles later on. When the steel is to be used, it is then picked up in bundles, and the entire bundle is taken to the shearing place, in front of the shear, and then fed to the shear. Now, then, the steel has a perfectly straight line passage from your steel yard right to the shear.

I visited a plant not long ago where it wasn't possible to run the crane into the shear house, but they had several large trucks equipped with wheels which made it possible to run on the railroad track. On top of the truck they had four rolls, and the truck was then pushed out to the steel yard, the crane picked up these bundles, and this truck was loaded up and rolled right into the shear. Any other method of handling the steel, inasmuch as it always comes in long bars, is very

cumbersome and very expensive. We do not open our bundles, because there is a disadvantage to that. In the first place, the bundles are all tagged and have certain heats and heat numbers, and God help you and your customer when you start arguing about a forging heat. It is a case of arranging with the steel companies, that the bundles be of such size that the cranes can handle them. It is a tremendous mistake not to be able to handle the whole bundle.

E. ROTH (Aetna Life Insurance Company, Hartford, Conn.): I would like to ask the speaker what his experience has been in electrical maintenance, due to the fact that I understand we have had a little trouble with that electrical cut-out, and also the magnetic cut-out.

MR. HERDEGEN: I would say that we have had very little trouble with them. There was one thing we did find though, we found that at first we had to place a booster in the line, to give us the requisite voltage in winter, because in the morning the load, due to lighting and breakfast cooking, lowered the voltage at the plant to such a point that we had a drop; so we put in a booster to give us full voltage. Now, we have a new line coming into the plant from an outside power company, consequently we will be able to eliminate the booster. But if you haven't the proper voltage, that is the cause of all troubles. If you get a low voltage, that means high current and all the other difficulties dependent on low voltage.

Experience in Electrical Tripping

MR. ROTH: Have you had any experience in electrical tripping; say, a forging is in crooked and the man tries to straighten it; have you ever had any experience along that line?

MR. HERDEGEN: If the forging was pretty crooked and the press came, we had to make a new die, but we never found anybody interested enough to get their hands in the way.

MR. ROTH: I find in my traveling around that a bunch of fellows try to save that unconsciously, after they trip the press, which is very easily done with the press running up, I would say 100 revolutions a minute, with about 37 stroke.

MARK A. KROGER (Chevrolet Forge, Detroit, Michigan): I would like to ask Mr. Herdegen about the use of that electrical push button system, which we have recently inaugurated on our presses as an experiment.

MR. HERDEGEN: Well, as I said, we go on the assumption that we block one button all the time. We have never tried it any other way. We get the result of having a double hand operation instead of one hand and foot.

It seems to me, to be frank, that the fact that we find it necessary to block one button is how most managements argue themselves out of spending some money. We supply every press we have with a little pair of tongs, so that if it is a forging that clamps, why, the fellow holds it with the tongs; and if we find one not using the tongs he is laid off for two weeks.

MR. KROGER: You feel, then, that in forging it is necessary to use a pair of tongs?

MR. HERDEGEN: Absolutely. If he is given a pair of those tongs and doesn't use them, he is laid off. I think I am correct in saying that the only accident we have had since we put in the use of these was because the man didn't use them. In other words, the only accident we have had in five years was that unfortunately he got caught before we had a chance to fire him.

MR. KROGER: I might ask the speaker or any gentleman in position to give me information on this point. Within the past year the company I am connected with now has had considerable trouble due to the chipping of keys, the operation of dies; and there has been considerable talk about treating these keys to avoid the

chipping. We have tried the treating process, and about the time we reached the stage where we thought it was O. K., along comes some fellow and shows that it isn't. The only way we have been able to get around that is to continually keep after the men through the foreman, to grind those keys.

G. A. KUECHENMEISTER (Dominion Forge & Stamping Company, Walkerville, Ontario, Canada): Mr. Chairman, I think the answer to that is coming out in the New Drop Forge Code.

CHAIRMAN HODGE: It is twenty minutes after twelve, and I want to leave a few minutes for you to visit the display of safety devices. I will feel that I have been an absolute failure as chairman if there is anyone in the room who has come to this meeting with some specific question on his mind, and hasn't put it before the meeting. Now, is there anything else to come up before the meeting?

I want to again express, in behalf of the Group, our appreciation of the very fine talk given us by Mr. Herdegen. I feel that we have had a most frank and free discussion this morning, and that our meeting has been of profit and interest to every one present.

ADJOURNMENT

Thursday, September 29, 1927

The third session was called to order at nine forty-five o'clock by the chairman, Theo. O. Meisner.

CHAIRMAN MEISNER: Before I start this program, I have a very sad announcement to make. Mr. Kroger, newly elected chairman of the Poster and Supplies Committee, had the misfortune to lose his wife last night at Muskegon, Michigan, through drowning. He asked me to tell you boys why he won't be here today.

The Industrial Commission of Ohio has requested this Section to send what pictures and models we have to Columbus to be shown in the Metal Section Exhibit of their Ohio State Safety Conference to be held in Columbus on November 9th and 10th. I have agreed to do that with Mr. Henning's permission to take them down there with me.

I think you all ought to know your new chairman. I am going to ask Mr. Henning to stand up, the newly elected chairman of the Section.

J. W. HENNING (Automatic Electric Company, Chicago, Ill.): I suppose it is in order to make a speech, but I am not going to make any. The only thing I would like to say is that while I am new in this game—that is, so far as the chairmanship is concerned—this fellow has had it for the last ten years. I have a good deal to learn and any cooperation I can get will be appreciated. I did have a little experience this year, in trying to get material together and it was quite a hard job. There is so much good stuff to be had that any little bit will help. I heard some appreciating remarks passed yesterday on stuff that people got and took home with them. They came a long way from home. What little we can give them ought to be given freely and everybody ought to give. Those who do give in that way, I know that the people will take it home with them and appreciate it very much. It helps the officers a great deal.

CHAIRMAN MEISNER: As you all know, this is a heart-to-heart round table talk on power press problems. We want you boys to present your problems and we will try and solve them here among ourselves. I have had a number of questions turned in here that we will probably get to later on in the session. We have a number of slides 84 in number that were shown to us and we would be glad to show any one of them on request.

Who has a problem he wants to put up to this Advisory Committee? Who will be the first one?

MR. FOIGER (Williams Meyer Company, Elmira, N. Y.): I have a proposition I would like to get some information on, and that is a Bliss 3 press. We had a girl get injured on that press due to the fact of riding the treadle. The question is, is it better to have a foot rest parallel to the trip, or must the foot be removed from the trip every time the machine is operated? I would like to find out what the experience of the other fellow has been in connection with that. Is it better to have the girl raise her foot probably a distance of eight or ten inches or is it better to have a foot rest so that the foot can be slid in a sideways motion? What would be the better thing to do to prevent unconscious tripping?

CHAIRMAN MEISNER: We have a lot of men who have traveled around a lot in outside plants other than their own.

MR. BORAKS (Liberty Mutual Insurance Co.): That was a problem with us about 15 years ago, how to keep your foot on the treadle when operating a press. Now-a-days we don't find it because we arrange our work so you don't put your hand under the punch. If you do that, it doesn't matter. Some operators can work better one way and some the other way. I think the main thing to overcome is

to put the work under the punch without putting your hands under, so that it won't make any difference; because if you don't do that, there is bound to be an accident no matter how you arrange the treadle. The main thing is to feed the work without putting your hands under the punch.

CHAIRMAN MEISNER: I happened to be in a plant in Ohio a short time ago and I noticed a white spot painted on the floor alongside the press. I asked the man with me what that was for. They had a positive rule that when an operator had tripped the machine and he was doing any work around the die his foot had to be on that particular spot. I might say, there were no guards on the press.

MR. ROCKOFF (Detroit Steel Products Co., Detroit, Mich.): It seems to me that raising the foot a distance of eight or ten inches is very high for a treadle, anyhow. It might insure, to some extent, the operator, if he were standing to take it off. In the case of women, they are generally sitting. It seems to be a different thing, and in that case it aggravates that condition.

The Advisory Committee Will Study All Problems

MR. ROTH (Aetna Insurance Company): I would like to ask our brother to confine himself to his line of work. We may then be more able to intelligently discuss this problem. This power press proposition is a comparatively new one with us. Perhaps it is true that the foot trip is too high. Perhaps we have to arrange for different styles of dies and different kinds of feeds, but in some of them it is almost impossible to have an automatic feed because for instance if you have a spindle bolt, you have to put in a groove, or you have to make a short cut off in the different parts of the bolt. It is really hard to get an automatic feed on it that will prevent a slide feed. That is the reason I am anxious for the information.

CHAIRMAN MEISNER: Let me suggest this. I understand that the Section for the coming year will maintain practically the same Advisory Committee that was in vogue last year. Any time you run into a problem like that, if you will be good enough to submit a blueprint and address your letter to Mr. J. W. Henning, Automatic Electric Co., Chicago, he will pass that information around among that Advisory Committee and they will endeavor to solve your problem for you. I wish all you gentlemen would bear that in mind. That is the intention of the Advisory Committee.

MR. BORAKS: On this question that was just brought out, I would like to advise him to get in touch with the Wickwire Spencer Co., at Springfield, Mass.

CHAIRMAN MEISNER: Worcester, it is.

MR. BORAKS: They handle a line just like he describes. They have a line of feeds in there that are very cheap. They are cheap enough. If you are making ten thousand pieces, you can afford to build one. I am sure they will be glad to give you any information they have.

CHAIRMAN MEISNER: Does anyone else have a problem? Mr. Henning, I want to ask you a question. I was in your factory not long ago and noticed you had several automatic feeds. Could you give me an idea as to what these cost and what the increase in production was?

MR. HENNING: I couldn't exactly give you the costs. I think the one in the Exhibit Room which we borrowed from the Lytle Machine Company, is running something like three hundred and some odd r.p.m. I am not exactly sure, but I could get that price. The increased production is about 250 per cent.

CHAIRMAN MEISNER: You are satisfied that it pays?

MR. HENNING: There is no question about it paying, if you have production big enough.

MR. THOMPSON (Detroit Insurance Co., Detroit, Mich.): I want him to bring out for you the idea that you just don't have to make the one mechanism for one

specific part. In your experience, Mr. Henning, how many particular jobs could one of those equipments cover?

MR. HENNING: We have three parts on it now and we will have a dozen on that same part. Right now, we have three parts adapted to it. Before the year is up, we will probably have a dozen to go on the same feed. All we do is just change the width of the magazine and probably the length of the stroke. That is adjustable. Outside of that, as long as the piece is about the same, you can run a good many parts on it.

L. B. BEINECKE (Casualty Co. of New York): I want to know if there is any objection to the proposition of always guarding every part of the trip treadle on a punch press, taking that additional precaution? We all know that a guard will be left on when it shouldn't be or the guard will be taken off; we know they are supposed to do a lot of things, but somebody may accidentally forget the treadle. Don't you think it is a good idea to have it guarded?

CHAIRMAN MEISNER: Personally, I do. I know of instances where diesetters have attempted to work on a die with the belt on the flywheel, when a wrench or something fell off the table or press, struck the treadle and tripped the press, this resulted in an accident; to be sure I would suggest the treadle be guarded.

A. W. SHINE (Onweld Acetylene Co., Newark, N. J.): I was wondering if any of the gentlemen in the room have thread roll trouble; that is, how they are doing a thread roll operation, what automatic machinery they are using, etc., or whether they are still feeding the old hand method of the Bliss type machine.

Discussion of the Thread Roll Operation

MR. MARES (Perfection Stove Co., Cleveland, O.): What number is that press?

MR. SHINE: These are the regular pedestal type and bench type thread roll machine. We have a battery and a hand feed machine running about forty strokes a minute.

MR. MARES: I never had any experience on No. 21 press.

CHAIRMAN MEISNER: He means a regular thread rolling machine.

MR. MARES: The double crank?

CHAIRMAN MEISNER: No, he is talking about a thread rolling machine.

MR. MARES: The only one we have is the spanning machine and that is made up on the same principle as a DM Junior press sweep guard. The only thing about it, it swings back and forth from around this way, and you put the swivel down on the bottom and have it swing up that way.

CHAIRMAN MEISNER: Is that a vertical press?

MR. SHINE: I don't believe you get what I mean. You are familiar, no doubt with the bottom top of a flashlight thread on the flashlight cap. You have all seen the thread rolling on the cap. We have a machine, Bliss, in Brooklyn. We have an upper and lower spindle with a thread roller on the bottom and one on the top and the upper spindle is brought down under the lower spindle by a cam. Our trouble has been that in putting the cam on to the lower spindle and the upper spindle coming down, there is a flange on the upper thread roll to hold the work on. If they don't get their fingers away fast enough, it will carry around, the flange will catch them and nip their fingers. While you are breaking new operators in, you have quite a number of accidents, until you get them to the point of efficiency. We have installed the Bliss semi-automatic, shutting down the feed and we are now thinking of installing a battery of Cameron automatic. What I wanted to get out is, whether there is anyone in the room that had experience with other automatics and whether we have been going in the right direction. I was wondering if anyone has had experience in that line.

CHAIRMAN MEISNER: We have a number of those identical machines. In most

instances, we have been able to feed them automatically. We put a cam movement on and a rod through the lower spindle to knock the work off. Does it happen to be tin or brass that you are using?

MR. SHINE: Brass. We use 22, 24 and 26 gauge brass.

CHAIRMAN MEISNER: I will admit that not all of the operations performed on that particular machine can be done automatically, but reasonably small round parts can be fed automatically. You take big heavy tops. There isn't much hope of putting them on automatically, but with small parts such as I saw in the Exhibit Room, I haven't the slightest doubt you can perform that automatically.

MR. BORAKS: The regular line of gravity feed automatic feeds are good, but sometimes they run into a lot of money.

The Remington Repeating Arms Company has feeds for their flashlights and I know just what the gentlemen's trouble is. I think that an ordinary gateway or railway leading to the lower roll just by the weight of its own piece, if you keep your shoe on it, the weight of the piece will bring them down. It is very easy to inject the pieces. Now, you can't equip all your rolls immediately with automatic devices, so what we do in that case, is to use a stop screw on the machine so the rolls will only open any amount you want, I suggest that you don't allow the rolls to open any more than three-eighths of an inch. You couldn't get your fingers in easily and it will help until you get some kind of a feed there. They will get accustomed to handling that work, with the three-eighth of an inch space between the two rolls.

A Magnetic Electric Pickup Desired

CHAIRMAN MEISNER: Louis, do you think you could get some blueprints that you could send the gentleman to help him out?

MR. BORAKS: I will try, I won't promise, because we have to ask our insured for the privilege of that. If they will do it, we will send them.

CHAIRMAN MEISNER: Will you get in touch with him later? Who else has something to discuss?

S. H. GRAHAM: I would like to ask if there is a magnetic electric pickup for steel parts. We have used a small magnet for putting the pieces in the press.

MR. ROTH: The nearest I could give him, instead of using electricity, is to use a suction. That is the nearest thing I would advise you to use. There are a lot of disadvantages in using electricity. In the first place, you have a lot of contacts to contend with there, you know, and you must just catch yourself at the proper time. If you use the air, it is easy. I wouldn't recommend trying to use electric current to insert a piece into a die. I think the thing is all wrong. Air will do it. With electricity, you neither can hear it nor see it, until the damage is done.

MR. HENNING: Not long ago, I saw in one of the magazines where you can buy these magnet lifters and I believe, you are right that the NATIONAL SAFETY NEWS editor can give you that information.

CHAIRMAN MEISNER: I have a question that was turned in. I don't know who wanted the discussion, but it is a simple one and it ought to create a lot of interest: "What is the best way to determine the angle of a gravity shoot?"

A lot of people are starting to experiment with sliding parts into a die. Mr. Thompson, what experience have you had along that line?

MR. THOMPSON (Detroit Insurance Co., Detroit, Mich.): In chutes and slides for over two years, I have found that it cannot and will not slide through location. In bringing out the point that Mr. Henning has and in the machine he is showing you, you have got a complete amplification of the principles made automatic. Mr. Kaems has shown you time and time again that his parts slide, heavy or light. I suggest to you in most every instance, you have a piece that is unusual for slide

and location. There are three principles that you can use, one is the straight slide, one is the incline slide and the other is the curved. They will launch the piece for you in almost any position that you want it. As your production increases, the demand becomes more insistent; then you naturally go into the push slide feed; and that is simple to make in most instances, by merely taking your slide and putting it under your blanking die and blanking it out and then rifling out that aperture large enough to give your piece freedom, fitting it into your slide and pushing it over your die and it drops into location. It can't do anything else.

MR. BORAKS: Will you please ask that question again.

CHAIRMAN MEISNER: What is the best way to determine the angle of a gravity shoot?

A Simple and Common Sense Rule Explained

MR. THOMPSON: I want to illustrate a principle that perhaps the boys will get easier. Here is an ink well. This ink well has a square to it. No matter which way you look at it, you have the square of the sides, top and bottom. Here is a watch. The watch is circular. Still it has a square on it. It has a square two ways, it has a square that way with parallel sides, and it has the flat surface top and bottom which is a square. You only need three points of contact at the extreme, two points of contact at the minimum. Now, in finding the line of fall, if you have a piece that is like the watch sliding, if that went down, it would naturally from its weight and from its size, slide over the top of any die or go into the die at such an angle that it would clamp.

The rule that I have followed is this: First square your object. Regardless of what its shape is, it has a bottom to it or a top to it or a side to it. There is some way it lies. Take the piece and lay it down. Then square it in that position and then find its center of gravity, and as you know, the center of gravity of any piece is the amount of weight distributed in any one particular location. Draw your line from that angle and you will find when you have your square of your triangle, that that is the best angle at which that piece will slide. Don't try to push the heavy end of your slide or the heavy end of your object, don't put it behind, put it in front, because that is going to be your leading member in launching itself into position.

In my experience I have taken the three slides I have told you about. I put on a ball and almost any piece, merely put that on that slide and on that you can elevate it or raise it at any angle you want it. A set of those three costs about \$5. Then put your die down here and go ahead with it and play a little while. You are going to find the exact angle. Go to the die cutter and say: "Make it so and so." He doesn't want to bother with your problems. He will make it and you will feed it.

Is there any question you want to ask on the three slides? I gave that story to you in Louisville four years ago. It, more or less, gives you a complete resume of just how the thing can be done, the quickest possible way for you, that is what you want to know.

MR. WALTERS (General Electric Company, Lynn, Mass.): What the boy out in the shop wants to know is: "How can I do it and do it well?" We take a piece of 64-gauge stock or a piece of cardboard and we will shape it up the size of your stock. Then we work by a rule of plumb. We tilt it and bend it until we get it and it takes us but a very few minutes. Take a piece of scrap stock and play with it until you get it and you will find out that after playing a couple of times, that you will get it in a very few minutes in each and every case. Mr. Boraks taught us that.

MR. BORAKS: I will add that there is a very good point there in that formula

of making a model or a templet or a trial shoot, and that is the fact that it won't shoot. You will find out before you build your chute, which is a good thing to do. That little model is just as good as the one you are going to build for your trial, your experimental work in other words. If you don't now, it won't go on the trial model. You know you have to get another way to feed it. It is a good thing to do that before you make it.

MR. MARES: With that slide, you would still put a stationary guard around the die?

MR. JONES (Indiana Enamel Company): I can't see the necessity of the guard, if you are feeding either strip or blanks from an inclined chute. Of course, I am talking of our experience in the Middle West. We know that there are some states in which you can't operate punch presses with incline feeds for disc work, banking, trimming or forming, without you have some sort of a guard for the point of operation. I feel that if you have an automatic projector there to take the material away from the press, if it is small enough, that there is no need for a guard.

MR. PUTNAM (American Can Co.): What are you going to do when the piece gets caught?

MR. JONES (Indiana Enamel Company): Use a hook.

MR. PUTNAM: Sometimes they don't use the hooks even when they are furnished. I am for chute feeds with a guard around them.

MR. JONES: If you are feeding through an enclosure, then you have to have something to take it out with and the hook is the only means that we know of. I came in to try and get some information about punch presses and I feel the only way to get it is through a discussion of this kind.

Guard the Chute on the Die

MR. ROTH (Aetna Insurance Company): I would like to say a few words on this matter. It is a very delicate situation. I personally believe that if we put a chute on a die and don't guard it, we have only given the man partial protection. I don't think there should be any limit to a thing; when a man feeds a job down the chute, he does things unconsciously and we have a barrier there something that is mechanically directing him all day long; but the minute we leave it wide open, how do we know but the fellow is going to follow the piece into the matrix of the die? If we have that guard or gate or barrier around, there is not a chance for that. A finger is always easier to use than a stick. We have provided a stick for them. You can't stand there with a baseball bat. I like to talk to them in a practical everyday way. I find in my business that a lot of fellows will use this so-called chute as a go-between. They try to compromise with you. If we haven't gone full length, I don't think we have done our duty.

Some of these fellows may think I am a fanatic, but I think if we are going to protect the man, let us go the full road. If something happens, our consciences are clear, because we have done everything we should do. The chances are remote for having an accident if they have the guard on. There is always a way of getting that out, or you will have a knockout of the die. There is a way of eliminating that trouble, if you stop to consider your die construction, your die is going to work 100 per cent.

MR. SHINE: We use the chute feed, although not entirely; we are using some shoot feeds. We haven't them completely on all the jobs, yet. Last October, we decided at our safety meeting, that none of our operators were going to put their hands under the die or the point of operation, and inside of three days we completely took every hand from under the presses. It was simple, just wherever we could apply it immediately. We took the easiest job first, just got a pair of pliers. We did something to take the hands from the point of operation.

MR. JONES (Indiana Enamel Company): That man's views are just exactly along the lines of my own. If I can get the manufacturer to put on a chute that will satisfy me with my 15 years of experience, I will put up my reputation that it will go through. Of course, you must take into consideration that the chute must be built to meet the conditions of the press. I don't believe in interfering with the production of the machine. That is one of the important points from the employer's standpoint. I do not mean that you should leave the press, if it is a hazardous operation, without the enclosure about it. Every press must be guarded individually and I don't know of any means of feeding a press better than the chute. I am very glad that this lengthy discussion has come up in connection with the presses. We have a man here this morning from Massachusetts, I believe, Mr. Morrison of the Liberty Mutual, who has had considerable experience in the East with punch presses. I would be glad to hear Mr. Morrison's views on that.

MR. MORRISON (Liberty Mutual Insurance Company): I just dropped in. I don't know how far the discussion has gone. From an insurance standpoint, you men are all interested in preventing accidents, and in saving money. I am your insurance rate. So far as our experience has gone, I string along with Mr. Boraks, that a barrier guard makes it foolproof, does not interfere with production and does give credit on your schedule rate, which amounts to a lot of money before the year is over. Of course, from an insurance standpoint, we don't enjoy seeing our premium income cut down but if anybody having power presses will make them foolproof by putting on a barrier guard, we are tickled to death to see the premium reduced. My friend here says that he does not need a barrier guard in his plant, but all of us don't have a Gus Kaems around to run this proposition and I dare say he can get along as well without barrier guards in his plant as some other man with barrier guards. The personal element enters into that. I don't know whether that point has been made or not; but you do save a lot of money by getting full credit on a power press, by having it guarded with a barrier guard. This adjustable guard, that Mr. Boraks referred to, is a simple proposition. You do get full credit for that. This is a fine meeting. I can't help but reminisce a little bit. Any old room would be sufficient for a meeting of this sort. It is a great inspiration to come in here and see you men working on a particular problem that has had us licked for a good many years. I am tickled to death to see the interest here. Don't forget that a barrier guard adjustable, that you can make in your own plant will give you full credit, will not interfere with the machine and will make it foolproof.

Any Rule Demands the Proper Supervision

MR. JONES: One big thing along with that is supervision. That is just one thing that you must not forget. If you have a rule that a person must use a stick or some other thing to straighten the piece out, that must be a rule and it must be obeyed. We have our troubles when we get in a new man from other plants. We have trouble with that new man. He has been in the habit of doing it his way; we are all subject to habit, and it is hard to get over it. There is just one thing he is told. If he is caught once, he is told and the second time he does it, he lays himself off for one week. We don't ask any questions about that. He just does that himself and if he wants to work for us and wants to abide by our rules, it is up to him. If he doesn't, he automatically lays himself off. If he hits his pocketbook in doing something that he ought not to do, he will quickly learn that he must obey the rules laid down. That is probably one of the things that we are strictest on. It goes so far that a man working with a new man, seeing him do that, immediately steps over and says, "The old man will lay you off for a week. Don't do it, because you will surely get it."

S. H. GRAHAM (Wichita, Kan.): Two weeks ago, I had a man lose a finger on

ing this 15 per cent. we have saved the price of the guards on the money that we have saved by not paying that 15 per cent extra. We use slides and we guard the die at the same time. We make it foolproof. The man is human and when a thing goes wrong and he puts his finger there, we close it up tight so he can't get at it. We close it up all the way around. We have had cases where the person got his hand around back of the die. We closed it up all the way around so they can't get at it from any side. We find those guards have well paid for themselves. In Wisconsin, you have to show them that you have had the point of that tool absolutely guarded. If you haven't, there is no question asked, you pay 15 per cent.

MR. SHINE: I just want to cite another instance. I wonder if the members in this audience of Wisconsin appreciate how much money that penalty can amount to. In a maximum case \$2,000. Think it over. Will it pay for the guard?

MR. ROCKOFF (Detroit Steel Products, Detroit, Mich.): It seems to me that we can sum it up in two things: First, let's have discipline and put on a guard. If we begin it there, the question is answered for everyone in the audience. That is the way the proposition looks to me. Anything less than that would be partial protection.

CHAIRMAN MEISNER: I think we ought to get off this question. Here is one turned in by Mr. Graves of Detroit: How can we best reach and interest the tool and die men in the smaller and medium-sized stamping plants? Has anyone had any experience in that?

Safety in the Small Shop Is Often Lacking

MR. THOMPSON (Detroit Insurance Co., Detroit, Mich.): I say with tears in my eyes, my experience is that you don't get very far with the small shop. You know, safety in the small shop and in the small die and tool maker's place is purely local option with him. We realize today that the big organizations, with their persuasive methods, with their authority and control, can say, "You shall do thus and so. That is the way we want it done and that is the way we are buying it." Every man today who labors for a living is selling something and he only holds his job as long as he maintains what he has got sold, as long as he keeps it sold. You stick on the job and when you don't keep it sold any more, you just "ain't there no more."

The same thing applies in the small shop. The only approach we can get and the only success I have gotten at all, is entirely in getting the man on the top sold. He has many angles from which to look at this thing. He, perhaps, has a good tool and die maker and he can't afford to let him go, because he can't experiment with somebody else. His margin of profit is smaller because he makes less of any one material. I can't answer that question and I don't think anybody in this room can intelligently answer Mr. Graves' question. I can only suggest this: Sell the man at the top and you won't have any trouble. It will come down below and the fellow down below will eventually get it. If you can get contact with him, sell him, too.

CHAIRMAN MEISNER: Anyone else?

MR. ROTH (Aetna Insurance Company): I would like to add a few words to that question. When we speak about the small manufacturer of a small jobbing shop, for instance, there was a certain individual in the room who was getting his tool made on the outside. He gets a price of \$30. That fellow is not interested in the safety part of that die. He is interested in making it for \$30. That is what he is interested in. Those are the big problems that we run up against. He says he can't afford to consider the operator, his interest is in the money. He wants the money for his die. I am using him. What am I going to do? I can't rebuild the die. Those are the problems we have to face. They are serious problems. A man in a jobbing shop is there to make a die for almost anything. He figures on so much an hour on a die. If he can't make out, he is going to lose money. He is not going to fiddle around. He is after his money like our brother there says. He wants his

money. Those are the big problems we have to face in going around the country.

MR. BORAKS (Liberty Mutual Insurance Company): For a great many years, as you all know, a die maker was told to make a die that would meet with the specifications. He was not told anything about making a safe tool or making a tool that would get out big production. He was just told to make the die. That is what he has been doing for a great many years. I will venture to say that die makers are probably more interested in safety than any other part of the factory, almost. They are going to make the tool and they want to make a tool that is going to make the piece right to the millionth of an inch. That covers them. They figure if they get that die out and it is right, that is all. They don't know anything about a feed. Why don't they put safety on the die? We all know that is the thing they ought to do. Why not put the protection on the die? It is because they haven't been educated up to that. I went in as an apprentice in 1900, apprentice die maker. The main things that interested my boss were that I get out a die that would make the piece like the drawing and how long it took me to make the die. He didn't care anything about any other part of it. He was ready to jump on me if I didn't do those things right. Now the die maker has to be educated to make a safe tool and a tool that will get out production.

But the Small Shop Is Becoming Educated

That is just the way we are interesting the small shop. The small shop is more interested in making \$1.99 in the jobbing shop. The big people don't need the money quite as bad, but with the small people, it is a matter of life and death to them to be able to get a job out as cheaply as they possibly can. They can't even quote prices unless they get in line and do the stuff right.

The small people are getting educated. We go to the man who owns that small place or the works manager. We don't go to the die maker and show him what can be done. Mr. Kaems has a feed that he paid sixty-five cents to make and he tells you he has run it for five or six years and I believe it, and you can see what it is. A man making 10,000, 20,000 or 30,000 pieces can spend sixty-five cents. He can spend \$5, I say, to make that tool safe and they are getting educated to it. There is only one way to get out of this dangerous stuff, in our opinion. In our organization we say, "Make your dies so you don't have to put your fingers under the punch."

Every one of your die makers in your small shops has just as much brains as the boys in the big shops. They haven't used them. They have got ingenuity. They can make these feeds for you. The problem today is to interest the big man in the small shop to spend a few dollars for experimental work. If he makes one feed, he will make two, he will make three, he will continue to do it. There is no question about it, because he will get production and production is what he wants first. If he gets production and safety, too, all right, he will take safety. He is glad to have it, but the thing that we interest him on is the production. If you can show him a tool where he can get production at a small extra cost that will give him safety, too, why he is tickled to death. He doesn't want any accidents. He can't afford to spend a lot of money for guards or safety devices, but for a cheap semi-automatic feed, he will do it any day because the production is what gets him.

L. B. BEINECKE (Metropolitan Casualty Co. of New York): I want to introduce a thought. We can hardly expect the operator of the press to be sold on safety very easily if he catches us doing a half dozen things on safety. If you study the average machine shop, the mechanic is working carelessly. He will work carelessly. He looks upon that man as a criterion, as an example, and I think the man should be careful about the example set.

CHAIRMAN MEISNER: People who have just started on safeguarding power press dies are running into the problem of rebuilding old dies. We have a man here who

has had a lot of experience on it. I am going to ask Mr. Rockoff to say a few words along those lines.

MR. ROCKOFF (Detroit Steel Products Co., Detroit, Mich.): When it comes to the designing and building of new tools, that is usually a comparatively easy problem because the tool maker has more or less latitude when he lays out his design and he can insert safety ideas that he has in his mind. When tools have run in the shop year after year and everybody has become accustomed to them and they go to the management and tell them they want to spend a few dollars on this tool and a few dollars on another tool, they get your estimate probably on one hundred or two hundred different tools that will cost anywhere from Mr. Kaems' sixty-five cents up to \$25 to protect, probably running into an average of several hundred dollars at the least. They wonder what good they are going to get from it and it is a little hard to convince the management that it is worth while to build safety into old tools that are already running and yet that is the problem that confronts many of us today. Take the tools that are already in the shop and build safety into them.

Three Ways of Gaining the Point

Just offhand, I would say there are three ways of doing this. The first and the easiest (and you can do this while you are arguing with the management about putting on something that is worth while), is to change the method. Very often a little change in methods will make a tool reasonably safe without adding one dollar or one cent to the tool itself. I remember once in our plant we had a little piece to form. It was just a piece that was formed into a shallow V. It was a piece about twelve inches long and about two and one-half inches wide. I came through the shop one day. We had girls running some of our presses at that time. Here was a girl forming these pieces. She would take each piece from the stock pile and hold it in her hand that way and put it in this way. In other words, her four fingers were on top of the piece as she laid it in the die. I stopped. I told her she would never get any more fingers. All I got was a smile. I had no further authority, so I had to leave it at that. Fortunately, she never had her fingers taken off. All she need to have done would have been to start her die by putting the first piece in it, to take the next piece and slide it across by shoving it with the next piece in the die. That would have been at least partial protection. That is the first thing we can do, partially protect the die by changing the methods. We can change the method by a simple movement.

I remember another instance we had in what we call a spring stripper. A spring stripper simply consists of a plate set up on two springs which goes down with the ram and after the piece is punched the piece stays on the punch and comes up with this spring plate under until the spring plate reaches the top and the pieces go on up and the piece drops out. In ordinary practice, the man must reach under to remove that piece and if the press should repeat, at the very least he has some very badly smashed fingers. All we did in that case was to have the man take the next piece on which he was to operate and hold it under and as the piece stripped off the punches, he slipped it under there and the piece that had been punched slid right off before him.

I saw the same thing done at Kelsey Wheel in Detroit, in which they blank rim clips. I believe all the man had was a barrel stave and as the press went up he slipped it under and caught about twelve pieces on the barrel stave and pulled them out. It required no addition to the tool and it didn't require one cent expenditure. That is partial protection, of course. I do not want to be classed as an advocate of partial protection. It is better than nothing. It is one way of building safety into tools.

Of course, besides that we have the old familiar method of attaching a chute or a slide. We have done that, too. In most cases the cost of attaching a chute or slide

is so slight that the average tool maker or the average tool designer need not get any appropriation to get it done. He can sometimes slip it over and it does not appear in the general expenditure afterwards.

Then, the third method, of course, is the change in design. My attention was called to this third method particularly in connection with this problem we have before us here, this wooden model. In this case, by a slight change in design, that is by putting the pilot pins in the upper part of the die instead of the lower and then by having a set of primary gauges, as you might call them, to partially locate the piece, close enough so that the pilot pins will enter the hole, we can then put on a slide feed. After those provisions have been made for a different method of gauging, the piece can be mounted on the new press and equipped with a slide feed so that the piece can slide down into the die because there are then no gauge pins to interfere with its easy movement into position.

CHAIRMAN MEISNER: We have about seven or eight minutes. I am going to conclude this meeting at eleven thirty. I am going to give the people time to clean up a little before lunch.

MR. SHINE: I wonder if anyone could tell us how they handle their inspection, whether they rely on the die setters or whether they have a machinist go around and try the brakes out and also their hangers and overhead equipment. Do they wait for a breakdown to take care of that? I would like to know how they handle it to see if we are handling it right.

MR. HENNING: I can answer the way we handle it. We make a weekly inspection on everything. That is gone over every week and every press is recorded. In that way, we have very little trouble.

MR. SHINE: Who does it?

MR. HENNING: We have a machinist. He reports direct to the safety man and not to the chairman.

MR. LAW (Connecticut Mutual Insurance Company): We assign the machinist and also the man in the pressroom and it is his duty (he takes his lunch hour before the regular noon hour at twelve) during the noon hour to go over every hammer in the place. The man in the pressroom does the same thing. These machinists are there at all times. It is their job every day in the week. They are held responsible for all maintenance of presses or drops.

MR. MARES (Perfection Stove Company, Cleveland, O.): We make an inspection every day of the presses.

CHAIRMAN MEISNER: Who does it?

KEEP YOUR MIND ON YOUR WORK

-AND
YOU'LL
KEEP YOUR FINGERS
ON YOUR HANDS

MR. MARES: I do it myself. I make one trip a day.

MR. ROTH: It seems to me, that although in a big plant the shop committee functions to a certain extent, it is their duty to report any particular thing out of order and call it to the foreman's attention. I believe we overcome a lot of trouble by those methods.

MR. HENNING: That is very true, but your shop committee does not go into where they see the thing and report it. There are so many things they don't see because they are actually working. You have to get somebody that is uninterested in that particular job. You have to get somebody whose business is to go after each individual item and that is the only way you can keep them up, as a press has to be kept up every day. It can't be let go for a year and then have it overhauled.

MR. BORAKS: We have with us today the safety engineer of the Edison Electric Appliance Company and I admire very much the manner he has of inspecting his presses. I wonder if we could call upon him.

MR. OVERHAUS (Edison Electric Appliance Company): Every Saturday every press is inspected and also during the week every day I parade around and whenever I see anything, I stop the press and have it fixed immediately.

MR. BORAKS: Is there an inspection made after each job is made on the press?

MR. OVERHAUS: Absolutely.

MR. BORAKS: Every time a new die is set up, he makes an inspection?

MR. OVERHAUS: That is the system we try to install in plants where we have safety organizations. We try to get the man that this work has been assigned to to make the inspection after every change of job. In that way, we eliminate a good many conditions that might bring about serious accidents. I might further state that our experience in punch work operations for the last number of years has been very successful. We have shown quite a decrease in accidents in the last few years.

MR. JONES (Indiana Enamel Company): There is one more thing. On the average big press there are connecting links between your levers and each one of those links is connected together with a key. We have taken a tap or screw inside of each one of those keys and put a wire through there so your key can't shoot out. That has eliminated a lot of our trouble. A man lost control of his clutch and that is one of the biggest hazards I have found.

CHAIRMAN MEISNER: Gentlemen, I think we have had a good discussion this morning and I appreciate very much your coming here and taking part in it.

In closing the meeting, I just want to remind you next year to bring models of dies, pieces, parts you are having trouble with and in the meantime send anything you have to Mr. Henning; we will all get together and try to solve it for you. I want to thank you very much.

MR. THOMPSON (Detroit Insurance Company, Detroit, Mich.): Before the meeting is adjourned, it seems to me that it would be in order for us at this time to request our secretary to send a letter of condolence to our new chairman in charge of posters who has been unfortunate enough to lose his wife.

MR. ROTH (Aetna Insurance Company): I second that motion.

(The question was put to a vote and carried.)

ADJOURNMENT.

*SIXTEENTH ANNUAL SAFETY CONGRESS
NATIONAL SAFETY COUNCIL*

Power Press and Automotive Joint Session

Friday, September 30, 1927

THEO. O. MEISNER, Chairman Power Press Section
Manager, Central District Safety Division, American Can Company,
Maywood, Ill.

A. F. DUNNEBACKE, Chairman Automotive Section
Safety Director, General Motors Corporation,
Detroit, Mich.

The joint session of the Power Press and Automotive Sections of the National Safety Council was called to order at nine forty-five o'clock, Mr. T. O. Meisner, manager of the Central District Safety Division, American Can Company, Maywood, Illinois, representing the Power Press Section; and Mr. A. F. Dunnebacke, safety director of the General Motors Corporation, Detroit, Michigan, representing the Automotive Section, presiding as joint chairmen.

CHAIRMAN DUNNEBACKE: As you know, this Safety Congress is the first in which there has been a division in certain interests. For years conditions have been working up where it has been thought advisable to separate certain activities connected with the Automotive Section, and last year there was organized a Power Press Section. That the move was advisable is shown by the attendance at the Power Press Section this year. I think we all realize that about 70 per cent of the accidents are caused by punch presses and naturally there are a lot of fellows who wish to know more about punch press accidents.

However, we did not wish to conflict with the interests of the Automotive Section, and with the approval of both sections felt it would be advisable to have a joint session where one might have subject matter in which both are interested. Therefore, I think the program this morning is going to be of a great deal of interest.

When a man gets up to talk he likes to know the type of man he is talking to. It aids so much in what he says and how he says it. So I have been asked this morning to present a little picture of you people who are here.

I am going to ask those men to raise their hands who are strictly safety workers, safety engineers, safety directors, or safety inspectors—the men down in the shop doing actual safety work. (Forty per cent). How many men here have charge as personnel directors of organizations which have safety as a part of their activities? (Fifteen per cent). How many men here are superintendents, foremen or executives, either managers or heads of divisions or heads of departments, but who are actually engaged in the operating and production processes? (Sixty per cent). That is a very fine representation. I am glad to see it.

The first thing I am going to ask this morning is if there are any reports of any

committees or any resolutions to be submitted. Mr. Miller of the Chevrolet Motor Company has some resolutions to present and I am going to ask him to read them.

H. E. MILLER (Chevrolet Motor Car Company, Gear and Axle Division, Detroit, Mich.): Yesterday the committee was appointed to draft a resolution on the death of the wife of one of our Automotive and Power Press members.

"Whereas, While in Congress assembled the Automotive Section of the National Safety Council has been notified of the tragic accidental death of the wife of one of its members, and

"Whereas, God in His infinite mercy has seen fit to remove one who is highly respected," and

"Whereas, We deplore accidents of any kind and particularly those whose results are so tragic;" and

"Whereas, Our heartfelt sympathy goes out to our fellow member in this time of tragedy and sorrow; therefore be it

"RESOLVED, That this Section offer their deepest sympathy and condolence to this member; and be it further

"RESOLVED, That a copy of this resolution be forwarded by our secretary to our bereaved member, Mr. M. A. Kroger, of Detroit, Michigan, and that a copy of same be placed in the minutes of this Section."

CHAIRMAN DUNNEBACKE: This makes us realize that we never know who will be picked for an accident and we never know when it is going to strike. We have a very efficient member of this Section, a member giving his presence to this convention for three days, attending the sessions, and all at once he gets a telegram that an accident has taken his wife.

E. H. COTCHER (Supervisor of Safety, The Murray Corporation, Detroit, Mich.): I move the resolution be passed.

(The motion was seconded and carried).

CHAIRMAN DUNNEBACKE: For our first subject this morning, "Training Foremen in Accident Prevention," we have selected Dr. Harry Myers, of the Delco Light Company and Frigidaire Company, of Dayton, Ohio.

Throughout the whole range of life there are certain fundamentals governing man's every day conduct. Dr. Myers has delved in and has grasped a wide range of that activity. He not only knows the philosophy of it, the esthetics of it, but he knows from actual shop operations, from actual work in factories and shops, the different links that connect these steps in our society. As personnel director of the Delco Light Company, he has been doing a very extensive work in foremen training, foremen development, and I know that he is going to give us a very interesting talk.

Training Foremen in Accident Prevention

Harvey Myers, M.D., Personnel Director, Delco Light Company, Dayton, O.

I asked Mr. Dunnebacke to take the census this morning that we might feel a little more acquainted with each other, a little more friendly perhaps; because I think these talks should be very, very practical, very personal; and certainly if we know each other better the result will be better.

I am sorry it has been my misfortune to be absent from the convention during these days. I know you must have had great sessions and I know now as you round out the closing day, you should be having an intense feeling of the need for action of some kind. So if you will allow me, I am going to get onto one of my pet subjects, which is that unless you carry this stuff back to your plants, into your work, and put it in operation, you have been a useless expense to your company. I want you to appreciate the seriousness of that problem. I know you will if you think it all over.

What are you going to do about it? What are you going to do about these things you have heard? Whenever a class leaves any of our rooms I wonder to myself, "What are they going to do about it?" Is this particular thing we are talking about going to show up in the plant in the next half hour, the next day, and so forth? Is this going to show up in your plants soon after you get back? Are your plants going to take on a different aspect because of your being here? That is the practical side of it, and folks, that is where most of us fall down. Some way or another we stop short of doing the necessary thing. One of the favorite questions I like to ask is this: What per cent of the things which you have heard or seen or read, that you have admitted would help you on your job and make you a better success in life, have you really done? I wonder.

Mark you this, of the things that will be said here this morning, the things you admit you can do and should do in the interest of your company and in the interest of yourselves, most of them you will forget. That is one of the reasons why they always take up the collection in church with soft music while you are still sitting, still in the atmosphere. They would never risk it after you get into the hall, because most of the people lose the atmosphere before they get out in the hallway.

How long can you hold an atmosphere? I wonder if you have read Elbert Hubbard? We have asked all our Delco people to read what he says about initiative. You have all seen that the world bestows its big prizes, both in money and honors, for but one thing, and that is initiative. What is initiative? It is doing the right thing without being told; but next to doing the thing without being told is to do it when you are told once. Hubbard divides the world into three classes of people: those who do it without being told at all, and to them go the prizes of life; those who have to be told once; and those who have to be told more than once. The successes of life lie in the first two classes.

The Measure of the Failure Class

When you have to be told more than once you are in the failure class. Is that logical? Watch yourself. Watch yourself in regard to anything that has been said in this convention that has been of new interest, anything in this whole convention about which you have said to yourself, "Yes, I am going to do that." Watch and see if you do it. Check up on yourself.

The first man we have any real record of having checked up on himself was Benjamin Franklin. If you have not read the autobiography of Benjamin Franklin, you should read it. We have sold over a hundred copies of that to our foremen in the Delco Light Company. Benjamin Franklin tells how he checked up on himself and made himself do the things that he should do. I recommend that book most heartily to anybody who, after he gets away from this convention, still finds himself not doing the things he promised himself he would do. You read that autobiography and I believe it will help bring the action that is necessary.

Here is another great big law that ties right in with Elbert Hubbard's talk on initiative, and that is this: My value is governed entirely by the amount of supervision I require. That is why the world bestows its big prizes on the people who don't have to be told at all, who need no supervision. That is why the man who can still do things when told once is a success. It means the least possible supervision. That is why those who have to be told more than once are in the failure class because they require the greatest amount of supervision and it is too costly; they fail. I am saying all this in a fond hope that the things which you promised yourselves you are going to do after this convention, you will do when you get back. Nothing could mean more to your plant, nothing could mean more to your personal success in life.

I am addressing a very mixed audience. I think 40 per cent are safety men. I wish I knew right now what your relation is to the foremen back in your depart-

ments, back in your shops. Then we would have a basis from which to start. I am talking now particularly to the safety engineers. I wish I knew how the foremen regard you. I wonder, because it would be entirely how you are now regarded in your organization as to how we must talk to you about training those foremen in safety work. I wonder if they are now interested in it; I wonder if they now look on you as the man actually helping production; or I wonder if they look upon you as a hindrance and hate to see you come into the department! The general managers who are here know what I am talking about.

I am wondering if the safety man in your organization is very popular. I am wondering if general managers here have an unpopular safety director. If so, he isn't a good one; and what is apt to make safety directors unpopular in their own organization is also apt to keep them from getting along well with the productive forces. You and I produce only indirectly. The employees get the stuff out. The foreman who directs getting the stuff out is making the money that is paying the wages, and I am wondering how you and I are regarded by the productive forces.

If you are not popular in your organization, I will bet I can point out one of the reasons. Did you every stop to analyze the difference between work and play? What is the essential difference? We say in Delco Light we are working on two big fundamental things, trying to make work a pleasure and trying to help people do well in life. One of the things which makes work distasteful, and the deep difference, I think, between men at work and men at play, is the question of authority. And I will say to the safety directors here, if you are not popular in your plant, ten to one you have used your authority unwisely. The very fact that you know you can stop a machine if it isn't fixed up with a safety guard, is a bad thing for you.

An Indication of Solid Character

That is one of the things which will keep you from being unpopular and unworkable in your organization, or wherever else you are. Nothing discloses real character like the use of power. It is easy for the weak to be gentle, but if you want to know what a man really is, give him power. This is the supreme test.

It is to the glory of Lincoln that having almost absolute power he never abused it except on the side of adversity.

Now when you go back and are inclined to talk hard to a foreman, knowing that you have the authority to close his machines down if he doesn't do what you want him to do, if you are going to get hard, nasty and unfriendly, just say those five wonderful words to yourself: "This is the supreme test." Just remember you are not measuring up under the test. How many thousand times I have said that to myself. I was going to lay somebody out because I had the authority to do it, but I caught myself and supervised myself, and I didn't.

What I am trying to say is that this is one of the ways not to teach foremen, by the authority you have. You can't train people by teaching if you don't know the fundamentals of good teaching. Most of the scrap back in your departments today is due to poor teaching, poor instruction. That is absolutely true. I will never forget the first meeting I had in the Delco Light. I was talking about the great need of better instruction; and the boss, Mr. Katering, came into the room. If you know him you know what a marvelous man he is. The boss listened for a while, then he got up; and he told me more about my own job than I had ever known.

He outlined three fundamentals as only Boss Katering can. He said, "Instructions degenerate and do not propagate." That is why it is so hard to teach. Instructions run out, they stop. If I tell a man a certain thing and it passes through four hands, you know what happens. Instructions do tend to degenerate, they don't propagate. They don't develop, they run out. That was the first thing Mr. Katering laid down. Instructions tend to degenerate, they don't propagate, and for that reason you have to be so definite in what you say.

Mark the next, too. He said, "You are poor instructors because you are poor actors. You don't like to do your stuff again and again in an interesting and entertaining way." He said, "Last night I went to see Ed Wynn. He is doing the same damn fool stuff that he did three years ago when I first saw him, and yet I sat there and laughed my fool head off; and then I thought: What has it cost Edwin to still keep doing that in such an interesting and entertaining way at the end of three years? Just the other day I saw his salary is something like \$5,700 a week! Why? Because he can do a thing over and over again and again and for years, and you like it."

Ketering said, "I am positive that most of your men want to do good work if you are smart enough to show them how in an interesting and entertaining way." Do you get that? Not with authority. Although it is true that most of our instruction in our organizations, in our plants, is given in the way of command. But are you interesting and entertaining? Take Ketering's word: "I am positive that 95 per cent of your men want to do good work if you are smart enough to show them how in an interesting and an entertaining way."

I believe that the foremen of your organizations will be interested in the safety movement if you are smart enough to take home the inspiration of this convention and give it to them.

Any Leader Has to Be "Smart Enough"

If you are going back in the same dill pickle state you came away in, if you have been anything but friendly and so forth, anything but pleasant and agreeable and cordial in your organization, and if you can't carry back from this convention this inspiration to your foremen, then you are not as good a safety director as you should be, and Ketering will say you are not smart enough.

Notice, he didn't say how smart; he said, "if you are smart enough." It simply means this, that if you are smart enough, if you can carry away the inspiration of this meeting, then I believe that your foremen are going to be interested in having you come in their departments on this question of safety; but if they are not interested, if they would rather have you out of that department when you come in, then, folks, you are defeating yourself in your project.

There was a third thing that Ketering said: "You are poor instructors because you are apt to teach the last thing you learned and not the first; so that poor devil is learning it from the wrong end." If there is some man in your department who is not as interested in safety as you are, just know that he hasn't the grasp of it that you have. Try to remember how dumb you were, how little you once knew, what first created an impression and interest in you. If you will start there and get that over to your foremen, I honestly believe that you will have interested them, and that is the first thing for you to begin with. If your foremen are not interested in safety I am very, very sorry for you. I believe that you can have interested foremen in this work, this marvelous work, if you will obey those things that Boss Ketering laid out. It is all in the teaching, and to get that started you must first have an interested group of people.

I believe, folks, that we go far afield when we consider safety something apart in itself. I have seen so many people do that, just as they have considered personnel a thing apart by itself. It is all a part of a big work, the development of the healthy, intelligent, interested working force and organization. The fundamentals that go into making safe departments are the fundamentals that go into making good foremanship. Good foremanship means safety and safety means foremanship. What are the fundamentals of good foremanship? When you go into a room do you say to yourself, "There is a good foreman"? When that department is clean and when it is in order, isn't that true? And right now when you go back, start the first thing to have a clean and orderly department and start the biggest thing for safety in your plant that you could ever mention.

The plants that fail are dirty, disorderly plants; the plants that succeed are the clean, orderly plants. Is that true in your experience? Can anybody dispute that? Have you ever seen a safe department that was a dirty department? Did you know that order, absolute order, is the first process of life? We approach the average foreman and the department is dirty and all disorderly. When you ask him about it he says, "I know why; they took one of my janitors away from me." Oh, what a mistaken notion of order. They are thinking in terms of order in janitor work. They don't think of order in the life process. We have all our foremen repeat this and mean it, "Order is the first step in production and if I can't manage the order of my department, I can't manage the department." Do you believe that?

The greatest step in low cost production and good production is order. We firmly believe in Delco Light that unless we can get a foreman interested in the question of order we can't get him interested in any proper question of manufacture. We go to great length. One of the little definitions of order is interesting. Order is a place for everything and everything in its place. In our definition of order we say, "A place is in order when there are no unnecessary things about and those things that are necessary are in their proper place." "No" in that sentence means not any, not even one. There comes the bite. Not even one. If you want to see how this is worked, come down to the Delco Works.

The Safety Movement Inspires Better Foremanship

I just want to make another point in conclusion. The whole safety movement means better foremanship; better foremanship means safety. The best foremen you have in your place are the safest foremen. Why? Because underneath the whole thing we know that the thing which makes for safety and makes for foremanship and makes for the better things of life, is the elimination of carelessness, and that is what is wrong with most of us. That is why we show such a low per cent in accidents. That low per cent most of you would have if you were honest about it. Don't you think that is true? Carelessness in your plants today is not only causing the accidents but is responsible for the poor work that you are sending out.

We know in studying the human side of this question, that the material side is rarely at fault. Most of the things you are sending out now to your customers are right, but not quite all. The big question is why aren't they all right? If most of the things are right it shows that your theories of manufacture, your theories of the fabrication of the articles, are pretty much right. The big question is, why don't they all go out right? Because of the human side—the failures, the frailties of human nature, and the biggest of all is carelessness. We have got a homely little definition for carelessness down there which I want to submit to you. "You are careless if you do not do anything as well as you can." Failure to do your best on anything means carelessness. You think that over, and then just ask yourself this: "How many times am I doing my best on a thing?" Folks, it is not added knowledge we need, it is an added something else that absolutely gets us by the nape of the neck and makes us do our very best.

Here is a little precept of three things that will absolutely eliminate carelessness in your shops and in yourselves: "Be clean, be orderly and have proper working equipment (and by equipment I mean everything that you use) and you can't be careless."

Folks, these things are all tied together. I can't separate them. Safety, accident way through, in shop or in home. I wish we had time for a discussion. I should prevention, is simply good foremanship, good managership, good management all the like to have your ideas. Of course, I am still wondering just as I did when I began to talk to you: What are you going to do about it when you get back?

AUGUST KAEMS (Kenosha, Wis.): I make a motion that we give this gentleman a rising vote of thanks.

(The motion was seconded and carried.)

CHAIRMAN DUNNEBACKE: While I should like to declare the meeting open for discussion, I hesitate because we have some other interesting talks and we need the time; but I think we will take about five minutes. There may be somebody here who has some particular thing he would like to have Dr. Myers emphasize more.

CAPTAIN FISHER (Illinois Manufacturers' Association): If I am quoting the doctor right, 95 per cent of the men will play the safety game if you are able to put it up to them. I am not asking a question, but I want to say something that will back up that sentiment. I have been doing this work for ten years, talking many times every day, and I get a better hearing in the shops and plants than a preacher does. Why? Because I talk along the lines of the things that interest men and that the men know are for their good; and I am constantly saying to managers, superintendents and foremen, "If you will get enthusiastic along this line the plant will get it." And it is true of my superintendents, like foremen, like workmen. It is amazing how much of the accident problem is due to the lack of enthusiasm among the foremen or the superintendent in putting this safety work up to the men. The men know it is for their good and they catch on and respond.

CHAIRMAN DUNNEBACKE: We will proceed to the next subject. The Fisher Body Corporation has done some wonderful work in safety, and Mr. N. M. Loney is here to tell us how they do it.

Application of a Cash Accident Prevention Bonus

N. M. Loney, Fisher Body Corporation, Detroit, Mich.

Some time ago I was confronted with the desirability of devising some way of bettering the performance in accident prevention in certain rather hazardous departments of the corporation with which I am connected. In order to meet the situation, the existing safety organization was expanded somewhat, the mechanical guarding was considerably improved, and a campaign of education was initiated. A little later, a cash accident prevention bonus system was installed, and as a result of these measures considerable improvement has been shown. I am unable definitely to allocate the improvement in the record to the various measures taken, but I believe that most of it is due to the cash bonus. I do not propose to go very far into the question of the desirability of such a system, but only wish to say that under a given set of conditions it has worked out very well for us.

It is very easy to decide to pay a cash bonus for accident prevention, but I found it quite a difficult task actually to set up the machinery by which this system would be administered. The reason for my appearance here today is that I believe, after considerable effort and experience, we have devised a system which may be of interest to those who may decide that their conditions justify the application of a cash bonus system, and this paper may be of assistance to others who may wish to use such a plan.

The first question which arose was: to whom shall the system be applied? An inspection was made of the records of payments for compensation and medical attention for several years back, and the departments where such payments had exceeded \$5 per year per man were selected as having sufficient expenditures to justify giving a bonus which would be worth while. This \$5, by the way, is the figure which was, more or less, arbitrarily selected as being one which would be large enough to attract the interest of the foremen, and still small enough to leave the possibility of an actual reduction in total cost of compensation and bonus. I might say here that our results have justified us in putting the whole proposition on a cost basis. The humane

side of it has not been overlooked, but we feel that this followed as a matter of course, and we all know that a policy which justifies itself financially is more easily installed and operated than one which has to be placed on an altruistic basis.

As stated above, this figure was adopted more or less arbitrarily after an inspection of the actual experience, but there is no reason why it could not be made considerably less as long as it produces sufficient remuneration to be worth mentioning. Most of the foremen whom we were trying to reach were those in direct contact with the workmen, each supervising on an average of 20 to 30 men, and this figure would produce an average bonus of from \$100 to \$150, which, if earned, would add materially to the foremen's earnings. The department foremen, who supervise the foremen, and who thus, in most cases, are one step removed from direct contact with the workmen, were also considered integral parts of the picture, and their bonus was made dependent upon the earnings of the foremen under them. All rules, of course, require exceptions, so that in order to take care of the exceptions a minimum for any foreman was set at \$20 per year per foreman, and a maximum of \$400 per year per foreman. Between these limits the system, which will be explained later, was allowed to work itself out to whatever it produced.

These limits having been established, the next question that came up was to make sure that the money appropriated was distributed on as equitable a basis as possible. This brought us immediately to the question of the relative hazard exposure of each foreman. Various insurance authorities were consulted, and a study was made of the available hazard ratings. None of these seemed to break down the hazard to fit the individual operations, and all of them were somewhat difficult to explain to foremen who ordinarily are not very well posted on this subject; I therefore conceived the idea of allowing the foremen to set their own hazard ratings.

Pointing Out the Most Hazardous Occupation

It happened that we had five mills doing similar work on the wood parts, and we had two press rooms and two die-making and maintenance shops. All together, these plants employed about 5,000 men, and the operations were quite similar in all of them; generally speaking, the hazard exposure in each was about the same. Small groups of these foremen were called together, and were asked, "What do you consider the most hazardous occupation in your plant?" In the case of the wood mills, the usual reply was that hand jointers, wood shapers and mitre saws were all quite dangerous and equally so. We said, "All right; then, we will tentatively assign to these machines 100 points on our scale of hazards." We then asked, "What do you consider the safest operation?" It was unanimously agreed that bench glueing of wood parts was the least hazardous, and we then set this up at 10 points on our scale of hazards. We then took up each machine or operation as listed on the rating sheet, which will be referred to later, and after considerable discussion fixed a rating on each between the above limits. In cases where helpers were employed, if there was a difference in the hazard exposure between operator and helper, this was fixed in the same manner.

Of course, quite serious differences of opinion as to the degree of hazard developed inside the various groups and between the different groups. In cases where the members of the groups differed, the majority was allowed to prevail; and the differences between groups were settled by a committee of superintendents of the various plants who finally adopted the figures used. These ratings were not entirely inflexible, as the safety department sometimes modified ratings for a particular plant or operation where conditions justified

this. For instance, the difference in the surface over which trucking was to be done might very well justify a change in the hazard ratings for this operation in the various plants. A record is being kept of actual experience, so that as time goes on it is hoped that these hazard ratings may be put on a more scientific basis, but since the whole underlying motive of the accident prevention bonus is psychological, we felt that if the men concerned were allowed to set their own ratings, it would be much easier to overcome the feeling that any individual was being unfairly treated.

As time went on, the system was extended to outlying mills, in one case to a saw mill, and also to take in the departments having to do with the preparation of metal (having first started with the stampings alone), and the hazard ratings for each department developed as described above. Attached in Appendix "A" are the following hazard rating sheets that have been adopted and are now used:

Wood Mill, Press Room, Die Shop, Metal Room.

These sheets are used as follows:

Assigning the Amount of the Bonus

A rating sheet is filled out in duplicate for each foreman by inserting in the proper spaces the average number of operators and helpers expected to be engaged under each foreman during the ensuing quarter. The rating for each operation is then multiplied by the number of workmen engaged on same, and the total extended and carried to a sheet total, which latter is the sum of the ratings of all operations under the foremen's supervision. The ratings for individual foremen are then added to get a total rating for the general foreman having several individual foremen under his supervision.

The next step is to assign the amount of the bonus. The theory here is to make the bonus of sufficient amount to be attractive and at the same time rather difficult to get. Considerable experimenting was done to fix a method by which any severe accident would eliminate the bonus for any individual foreman during the quarter in which it occurred, so that we, at this point, arbitrarily set up an allowance which may be said to express the probable normal percentage of time expected to be lost on account of accidents to the total time worked under each man's supervision. Any foreman exceeding this allowance would lose all of the bonus set up, and any foreman losing only a portion of the allowance set up would lose only a proportionate amount of bonus. You will note that the allowance is proportional to the hazard. The allowance is taken as one-tenth of the rating, and the bonus is based on twenty cents per point of allowance, or as a short cut, two cents per point of rating.

In the case of general foremen, the allowance is taken as one-fortieth of the sum of the ratings of the foremen reporting to him, and the bonus is based on forty cents per point of allowance, which, as a short cut, is one cent per point of rating. (Appendix "B" is shown as a typical summary for one plant.)

The allowance and bonus figures are then carried to a printed bulletin sheet, which is posted in a conspicuous place in the plant in a neat glass case, subject to the inspection of all concerned. At payroll periods the total time worked under each foreman is roughly computed, and the percentage of time lost is deducted from 100 per cent, and the result posted in the column shown.

It may appear that computation of the time worked under each foreman would be quite burdensome to the time department, but a little calculation will show that a five or ten per cent variation in the total time worked will only appear in about the fourth place of the bulletin rating, and will not

affect the bonus materially one way or the other. The reporting of the time worked under each individual foreman has been left to the foreman himself or a clerk, who reports to the safety man, who, in turn, ordinarily operates the system; and if the total time reported by the foremen checks within reason against the timekeeper's records of the total time worked, it is accepted as correct.

Here, again, I want to make the point of the psychological effect. It was felt that if the men were convinced that the system was being administered fairly it need not be scientifically exact to accomplish the result desired. Therefore, we accepted the approximation of the time worked, rather than going to the expense of actually keeping a check on the time records. In some departments it happened that the time was already kept as desired for this purpose, and of course where this was the case it was used.

When the ratings are posted at each pay period, there is also posted on the glass of the bulletin board a typewritten summary of the time losing cases, giving the name of the workman, name of the foreman, nature and cause of the accident, the time lost, and usually some warning pertinent to the record.

The Bonus is Paid at Quarterly Intervals

In the above discussion, the system has been referred to on an annual basis; in actual operation the bonus is paid at quarterly intervals, and new bulletins are posted at each quarter, no lost time being carried over from one quarter to the next; so that if a foreman has made a poor record in one quarter, he is encouraged to make a fresh start in the following quarter. At the end of the quarter the amount earned is computed in proportion to the time saved out of the allowance. A cumulative record is carried in successive pay periods so that the last column automatically gives the rating of time saved out of the allowance.

In conclusion, I wish to present some statistics as to the actual results accomplished during one year's operation of this system. It was applied to an average of 5,783 men who were supervised by an average of 215 foremen. The bonus set up amounted to approximately \$28,700 for the year, about \$4.96 per man and \$133 per foreman. The amount earned was approximately \$22,200, about \$3.84 per man and \$103 per foreman.

We had a couple of plants with a rather bad record—one plant in particular having paid during the previous year for compensation and medical service arising from accidents \$35 per employee. This plant employed from 500 to 700 men. In the succeeding year, we paid out in compensation something less than \$8 per employee, and for bonus about \$4 per man, so that there was an actual net saving in the total expenditure of about \$23 per man per year. Another plant paid in the previous year approximately \$40 per man for compensation and medical service, and in the succeeding year only about \$14 per man for compensation and medical, and a bonus of about \$4 per man, showing a saving of about \$22 per man per year.

In the plant in which there was the least improvement, the sum of the compensation and bonus paid just exceeded the amount paid for compensation alone the year before, and statistics indicate that the weighted lost time was reduced by approximately 70 per cent over the previous year in three of our plants, and from 40 per cent to 50 per cent in the balance. The actual net saving in the departments to which the system was applied was in the neighborhood of \$10 per man per year.

I trust that I may be pardoned for lugging these actual figures into this talk, but it again illustrates that any good safety device actually pays.

In the above figures, no allowance was made for the expense of operating the system. This was mostly done by the existing safety organization, and the total expense for this department was very little, if any, greater than it would have been if the bonus system had not been employed. When the system was first proposed, it was feared by a great many of the production men that production would suffer on account of it, but in the whole year's operation no complaint on this score has been brought to our attention, and on the other hand, it has undoubtedly served to increase production since it has prevented the unaccounted-for loss of time which inevitably occurs whenever a serious accident occurs.

In connection with the statistics, it is interesting to note that 35 foremen out of a total of 215 went through the entire year without an accident, but no foreman failed to receive some bonus. It has been found to develop a healthy spirit of rivalry, and the bonus, being distributed quarterly in the form of checks to the assembled group of foremen in each department, it gives the safety man a very good opportunity to review the record of each man during the previous quarter and draw the necessary lessons therefrom.

As we are extending this system to our outlying plants, we are saying to the foremen affected that we feel we have been paying the insurance company or the compensation department money on account of accidents which we would much rather pay to the foremen if they can prevent accidents, and at the same time we expect to make a saving on the total cost. Now that we have the benefit of the experience in the record quoted above, we are finding it very easy to make real safety men out of foremen who were formerly quite indifferent.

In closing, I wish to repeat that I am not advocating the adoption of the bonus system for accident prevention, as such. I only wish to give others the benefit of our experience with it, and in that connection I shall be very glad to answer any questions and to show privately to anyone interested, the actual detailed records which I have with me.

CHAIRMAN DUNNEBACKE: There is no question but that the idea of paying a cash bonus to foremen for doing safety work which we generally consider as being a part of the everyday work, is rather revolutionary. However, it is also true, as Mr. Loney said, that any principle or any movement that you want and can put over through a financial means, instead of altruistic ideas, will go over quicker. Now, no doubt there is many a manager who would be willing to pay real honest money for safety work if he knew that he could get that money back. Here is one instance of a company that is doing that. They are actually paying out cash bonuses to foremen for doing safety work, and by doing that they are saving money. It is a business principle. They are not only saving money but back of it all they also get these other things that we get through humanitarian ideas, love of their fellowmen.

For instance, there is one case, Mr. Loney cited, where over the past year they paid \$35 compensation per man in the plant. After they put in the system the next year they paid \$8 and an additional \$4 bonus to the foreman, with a total cost of \$12 against \$35 the year before.

Here is a system, machinery that is all working and has been working for eighteen months. While I am not satisfied in my own mind as to whether we should pay foremen cash for doing safety work, here is a system that is working and actually paying money to the men. As Mr. Loney says, if you are interested in it, and want to go into it, you are absolutely welcome to his machinery.

H. E. MILLER (Chevrolet Motor Company, Detroit, Mich.): I should like to ask Mr. Loney what the reaction has been among the men on the production floor, the

actual producers, on the paying of the cash bonus to the foremen, when they are participating in none of the dollars and cents.

MR. LONEY: I am going to ask Mr. McCarthy, one of the operating men, to answer that question.

M. J. MCCARTHY (Fisher Body Corporation, Detroit, Mich.): Mr. Loney stressed the point as far as the cash is concerned. The cash bonus has gone on for eighteen months, but I want to say that the cash part of it is practically out of their discussions at this time. The bonus affords the plant management an opportunity to see at the end of that bonus period what percentage of reduction has been made in accidents. Consequently, at the end of that bonus period, the whole period for all the foremen, the percentage is worked out. For instance, in one period it might be 78 per cent of the bonus paid. The next period will come along and if the bonus paid is less than the previous bonus period, we have had a greater number of accidents. If the bonus paid is higher, then the accidents have been less, of course. If it is higher, naturally a higher bonus is paid, and if it is lower, someone has to explain why.

The Foreman Sees the Injured Man In His Home

I will mention a welfare point. When a man has an accident the foreman doesn't let it go at that; it is called to his attention by the safety man and the foreman calls at the injured man's home that night to see if there is anything that can be done. He will get him in to work a great deal quicker by showing this interest. Don't forget the cash is some incentive of course. But they all want to get that percentage higher than it was in any previous bonus period. I can cite one shop in particular, the die shop, where in the last bonus period they had 96.6 per cent of the total amount of bonus that should have been paid. An unfortunate accident was all that kept us from 100 per cent.

The bonus is the greatest thing I have ever seen. A lot of people condemn the idea of paying cash to a foreman, but I have worked at quite a few manufacturing plants and it is the greatest thing I have ever seen.

As far as the workman is concerned the cash paid to the foreman seems to have gotten out of his mind entirely. The cash part of it seems to be forgotten. The chart being shown in their plant brings up the percentage. The men in the shop don't mention the cash, but they will speak of the percentage of bonus that was paid. It seems to bring out the point that accidents are being prevented in their department if the large amount of bonus is paid, and the actual cash being paid the foreman doesn't seem to enter into it. I have never heard a complaint about it. But the greater percentage of cash bonus paid in that department naturally makes them feel that they are helping to cut down accidents.

MR. LONEY: I should like to hear from any more of the Fisher Body men here operating the system or in contact with it. Have you ever had any grievance, fancied or real, on the part of the workmen on account of the foremen getting money? If any of you have, I should like to have you speak right up.

MR. MILLER: Our men have never participated in the actual cash plan.

MR. LONEY: The underlying theory is that this foreman, if you want to put it that way, is his brother's keeper in regard to accidents. It isn't the workman's job so much. It is the foreman's job to train the workman to be safe, and the foreman is being paid for his work in training the workmen, and not the workmen. It would be rather ridiculous to pay a man to save himself from getting hurt. The man who trains him, I believe, is entitled to his reward.

O. J. OLSEN (Fisher Body Corporation, Detroit, Mich.): Is Mr. Saborin here? Mr. Saborin is the general foreman over the metal shop: that is metal stampings after it leaves the presses. Mr. Saborin and several others, in my mind, stand out among all the foremen. The first thing Mr. Saborin did was to put his house in

order. That was housekeeping and that is the important part of the whole business in safety. Then he went further and equipped guards on the machines. All right. He wanted to go further than that. There were a lot of accidents occurring in the department. One of them was to a man who was continually going into the hospital for slight lacerations. So he gave the medical authorities a list of his foremen and when any of them had any accidents the first aid attendant notified Mr. Saborin several times a day in regard to them.

By this analysis Mr. Saborin found that a particular man was continually going to the first aid room. He looked into it and found that it could be corrected by putting a little tape on the man's finger; so the man gets this tape on the finger every morning or twice a day.

There is another man in our organization, a foreman in our wood mill, who has about 30 miter saws or table saws. This foreman has gone through 14 months without a lost time accident. The miter saw is a very dangerous piece of equipment.

You talk about the men under the foremen and their reaction to the fact that the foreman is getting a cash bonus. There was some little reaction to that, but it was only in a few isolated cases. I should like to have Mr. Saborin tell you whether in his group of men (I think he has around 250 men) has any experience with that.

Apparently the Bonus to Foremen is Not Resented

S. SABORIN (Fisher Body Corporation, Detroit, Mich.): The fellows don't feel they should be in it because we are keeping them working.

MR. OLSEN: They feel you are keeping them on the job. I think that is a good answer.

There is another man here, in the Press group. Mr. Schnapp, have you heard anything from the men under your supervision about resenting the foremen getting a bonus and they not getting part of it?

MR. SCHNAPP (Fisher Body Corporation, Detroit, Mich.): Not at all.

MR. OLSEN: Mr. Luce has charge of the press shop, is superintendent of it. Mr. Luce, have you heard in your contact with the foremen, anything about it? I know that Mr. Luce is very close to his foremen.

FRANK LUCE (Fisher Body Corporation, Detroit, Mich.): The press room workers are all working on piece work and we find that they like to get the piece work and they don't feel that the foremen are getting too much.

MR. OLSEN: You haven't heard any of the men say that they felt they ought to be a party to it?

MR. LUCE: No, sir.

R. F. THALNER (Buick Motor Company, Flint, Mich.): The testimonial from the foremen is all very well and good, but how many of the fellows come in and kick to the foremen? I think the testimonial you want to get is from the men in the department. They are the fellows talking it over.

MR. OLSEN: Mr. Thalner, I personally have gone down below the foremen.

CHAIRMAN DUNNEBACKE: I am going to reserve any future discussion on this subject until after the next speech. We may then have some time left and may have some more pro and con on the idea.

The third and final paper is one dealing with the question of safety as a part of every foreman's responsibility and the subject is going to be handled by Mr. Art Williams, who is now safety director for the Chrysler Motor Car Company. He has had many years of experience along safety lines with the American Telegraph and Telephone Company. He was last Tuesday elected to the chairmanship of the Automotive Section and I am sure we will get some very good information from Mr. Williams' talk.

Safety—A Part of the Foreman's Responsibility

A. M. Williams, Safety Director, Chrysler Corporation, Detroit, Mich.

I had a very, very nice long formal paper prepared here. I thought a whole lot of it. After Dr. Myers got through this morning I made up my mind I would put it in the waste paper basket. It seems to me that our whole job, before I get down to the subject assigned to me, is keeping this entire safety program and our educational program in very nice balance. What I mean by balance is this: We can start a safety inspector out in the plant and say, "Now, Bill, we have checked our accidents for last year and find that 85 per cent of them could not have been prevented by improved mechanical conditions. Fifteen per cent of them might have been. Therefore, weigh your time and let's go at this 85 per cent."

That is the job that we have to keep uppermost in our minds all the time. Naturally, as soon as he gets down on the floor he runs into Bill Jones and the safety competition is pretty keen. It is over in our place, has been running now for two years, and the management is doing a lot of racing and a lot of rooting. Some are on the carpet for bad records and some for good records, and every foreman is fighting to get his men back; no bonus in it, by the way, but just his own reputation and his own obligation as head of his department; his reputation is at stake. Naturally the foreman says, "Well, when am I going to get that guard on that machine? I put an a.d.o. (as we call them, merely a memorandum) through the maintenance department, asking for a certain machine, day before yesterday, and there hasn't been a darned thing done about it yet. When am I going to get it?"

To get the foreman away from the mechanical side of it and to talk about Bill Jones and Charlie Smith working on a sheeter, with long sleeves, possibly in violation of safety rules, to get him back on the educational side of it, is the big job, because every foreman (I know how they feel because I was a foreman myself for years) looks at the mechanical side of it; he is machine minded, material minded. And he doesn't give enough thought to that third side in the triangle.

I don't know whether we are going to tie a string around the fellow's finger to keep him in balance so that he will have something to remind him or not. If we don't, he is continually being driven right back to the mechanical thing instead of standing on two feet and saying, "Wait a minute, Bill; that thing is going through. I am making a memorandum now and we will see that you get it. But how about these new men down here? You had three new men yesterday. You go over the safety rules with them and see they qualify. They may not be, just through ignorance; they are green here and they may slip. If they do slip your record for the last year and a half without an accident in your department is knocked into a cocked hat."

Naturally when we started this, our foremen asked for help. They said, "If I am going to teach, if my job is partly that of a teacher, what have I got to work with?"

Well, we went through all the educational material we could pick up and you boys have contributed a lot of it. We stole your ideas wherever we could find them, we wrote many of you for ideas; remember the foremen were asking for this information. They were asking for help. We got out altogether six pamphlets, by trades, so that a man could have a first reader in safety to use in teaching the green man about the hazards of his job. We started each one of these with general rules that are common to all of the six.

Then the last part of the book is devoted to the specific hazards of the department that the man is working. "How about these new employees now? We are taking on a great big bunch of men and I can't see all of them. Can't you give us a lift?" the foremen asked.

So we set up a routine at the request of the foremen and when the new employee comes into the employment office and is qualified by the interviewer for the job, he

next goes to the physical qualifier; but before he goes, the qualifier calls his attention to the fact that he is going out on a welding job and there is a book of instructions to welding operators and he will be expected to learn those rules and stand an examination on them. But he doesn't get the book yet. He goes over to the physical qualifier and the physical qualifier notes on the card of introduction that he is going on this type of work. He also, while talking with him and getting his history and writing him up, checks that same angle and says: "You are going to be given one of these books and later you will be examined, because there is a safety campaign on in this plant and if you want to get yourself into ill repute, I don't know any better way than for you to get mugged up in an accident."

He goes back to the employment office and the clerk, after giving him the tools, gives him the book. The man who introduces him to the foreman talks to him on the way out. He is turned over to the foreman and the foreman gives him the final shot and says: "Some time in the next three or four days I am going to get to you and see if you can pass the examination on these rules." In the beginning, the question was whether the men would read the rule books. The question from the foreman was, "Will they read them?" I think they are put across in a friendly way and it brings out one point, if you will permit me to digress. As chairman of the Automotive Section, I am going to submit to the Executive Committee sometime in the next two or three months the plan of standardizing, or appointing a committee on standardizing, safety rules, safety instructions, for use by all of the plants, something that all men who are working in automobile plants will get in the same way, at Packards, at Buicks and at Chryslers. Therefore, when the man leaves your plant and comes to mine he is familiar with these rules, he has been over them and knows what to expect, and what to expect in the way of discipline.

Industry Parallels the Army Organization

I made a few notes here, getting back on safety as a part of the foremen's responsibility.

Industry today tallies very, very closely, or follows very closely the old military traditions of the Army. In fact, when we set industry up in large groups as we have today, we just simply stole the system from military experience; and we should gather this from it, that responsibility and authority always must rest on the same shoulders and cannot be split. There are many safety departments that are made responsible for the prevention of accidents. The responsibility is placed there, and the foremen feel that it is the safety department's job. My job is to get out production. Our job must square with the organization. It must also square with the man in industry as he is. In squaring it with industry, my picture is this, that we must place the responsibility for the accidents back on the same shoulders that carry the authority for the discipline, the authority for the production in each department.

In other words, we can say to the foremen, "There is your safety job right there on the floor, Bill. It is yours, and whatever you do with it, if it is a good record, will be yours; and if it isn't it will also be yours. We are going to help you shoulder it but we are not going to carry it for you. We are going to help you in any way we can. We have a potential malinger in your department which we are going to help you clear up. If you want some help in getting mechanical conditions corrected, we will do that. If you want an instruction book, something that you can sit right down with a man and go over with him, that will simply pin his attention and your attention right down to the high spots that this man must get to keep himself in the clear, we are going to help you.

"We are also going to do this: We are going to put a performance rating on the whole job; we are going to give your department a mark to shoot at and that is going to be determined with the rate of hazards in your department. So that you in

the press room are on an equal basis with the man out here handling material, or the man over here on other machine operations.

"And to get that we have worked out something that we are proud of. It has run a couple of years and the foremen are all sold on the fairness of it, and the man in the press room can compare his department with the man in the other department. We secured the figures from the insurance reports, worked them out and translated them through the wage rates in the different trades, so that it represents the thing in man hours, and the foreman has something in man hours that he can show every man in his employ. He doesn't have to talk to the man in dollars and cents and set up in his mind the thought that the company doesn't care anything about his life, that it is merely a dollars and cents proposition to them. When you talk in hours, that means the hours of time saved, and something of the loss that all of the men will sustain. For instance, here is a report that goes out to the physicians every two weeks. It is a performance rating report. The first is the inter plant, and the next is the intra plant. Each sheet in the intra plant shows each department, the name of the foreman, the number of hours allowed, the number of hours we might expect that we would lose due to accidents; also the number of hours that were actually lost, and then the percentage of hours saved, and they are rated on a percentage basis.

The Original Estimate Very Nearly Right

We worked these figures out expecting that we were going to shoot at it at 30 cents per hundred dollars of pay roll rate; and the first quarter that we ran this two years ago we came out almost to a cent. We were only 4 per cent off. This report takes us down to the current quarter, to the tenth of the month. This is the last report I have and there will be one other that will close out the quarter. This shows that, according to the insurance figures, on a basis of 30 cents per hundred dollars of pay roll, we could have expected 39,000 lost hours at all plants—39,000 lost hours. We didn't lose that many; we lost 12,000; so we made a net saving of 70 per cent. That will give you the picture of about what the rate will run for the quarter.

In press rooms (going back for one moment to pin down the 85 per cent theory due to education), we got across to the press operators in our plant this year that our amputations have been reduced 80 per cent. So we can feel we are getting down pretty nearly to the minimum of accidents from the educational side of it, so far as press operations are concerned; therefore, the 20 per cent will be largely the job of better dies and better guarding.

I will wipe the whole slate and bring this one point: If safety is a teaching job we will have to think of teaching and all the fringe that goes along with teaching. In our schools the teacher not only follows the curriculum and gives the student all of the material in the curriculum, but you have the adjustments that that person has to make to social and political life; and there is one big adjustment yet to make and that is the adjustment to industrial life. That is a part of the foreman's job as a teacher, and if in years gone by we had put our teaching on a premium basis or on a bonus basis, I wonder if we would have had the same value and would have secured the same value in this training (as you might call it), that we have secured in preparing young America for the place that he must occupy in social and political life.

CHAIRMAN DUNNEBACKE: We have ten minutes before twelve o'clock and as much thereafter as you wish to take for discussion. I will throw the meeting open to discussion on any of the three papers. Dr. Myers', Mr. Loney's or Mr. Williams'.

E. F. BLANK (Jones and Laughlin Corporation, Pittsburgh, Pa.): I am very much interested in Mr. Loney's paper on this cash bonus plan. It brings up three questions which I would like to ask. First, is not safety an operating problem?

Second, isn't the foreman's job one to prevent accidents or look after the safety of his employes as much as it is to get out production? And third, if this is true, why pay the foreman any bonus to do his duty? Mr. Loney stated that this plan wasn't a panacea for all the accidents. There are a good many other plans. It seems to me there are a lot of simpler plans that will get the same results. I think most of us have ratings and charts in the time and pay roll departments which take less time. It may not be so much work as it appears on the surface.

We are using the competitive plan and think we are reaching the workmen better than we have ever been able to reach them before. I have the same reaction that Mr. Miller had in regard to "Doesn't this react unfavorably among the men themselves?" It is a good thing for the foremen and makes them pay some attention to safety in their departments. I should think a plan which would let the men in would be much better; and as far as getting a reaction from the men themselves, about the only way you can get that is to put some "gumshoe" workman out there and let him find out what the men are talking about. They won't talk to Olsen or McCarthy or to the foremen because they know they are identified with the plan.

CHAIRMAN DUNNEBACKE: Mr. Loney, will you answer that?

Give a Bonus for Safety as Well as Production

N. M. LONEY (Fisher Body Corporation, Detroit, Mich.): If I understand Mr. Blank right, the first point that occurred to him was that this foreman was expected to produce safety as well as production. I am going to ask Mr. Blank an individual question. Does Jones and Laughlin Company pay you a bonus for good performance? The General Motors Corporation does. As you all know, they have a published system awarding every one a bonus according to production. If a man gets a bonus from his production and safety is equally important with production, why not give him a bonus for doing part of his job?

As I said in the beginning, if I conveyed the impression that in my mind this is the only system for securing safety, then I am all wrong, because this is only a tool. We are using all the other tools available. Please don't run away with the idea that we think this is the only way to produce results. As I remember it, the difference between Mr. Williams' system and ours is that we have possibly a little more tangible reward, and the spirit of competition for getting money I think is just as strong as the competition for getting on. I know I am interested in competition for the money I get and I don't doubt that our foremen are interested to know that they are in competition with the other foremen to get this financial reward.

MR. BLANK: Those three questions are pretty well answered. The only thing I would bring out is Mr. Loney's answer with regard to the bonus. As I understand, your bonus is for efficiency and good service. My point is that that bonus bit from the main event. We try to make safety part of the main event and not a side show.

MR. LONEY: As I stated in my paper, we have some pretty hard boiled production men who fought this system rather bitterly before it was installed. I asked the leader of this opposition, "Do you know of any case where this has interfered with production?"

He answered no; so it has not interfered with production, and the foremen have not sacrificed production to get it. I just want to repeat again that we tell our foremen, "Your job to get safety is just as important as to get production," and possibly we err in over-emphasizing the safety; but some of the departments of General Motors do what you propose. They make a certain assignment, the amount earned on account of safety. As I said a while ago, I believe that if the men

understand what it is all about, you get better cooperation. I don't believe that any manager can go out and explain to his workmen the insurance rating scale which is used in setting up these rivalry systems, which to my mind have this inaccurate feature, that they are somebody's opinion. Here is something that is nobody's opinion except a group opinion. It is a mere matter of arithmetic after you have the group opinion to apply it to the original case.

E. H. COTCHER (Supervisor of Safety, The Murray Corporation, Detroit, Mich.): You might be interested in knowing that the Program Committee of the Automotive Section, in suggesting this pair of papers, had in mind just this discussion that has come out. Psychologists tell us that there are two actuating motives that influence humanity, the financial motive and the vanity motive. As you will note, these two systems take into consideration these two motives and we put this on the program for the very purpose of bringing out the strong points of each of the motives. We mustn't overlook the fact that no individual is actuated entirely by the financial, nor is any individual actuated entirely by the vanity motive; so I have been gratified with the discussion. We deliberately set the stage for it. However, it appeals to me that there is something worth while in both Mr. Loney's proposition and the one that Mr. Williams is conducting, and I think if we follow out Dr. Myers' suggestion and try to dig out what we can from these things for ourselves and go back and see what use we can make of them, we will be doing well.

The Bonus as An Aid to Cooperation

CHAIRMAN DUNNEBACKE: Dr. Myers' talk created a great deal of interest, and it just occurs to me there is possibly someone in the crowd who would like to ask Dr. Myers a question on some phase of his subject. I think we still have time for a few words from Dr. Myers if anybody has some particular question he would like to bring up.

H. E. MILLER (Chevrolet Motor Company, Detroit, Mich.): Dr. Myers' message struck me as being so inspirational to all of us, whether we be safety directors, managers, foremen or what not, that I should like to go on record as favoring the printing of his message in pamphlet form. I should like to have a copy of it to keep on my desk as an inspiration for the years to come.

MR. SMITH (St. Louis, Mo.): I think there are two parts to both of these questions that might be well worth considering, and that is the case of the bonus, the fact that the foreman gets a bonus serves as an incentive for the workmen that come under him. In the case of the foreman who does not get a bonus, if he protects himself as a foreman he will get more wages.

CHAIRMAN DUNNEBACKE: The big point for me is, if everyone realizes that through the bonus system his foreman is going to give him more profits and he is reasonably assured that he can work from day to day without accidents, there is his reward. Anything else?

MR. COLE (Atcheson Graphite Company, Niagara Falls, N. Y.): During the discussion on this bonus, one gentleman brought out the point that the men were so interested in the percentage that they were carrying this thing on. I believe that this method has been a tool to create interest in safety. I should like to ask the gentleman who made the statement, if he believes now that if they took off the financial payment of this bonus it would interfere in any way with the safety movement in this plant?

CHAIRMAN DUNNEBACKE: That is an interesting question. I should like to know, myself. Suppose you reach your millennium of having no more accidents, or supposing you cut out the cash bonus altogether. Do you feel reasonably certain that the interest in safety would continue?

MR. LONEY: I am sorry I am not able to answer that question. It is a question that often turns over in my mind. All my life I have practiced the theory of not crossing a bridge until I came to it, and we are not anywhere near the portal of that bridge, so I beg to be excused from answering it.

ADJOURNMENT

SIXTEENTH ANNUAL SAFETY CONGRESS
NATIONAL SAFETY COUNCIL

Public Utilities Section

New Section Officers

- Chairman*, CARL J. RUTLAND, Texas Power and Light Company, Dallas, Texas.
Vice-Chairman, In Charge of Electric Interests, W. R. LOYD, Alabama Power Company, Birmingham, Alabama.
Vice-Chairman, In Charge of Gas Interests, IVAN L. SCOTT, Wisconsin Power and Light Company, Madison, Wisconsin.
Vice-Chairman, In Charge of Telephone and Telegraph Interests, H. L. MEADE, Ohio Bell Telephone Company, Cleveland, Ohio.
Vice-Chairman, In Charge of Water Works Operations, H. F. WEBB, West Penn Power Company, Pittsburgh, Pa.
Secretary, C. B. BOULET, Wisconsin Public Service Corporation, Milwaukee, Wis.
Poster Committee Chairman, E. S. BEAUMONT, The Peoples Gas Light and Coke Co., Chicago, Ill.
Membership Committee Chairman, F. S. ARMSTRONG, Central Illinois Public Service Company, Springfield, Illinois.
Slide Committee Chairman, C. P. RYAN, Indiana Electric Corporation, Indianapolis, Ind.
Fire Protection and Prevention Committee Chairman, H. B. HARMER, The Philadelphia Electric Company, Philadelphia, Pa.
Statistics Committee Chairman, G. A. DOELLER, The Dayton Power and Light Co., Dayton, Ohio.
News Letter Editor, N. L. DEVENDORF, Consumers Power Company, Jackson, Mich.
Councilors:
C. B. SCOTT, Bureau of Safety, Chicago, Ill.
GEORGE C. A. OPP, The Detroit Edison Company, Detroit, Mich.
H. W. MOSES, The Edison Electric Illuminating Company of Boston, Boston, Mass.
J. C. HUBBARD, The Western Union Telegraph Company, New York City.
H. M. WEBBER, Illinois Bell Telephone Company, Chicago, Ill.
B. FRANK DAY, The Philadelphia Electric Company, Philadelphia, Pa.
HERMAN SPOEHRER, Union Electric Light & Power Company, St. Louis, Mo.
B. B. MCCULLOCH, Bureau of Safety, Chicago, Ill.

Retiring Officers

Chairman, GEORGE C. A. OPP, The Detroit Edison Co., Detroit, Mich.; *Vice-Chairman, Electrical Interests*, C. J. RUTLAND, Texas Power & Light Co., Dallas, Texas; *Vice-Chairman, Gas Interests*, C. HOWARD STEWART, Laclede Gas Light Co., St. Louis, Mo.; *Vice-Chairman, Tel. & Tel. Interests*, H. L. MEADE, Ohio Bell Telephone Co., Cleveland Ohio; *Secretary*, HARRY M. KELLER, Northern Indiana Public Service

Co., Hammond, Ind.; *Past Chairman*, B. B. McCULLOCH, Bureau of Safety, Chicago, Ill. *Committee Chairman: Publicity*, H. E. WEBB, West Penn Power Co., Pittsburgh, Pa.; *Poster*, IVAN L. WEBBER, Illinois Bell Telephone Co., Chicago, Ill.; B. FRANK DAY, The Philadelphia Electric Co., Philadelphia, Pennsylvania.

Tuesday, September 27, 1927

GEORGE OPP, Chairman

Safety Engineer, The Detroit Edison Co., Detroit, Mich.

The first session of the Public Utilities Section of the National Safety Council was called to order at nine-thirty o'clock by the chairman, George Opp, safety engineer, The Detroit Edison Company, Detroit, Michigan.

CHAIRMAN OPP: The Public Utilities Section of the National Safety Council now opens its Sixteenth Annual Congress. We are happy indeed to greet such a large number in attendance. We trust that you will find these meetings of the utmost value to you; we are desirous of letting you see the officers of your section, that is the reason for the dressing of this stage. You doubtless have wondered who does the work of the section, and by reason of the fact that there is only one name signed to the letters you receive you doubtless have the impression it is a one-man job; but not so in the Utilities Section. In this Section every man works. We have had the most splendid display of teamwork in the past year that I have ever seen; it cannot be excelled on any college football team. Everybody works. It is with keen pleasure that we will proceed to the reports of our various officers; we will do it as hurriedly as possible, and we are going then into the program as outlined, because we are not going to keep you one minute over time, you can rest assured.

In the organization of the meeting the chairman is supposed to make a report the first thing; I am hoping there will be no need to make a report, and in view of the fact that we are going to have some discussion here, I will not make a report unless it is found necessary to bolster up the pages of the transactions; I do not think that will be necessary because of the interest in the Public Utilities Section and because of your active participation in these discussions, I believe there is going to be ample printed matter in the Transactions.

Now the next item, and one that really belongs to the chairman, as far as his part of the program is concerned, is the introduction of the officials; it gives me great pleasure to introduce the Vice-Chairman in Charge of Electrical Interests, C. J. Rutland, safety engineer, Texas Power & Light Company, Dallas, Texas.

MR. RUTLAND: I think we have had closer cooperation this year in our Public Utilities Section actively than we ever had before; possibly it is due to the inspiration that our good friend and leader, George, has given us throughout the year. We are building a foundation now for a still greater year.

We are going, of course, to need your support, the support of everyone, and we need your criticisms and your suggestions. One item in particular that I want to mention is the conference that was held in Kansas City about four months ago. I

was a little disappointed that we did not have more Public Utility men from that section of the country present.

The National Safety Council has held regional meetings in several different parts of The United States with the sole purpose of enabling some of you men who possibly are unable to get to the conference annually, to at least attend these regional meetings and get the good out of them. We were sorry and disappointed, frankly, that we did not have as many men from the mid-west and Pacific Coast districts at the Kansas City conference as there should have been.

I want to urge on you in this coming year to attend any regional conference that is held in your section of the country. I do not know just yet how many may be held, but you will be advised in ample time. We want you there, and we want you to participate in all the discussions.

You know it is a hard matter for just a small group of men to do a lot of work. There are just as many men and possibly more in this audience this morning who are capable of filling executive positions as the men up here now. We need new material, and new suggestions. The fact of the matter is we are almost crying for your help, not that the work is not going along fine, for it is, but it is almost getting beyond us.

CHAIRMAN OPP: In addition to the active part Mr. Rutland has taken in connection with the regional conferences he has been active in circulating questionnaires which have been of use to this Section, particularly on the question of unloading poles, on which we are going to have further discussion and demonstration this morning.

It gives me great pleasure to introduce one of your officials who has kept us very closely tied in with the telephone and telegraph interests, Mr. H. L. Meade, general plant employment supervisor, Ohio Bell Telephone Company, Cleveland, Ohio.

MR. MEADE: I have no special report to make other than what the Secretary will make; but I do want to say, however, that I am very glad to have had the opportunity of associating with you members, and I have enjoyed the work very much. I have become more intensely interested in the work by having taken active part in it.

CHAIRMAN OPP: Unfortunately our Vice-Chairman in charge of Gas Interests is unable to reach the meetings. I understand that there is a message from him for us through Mr. H. E. Barada of his organization.

H. E. BARADA (Laclede Gas Light Company, St. Louis, Mo.): Mr. C. Howard Stewart, Vice-President in charge of the Gas Interests, assistant treasurer of the Laclede Gas Light Company, St. Louis, Missouri, requests that I bring in his regrets at being unable to attend these meetings.

As it happens, this is the first Congress that Mr. Stewart has not attended since 1916, and you can readily appreciate that anything that would keep him away is important.

CHAIRMAN OPP: Now we will have the report of Mr. Harry M. Keller, manager, Safety and Claims Departments, Northern Indiana Public Service Company, Hammond, Indiana, as Secretary of this section. There is no man in the organization who works any harder than the "quarterback," the secretary of the Public Utilities Section.

Report of the Secretary

During the year just completed, your Executive Committee held five meetings—at Detroit immediately following the 1926 Congress, at Cleveland in December, Chicago in February, New York City in May and again at Chicago during June. The attendance was gratifying and reflected the genuine interest of those on the

Your committee would like to express its appreciation of the cooperation on the part of the author contributors listed in this report and recommend the continuance of the Publicity Committee as a definite part of the Sectional activities.

H. F. WEBB, Chairman

CHAIRMAN OPP: Last year it was the pleasure of your committee to establish a Fire Protection and Prevention Committee. Not only have we upon our own sectional program a feature address on that subject, but an entire session of the Congress is devoted to the matter of study and consideration of fire protection and prevention features. Our Fire Protection and Prevention Committee is headed by Mr. H. B. Harmer, safety engineer, Philadelphia Electric Company, Philadelphia, Pa.

Suggestion Needed For the Committee

MR. HARMER: I have no set report for you, but I would like to tell you a little story. A lady and gentleman stopped on the corner over here in Chicago, not so very long ago, and they asked the boy on the corner to direct them to Adams Street. He said, "I don't know where that is." They said then, "Where is the City Hall?" He said, "Oh, I don't know." They said, "Where is Clark Street?" And he said, "I don't know where Clark Street is." Then the man said, "Well, you are pretty dumb, aren't you?" And the boy said, "Well, I know I am, but I am not lost."

Now, ladies and gentlemen, we are going to get lost in this new endeavor of ours if we do not get from you, the members of this Section, suggestions as to what you would like to have us cover.

I can hardly see why fire prevention and accident prevention have been divorced so long; I think the time has arrived when we must all realize it is one subject that must be covered by us in a subject in itself, in its entirety. That is all I have to say.

CHAIRMAN OPP: Of course we cannot live unless we grow. The world does not stop; no part of it stops; and of course the growth of your section in membership is a very important feature, so it gives me very great pleasure to introduce the man who is responsible for the splendid growth of the membership of the organization in the past year, Mr. F. S. Armstrong of the Central Illinois Public Service Company, Springfield, Illinois.

Report of the Membership Committee

I am not responsible for the Section's growth in the least. I have written a good many letters, but the Utilities Regional Membership Committees and Mr. Opp are the ones who are responsible. I have had splendid cooperation from the Regional Committees, and if it had not been for them I don't know what we would have done. We would probably have suffered a loss.

It seems to me that if the safety story is worth listening to, or worth talking about, that everyone who is interested in it should be a member of the National Safety Council.

I should judge from glancing over this audience that there are about 400 or 500 men here. Now, why can't you, each one of you, appoint yourself a committee of one to get another member for the National Safety Council during the coming year? If you have any hesitancy in approaching anyone to join, let me suggest that you write to the chairman of the Membership Committee, or to the chairman of the Utilities Section, and if he is a live prospect at all, we will get him in.

I appreciate the work and the assistance that the regional committeemen have given during the past year, and at the close, or some time during this meeting, I would be very much pleased if any of them are here. If you would come to me and introduce yourselves so that I may know you personally.

Letters are cold things. We need to get our hearts against each other, so that we may know each other.

Now as to the new companies that have joined our membership, as I read the names, if there is anyone from those companies representing them here. I wish they would please arise so that we may all know them.

 Hilo Gas Company, Ltd., Hilo, Hawaii, Frank Wilson, Mgr.
 Porto Rico Irrigation Service, Guayama, Porto Rico, A. Lucchetti, Chief Engr.

The summary of all figures shows an increase in the Section by new members during the year of 35. Cancellations of membership were 12. The net gain in membership therefore totals 23.

F. S. ARMSTRONG, Chairman.

CHAIRMAN OPP: We have had in mind for some years the idea of introducing new members, but it has not been practical. We are very happy to have had the response made by these new companies in sending their delegates to the Congress.

The Membership Committee's work might be elaborated on a little bit more in connection with the fact that Mr. Armstrong has taken rather seriously the fact that 12 companies have retired from our membership this year. But just to console Mr. Armstrong, let me say, those 12 companies had a total number of employees of 2,189, and of that number over 1,700 were taken back in to the Utilities Section by reason of consolidation with bigger companies. So our net loss is small.

On the other hand, the new members constitute companies with from 30 employees up to 3,000, in two cases, so the additional number of new employees added this year is 12,505. It has made a net increase of 23 members and 10,316 employees.

Report of the Past Chairman on Plants Visits

Now we have, as a member of the organization, the chairman of the previous year. He is known as the "Past Chairman." I do not like the term. It sounds too much like a "has been," and in the present case I am going to call that officer the "Present Chairman of Last Year," so as to get away from that particular inference. It is a pleasure to call on Mr. McCulloch, who will now give us the details of the arrangements he has made so splendidly at the Chicago end for the reception of this Congress.

B. B. McCULLOCH (Secretary, Bureau of Safety, Chicago, Ill.): Mr. Opp has told you how well each member of the sectional committee and each of the officers

of the section handled his work during the past year; the result has been that there was very little for the past chairman to handle. For that reason, and the fact it is already late, and we have quite a program to take care of, I am not going to attempt to make any report on any activities I may have been connected with during the past year. But I do want to take just a minute or two to make an announcement of what has grown to be one of the features of the Annual Congress, and that is the annual plant visits.

I do not think there is any other section in the Council that takes as much interest in these plant visits as is shown in the Public Utilities Section.

This year we have made arrangements to visit four plants; that is, you have your choice of any one of the four visits. They will be made Thursday afternoon at the same time, 2:30 p. m. I will read the list.

Chicago By-Products Coke Company Plant

You are invited to inspect the plant of the Chicago By-Product Coke Company, at 39th Street and Crawford Avenue, on Thursday afternoon, September 29. Busses will leave the Stevens Hotel at 2:15 P. M.

This is a combination coal and water gas plant covering about 175 acres of a 600 acre track.

Coal gas is produced in 110 ovens which have a rated capacity of 24 million cubic feet daily. The by-product coke is supplied as required to the eleven foot water sets of which there are nine with a rated capacity of 30 million cubic feet. Total rate of gas production is therefore 54 million cubic feet per day.

Guides will explain the details of construction operation, fuel storage and consumption, by-products and other interesting information.

Crawford Station—Commonwealth Edison Company

Largest station in the world, it has a capacity of 335,000 K.W.

The last unit installed has a capacity of 94,000 K.W. and is the largest single unit put into service up to the present time.

Covers a ground area of 72 acres.

Has a daily output of over 4,000,000 K.W. hours.

Which requires 2,800 tons or about 60 cars of coal a day.

Three hundred and seventy-five thousand gallons of river water are pumped each minute for condenser cooling water.

Coal cars are unloaded by a car dumper which completes the operation in less than three minutes.

Carried 185,000 tons of coal in storage at the plant at the beginning of the Coal Strike, April 1st—enough to carry us at normal loading for 10 weeks.

Energy transferred between our station and the other stations is done by cables laid underground and operating at 66,000 volts.

Construction work is in progress for the installation of No. 6 unit to be available August, 1928, and will have a capacity of 100,000 K.W., twice the capacity of our No. 1 unit installed only three years ago.

New Rapid Transit Shops, Niles Center, Illinois

When these shops are completed they will have cost approximately \$4,500,000. The ten separate units necessary to consolidate all the shops in one location will cover an area of five acres.

The first unit is the paint shop which is 200 by 224 feet in outside dimensions. The walls are of old English brick with cast stone trimming. This paint shop is modern in every particular and is considered the last word in paint shop construction and facilities.

Illinois Bell Telephone Company

More telephones are served from this office than are in use in such cities as Akron, Ohio; Birmingham, Alabama; Omaha, Nebraska; or Syracuse, New York.

Each day a half million telephone connections are handled through the office.

During the busy hour of the day the equipment cares for twenty calls each second.

In order to care for this volume of business 18,000 vertically moving rods are used in completing the calls, an average of three rods being used for each call. Each rod is approximately ten feet high and the size of a finger in thickness.

There are approximately 50 soldered connections in the average radio set. The equipment in this office has enough such connections to supply 140,000 radio sets.

The ordinary radio "A" battery will supply 1 ampere of current for 80 hours. The storage batteries at State-Central office would supply this amount of current for over four years.

While the radio set uses 2 amperes of current, the equipment in this office at busy periods requires as much as 3,600 amperes.

Equipment Housed in State-Central Office

Number of subscribers' lines served.....	16,112
Number of subscribers' stations served	41,726
Total number of calls handled per day.....	520,089
Maximum number of calls during the busy hour.....	73,377
Number of soldered connections	5,000,000
Number of selector rods	18,000
Weight of solution in battery tanks—tons.....	55
Number of plates in batteries	2,736
Capacity of 24 volt battery in ampere hours.....	36,000

MR. McCULLOCH: If any member desires to visit any other industrial plant here, if he will make his desire known we will make the arrangements for him to visit the plant.

CHAIRMAN OPP: It is fine to have this reception, and I trust all of the delegates will avail themselves of one of these four proposed visits, in addition to any others that they may care to make.

The next committee which we are supposed to hear from is that of the Engineering Committee; unfortunately Mr. C. R. Beardsley of the Brooklyn Edison Company, Brooklyn, who has been doing wonderful work in that capacity is unable to attend, and he has written his regrets. We are sincerely sorry that he cannot be with us to participate in the program which he helped to prepare.

It is the prerogative of the chairman to make certain suggestions to the incoming Executive Committee. It is to secure, if possible, an intensified interest in safety work, and the most effective safety work, in the Public Utilities Section, by the various methods available.

One of the most constructive of these, it seems to me, is the taking of a Congress like that assembled here today to the doorsteps of the various members, if it is possible, and it can be done to a limited extent by means of regional conferences or regional safety meetings.

Last year we had a wonderful series of these meetings, beginning at Grand Rapids on March 21 and 22, Kansas City, April 13, 14 and 15, both of them wonderfully attended meetings—Newark, New Jersey, April 27, in which our Engineering Representative, Mr. Beardsley, participated; Sheboygan, Wisconsin, June 14, in which your chairman had the pleasure of participating; and the Michigan Industrial Safety Congress, June 28, 29 and 30, in which we gave active participation; and

down at Blue Ridge, Asheville, North Carolina, August 5, 6 and 7 in which your chairman had several assignments to handle on the splendid program.

Now we want a wide diversity in the holding of these regional conferences this coming year. We want your participation in them. If you have any suggestions to make to your various committee chairmen as to the selection of a location be sure to let us have those suggestions.

If, perchance, a regional meeting comes to your vicinity, get out as big a representation of delegates as possible. It is a wonderful way of introducing the National Safety Council to those who are not yet members of the organization, to take advantage of the meetings, and especially for those various members who, due to distance, or due to vacation periods, or due to many other excuses given in the numerous letters of regret, doubtless are unable to attend today; so it is my sincere wish that you participate in the regional meetings, whenever and wherever held.

Another suggestion to the members of the Executive Committee is that they by all means retain the chairman of the Membership Committee of the past year. His work bespeaks his merit.

The next item is a matter that has given me keen pleasure. Last year, as an innovation, as a much desired move to broaden our activities and interests, we started to increase the official family by the addition of so-called Councilors. And good Councilors they have been, every one of them participating with utmost diligence and earnestness, not only in the correspondence that has of necessity radiated from them, but also by active participation in our meetings, and my next recommendation is that the Councilors be retained by the incoming officers.

These councilors, for the year (unfortunately they are not all here today), are none other than our good friends Mr. Charles B. Scott, Mr. H. W. Moses, Mr. J. C. Hubbard, Mr. H. M. Webber, Mr. B. Frank Day and Mr. Herman Spoehrer. Have you a word to bring, Mr. Stiver, from Mr. Spoehrer?

Progress Through the Cooperation of All

E. B. STIVER (Safety Director, Union Electric Light & Power Company, St. Louis, Mo.): Nothing more than the letter he wrote you indicating that he could not be here, and setting out the information that he desired. I think he made it a point during the past year as to any questions brought up by you to take special pains to answer them, and help the Executive Committee in planning out its safety features.

CHAIRMAN OPP: That is splendid. It is much better to have it said from the floor than to have me read it, knowing his active participation in the affairs of the Council. I know it is a matter which requires his most personal attention that keeps him away from here today.

Mr. C. E. Morrison of New York was the final member of our Board of Councilors.

Now, for the sad words: It has been a year of intense pleasure, and one of fulfilling of desires on the part of those who want to do something definite and something concrete for the Public Utilities Section; and although it may be with somewhat of a sense of pride that those things have been accomplished, it nevertheless is fully deserved pride, I believe. The participation of all of the officers this past year has been an inspiration for one to do the utmost that is in him, and if there is any success attached to this Congress it belongs to all of the officers of the sections, the committee chairmen, the councilors, and all those individuals who, from the outset of the organization of the official family itself, have come in with valuable contributions. To each and everyone of those I extend my sincerest thanks. I wish to express thanks for the happy cooperation existing with the American Gas Association, the National Electric Light Association, the National Fire Prevention Association, the American Institute of Electrical Engineers and the Society of Indus-

trial Engineers with all of whom we have had very pleasant personal relations during the past year.

This morning's program was prepared not by a single individual. This time we have had no Program Committee Chairman sitting up burning the midnight oil, framing up something that he thought might be of interest to you, but we have solicited suggestions from the organization at large. We have had two entire sessions of our Executive Committee devoted to nothing but program topics, and then selecting the topmost speakers to present the points that we thought would be of most interest to you. So this program is not the result of any one man's effort, but is the composite work of your official family endeavoring to give you the very best there is in accident prevention. And certainly there is nothing that could be better than the first topic assigned on this program, and when it is presented by that most pleasing personality, Mr. Charles B. Scott, it is no wonder we have this attendance here this morning.

Qualifications and Work of the Safety Director

Charles B. Scott, Bureau of Safety, Chicago, Ill.

An ambitious committee, ardently interested in the cause of accident prevention, has requested the portrayal of the most suitable type of man and an outline of the most effective procedure for the safety director of a public utility. With respectful appreciation of the implied compliment, there comes a realization of the audacity of this attempt. The vocation and work are too new and undeveloped for that complete knowledge necessary in the formulation of practical and valuable conclusions either as to the measure of the man or the specifications for his work. Fortunately our Annual Congresses present a forum where, unashamed and without apology, we may freely and frankly relate our experiences and express our personal opinions. Such custom may make this talk pardonable.

The success of all human endeavor is dependent upon the competency and devotion of those charged with the responsibility of the undertaking. Many worthy projects have wholly or partially failed because of this; hence the importance of the right man for the job. In industry there is no more difficult task than the proper selection and placement of workers. Misfits are responsible for much woe and the slowing up of progress. It is not the purpose of this presentation, however, to deal with the general subject of human efficiencies and shortcomings. This problem has ever been with us and will be with those who are to follow. Any venturesome comment as to ways and means for selecting men of fitness and ability in industry or elsewhere is likely to be of questionable value. This may be true of comments designed for the selection of a single safety director.

There are preferred types of individuals for almost every vocation (if ideal types cannot be secured) and there are men with certain endowments that fit them for the position of safety director or safety engineer. Years of experience may justify reference to some of the more outstanding qualifications desired in one who is to make accident prevention his business.

Delight in work and pride in accomplishment are potent influences for success. This is especially true in the comparatively new vocation of safety director. Herein lies the fundamental and most essential qualification of the man best fitted for safety work. The desire to conserve life and to make the lives of others better and happier is the most effective stimulant in accident prevention activity. Safety workers with this incentive are more successful than others with a materialistic view prompted only by the economic results of their efforts. The safety director should possess and cultivate an agreeable personality and

those qualities favorable to personal influence. These serve well in the educational work constituting such a considerable proportion of the safety job.

It is of the utmost importance that the safety director shall have an appreciation of his position in its relationship to the operating organization. There are few, if any of us, who would not resent having some one, supposedly an expert, come into our immediate organization for the purpose of making adjustments therein designed for its greater efficiency. It is but natural for the man who has spent years in developing the plans and personnel of which he is in charge to believe his methods for carrying on his work are nearly or quite above just criticism. He, more than anyone else, knows the qualifications and shortcomings of the men associated with him. He is familiar with the hazards of machinery and other property and with the measures he considers advisable to overcome these hazards. To have some delegated one step into such a situation with a view of making innovations and changes in personnel, practices or machinery is quite apt to prove irritating. This relationship between the safety and operating departments requires tactful handling by the safety director. A tactless man cannot possibly secure and maintain the cooperation of the operating forces, and particularly is this true with respect to the supervisory operating forces.

Technical Knowledge of the Work Necessary

The safety director must not only have a fair understanding of human nature and its relationship to his work, but he must also have knowledge of the work he is trying to make safe. In order to take such steps as will make the performance of any class of work safe, the director must carefully and fully inform himself as to the details of certain operating technique. He cannot otherwise properly discuss the subject with those who are familiar with and engaged in the work. No doubt many failures in accident prevention can be attributed in part at least to lack of knowledge by the safety director as to the working operation he is trying to safeguard.

Summing up these needful qualifications for a safety director, we have the following:

He must be interested in and pleased with his work. He must be sincere and have faith in the results to be accomplished. He must have those qualities of heart, mind and conduct that insure respect and influence. He should have an appreciation of the relationship between his and the operating departments, and possess the tactfulness to overcome the difficulties presented by this relationship. He must know human nature and understand the work he is trying to make safe. These essentials, supplemented by diligence, patience, study and hard work will develop a most efficient safety director, save the lives of workers, and make him and them better and happier.

There are certain fundamental conditions that must be in evidence within the organization with which the safety director is connected. First in importance, his work must have the earnest and sympathetic support of the chief executive, a support that carries with it an appreciation of the needfulness of the efforts and faith in the results. The first task of the director is to establish the proper spirit toward accident prevention in the executive, his subordinates and the rank and file of employees. This represents the sowing period for the coming harvest and unless the most careful attention is given to the creation of a fertile and well planted soil, the reaping of a good harvest cannot be expected.

At this point in the progress of his work, the new safety director is confronted by a situation requiring the most careful thought and action. Much depends upon how he meets it and the program decided upon for his further activities. The director is justly pleased with his success so far and is at the peak of his

enthusiasm. His associates have confidence in his efforts and are in favor of immediately putting into effect an extensive organization and an elaborate and colorful series of stirring and attractive festivities under the guise of safety. The safety director should resist the temptation and inclination to do these things. The time calls for the most thoughtful preparation of organization and procedure and for earnest counsel and cooperation of executives, department heads and director in framing the plans to be followed. These plans must be sound, conservative and practical. They should provide for a simple safety organization with a minimum number of carefully selected members. They should be systematic and designed for continuous accident prevention and for that purpose only. If the probability of future changes is taken into consideration, the plans should be prepared so that afterward they may be made more elaborate instead of later curtailing them. To make the mistake of providing an inadequate organization and program is decidedly less harmful than to overdo these because the latter mistake is much more difficult to remedy. Time will not now permit detailed recommendations as to organization, the proper building of programs of activity and discussion on the many other important duties of the safety director. These features have already received much publicity and attention and are largely dependent upon the local conditions presented. Wise consideration of such conditions will determine most of these details.

The First Step Is in the Employment Office

In many operating companies diligent efforts have been made by efficient safety departments to employ every possible preventive measure for the minimizing of the number of accidents. These efforts have resulted in considerable progress in organized accident prevention. Certain plans, precautions and innovations have been successfully tried out in individual companies, about which the industry and safety directors generally are not informed. In order to give information as to the most effective of these developments, inquiries were addressed to a number of companies. The replies to some are herewith incorporated.

The following is quoted from the Rochester Gas & Electric Corporation, Rochester, New York: "The first step in accident prevention is in the employment office, with the proper selection of men for the job. Strong emphasis is placed on this, not only from the standpoint of securing and placing competent men, but the process carries through to the proper introduction of the new men to the job. In this company we conduct meetings of new employees where company policies, requirements and as much company atmosphere as possible are given to the new man. At these meetings the necessity of thoughtful and safe conduct is thoroughly emphasized. The next step in the progress of the new employee in which the safety director is interested is education on the job. This may require months or often years of training. Job education is conducted through job schools which are maintained by the company in various departments and through outside schools which have facilities for teaching subjects which are pertinent and necessary. Job training is prescribed for both the new and old employee where the need is indicated. We definitely locate responsibility for all operation, including accident prevention, with the operating superintendent where it belongs and make the safety director responsible for safety education in its broader sense and for an independent inspection service."

This same company makes these further important comments: "When serious accidents occur or accidents which by nature of their cause might have been serious, it is essential that the safety director have all the facts and present them at a meeting composed of the interested department heads, together with all the men who are familiar with the details, including the man who was in

charge of the work. The evidence thus presented is thoroughly discussed to the end that the necessary steps may be taken to eliminate so far as possible the recurrence of any similar accident."

The outstanding development in the accident prevention plans of the Commonwealth Edison Company, Chicago, during the past few years has been the fixing of departmental responsibility. This responsibility is not limited by the general conception of the term as applied to accidents, but includes responsibility for accident prevention work. The several departments of this company thoroughly appreciate and meet this broader responsibility and therefore take the initiative in lieu of the safety departments for planning the details of accident prevention involved in such matters as safe working practices, maintaining an interest in safety work, safety training of foremen and workmen, conducting safety meetings for employee groups, departmental committees and foremen. There has thus been established a definite and effective safety organization within each department, resulting in their continuous and diligent attention to all safety matters, particularly those applying to the work of the department. The results of these developed plans have been very satisfactory. This company reduced its lost time accidents 32 per cent in 1925 and made a further reduction of 18 per cent in 1926. The most noticeable improvement was in the street department, which showed a reduction of 40 per cent in 1926.

Each Injured Employee Is Personally Interviewed

The Edison Electric Illuminating Company of Boston, Massachusetts, follows the practice of having a representative of the safety department call upon and personally interview each injured employee as soon after the accident as seems advisable. These interviews are not only intended to show the company's regret for the accident and its interest in the injured employee, but also to secure the injured's opinion as to how the particular accident could have been prevented. This practice has resulted in establishing a better relationship between injured employees and the safety department and has brought out many valuable suggestions for the prevention of accidents. The Philadelphia Electric Company has substituted letters to the injured in lieu of such personal visits and this modified plan has also been satisfactory in lesser degree.

The Philadelphia Company, through its accident prevention department, emphasizes the importance of fire prevention and gives each individual employee a definite responsibility in this regard, with sufficient instructions with reference thereto. As a rule, safety departments are not sufficiently impressed with the importance of giving attention to fire prevention. This company also maintains an intensive program wherein all employees report unsafe conditions of the company's property or equipment. "This practice," says the company's safety director, "has a tendency to educate all classes of employees and make them individual safety inspectors."

Studies made by the Brooklyn Edison Company, Inc., of Brooklyn, New York, convinced the executives that the physical and mental condition of employees after excessive overtime work was quite conducive to accidents. Frequency was found decidedly greater on the overtime jobs. About three years ago an executive order restricted overtime in all departments and prohibited it in a few. In those departments having to do with physical processes in which it was practically impossible to eliminate it entirely, overtime was limited to an annual gross per person of 10 per cent. At first this was allowed to be consumed all in a short period. Later the 10 per cent limit was applied as a monthly check—that is, if a man works 200 hours normally per month, he may in addition work 20 actual overtime hours. Each request for permission to work overtime is carefully scrutinized for validity of reason. The average overtime for all de-

partments is now about 1 per cent. Each department's weekly return is tabulated and scanned by the executive. Coincident with this reduction of overtime and in part it is thought due to it, there has been a marked reduction in number of accidents. Greatest reductions occurred in the group which achieved greatest reduction in overtime, although that department had been by no means the greatest offender in frequency.

The West Penn Power Company of Pittsburgh provides special arrangements for accident prevention on jobs involving particularly hazardous work. These special arrangements are as follows: Each gang is provided with a safety guard selected from the men in the gang. It is the first duty of this guard to think, talk and plan safety methods and the foreman allows him such time as can be properly devoted to safety work. It is understood that he is not to leave the gang and that at any time he is not busy on safety work he will be engaged in his regular duties. The foreman appoints the safety guard to serve for one week until every man in the gang has thus served and then repeats the procedure.

There is no single phase of accident prevention work that can be relied upon to cure all of the evils of hazardous work and thoughtless performance by employees; nor is there any royal road to success that pioneers might point out to the new safety director. Like the other vocations, this comparatively new one requires much thought, ingenuity and hard work, and these must be carried on unceasingly. No one man is sufficiently equipped with wisdom and experience to perform the task by relying entirely upon his own efforts. Be he ever so well qualified he must have the sincere interest and hearty cooperation of all the men with whose safety he is concerned. Above everything else there must be maintained an earnest appreciation of individual responsibility throughout the entire organization, so inclusive as to take in every executive, supervisor and worker. The task of the safety director is one that will be found difficult but worthwhile, requiring ever present patience, diligence and faith, with a clear conception of human relationships and the true purposes of life in its higher and proper sense.

There is a Cause for Backsliding

I want to say in closing, and with the utmost earnestness and seriousness. I believe that there has been a backward swing in the progress of safety work. I believe that we have not made the progress that we should have made considering the time and money that have been devoted to the work; and I think there is a cause for this. I believe that safety directors have magnified the engineering side of accident prevention, and have sacrificed efforts that in the beginning were devoted to the human side of our industry. Therefore at this Congress I want to throw out a warning to safety men, of the peril of forgetting what was once the fundamental factor of accident prevention. There is no one other thing that will solve our problem, and in emphasizing this I am not losing sight of the importance of other things. But until you secure an appreciation from each workman of what safety means to the man himself and to his family, and until you get him to know that he is the most interested one in the cause for which you are working, you will never get anywhere in accident prevention. As for me and my household, we are going to go back and do some of the things that we have neglected. An understanding of human relationship, and an understanding of the purposes of life on the part of the safety director are the things that will enable him to accomplish his work.

Yesterday morning I heard another speaker say, "When you are selling a piano do not sell the piano, sell music; when you are selling an automobile, do not sell

an automobile, sell the great outdoors." How true that is! How much better is that plan than trying to sell the cold machine.

In selling safety, don't sell safety, don't sell printed posters and rules, supervision and safeguards; sell the conservation of life, sell human happiness, sell prosperity, sell a better employment relation and happiness, and all those things that go with safety work.

A true conception of safety in this way, an earnest heart, a love for man, diligent, hard work, square dealing, good character—these all combined will bring to you success in safety work.

CHAIRMAN OPP: Now we are going to get the executive side of the story, and it is going to be presented by no less a personage than Mr. Frank W. Smith, vice-president of the United Electric Light & Power Company, New York City.

Ways and Means of Impressing Executives and Operating and Designing Engineers

Frank W. Smith, Vice-President and General Manager, The United Electric Light and Power Company, New York City

The topic assigned to me would seem to carry the implication that some executives need to be sold on the "Safety Idea"; that they are not now sufficiently interested in the movement which has brought together today thousands of men who are devoting a large part of their time—some of you 100 per cent of your time—to the business of accident prevention.

There is no doubt of the interest in safety, the humanitarian interest in the protection of life and limb, held by all of us and by the greater number of industrial executives who have not been able to attend this Sixteenth Annual Safety Congress. The real question is: "Mr. Executive, what are you *doing* about it?" Are you merely authorizing safety work and approving vouchers for the expense involved, or are you personally getting right on the firing line with your safety engineers, your superintendents and managers, and helping them carry on the fight with your own personal efforts as well as your signature and your sympathetic interest?

An example of this practical type of interest in the safety movement was shown at the last safety rally of the Metropolitan Section of the National Electric Light Association held in New York City. This division of the association is made up of several thousand employees of the local electrical utility companies in greater New York. At this meeting there were present chief executive officers of nearly every one of the utilities in the district—presidents, vice-presidents and general managers. Many of them spoke, others encouraged the safety committees and employees by their presence and cooperation. There were more than 3,000 employees present at this rally and for "safety" the police were obliged to close the doors before the meeting could be gotten under way. This explanation is made because I do not wish, in the remarks that follow, to be understood as implying that on the whole the executives of the utilities are not actively interested in safety.

Since the earliest days of the safety movement it has been axiomatic that to succeed in any permanent campaign for the prevention of accidents it is first necessary to sell the safety idea to "the big boss" or, as we are more likely to say today, to the chief operating official. It was recognized at the start and it is just as true today that the safety spirit must saturate an industrial concern or a public utility from the top down; that the rank and file of employees, foremen, superintendents and even higher plant officials would not do their best

to prevent accidents unless they were sure that the top man was thoroughly sold on the idea.

And so from the earliest days of the movement professional safety men and others interested in the subject have made speeches and written papers on how to create and maintain the executive's interest in accident prevention. Undoubtedly hundreds of addresses have been made on the subject, many of them inspiring addresses, but largely they have sung the same song: "Show him it **PAYS** to prevent accidents"; "Convince him it is cheaper to **PREVENT** accidents than to *pay* for them"; "Prove the economic soundness of accident prevention"; scores of titles, but all using the same technique.

Now with your permission the speaker will depart from this technique, for it is his belief that the dollars and cents value of the safety movement has been very much overdone. Granted that money invested in accident prevention will—when the work is carried on in a thoroughly organized and efficient manner—yield a fair return on the investment; and let us go further and accept the statement, often made, that certain companies have secured a higher percentage of return on the money invested in safety work than on the investment in manufacturing equipment. Still I venture the opinion that it is a mistake to concentrate on the economic value of accident prevention in trying to interest executives.

Characteristics of the Executive

Let us examine for a moment this unusual species of man known as "the executive" or "the big boss," sometimes endowed also with such adjectives as "hard-boiled," "cold-blooded," "hard-to-sell," or just plain "stubborn," who, some seem to think, must have his interest in the saving of human life and limb created in some special mysterious manner. As a matter of fact, your executive usually has a wife and children; he probably plays golf (let us hope he does) or he is interested in some other attractive and health-giving, out-door sport. He has, or he ought to have, a sense of humor and enjoys a good story; sheds a tear in the theater now and then, and eventually goes the way of all flesh. In other words, the executive is usually an ordinary human being with the same warm blood, the same emotions, the same love of life and the same aversion to suffering and premature death—both for himself and the other fellow—that all human beings have.

Yet we too often try to interest such a man in the saving of human life wholly on the strength of the dollars and cents value of safety.

I have in mind an incident which illustrates the point I am trying to make—that the legend of the big industrial executive as essentially a cold-blooded business man is fictitious. Several years ago there was undertaken in New York City a campaign to demonstrate, through one week's intensive effort, that radical reductions in accidents—both public and industrial—were possible even in the rush and bustle of the biggest city in the world. The leaders of this movement felt that its success depended on their ability to secure the sponsorship of an outstanding man whose identification with the campaign would bring the interest and support of the entire community of seven million people. And so Judge Elbert H. Gary, chief executive of the United States Steel Corporation and one of the founders of the safety movement, was asked to head the campaign, which he consented to do.

Judge Gary, in whose death, a few weeks ago, the nation and the whole world lost one of its outstanding men, was at that time 75 years old and was personally directing the biggest business enterprise the world has ever seen. Because of these two facts and the further fact that for many years Judge Gary had

confined his public addresses to the annual meetings of the Iron and Steel Institute, the delegation (headed by Arthur Williams, vice-president, commercial relations, of the New York Edison Co., and president of the American Museum of Safety), which persuaded him to accept the chairmanship of the Safety Week campaign did so with the understanding that he would not be expected to make more than one speech during the week, that on the opening day of the campaign.

Well, to cut the story short, the Judge so warmed up to his subject in that first speech, he was so impressed with needless waste of human life through accidents still going on 20 years after the start of the safety movement, that he made, not one speech during the week, but more than a dozen. He spoke twice a day in widely separated parts of greater New York, and, if I am correctly informed, made three addresses on one day. Incidentally, the dollars and cents value of safety was not even mentioned in this great conference to help put public safety on the map.

Judge Gary Spoke on Accident Prevention

We have heard it repeatedly stated that the Steel Corporation has spent millions of dollars for safety and has made millions of dollars upon this investment. The late Judge Gary had repeatedly made public utterances concerning the corporation's interest in safety as a good business proposition, wholly aside from its humanitarian aspects, but the most significant statement concerning both the economic and humanitarian value of this great work that I have ever seen comes also from the pen of Judge Gary; in fact, from his last published statement. I quote from the current issue of "Coal Age," in which Judge Gary said:

"During the last fifteen years we have spent upward of \$170,000,000 for safety, sanitation and employee welfare activities. These expenditures have been fully justified. They have been more than recovered in dollars and cents. But of far more importance than the recovery of the expenditures, the happiness and gratification resulting to our many thousands of employees and their families, as well as to the management, through good health and safety of life and limb, have been beyond computation, beyond any measure in dollars and cents."

It is time we stopped thinking of chief executives, chief engineers, and other high supervisory officials primarily as cold-blooded men who are influenced in their business decisions only by logic, statistics, or financial considerations. Of course, it would be just as bad to go to the other extreme and assume that they are sentimentalists and can through mere "sob stuff" be made as vitally interested in safety as in the business or profession to which they have devoted their lives. But is there not a middle ground?

There can be no doubt that most executives appreciate their personal responsibility for the welfare of the men and women making up their organizations. I believe it means much more to an executive to hear that John Smith has lost an arm or an eye than it does to hear that the company has lost a sum of money through such injury. And I am sure it means much more to any general manager to be told that "we didn't kill or seriously injure a single employee" than to hear that so many thousands of dollars have been saved in compensation costs or insurance premiums.

There is another, and important, reason for using something, other than the dollar and cents technique in trying to interest executives, not already so interested, in safety (if there be any such). I refer to the fact that it is impossible to measure the value of human life in terms of dollars. Suppose, for instance,

a certain young employee of the General Electric Company, who was later to be known the world over as "that wizard Steinmetz," had been killed in a shop accident. Could any of you tell the General Electric Company or the electrical industry as a whole what the accident cost the company and the country? Or, if you think you are good at figures, estimate the dollars and cents cost of an accident that would have taken Thomas Edison from us 40 years ago, or even now.

It may be true that there are not many potential Edisons or Steinmetzes among the men who are killed or permanently incapacitated through industrial accidents—and yet who knows?—but it is nevertheless impossible to measure accurately the real cost of such accidents, even when the victim is the most unpromising common laborer. First of all, to his own mother, wife, children and brothers or sisters, he is as dear as the man in the most exalted position. But wholly aside from that and aside from the cost of accidents in terms of compensation, which is too frequently referred to as the total cost, there are incidental costs which it has been difficult to measure accurately, and which probably greatly exceed all the figures that have thus far been used to estimate the loss to industry, to the workmen themselves, and to the nation, resulting from preventable accidents.

Some of the Incidental Costs of Accidents

Here is a list of the incidental costs of accidents recently compiled by one of the leading insurance companies in the country:

- 1—Lost time of injured person
- 2—Lost time of other employees
 - a—out of curiosity,
 - b—out of sympathy,
 - c—assisting injured,
 - d—through shattered nerves.
- 3—Time lost by foreman—
 - a—assisting injured employees,
 - b—investigating cause of accident,
 - c—arranging for injured persons to be done by others,
 - d—selecting, training, breaking in new employees,
 - e—giving information for state reports or attending hearings before the industrial commission.
- 4—Time spent on case by first aid and hospital staff
- 5—Injury to machinery or spoilage of material
- 6—Interference with production
- 7—Cost of continuing wages in full when injured employee returns to work after recovery, even though his work may be only 50 to 75 per cent of normal value.
- 8—Loss of profit on injured employee's productivity.

The person who prepared this list adds as a ninth item the question: "What would you count the cost if you lost one or two of YOUR fingers?"

It should of course be borne in mind that this is only a partial list of the incidental costs; that it does not include compensation costs, or the cost of medical staffs and hospitals. There seems no doubt that if it were possible to gauge accurately these incidental costs it would be found that they are greater than the compensation costs of accidents which are now often erroneously referred to as the total cost.

The remarks thus far made would seem to be devoted in large measure to "How *not* to sell the safety idea to executives and operating officials," and

perhaps an apology is due those in attendance at this meeting, in view of the title of my subject, for having stressed this point. The speaker believes, however, that when it is recognized that executives are interested in, and influenced by, considerations other than financial, the most desirable method of getting executives interested in safety, and keeping them interested, will be developed by a study of the particular man and the situation within the particular property. There is no one best way of selling the safety idea to executives, because executives, no more than other human beings (thank Heaven!), are not yet standardized.

There seem to be, however, certain considerations which should appeal to operating officials and other executives of public utility companies. The person interested in converting an executive in this industry to a firmer belief in the value of thorough-going safety work might do well to take these special considerations into account.

A Sense of Obligation Among Public Utility Men

First among these is the sense of obligation for the safety and welfare of the public which utility men probably possess to a greater degree than executives of other industries, because life and health are directly dependent upon their services. The continuity of service—whether it be gas, electricity, water, telephone or transportation—is the first consideration of every official and every conscientious employee of a public utility, simply because it is recognized that a break in the service may result in death or injury, as well as inconvenience to some in the community. It is not necessary to dwell on this because it is in the blood of all public utility men: and if it is true, as it certainly is true, that "a public utility is a business affected with a public interest," it is equally true that the first and foremost argument in favor of the utmost safety precautions in a utility is the PUBLIC INTEREST IN THE SAFETY OF THE UTILITY WORKMEN. The community is not protected against a break in the service or against accidents to the public unless the employees of the utility are working under the safest conditions, and with a spirit that can be engendered in the employees only if the company is saturated with this spirit of safety from the top down.

Let me give you an example of this sense of obligation to the public. In the company which I have the honor to represent, and, in fact, in the entire group of companies affiliated under the parentage of the Consolidated Gas Company of New York, every employee, both male and female, from the office boy to the president of the company, some 33,000 in number, has been instructed in and examined for proficiency in the prone pressure method of resuscitation. This work is being intensively carried on, not because the office workers or sales force or the executives are in any particular danger of electric shock or gas asphyxiation, but because it is believed that by having every employee in our companies instructed in this method of resuscitation, we are reducing throughout the community the chances of accidents and death to the public at large. We have a large number of cases annually where lives are saved to the general public from accidents entirely apart from the operations of our own business, such as drowning, etc.

The second special consideration upon which we might seek the interest of the utility man (not already sincerely interested in safety)—and again, I say, if there be any such—is the fact that our industries are *not inherently hazardous*. This is another way of saying that most accidents in our field are preventable. There was a time, not so long ago, when the steel industry was listed as extra-hazardous by insurance companies and others because it was

thought that many of the fatalities in this industry were unavoidable, that they were legitimate risks of the trade, inherent to the industry, but now men have revised their opinions and the steel industry is no longer classed as an extra-hazardous industry.

As a matter of fact, there are now comparatively few really inherent or unavoidable hazards, and it is the writer's belief that those executives in our field of endeavor who are not now as interested in safety work as they should be, are laboring under the impression that "accidents are going to happen anyway, and you cannot prevent them." Concentrate on convincing such an one that "It can be done" rather than on how much money he will save if it is done.

Finally, having impressed the executive with the fact that his interest in the safety of the community and his interest in good public relations should presuppose the most thoroughgoing safety work on his properties; having impressed on him—with the substantial evidence available—the fact that ACCIDENTS IN THIS INDUSTRY CAN BE LARGELY PREVENTED, go back to my original premise that the executive is also a human being and show him his opportunity, not to save money, but to save men, fathers, brothers and sons.

Try to Understand What Safety Really Means

In a recent editorial in the *New York Telegram*, commenting on the report of the New York State Department of Labor, and following the statement that "measured in accidents to workers, the high cost of industry appears to be climbing," the editorial continues:

"One trouble with reports like this is that we learn of these injuries and deaths in figures, and figures are cold and dryly statistical. If we could go into the hospitals and homes and see broken heads, stubs of arms and legs, sightless eyes, saddened wives, widows and orphans, and the hopelessness of humanity in stricken homes, we could understand better what the figures mean. Try to connect the figures with American homes when you read the statement of facts and figures in the report. * * * Those of us who have two arms, two legs, two eyes and a full complement of fingers and thumbs might well pause a moment to think something of this part of the high cost of comfort."

This comment on the part of the public press brings out the point that I am trying to make, and throughout these scattered remarks the human rather than the economic side of safety has been stressed. From the economic side, the accomplishment has been great, but there is evidence to show that there is still much to be done, and it is not impracticable to estimate that this further decrease in the economic loss could be made a billion and a half dollars annually in both public and industrial accidents, a figure which would represent not only a tremendous economic gain, but, what is far more important, saving in happiness and lessening of hardship in American homes and families. It is this last humane saving that should be the inspiration of all who are interested and to all actively engaged in this safety movement, which after all is one of both brain and heart.

CHAIRMAN OPP: Mr. Smith is the past president, not only of the local section of the Metropolitan National Electric Light Association, but also past president of the National Electric Light Association itself, so it has been indeed a very happy combination in which we worked. We certainly do appreciate very much the happy cooperation of the National Electric Light Association, and particularly are grateful to Mr. Smith for coming over from New York to give us this splendid paper on which Mr. S. C. Mumford, Treasurer and Chairman of the Safety Committee of the Detroit Edison Company, is going to open the discussion.

Discussion of Mr. Smith's Paper

S. C. Mumford, Safety Director, Detroit Edison Company, Detroit, Mich.

Executives, like the Gaul of Cæsar's time, may be divided into three parts:

1. Those who are vitally interested in the safety of the employees serving under them, and who insist that everything humanly possible be done to prevent the occurrence, or reoccurrence of accidents.
2. Those who are interested, but not very well informed, and with the attitude of "let George do it."
3. Those who have little, if any, interest in any safety program, and only do what the law requires.

In his refreshing talk Mr. Smith refers principally to executives of large utility or industrial corporations. I agree with him that all of them are men of heart as well as brains, but they do differ in their degree of interest and activity. The question is, in motor language: How can they all be brought to "hit on all cylinders."

Those who have immediate charge of the safety program should keep the executive informed by comparative charts or records, in more or less detail, showing all lost time accidents; primary causes; carelessness of employees, or fellow-employees; defects in equipment; lack of safeguards, et al. Also lost time, cost to the company (direct or indirect), and cost to the employees. This should be supplemented by periodical reports showing the nature of the injuries suffered by the men, whether fatal, or to head, arms, legs, or body, in other words present the "butcher's bill." Likewise the percentage of decrease in efficiency of those who continue to work for the company or other employers down to those totally disabled. This should arouse or maintain the interest of any human being.

The executive should keep his finger on the pulse of the safety movement by periodical meetings with his accident prevention committee superintendents, and principal foremen, both operating and construction. Such displays of interest and cooperation would have effect far beyond any sporadic efforts on his part, at occasional specially staged safety drives.

Executives of small companies are not yet enlisted as they should be for safety. Splendid as the record of the National Safety Council has been, the work of bringing the lesser organizations into the local councils has only begun. Such executives must be shown very clearly that it is a matter of dollars and cents. Analyses of the true costs, direct and indirect, may gradually be supplied him by industrious locals, to convert him to spend money (often his own, as he is usually the largest stockholder) for accident prevention, and to spend some of his own time in directing the work himself. Of course, the local council may help impress him by writing him to send his foreman to foremen's meetings, where the safety idea is contagious. Later the "old man" himself may be brought into the fold.

CHAIRMAN OFF: We will have just a word in addition from Mr. John Price Jackson of the New York Edison Company, New York City.

MR. JACKSON: I am very glad to have the opportunity of congratulating the chairman of the Executive Committee in picking out Mr. Smith to bring us the message from the executives. Mr. Smith, in addition to being one of the former presidents of the National Electric Light Association and following up the subject of safety generally, is manager of one of the dozen largest electric light and power companies in the United States, and chairman of the board of another one nearly as large, and he holds many important positions of other kinds. He is I presume, a man who, in New York City, and all over the country, would be selected as a typical executive.

We all feel the difficulty of dealing with the executive, but I think the message

he brought us today is one which could go down as a slogan and as one of the best messages that could be received by this great group; namely, that after all, the chief executive is just an ordinary human being; secondly that the chief executive is interested in his nation, his community and in his own employees as a humanitarian matter first and foremost; and thirdly that he is also a good sound man who must make ends meet in order that he may meet his payroll and other expenses. I believe, Mr. Chairman, you have gotten a very fine message today.

I tried to make a resume of what I believe is Mr. Smith's talk. I believe you made a great killing, if I may use that word, in obtaining a man of Mr. Smith's standing, to give us a message so clearly and to the point.

If we are going to get our executives to lead in this safety movement we must feel that we have to deal with them as human beings, and also as successful and sensible business men.

CHAIRMAN OPP: Mr. Smith, I want to thank you for the Executive Committee for presenting the paper, and you, Mr. Mumford, and you, Mr. Jackson, for your comments in addition to the paper.

The next item on the program is a very important one. We are going, now, to receive the report of the Nominating Committee for the officers for the ensuing year. The Nominating Committee is made up of Messrs. Charles B. Scott, H. B. Harmer, and H. M. Webber.

Mr. Scott will make that report.

CHARLES B. SCOTT: Your Nominating Committee begs leave to submit the following nominations for officers of this section for the ensuing year.

Report of the Nominating Committee

Chairman, Carl J. Rutland, Texas Power & Light Co., Dallas, Texas.

Vice-Chairman (Electric Interests), W. R. Loyd, Alabama Power Co., Birmingham, Ala.

Vice-Chairman (Gas Interests), Ivan L. Scott, Wisconsin Power & Light Co., Madison, Wis.

Vice-Chairman (Telephone & Telegraph Interests), H. L. Meade, Ohio Bell Telephone Co., Cleveland, Ohio.

Secretary, C. B. Boulet, Wisconsin Public Service Co., Milwaukee, Wis.

Submitted by the Nominating Committee:

MR. SCOTT: I move that the officers designated be selected.

(The motion was seconded and carried.)

CHAIRMAN OPP: The report stands approved. I thank you for your work, and you are now discharged.

We have a very unique delegate in attendance at this Congress. This unique personage is Miss Elizabeth Lee of Birmingham, Ala., a member of the National Accident Committee of the Electric Light Association, and a member of the Women's Committee of the National Electric Light Association. Miss Lee, we are happy to have you with us, and I trust you will participate in the rest of the discussions in these meetings.

I have here the number of delegates from each of the different states.

From Canada	6

Total from 24 States and Canada.....274

CHAIRMAN OPP: The next item on the program is going to be one of intense interest; one that I know is going to appeal to you very much. It is to be illustrated by a model. Speaking of models, we are to have one also on Thursday, a very unique exhibit. The model on Thursday is going to be a demonstration of the operation of an electrical system by an electric model. The model to day is one that ties in very closely with the work conducted by the National Electric Light Association Accident Prevention Committee, as the result of the questionnaire by Mr. Carl Rutland in connection with the unloading of poles from railroad cars. It will be given by Mr. W. H. Brown, Secretary General Safety Committee, Northern State Power Company, Minneapolis, Minn.

Rules for Unloading Poles

W. H. Brown, Secretary, General Safety Committee, Northern States Power Company, Minneapolis, Minn.

General:

The rules for unloading poles from cars herein provided, have been made in the interest of safety to all employees engaged in every phase of the handling of poles.

It is impracticable to include rules to meet all contingencies and employees in an emergency not provided for in these rules are expected to act under the instructions of the foreman.

Necessary time should be taken to determine where danger may exist.

When possible, unload the car in the same direction that the load leans.

It is absolutely necessary that these rules be understood before attempting to unload poles.

UNDER NO CIRCUMSTANCES ALLOW ANYONE ON TOP OF THE LOAD.

Preparing the Load:

Block car wheels foreward and aft to prevent movement of the car in either direction on the railroad track. ("A" Figure 1-2 & 7.)

Wedge four tight fitting blocks between railroad ties and car beam opposite the unloading side. One should be placed near each end of car, the other two spaced proportionally in the center to evenly distribute load. ("B" Figure 3-4 & 5.)

When car leans opposite the unload side it is advisable to add two additional wood braces, one at each end of the load ("BB" Figure 4), when same are available.

Provide wood skids for rolling poles from the car to ground or storage skidways. ("C" Figure 1-7 & 8.)

These are made using short poles or car stakes placed against the car, one end

Photo. P. S. #21 - (2055)

Figure 1. Illustrating the wooden skids.

level with the car deck, the other one on the ground. These skids to be reinforced by wedging cross timbers at intervals so that they are perfectly rigid.

Place stranded wire cables ("D" Figure 1) (not hemp cord) (approximately $\frac{3}{4}$ "), near each end of the load and fasten securely to the car truck chassis on the side to be unloaded. ("E" Figure 2.)

It is preferable to use a chain with hook on this end of the wire cable.

In case of a double load of poles, three cables should be used, the additional one being placed in the center. However, should only two cables be available, the car can be unloaded safely by placing the cables closer together being sure to catch both top and butts of poles.

Pass the cables "D" over the load near the inside stakes to the opposite side of the car; take out all the slack and wrap twice around the car truck chassis ("F" Figures 3 & 5), then twice around the bumper at the end of the car. ("G" Figure 5.)

Use in Pulling Hoist #21-12032 ✓

Figure 2. Block the car wheels fore and aft.

One man should hold the end of each cable until ready to pay-out the load, standing opposite to the side from which the load is to be released, and clear of the end of the load.

In case of a carload of poles where length requires a tender car as Figure 3 be sure man does not stand too close to load ("H" Figure 4) but far enough back to be entirely safe.

Secure a rope hand line at the top of stakes "J" to be used in an emergency should the stakes not break readily when the load is released.

If special wire cutters provided for unloading poles (Figure 6) are not available then an ordinary pair of bolt or wire cutters can be used ("K" Figure 5) fastening one handle securely in place on the stake attaching a hand line ("L" 5) to the other handle so that the top wire can be cut from safety when required.

Cut binding wires "M" and remove all inner stakes on the unloading side of car, leaving the two end stakes "J." (Figure 7.)

Figure 3. Secure the cables around the car truck.

Should an end stake be broken or frail leave the next nearest one.

Cut end stakes "J" about one-half way through on the unloading side of the car. ("N" Figure 7.)

Cut to be made just above stake holder and as close to car deck as possible.

Cut binding wires "R" on unloading side stakes "J."

Use special wire cutters provided, standing at a safe distance.

Sometimes poles are loaded having two intermediate wires between; in this case cut both of these wires at this time.

DO NOT CUT TOP BINDING WIRE "S."

UNDER NO CIRCUMSTANCES ALLOW WORKMEN ON TOP OF THE LOAD.

Releasing the Load:

Have special wire cutters provided in readiness to cut top binding wires "S" on

stakes "J" on the opposite side of unloading.

If special wire cutters (Figure 6) are not available and it is necessary to use ordinary wire or bolt cutters these should have been placed in position before cutting binding wires as instructed above.

Foreman shall inspect all conditions and be sure all men are clear.

Cut wire "S" on stakes "J" at both ends of car simultaneously.

Men should stand clear of the end of load and both wires "S" should be cut at the same time.

Work: Pull in Skid #21 - (2008) ✓

Figure 4. Add additional wood braces.

After the binding wires "S" are cut, the load will drop easily into the cable loops and the poles will remain parallel (Figure 8). Workmen holding ends of cables will then pay-out or slack off the load until the poles reach the skids. (Figure 9.)

When poles reach the skids (Figure 9), the cables are loosened and the poles rolled away.

Handling Poles:

Never apply pikes or cant hooks on the ground line portion of a Butt Treated pole. Part of the value of the treating application is lost if the ground line of the treated butt is injured or punctured.

Never apply pikes or cant hooks into the top of poles. Splitting of poles is likely to result, also holes are made allowing rain and moisture to get into the pole, causing decay.

Poles to be stored should always be placed on skids to prevent rotting.

Given: February 1911 #21-(2060) ✓

Figure 5. Be sure the man does not stand close to load.

MR. BROWN: We have these rules printed to show our employees who unload the poles what they should do, together with actual photographs of a carload of poles showing how they should handle them.

The first thing we attempt to do when a car comes in is to have the car securely blocked with blocks; we slip them in in this way (indicating.)

If we are going to unload on this side, we wedge the car on the other side, so as to make the car lean this way.

Figure 6. A special wire cutter.

There are usually five wedges, and they are driven in in this way, and that leans the car that way (indicating.)

Then the next thing we do is to bind the load; we use a cable for this purpose; I have on the end here a small chain, this chain is thrown around the truck of the frame of the car and brought over the poles and then taken twice around the frame of the car to this side, and then pulled tight; the man holding this must stand away from where he would be struck by a pole should it happen to go the wrong way. If you want additional snubbing, which we do at times, you come around the bumper here.

Next are your stakes; if you are in the country where you do not have stakes, as you have in your pole yard, it is necessary to remove some of your stakes. The

stakes can be put in there (indicating), with another stake put in the mud, but I am going to unload this model as we would unload it in the yard.

These are your stakes. The next thing is the removing of the stakes—of course they are chopped off. Now we cut these stakes. And on that point I want to say that we do not allow any one man to cut the stakes, we have a long bow-handled cutter by which they can be cut from the ground. We frequently find that the stakes do not break when cut so we have a hand line with which the man can pull the stakes out in case they do not fall when cut, and the man will not be near enough, when the poles do go, to get hurt.

Next we cut the line wires. Then the next step is the cutting of the binding wires which the men are not permitted to do, but that is done by a man at this

Figure 7. Cut end stakes about one-half way through.

distance, with a cutter long enough to reach it. This should be done by two men cutting simultaneously so that it breaks evenly.

And then your poles unload like this (illustrating).

I want to say also this, that the *Safety Service Magazine* has published in detail an article on the unloading of poles. Mrs. Thompson, editor of our magazine, will be glad to furnish you with copies.

CHAIRMAN OPP: That is very splendid indeed. We are going to have some discussion from Mr. Carl Rutland with reference to the questionnaire that he circulated some time ago.

C. J. RUTLAND (Safety Engineer, Texas Power & Light Co., Dallas, Texas): It seems there were several companies in the particular geographical section of the country in which I am located which had had quite a few fatalities from

unloading poles. A good many companies have special provisions made in their pole yards, but there are a good many companies which are building high power transmission lines and have to unload poles where they do not have trained employees to unload them. Every once in a while some fellow was killed by getting on the top of the car, or on the side of the car when the last stay wires were cut, or attempting to pull the tie stakes before they were fixed.

We thought it would be a good idea if, at this meeting, a standard rule was adopted, and we found that there are a good many companies which have standardized that feature. I was particularly surprised at the good work that has prevailed with the power and light companies through the United States, at least those which answered these questions with reference to fatalities in unloading poles.

Gloss: Pullman Straps #21-2662 ✓

Figure 8. The loops will remain parallel.

There were 168 companies reported and of those 168 there were eight which had fatalities; and the same number did not have any rules at all in effect. There were 55 companies which had rules in effect, and of the remaining number, 103 did not have any method at all of unloading poles, and out of those 103 companies eight men had been killed over a period of 12 months.

If any of you here are experiencing any trouble in that respect, or do not have any rules in your own company, but feel that you should have, I suggest that you communicate with Mr. Brown and have him give you what information he can; and if you want to make any change in your local conditions, of course you are perfectly welcome to do so.

CHAIRMAN OPP: We are certainly indebted to Mr. Brown for the preparation of such a splendid model, and giving such a splendid exhibition.

Photo taken from Trip #21 (2063) ✓

Figure 9. As the poles reach the skids the cables are loosened.

Incidentally we are very much pleased to have Mrs. Thompson here; unfortunately she has gone from the room. By the way, we want to comment on the paper of which she is the editor. It has been commented on in many places as being one of the "prettiest plant magazines" in the country.

ADJOURNMENT

Wednesday, September 28, 1927

The second session was called to order at nine thirty o'clock by the chairman, Mr. George Opp.

CHAIRMAN OPP: I want to call your attention to the poster display at the rear of the room. It incorporates an idea that we have had in mind for some time, an idea that is to be elaborated on for next year's demonstration and exhibit: it includes rules, codes, home made posters, safe practices, pamphlets, and other things of that nature that will be of interest to each delegate, so be sure to view the exhibit before you leave.

I might make an announcement at this time relative to the new film slide service developed through the National Safety Council by reason of the inspiration that came out of the Public Utilities Section due to considerable effort on the part of Mr. B. B. McCulloch. The service is available now. There is quite a large supply of film slides, all arrangements have been made whereby we can secure the use of the slides and films at nominal cost. The films may be purchased through the National Safety Council at reduced prices.

We have doubtless heard and read a lot about mental causes of accidents. We have had the opportunity to read some of the reports on fatigue, and the effect of conditions within the body upon the causation of accidents. We wanted to get the full picture so we put the whole thing into one subject, and we have an opportunity this morning to hear a man who is going to paint for us that picture.

It is my privilege now to introduce to you Dr. Hart E. Fisher, Chief Surgeon of the Chicago Rapid Transit Company of Chicago, Illinois.

The Mental and Physical Causes of Accidents

**Hart E. Fisher, M.D., Chief Surgeon Chicago Rapid Transit Company,
Chicago, Ill.**

After viewing an accident outside your own industry, have you ever stopped long enough to analyze the cause of it? Did you fail at a solution, and did you stop to think how such an accident could be prevented in the future?

Permit me to describe just how the average man (not the safety man) would go about analyzing an accident and seeking a method of eliminating a repetition.

Take the case of a speeding automobile accident case, a small child on the parkway and in apparent safety. The child is about six years of age and all its waking hours are taken up with getting everything possible out of its play-time. It knows nothing of being safe or being in danger. It is true, possibly, that the child's parents have threatened it with punishment for going beyond the curb line. The street is forbidden ground. Possibly some effort has been made to explain the dangers of the street. If so, then the child is fortunate.

To continue—the child is at play and the ball bounces out into the street. Having been warned when given the ball not to lose it, he darts out after it, crosses the deadline of safety and heedless of all danger, runs directly into the path of an automobile driven by a man who does not see the child until it is too late to stop. The scream of the youngster is drowned out by the screeching of the brakes, and then in the dead silence, the little form is picked up, crushed and lifeless. The police arrest the driver, who explains that the accident could not have been avoided. This is verified by witnesses and the Coroner's inquest

finds the driver "Not Guilty," and he is freed. An article appears in the newspapers, and another child's life is added to the grand total.

This happens so often, and we become so accustomed to it, that we take it for granted that such things have to happen in a large city. Friends, we are wrong. There is a cause for that accident and it can be remedied, just as surely as you are sitting there in your chair. You smile and ask, "How?" By safety slogans, campaigns, buttons, speeches, etc.? Yes. Partly so, and with the aid of laws passed by our legislators and other law-making bodies. However, the real solution and remedy is one of the things that the average man knows very little about—the physical and mental causes of accidents, which I have been advocating for the past ten years.

After participating in various safety campaigns, I very soon found out that accidents still occurred, no matter what rules, laws, etc. were made, and despite all safety appliances furnished to protect the workman at his daily task. Please do not think that I am belittling the wonderful work so far accomplished by the Safety, or the Spirit of Caution, Movement under the guidance of the National Safety Council and its local branches. I am sincere in my belief in the immeasurable good they have accomplished, and I know that they have overcome almost insurmountable obstacles to gain the tremendous advantage they now have in accident prevention. But, gentlemen, these accidents still occur and are occurring and will occur in the future, regardless of all they do. Why? Because in the past we have been remedying the cause by eliminating all hazardous machinery, applying safeguards, substituting safe for unsafe practices and endeavoring to educate the workman in the spirit of caution through various media such as above outlined. Then when man-failure occurs and an accident happens, perhaps with a distressing injury to the worker or to his fellow workman, it is agreed after analysis that the man was careless and he was not exerting 50 per cent of caution.

There May Be Another Word About "Carelessness"

Very often the employee is told that he has been careless when he knows in his heart that this was not the case. I wish to say here that we should hesitate quite a while before pronouncing a workman careless. If he knows that he has not been careless, he will rightfully resent the implication that he was an unsafe workman and did not live up to the rules of caution.

So far, I have talked a great deal and said, perhaps, very little which is instructive, but before I am through, I hope you will agree that some of the statements I make fit in with little occurrences in your own life, and when I close I trust you will be able to see what caused the automobile driver to maim and kill the child in the street. You will also, I hope, see a real remedy for these accidents which are occurring despite all that we can do.

My intention is to take the mental and physical makeup of the man and dissect him, if you please, to learn just what physical and mental defects are productive of accidents. How is this to be determined?

Through a branch of the safety work, the industrial physician and surgeon cooperates with all those agencies toward the one goal—the elimination of all accidents that produce misery, suffering, death, and economic loss to the commonwealth. The physician's first step is close cooperation with the employment agent, as safety in any industry has its beginning in the employment department, and the employing man is the first safety man or engineer. Safety, or the spirit of caution, should be uppermost in his mind in the selection of applicants for employment. He should choose men best suited for the particular class of work to be done—large, robust men when muscular effort is required.

small men whose task requires working in and about machinery, and quiet mannered men for work requiring close application. In other words, choose the man after careful study of the physical requirements of the job. It is essential that the worker in America speak, read and write the English language, in order to understand orders and directions when spoken by the foreman, or in the form of rules or safety slogans.

It is money well spent, and dividends are large in return to that industry which makes an effort to educate illiterate employees and to nationalize those taking this work. To be a literate, American citizen is a big boost for a safe man.

Judging by personal appearances, the clean, neat man is often a cautious man at his work and will be careful. The slovenly (I dislike the word) man will very often prove to be the same at his workbench, and because of the disorder is very liable to have an accident. The nervous, excitable man is often the direct cause of injury to himself or others because of his quick, impulsive way of doing things. This type of man may be a foreman and by his actions cause his men to do things quickly or in haste, which leads either to the hospital or the grave. The loud, boisterous fellow is apt to repeat his false front in his work, and in order to prove that he is a superman, will take risks which a more even-tempered man will not do.

One factor of safety, often overlooked, is the employing of a man who is constantly changing from one position to another. He does not remain at any one place long enough to learn the safe and unsafe practices. Men who remain at one position only a short time do not readily assimilate the spirit of caution, and, as a rule, do not care to cooperate with anything that seems to be of benefit either to themselves or their employer. Inquiry amongst previous employers will often prevent taking into the service a man who is a hazard. The prospective employee may be all right, judging by external appearances only, but be mentally and physically unfit for the work he is to do. The only way to determine this is by a proper physical examination under a set standard of requirements for the particular class of work he is to do. If the applicant is unfit for one position, he may be assigned to work where he will be less of a hazard and his defects fit in safely.

The industrial physician who is to determine these various qualities must be trained in his particular industry. He must know the tools, machinery, classes of work, environment of the workmen and just what is required mentally and physically of the man starting to work. Many employees are examined by physicians who have not the slightest idea of what the work will require of that man.

Physical illness and defects are causes of accidents. Accidents due to physical illness are prevented by the examination of new employees and by frequent re-examination of all employees in a medical survey.

Defective Vision As a Cause of Accidents

Defective vision, undetected, is a direct cause in a great number of accidents that are otherwise attributed to carelessness on the part of the injured employee. A person with defective vision, either near or far range, is a poor judge of distance and slow at accommodating. For that reason he does not see the source of danger as readily as the man with perfect vision. Poor vision is a constant hazard near moving machinery. Very often when one is working at a machine, it is necessary to concentrate the vision on a certain movement and when the eyesight is defective, the eyestrain is often productive of accidents. Frequently, when a man is told that he has defective vision,

he replies that he can see as well as you or I. That may be a fact as far as his opinion is concerned, but nevertheless he is under a constant strain and it is only a question of time before the sight becomes more impaired.

Sometimes an injury, which might be trifling to a normal eye, will result disastrously to an eye that has defective vision. Stereoscopic, or double vision, is very often the direct cause of accidents. Astigmatism, with accompanying fogging of vision, both partial or complete, in one or both eyes, for a certain period of time, will occur just when normal sight is most needed, and then we have another accident to analyze.

The remedy for defective vision is properly fitted glasses to relieve the nervous strain and correct the error of refraction. However, glasses, in themselves, are often a source of danger. They may be left at home, lost or broken and the employee who goes to his work without them runs the risk of having an accident because he is not accustomed to working without glasses. Very often lenses fog from the cold or perspiration, partly obscuring the vision, and the man gets hurt. Even soiled or smeared lenses are cause of injury. One of the greatest risks is that of the glasses being broken and a piece of glass injuring the eye, even though the object which struck the glass could not have struck the eye itself. Colored or tinted glasses are taboo, especially in train service, where they may cause a change in the man's ability to distinguish signals. It is needless to say that any man who is color blind has no place in railroad or marine work, if he is to handle the public safely and operate trains or train signals competently.

The colors that are most often confused by color blind people are unfortunately, the very ones that designate train signals, red—danger; green—clear. Let me stop here long enough to tell you how some color blind men work, apparently in safety. They watch the switch points when they see a signal color or the signal arm, and if two lights are used, they know which is the red and which is green, by the way it is lighted, top—red and bottom—green, or vice versa.

Defective Hearing As a Cause of Accident

Defective hearing is insidious in its onset, and comes on gradually until the deaf man finally has an accident because he did not understand orders properly, or in his effort to hear, he became confused and an accident resulted. Some people who believe they are becoming deaf, find that they hear perfectly after removal of impacted ear wax. Deaf people are prone to become irritable due to their defect and act impulsively, thereby causing an accident. Some deaf people operate trains with apparent safety, by watching the hammer of the signal bell, looking out to see that all is clear before starting, etc. In litigation, the placing of an employee who is deaf on the witness stand makes a very unfavorable impression on the jury. Permit me to state here that there are a great many people with defective sight, color blindness and deafness, driving automobiles, who are the cause of accidents.

Defective Hearts As a Cause of Accidents

A man with a defective heart may have a sudden weak spell, and during this spell, meet with an accident. The lifting of heavy objects by a person with a defective heart has often resulted in death. A man may have a stroke of apoplexy, epileptic convulsion, fainting attack, coma from Bright's disease or diabetes, and by reason of same be severely injured. A man with high blood pressure may have a sudden attack of dizziness following heavy or strenuous work, and while in this state, meet with an accident to himself or

be the cause of injury to others. Electrical current, especially the lower voltages, is more often fatal in defective heart cases than where the heart is normal. Many cases of heart failure have been mistaken for electrical shock because the man was found in a dangerous place. People with defective hearts cannot stand extremes of heat and cold as well as those with normal hearts.

Very often an employee, who has had an accident remarks that he cannot remember what happened. He is correct in this, for he undoubtedly had a fainting spell or heart failure and cannot recall the details of his accident. These cases should be examined to determine if the heart is not the offender, rather than the employee's carelessness. Defective hearts are also the cause of absenteeism from work. Employees should be carefully examined for heart conditions after illnesses such as reumatism, infections and contagious diseases.

Rupture As a Cause of Accidents

This is my pet subject and I only wish I had sufficient time to go into it thoroughly, but I will only say at this time that an employee with hernia or rupture is very liable to be overcome by a sudden weak spell or pain in the groin or back, which is causative of injury. If you question a man who has dropped some object on his feet, or suddenly let loose of something with disastrous results, he will very often say that he had a pain or felt weak and let go. He should be examined for rupture. If these employees wear trusses, they are handicapped by the truss which often slips on exertion and is the cause of injury. All hernias in young or middle aged men should be operated, and when they are found in old men they should be placed on jobs where muscular effort is not necessary. Symptoms of hernia will detract a man's attention from his work. An unsupported hernia is liable to strangulate and cause the death of the patient. What is more "safety first" than the subject of hernia?

Varicose Veins As a Cause of Accidents

Varicose veins in the legs are often the cause of injury. The employee will not act quickly when danger is at hand because of the pain and ache of the varicose veins. Also, sudden pain in the legs may cause him to let go of his work, and his feet might be injured by dropping material upon them. Men with varicose veins who are on their feet constantly have their mind diverted because of the pain, and injury is in the offing. Trivial injuries become serious in presence of varicose veins.

I do not want to linger here too long, as I wish to get on to the subject of the mental causes of accidents before you are fatigued, but I must say a word regarding old age trying to do youth's work. How many poor old men have met death or injury because, through neglect of proper supervision, they were allowed to do work far too strenuous, or were placed at tasks requiring the quickness and ability of youth? Oh, for a more careful selection of workmen, with the human factor at the bottom of our hearts!

Employees must have the full use of legs, arms and fingers to protect themselves properly from injury. Stiff and crippled limbs are conducive to accidents. Many automobile railroad crossing accidents result from insufficient protection due to aged, crippled crossing attendants. In the old days, crossing flagmen even though they were aged and crippled, were able to do their work carefully with the slowly moving horse and buggy, but today, with the swiftly running automobile, it is necessary to have a youthful, alert and agile man to command respect by his physique, and protection by his ability to get out and onto the crossing quickly.

Mental Causes of Accidents

By mental causes of accidents I do not want you think I mean those who are mentally deranged or insane, but I want you to understand that every man is as different from his brothers in mental makeup as day is from night. What is perfectly normal and logical to one man may appear irregular and abnormal to another. It is with these various states of mind that I want to spend the next few minutes, and I will try to be as brief as possible.

The worried, troubled or agitated state of mind is the cause of innumerable accidents in industry today. Worry over financial matters, grief over family illness or death, anger or strife in the home or at work, hatred, malice or envy of one's fellowmen, are all conducive to accidents. When a man is angry and in a temper, he acts impulsively and in a fearless attitude, taking chances and doing things that he would never think of doing in a peaceful frame of mind.

Diversion of an employee's mind while at work may be accomplished by various factors, such as confusion following distracting disturbances, work becoming so familiar that an accident results from over-confidence, and repetition of work palling on the worker so that interest is lost. When interest is lost, look out for an accident. If the work at hand calls for constant repetition, the man assigned to that task should not be of a nervous or temperamental makeup. There is the fixed mind which minimizes all rules, work, or anything coming from the employer, such as the radical, who is this type. Also, the old employee who has been in the habit of doing a thing his way and will not be told how to do it in a better or safer manner.

Mental ignorance on the part of the worker causes him to fail to understand properly or assimilate what his employer intends to convey to him as safe practice. What is unsafe to one man does not appear so to another. As stated above, understanding of the English language is a safeguard to a great many accidents. If it is necessary to have foreign labor, men who do not understand English, then place all those speaking the same tongue in one gang, with a foreman who speaks and understands their language. Misunderstanding of spoken orders causes many injuries to the unfortunate worker.

Very often the worker is ignorant of hazards about his work because these hazards have not been explained to him, and if so, once telling is no guarantee that the worker understands. Then there is the state of mind in which the worker has no sense of rhythm and for that reason does not know by the sound of his machine when danger is at hand. This is best explained by an example: An engineer places his hand on the journal box of a revolving drive shaft to ascertain if the bearings are heated. With a perfect sense of rhythm, he does it automatically, but if a man lacking this sense of rhythm is placed on the job, he will put his hand on the shaft at the wrong time of revolution and thereby receive an injury.

Some people have lack of balance and are unable to ascend to high places without becoming dizzy and falling. This is due to the semi-circular canals in the ears. If these are defective and the employee mounts a ladder, he will become dizzy and fall. Was he careless? This sense of balance is necessary to aviators.

Mental Limitations

In this class of men you will find the accident repeaters, or the man who does not learn from previous accidents. His mind does not allow him to detect danger. There is the case of the man who lost a finger and in demonstrating to his friends how the accident occurred put another finger into the machinery and repeated the accident. These men fail to make use of safety appliances.

The opposite to this class is the man who can foresee dangerous practices and imagine or portray accidents before they really occur. In other words, he is able to foresee what the other fellow may do that will cause an accident. This is the cause of a great many automobile accidents; the inability of the motorist to do the thinking for the other fellow. You never know what he is going to do.

Routine fatigue of the mind is one of the greatest factors in accidents. I do not mean fatigue from labor, but fatigue of the mental facilities on account of the routine nature of the work. A man listening to the constant click-click of the wheels passing over the fish plates is soon lulled into a drowsy state of mind and his faculties become clouded. Although apparently in full possession of his senses, he fails to apply his brakes in time and an accident occurs.

There are many other forms of mental illness which are causes of accidents, but I will hasten and in concluding mention some other things which are productive of accidents. Poor ventilation or working in a temperature which is too warm, will dull the mental sense and produce drowsiness. The shop which is too cold will numb the hands, feet and body of the worker and dull the mind. Poorly illuminated working quarters will encourage accidents, as will also the glare from the interior of a shop too brightly lighted. The man who overeats or stuffs himself is very liable to run into an accident because he becomes drowsy following a heavy meal. Likewise, the man who does not eat or eats too little becomes weak. Calls of nature have been the cause of accidents, as the man who puts off attending the nature's calls when she bids him has his mind diverted and often, in his haste to finish his work before he goes, an accident occurs and injury results.

There are Nearly a Dozen Remedies

Now, to return to the mental side for just a moment to explain how fear will cause accidents. Fear of the foreman who is a driver of men will cause the ignorant or fearful foreigner to do things quickly, with accident resulting. Fear of failure to please in the work by a new employee often causes injury, as well as fear of his own health or that of his family.

What can be done to remedy these things, over which there is seemingly no control? Think over these factors and see if they may not eliminate a great many accidents:

- (1) Do not select hazardous material for employees.
- (2) Do not take physically or mentally unfit people into the service. Be positive of what you are buying by a medical examination.
- (3) Fit the man into the position which his physical and mental limitations will permit him to handle with safety.
- (4) Overcome the ignorance of employees regarding the hazards of their work, by properly introducing them to their jobs and assuring yourself that they understand what you intend them to do.
- (5) Closer personal study and contact between foreman and their men.
- (6) Medical examination of employees to eliminate the hazards of physical defects and to forestall a trivial injury developing into a serious one.
- (7) Educate and Americanize foreign employees.
- (8) When a man does poor work or commits many errors, analyze the cause and forestall an accident.
- (9) Foremen should report illness or injury of any one of his men to proper authorities so neglect may not cause accident, injury or death. Get on intimate terms with your doctor.
- (10) Study the mental makeup of your employees and the requirements of

the job he is to take and see if his mental characteristics will permit of safe operation, if he has mental capacity to assimilate safety.

- (11) Watch your men for signs of grief, worry, anger, etc., and use your best judgment to allay same, as an accident will probably occur, if neglected, on account of a troubled mind being somewhere else when clear mental facilities are needed for work at hand.

In conclusion, I wish to ask if you have analyzed the automobile accident I spoke of at the beginning of this paper? If not, here is the only way of ascertaining the cause:

Was the driver mentally and physically able to drive his car with safety? Was his mind preoccupied with thoughts that distracted his attention from his driving? Did he have the mental limitations of being unable to foresee such an accident and to imagine such a chance? Was his mental capacity even normal and had he no sense of danger to anyone else? Did his eyes fail properly to give him position sense, or cause him to judge distance incorrectly? Did he fail to react to bring his car to a stop when he felt the danger stimulus? Were his eyes defective and did we not see the child until too late to stop?

I am sure that if a careful, painstaking inquiry had been made, the man would have been found to have a diverting mental factor which made him obvious to all accidents, or he lacked normal physical sense. He is at large to repeat his offense.

I want to ask that we make a united effort to aid a mentally and physically handicapped brother worker to protect himself and save him to the commonwealth as a careful citizen and worker and that these unfortunate be mentally and physically examined before placement in industry.

Using Habit to Overcome the Difficulty

CHAIRMAN OPP: Thank you very much for the presentation of that paper. It is full of many good things to discuss, and we have the rare opportunity of having Dr. Fisher here to participate in whatever discussion there may be. He is ready to answer any question that you might want to put at this time.

WILLS MACLACHLAN (Consulting Engineer, Toronto, Canada): In connection with one feature of Dr. Fisher's paper, dealing with the mental angle of it, he raises the problem in connection with a man thinking of something else at the time of the accident; it might be someone sick at home, financial troubles and so forth.

Some of us have been wondering if we cannot use habit to get over that difficulty. When you get up in the morning you put on your left shoe first, and put it on every morning in the same way; you are not thinking of that, but you are thinking of something else. So, for instance, where linemen are climbing poles, and have to put on rubber gloves, if they put them on at a certain point all of the time it becomes a habit. Why can't we teach them to take off or put on the rubber gloves at the same point all of the time? If we did that, they would soon be doing it mechanically and there would be no danger from that point. When they are climbing up the poles they won't take off the rubber glove and put their bare hand on the primary when thinking of something else.

DR. FISHER: I would like to say that that is very well illustrated by the use of goggles. We have been working for the past three years to produce a goggle that the employee does not have to remember to put on.

Some of the companies are using goggles just such as the glasses I have on here, but a little bit larger, and adaptable to the employee's vision, though made of different glass. He puts these goggles on at home and leaves them on until he comes back home.

If a man is mentally upset, an ingrained habit will still control him in his daily duties.

There is one question that we have to contend with seriously—the fact of domestic trouble in an employee's home. You and I don't know what conditions are, and when the employee is unsettled at home it makes a very serious mental condition that we have to cope with. I know a man who lost his leg by reason of a fight with his wife that morning. Away from home he began to think about it, and began to think that he was abused and run down and all those things; and by the time he got to the job his mind was so taken up with the fact that he was abused that he walked past one train over a shortcut which he had been forbidden to take, and he was hit by a switch engine which threw him to the ground and cut his leg off. He afterward said he was absolutely taken up mentally with the thought of the fight at home.

Then again we have discipline, that is repeating the same thing, going over it again and again, the same as they do in the army, so that man will act automatically because of that repeated drilling and repetition of orders. It becomes so ingrained in our minds, just as Mr. MacLachlan said.

Two Accidents in the Electrical Division

H. C. DENNIS (Westchester Lighting Company, Mount Vernon, New York, Assistant Chief Electrical Engineer): We had two serious accidents in our electrical division this summer, and both of them bore out what the doctor said.

The first one was a fatal accident to a lineman, who had been with the company a number of years and whose safety record was very good. Our investigation disclosed the fact that the wife was expecting her first child. In view of the circumstances of the accident, and his previous record, I think that that contributed very materially to a state of mind which dealt with the accident itself.

The second case was that of a construction man who had been with the company over five years, with an excellent record. He was selected to do some careful work because of his record for work, and in a moment of inexplicable mental fatigue, or something, the man touched a section of the structure which he knew was alive, and which he had no occasion to come close to and was hurt.

Investigation after the accident disclosed the fact that this man had been engaged in overtime work beyond a period where it was probably safe.

I think we can help that situation by tying it in a little better with the Employees Benefit Association which places at the disposal of the employee financial relief, as in the case of the expected child. The financial difficulties involved might be relieved by application to the employees association where loans could be made under very favorable terms.

In the second place, I think we have found a solution in limiting the overtime work where there is any liability of carrying the man beyond the point where his brain becomes fatigued.

C. E. McBRIDE (Safety Engineer, Northern Indiana Light & Power Company, Fort Wayne, Indiana): I would like to ask Dr. Fisher if it is possible for the thyroid gland to be found subnormal as well as over normal, and whether that same percentage from 40 to 90 per cent correction can be made under normal as well as over normal.

DR. FISHER: It is just like the opposite to your high current line, where you have too much secretion or over-function of the thyroid gland you have the opposite situation of hypothyroidism, or lack of necessary thyroid substance.

Anything that affects the thyroid gland one way or the other produces a certain amount of pathological changes both in the mind and in action.

Any person who has a lack of thyroid glands, or not enough thyroid secretion, hypothyroidism, that man's mentality is low, his reaction at times is lower, and also his coordination. If he is measured by the time it takes him to pick up something, the time he reacts to pick it up, or the time he reacts to let it go is below normal, and as a result he is sluggish; that is all produced by this thyroid substance, and he does not react normally.

It is a fact that you can put those cases under medication and at least improve them. That calls for close observation to detect those people, and you only get that through medical contact.

But if a lot of foremen would notice men doing something in a peculiar manner, or notice them making errors, acting peculiar, or notice certain changes in their usual occupation, then is when they should be reported to the medical officer, and if he is reported, it will enable them to avoid maybe some accidents in the near future.

You can all cite all kinds of experiences where these incipient accident-makers were detected by the foreman or some brother worker by some peculiar speech or certain remarks that the man makes that shows the mental slant that the man's mind is taking; and that constitutes about 50 per cent of our working force. Fifty per cent possibly average normal intelligence; then there is about 20 per cent a little below grade, and then it dwindles down to 30 per cent which really needs mental re-education.

CHAIRMAN OPP: This has been a very instructive discussion, and we have enjoyed every bit of it. We will now have to pass on to the next item on our program, the next paper to be offered is by E. S. Beaumont, supervisor of safety and fire prevention, The Peoples Gas, Light & Coke Company, Chicago, Illinois.

Safe Practices in Manufacture and Distribution of Gas

E. S. Beaumont, Supervisor of Safety and Fire Prevention, The Peoples Gas, Light and Coke Company, Chicago, Ill.

Safe practice in the manufacture and distribution of gas covers quite a little territory. I am going to assume, of course, that what you are particularly interested in is accidents peculiar to the gas industry and not those accidents which are general to every industry.

I am fortunate that a number of the members of the distribution department are present today, and they will be able to bolster up this talk with the actual circumstances and experiences with which they are more familiar than I am.

The most dangerous possibilities in our business for injury are fire and explosion, also burns and asphyxiation.

Probably the easiest way to consider them would be to start in from the time the fuel is brought into the plant and follow it through to the delivery of the gas to the consumer.

In our actual experience statistics show that about four to six per cent of the accidents are actually due, or caused by fire, explosion or asphyxiation through gas. Although there is that low percentage, that does not by any means indicate the importance of those hazards. In fact we might follow some of our college methods, and have a formula on it, but the accidents are inversely in proportion to the hazards.

Accidents, when they do occur from fire or explosion, of course are particularly serious. Asphyxiation is more likely to involve a small number of people. Of course, death by asphyxiation is probably more serious than the loss of property by fire or explosion.

The first contact is with the fuel. The storage of large amounts of coal affords the opportunity of spontaneous combustion in the coal pile. That does occur from time to time, and the principal consideration, of course, is the loss due to the fuel destroyed. I need not go into the methods of preventing that, because you are all familiar with the methods of storing coal, and the methods of prevention. The handling of coal by conveyors involves another hazard, that of dust. Where a great amount of dust is allowed to collect, and there is a possibility of explosion from dust collections, of course the important thing is to eliminate the collection of dust as far as possible, and also to insure that there is no danger of explosion by eliminating sparks or open flames in the vicinity.

The handling of oil concerns us mainly as a housekeeping measure, that is, we should take care of the unloading and storing of the oil in such a way as not to permit of loss through leaks, or the collection of vessels around the plant which may become ignited by any open flame, or handling of any hot ashes, clinkers or such things.

Methods in the Boiler Room

Of course, the proper handling of oil storage tanks is of considerable importance.

Then we go into the boiler room, our consideration there is the same as any boiler room in general. I think what we should emphasize as of particular importance, equally true in any boiler room, the necessity for watching out for protecting the steam lines or blow-off lines when men are doing any work in the boiler room. As obvious as that precaution is, a number of accidents, and very serious ones, have been caused through neglect of just that point.

Of course, the proper handling of the ashes is important to prevent the ignition of any material, wood material, particularly that which is used in disposing of the ashes.

In the generator house one of our most common accidents (that is the most common in the number of accidents) is the handling of the ash buckets. That, of course, is a general hazard, and needs, I think, more perhaps, close inspection and observation: but they do seem to get careless, and they get mashed fingers and broken bones that do not seem to be necessary at all.

In the charging machines, ordinary precautions should be taken, of course. First we must be careful to see that the charging doors are opened properly: the gas maker must be in complete charge, and certain that the conditions are proper for the door to be open. The door, of course, is first opened a crack before being swung clear back. There have been a number of burns received in that operation simply because of the lack of proper method in doing the work.

The staggered operation of machines, where there is a number of machines on the line, is important, of course, in keeping pressure controlled properly so that the sills will not be blown and the gas backed out of the line into the plant. Quick action valves between the watch boxes and the sill pit are desirable, in case the pressure does get away from the plant operators, so a shut-down can be quickly made and prevent the gas backing up in the plant.

It is important to have the gas maker follow the proper sequence of his valve operation to make sure that he is the type of man that will follow through right along. In most cases it becomes, as suggested by Dr. Fisher's talk, a matter of habit to do the thing in proper order.

And another thing, the inspection of the valves is important because it is the seating of the valves that insures that the gas line is on.

Explosion ports—of course you are all familiar with them; they are in common use.

The proper control of the oil line is important to make sure that the oil line is closed before any of the charging or clinkering operations are undertaken.

In the clinkering the hazard is first the handling of the doors, which requires teamwork and supervision by the straw boss; and then, of course, the hazard of the very hot clinkers, and the punching of the same when water is thrown on the hot ash and there is steam developed. This is simply a matter of precaution by the man in charge of that operation for the safety of the workmen.

It is important to mention the necessity for locating or projecting the gas or steam lines to the machine when the gas machine is down, for the same reason as in the case of the boiler operation, the blocking off of the heat valves so that they might not be operated and bring disaster to anyone inside.

In the rechecking machine, or moving the checker from the machine, I might mention the desirability of having a chute, or a closed chute for disposing of the brick from the operating machine to the floor.

In spite of the fact that that work has been done for a number of years with an open chute, and nothing happened, still it is better to have a closed chute.

In getting into the machine, it is desirable also to see that the arch is in good condition so that the workmen may not be injured by anything falling from the archway while doing their work, that of cleaning the sills.

It is also important to see that the wash box and line is purged with steam so there is no remaining gas to cause trouble.

Thorough Inspection While Machine is Down

While the machine is down on the floor, that is the time for inspecting all of the valves and the other instruments on the steam and oil lines.

In cleaning the shaving scrubbers, or renewing material there, it is desirable to make certain the line is shut off and then open the top so that the draft is upwards and not back towards the workmen.

It is also important that there be no smoking or open flames around when that work is being done.

Then in starting up after the filling of your scrubber, the desirability of opening up the outlets first is apparent.

The purifying house is probably one of the most dangerous parts of the plant, and obviously every precaution should be taken there to make certain there is no possibility of a spark or open flame; and it is important to see that the seals in the water seal box are kept at the proper level. A safety seal which would break at lower pressure than the regular seal installed, would give you a safety factor there.

Outside control of the water valve should be supplied so it is unnecessary for the man to get into the purifying house and refill the seals. When they do go into the purifying house, after going into the box it should be apparent that the man going in should be observed, and if possible connected by rope to men on the outside to make certain that the house is clear of gas that might overcome him.

In pumping the purifying box you are all familiar, of course, with the necessity for quick action there. It is extremely desirable to get the box empty the same day you start, and not leave it overnight because of the possibility of spontaneous combustion. It is desirable to keep close watch of the workmen there to make sure that they are not being overcome by the effects of gas.

The operation of holders is comparatively simple ordinarily. Of course it is important to remember the necessity for purging and taking safety precautions in purging a new holder, getting all of the air out of it, and getting on it a screen

outlet so there is no possibility of the gas igniting the escaping mixture and flashing back to the holder itself. Holder release alarms are common for giving information in the engine room, by a tell tale light, so that the engineer can make certain as to the height of the holder, and see that it is within the safety limits.

In main work, possibly one of the first things I think of would be the proper barricading of the ditches for the protection of the public, and then the proper bracing of the ditches, making certain that the ditch was barricaded properly for the protection of the workmen.

Then the question of proper spacing of the workmen comes in, and it is surprising how frequently men are injured by working too closely and not working together.

The testing of the mains when laid is common knowledge to you all. Testing with the air for leaks, and if leaks are found, finding them through the usual method.

The purging of the mains in a somewhat similar process to purging the holders, making certain you have vents expanding well up in the air with screens protecting them from any possible flash back from sparks that might be in the neighborhood or passing.

Making Use of the Gas Mask

Similarly testing accessible gas by the old book method, or chemical analysis, to make certain when the gas has reached the proper gravity.

In tapping the mains the workmen should be protected by using a shut-down, or where that is not possible by wearing a mask, if there is any appreciable pressure on the line at all. The masks, of course, should be kept in good condition, and always available for that sort of thing, and where the supervisory force feel, as they do in some cases, that a mask may not be necessary because the pressure is so slight, the precaution should be taken to see that the workman is watched and protected against any effect of possible escaping gas.

The question of bonding and cut outs is of particular importance in the larger cities where there is always an electrolysis condition, and some current in the mains. A bonding, of course, will give protection against the possibility of sparks when making cut outs.

Obviously gas will not light from a cigar or cigarette, still the smoker is apt to light his cigar or cigarette at the psychological moment; so it is desirable always to keep smokers away.

The old method of testing leaks was to use a line and a piece of tallow candle, light it, stick it up there and see what happened. There are, however, other methods of which you are aware, and we use the soap solution now.

In your street work the particular hazard is the possibility of striking electric lines, high voltage lines in the larger cities, when excavating for main trenches, or digging for leaks, or anything of that sort. There are several precautions. First off, we do not feel that insulated tools, the wearing of boots, and that sort of thing, is of any great value because of the rapid deterioration in the equipment, and also because of the false sense of security it gives the workman. He is liable to strike the hot stuff just when his equipment is not right, and feeling he is protected he is taking more of a chance than he would otherwise. The only method that we have ever taken for protecting ourselves against that sort of thing is first, the insurance; and having our foremen thoroughly aware of the hazards there, and that they inspect the streets and manholes adjacent to where the work is being done to get a good idea of where the electric lines are lying, as compared to the gas lines to be repaired or taken care of.

In important jobs there is a possibility of course, of getting in touch with the electric company, and getting more specific information, although sometimes it is

impossible to get it any more specific than we can locate it through the street manholes ourselves.

One of the biggest hazards, perhaps, of our street work is the traffic. We have to work, in general, during the day time when the streets are the very busiest, with traffic passing on all sides, and unfortunately the people engaged in the traffic frequently have very little consideration for the workman; they feel he is an intruder on the street, and just making it difficult for them, and deserves no sympathy at all. Obviously the men have to keep strictly on the alert to avoid traffic accidents. I know that we have more fatalities through our street mains being involved in traffic than we have through gas.

The importance of keeping traps clear is apparent to everyone. Clearing the mains and street pumps, that is also obvious.

You are all familiar, no doubt, with the safety tee used for tapping lines; it is the tee in which the rubber stopper is inserted, so that after the tapping is made and the tee put in the main no gas goes through until the service is completed by removing the rubber plug and replacing it with the metal cap.

Then in the meter changing work, it is important, of course, to see there that nothing is done to the gas line, no changes are made unless the fitter can get into the premises concerned, and notify the owner and inspect the pipe and equipment to make sure there is no leak or appliance left on while the change is being made; and repeat that inspection after the change is made, to make sure that the line is purged out and everything connected up tight, and no gas turned on before being lighted.

Good Housekeeping Is the Essential Need

The consideration of fire, explosion and asphyxiation in the production and distribution of gas is boiled down largely to a matter of good housekeeping, and good practice. If we can get that instilled in the minds of the workmen, to have good workmanlike housekeeping jobs, particularly where it is highly essential, then we are pretty well protected right there. Supervision, of course, is the main thing. Close supervision by those in charge to see that every precaution is taken. The "No Smoking" precaution, and the use of no open flames or light of any kind, is the really important rule of our work; to make sure that that is strictly followed out to the letter in any of the places where gas is likely to collect and ignite.

The methods of prevention, of course, are the important thing; however, it is desirable to be prepared for emergencies, and obviously our plant and equipment must be protected with the best fire equipment available. The water lines in the plant available at the proper location, and the hand extinguishers located wherever necessary. Not only should the equipment be there, but the man must know how to use it.

I rather blush in mentioning one incident that I found, where a fire extinguisher had been used, and an inexperienced workman, apparently in attempting to do the job up quickly, had taken the fire extinguisher charge and put it in, not even unwrapping it, and then filled it up with water, and put it back in its case.

Now, as to gas masks, I believe most companies are sold on the gas masks which furnish air pressure; that is preferable to any other kind of mask.

Further along the line of being prepared for emergencies, I feel that first aid work in our company has been very helpful in reducing the number of accidents and loss of time through accidents, helpful directly and indirectly in that it has provided a better contact, closer contact of the men in the plant with the safety division; it has secured their cooperation in a much larger measure than we would have if we had not had some provisions such as this. Of course, every employee

must be skilled in the particular job that he is doing, and be ready for all emergencies. I might be pardoned in saying that our employees have always shown themselves to be quick in cases of emergencies; and for such actions, five of them are to be presented with the McCarter Medal in rescuing other employees.

I think that covers the main points in brief. We have, of course, a committee organization; also the large organization which receive suggestions from the employees themselves on better methods and better practices. I think even that is helpful in getting cooperation and help from the employees and understanding from them of what we are trying to do.

I will be glad to have you ask any questions about specific phases of the production and operation. I know there are men here who are a lot more able to answer them than I am so I will call on them if you will ask your questions.

CHAIRMAN OPP: Thank you, Mr. Beaumont, for the presentation of the subject. any questions you wish to ask while Mr. Beaumont is here with his corps of experts? He has his corps ready to send into the fray if he is unable to answer your question.

There Is Always a Reason For a Mistake

C. W. BENNETT (Northern Indiana Public Service Company, Lafayette, Indiana): Two months ago there was a poster came out in the National Safety Council, and later it was printed on the back of the magazine regarding the use of hose in drenching coke from the retort.

Down where I come from that caused quite a discussion among the workmen; we had always used the bucket method. They had not had a fatality down there or an accident of any kind for ten years, but the first day that we changed over to the hose a man was seriously hurt by reason of the fact that the coke is brought back here by the bucket method where the man is waiting to pour the water from the bucket over the coke. But with the hose method he draws it back here and the man with the hose sprayed it and the resulting steam enfolded the man with the coke, and as a result he was badly burned about the legs and laid up. Now, in pulling this retort, the rake is about 20 feet long; in using a bucket the men did not throw or drench the material until the man was back even with him. On this same question the man that has the hose was way up there like that and he was burned around both legs pretty seriously.

Now, the stokers down there will not use the new method as advocated, and have gone back to the old method, and I would like to hear a discussion pro and con so as to get your ideas on this matter.

W. H. BROWN (Secretary, General Safety Committee, Northern States Power Co., Minneapolis, Minn.): I believe the hose method is not adaptable to the small plant for drenching coke. I believe the old method of drenching coke is by far the safer proposition.

When the man is back with the rake he throws water on the coal, when the man gets back to the retort with his rake the steam has arisen from the hot coke. Personally I would not use a hose method for drenching coke on the floor where you have about a three-quarters depth vent; absolutely I would not use the hose method.

MR. BENNETT: I would like to hear both sides of this, if there is any. I wonder who submitted the information for that bulletin?

CHAIRMAN OPP: We cannot go into minute detail at this session, but it holds out a word of warning to the Poster Committee to be on their guard in every respect to make sure that information is not released until it has been fully tested either by the committee itself, or referred to someone who will finally decide its merit.

MR. BENNETT: Here is the point: They look up to the National Safety Council

for final authority, and when they publish a poster and bring it out in the book on the back of the safety bulletin, and the men try to live up to it, and then a man is hurt it looks pretty bad.

CHAIRMAN OPP: Your point is well taken, and it is up to the committee to make mighty certain that that sort of thing is not released until fully tried and tested.

Our program this year represents, as I indicated yesterday, the work of all members of your official family. Last year we constituted for the first time, a Committee on Fire Prevention and Protection, particularly with reference to work to be done in the public utilities. The first chairman of that committee was Mr. H. B. Harmer, and it was through the efforts of Mr. Harmer that the subject was sold to the National Safety Council for their general session next Friday morning.

Of course, having fostered this idea, we could not very well pass it up without making use of it ourselves. We have that feature this morning, and I am going to turn over the conduct of this branch of the meeting to Mr. H. B. Harmer.

(Whereupon Mr. H. B. Harmer, Safety Engineer, Philadelphia Electric Company, Philadelphia, Pa., took the chair as Chairman of the meeting.)

CHAIRMAN HARMER: I don't know, sometimes you get biased on things, that is, things you are doing over and over again, so that you get over-saturated, or something of that character.

I don't know of anything you men are doing that appeals to me that we ought to stress more than the absolute destruction that happens after a fire. Of course everyone of us is primarily and particularly interested in the preservation of life; there is no question about it, the whole convention is for that one purpose. I find in our human accidents we mostly have a chance of bringing back the injured person to almost the original condition. In other words, we save him for future use. But in fire, the thing that is burned is absolutely destroyed, and there is nothing that brings it back.

I am glad to think that our particular Section has the opportunity of having with us a man that is an authority, connected with an association that is nationally known and recognized, dealing with that demon called fire destruction, and it makes me feel that we have in our Section, the Public Utilities Section, something just a little bit different from the other fellows; and it certainly is with a great degree of pleasure and satisfaction that I wish to introduce to you our speaker, Mr. Smith.

Fire Prevention for Public Utility Companies

E. J. Smith, Engineer, Gas and Oils, Underwriters' Laboratories, Chicago, Ill.

The public utility company of today supplying light, power, heat, transportation, or communication is prepared to furnish its particular commodity upon demand, irrespective of the time of day or of the volume required. Successful accomplishment has been such that the present day citizen, of our large municipalities at least, is favored with public utilities so reliably that we all fail to appreciate the constant care and attention; the readiness to meet any emergency, and the vast engineering intelligence necessary to produce this modern marvel.

Fire prevention in all of its phases, studied intensely as it has been for the past forty years, undoubtedly has aided in securing the present large measure of reliability and safety provided in our modern public utilities. Improvements in electrical equipment; improvements in gas generating equipment; improvements in building construction, and, in fact, improvements along so many lines that to list them would require a volume in itself, have all had their effect, even though they have not in all cases been developed as fire prevention measures.

The wonderful work done by the National Fire Protection Association, which includes in its membership the various associations of public utility, organizations, and related trade organizations as well as individuals directly interested in public utilities, has most certainly accomplished results that may encourage us to go forward in the effort to still further reduce the cost of our national fire loss. To prove there is need for continued effort in this direction it is only necessary to bring to your attention the fact that the committee on statistics of the actuarial bureau of the National Bureau of Fire Underwriters, in their report for 1926, estimates the fire loss of the United States at \$560,348,642. This is a per capita loss of \$4.79 for the nation as a whole, a tax on the individual that if directly applied, would soon bring to our consciences a fuller realization of what our fire loss actually means. Some of our public utility companies have set an example in accomplishment which, if applied to the country as a whole, would soon reduce our fire loss considerably. May the day soon come when we will build with fire prevention and fire protection in mind.

Good Examples of Fire Prevention

The field covered by the term "public utilities" is such a broad one that, coupled with the term "fire prevention", it is difficult, within a limited space of time, to do more than touch on items of even the greatest importance. Realizing, however, that by referring to such examples of fire resistive construction and meticulous housekeeping as are exhibited by some of our telephone companies, we may safely say—Go thou and do likewise; build with the possibility of fire in mind. Use standard materials, the values of which have been shown by test; assemble these materials in a manner to isolate any possible fire and prevent its spread to adjacent property; enforce good housekeeping rules, and provide and maintain adequate fire extinguishing equipment.

At the present time we are provided with a vast fund of knowledge regarding fire resistive construction. Carefully prepared building codes are available, and the National Board of Fire Underwriters, together with the National Fire Protection Association, can furnish unlimited suggested regulations on the do's and don'ts of fire prevention. You of course are familiar with the National Electrical Code—that set of specifications has become the watch-word of the electrical industry. Similarly, we have regulations covering most common and special hazards, and likewise regulations covering various methods of combatting fires, including first-aid appliances and more elaborate systems designed to aid and assist our public fire departments, upon whom we depend for a service no less reliable nor less instantly available than the ever ready light and heat at the turn of a switch or valve. All of these regulations can be easily procured by anyone needing them. More use should be made of them in our daily life and every public utility company should see that its employees are familiar with the rules applying to the particular class of work which is a part of their daily task.

Undoubtedly the most spectacular part of fire prevention is that relating to fire extinguishment. None will deny the urge to follow the fire engine, clanging its way in response to the call of an alarm that may have been turned in from a point miles away. Spectacular as it may be, fire extinguishment is based on cold chemical facts, which properly and promptly applied, may often result in the fire department's return to its quarters satisfied with having been ready, though actually not required to put out the blaze. First aid fire appliances of all types, automatic sprinkler systems, automatic and manual fire alarms, and many special appliances, all aid in the prompt control of fire which is ever ready to change its position of servant to that of master.

The value of water in fire extinguishment is, of course, not to be denied. No one would care to propose its elimination from the scheme of things. On the other hand, we all recognize that it has its disadvantages, and give ear to other means for the quick control of fire in its incipency to avoid the necessity of throwing volumes of water to fall upon the burned as well as upon the unburned. Hand chemical extinguishers, as well as chemical engines utilizing water solutions of bicarbonate of soda, coupled with sulphuric acid, were the first steps in the way of fire protection tending toward the reduction of water necessary to combat fires successfully in their incipency.

The cooling effect of water or of solutions largely composed of water, was for many years the sole means for attacking fire, and it was not until less than a quarter of a century ago that the blanketing of fires really became recognized. The first step in this direction was the so-called carbon tetrachloride extinguisher. This type of apparatus was first brought out in the small one-quart size, now so commonly known and so generally used by public utility companies. This particular type of apparatus serves a most useful purpose as a first-aid appliance, and in special forms is of use under conditions which may be placed beyond that intended when we use the term "first aid." The foam extinguisher closely followed the carbon tetrachloride extinguisher and soon made a place for itself which makes us now wonder how we did without it before it took its place in the scheme of things. The next candidate for honors in fire control is the use of an inert gas such as carbon dioxide. This material properly handled may be expected to fill a need which is of prime importance to public utility companies who must constantly have in mind continuity of service with a minimum shut down period in emergencies. It would be unwise to predict the relative growth of any particular type of fire extinguishing equipment or to anticipate the use of new elements or new methods. On the other hand, there is so much to be learned and relearned in connection with the equipment now available that we may well lay predictions aside at this time.

The Best First Aid Appliance

Perhaps you may ask me what is the best first aid fire appliance or what extinguisher is most suitable for all purposes? My answer would be that each serves a useful purpose, but none is suitable for every service. If you anticipate fire in ordinary combustible materials, such as wood, rubbish and the like, you should select an extinguisher providing the quenching and cooling effect of water. If the building contains gasoline, greases or oils, select an extinguisher designed for its blanketing and smothering effect so highly essential for fire fighting in these materials. If electrical equipment is involved it is desirable to use an extinguishing medium which will eliminate the hazard to life that may be present where water or water solutions are used. Extinguishers using special carbon tetrachloride liquids peculiarly lend themselves to electrical fires, owing to the fact that these liquids are tested and shown to have a high resistance before being acceptable for use in connection with extinguishers of this type. If you will refer to the list of inspected fire protection appliances published by Underwriters' Laboratories, you will find a definite statement with regard to the classes of fires for which most types of extinguishers are adapted. In some cases you will find that an extinguisher is suitable for more than one class of fire. In the list mentioned the above three classes of fires are referred to as Class A, Class B, and Class C. Class A fires are defined as incipient fires on which the cooling and quenching effect of water is of first importance. Class B fires are incipient fires on which the blanketing or smothering effect are of first importance, and Class C fires are incipient fires involving electrical

equipment where the use of a non-conducting liquid is of utmost importance. It is mentioned before that some types of extinguishers are suitable for more than one class of fire. Examples of this are found in the case of foam extinguishers which are suitable for both Class A and Class B fires and of carbon tetrachloride extinguishers, suitable for both Class B and Class C fires.

Another item you will find in the list is a guide to indicate the number of extinguishers ordinarily used to protect any given area, this being based upon practices recommended in the regulations of the National Board of Fire Underwriters for the installation, maintenance and use of first aid fire appliances. In carrying out this scheme, the classification of the different extinguishers is given in the list and each extinguisher is marked with its classification. It is, of course, to be understood that these are minimum requirements and that where necessary more may be required in the vicinity of special processes. In selecting extinguishers care should be used to select the proper type of equipment and to locate it so as to limit the distance to be travelled when attacking a fire. No general rules can be devised to cover special conditions adequately. Each situation may present a problem in itself and a long range attempt to advise may not give the best results. A relatively recent development illustrating this fact is the introduction of carbon tetrachloride extinguishers having a capacity in excess of one or one and one-half quarts. Devices of these larger capacities have been found to serve a most useful purpose, especially in electrical power stations or for special industrial conditions where consideration has been given to the large quantity of liquid and where such devices are usually operated by men familiar with their use and efficient supervision prevails. On account of the large amount of carbon tetrachloride extinguisher liquid used, it is necessary to take precautions to protect operators and others from possible toxic effects from vapors, especially when using these devices in small rooms or confined spaces. This particular reference to toxic effects from vapors given off in the application of carbon tetrachloride extinguisher liquid may cause question as to the general use of such liquids. Frankly, if we could rebuild chemistry we might make fire fighting a most enjoyable profession. On the other hand, we must work with the tools given us and no substitute has yet been found for carbon tetrachloride. In fact the effects of carbon tetrachloride are probably no more annoying or toxic when the products of combustion which naturally accompany every fire. Undoubtedly many of the reported cases of discomfort attributed to the use of carbon tetrachloride extinguisher liquid are to smoke and other combustion products. Another special type of first aid appliance is the carbon dioxide hand fire extinguisher which is of special interest to those who have large switch boards to protect, such as in telephone exchanges and similar premises. This class of device is useful where the blanketing effect of the gas may be utilized and where the conditions are such as to permit close approach to the burning area.

Instruct Employees Thoroughly in Use of Appliances

The selection of the proper first aid fire appliance and its suitable location is but the first step in the fire fighting problem. Employees should be instructed in the use of the equipment and above all the equipment must be maintained in a condition ready for instant use. No device has yet been made, that will stand for years without care or attention and ready to function reliably. If actually undisturbed, most extinguishers will remain in an operative condition for so long a period that many people believe we are unduly conservative when we recommend an annual or more frequent inspection and test, or in some cases, the complete discharge, cleaning and recharge of the extinguisher. Un-

fortunately an extinguisher hanging on the wall cannot advertise the fact that it has been tampered with or that it has not been recharged nor examined since it was hung in place. The only sensible thing to do is to put the care of extinguishers in charge of one man and so place the responsibility on him that his pride in the performance of the fire equipment will assure its readiness when the emergency arises. The care of an extinguisher is not difficult and the simple rules to follow will not tax the intelligence of the ordinary employee having sufficient education to read and write. Condensed to its simplest terms his instruction should be to follow the directions given on each device and to use the recharges, furnished by the manufacturer, exactly as specified.

Perhaps some will say that extinguisher recharges furnished by this, that or another manufacturer are "just as good" and especially when price is a factor there is a definite tendency to select the lower priced material. This is true particularly in the case of carbon tetrachloride liquids which are so frequently purchased from other than the extinguisher manufacturer. Unfortunately on account of the use of the term carbon tetrachloride we find that many of the so-called extinguisher liquids are nothing but plain carbon tetrachloride, perhaps sold by their vendors in the mistaken belief that this material is the same as that furnished by the extinguisher manufacturer. All too often this plain carbon tetrachloride is not even relatively pure and free of ingredients harmful to the extinguisher mechanism. Many extinguishers have been ruined by a false sense of economy. Even a slight amount of water, such as often is found in poor grades of carbon tetrachloride, is sufficient to make all extinguishers of this type useless within a short time.

Reasons For Variation in Recharge Cost

Remember that the difference in cost of recharges may largely be traceable to the difference between the original ingredients used and the care exercised in proving, by careful tests, that the finished product conforms to the standard established for this class of liquid. It is likewise true that with other types of extinguishers it is not safe to obtain recharges from sources other than the manufacturer of the extinguisher with which the recharge is to be used. Of course, with the soda-acid extinguisher we all know that the chemicals are easily obtainable and that, practically speaking, the recharge for this type of extinguisher may readily be obtained from the drug store. Even so, it is well to place on the manufacturer a certain degree of responsibility which he will not have if recharges other than his own are employed. With foam extinguishers it is practically imperative that chemical recharges should not be interchanged indiscriminately, but as quite a number of foam devices have similar characteristics, interchange of recharges in such instances will cause no harm.

On the other hand, as there are instances of critical variations in characteristics, the safe rule to follow is to comply with the manufacturer's directions in all cases. This rule, important as it is, perhaps is more frequently challenged than any other. Nevertheless, remember that having built into his device the necessary characteristics, the reliable manufacturer, wishing to stand back of his device, can not properly be held to account if alterations or repairs are made without his knowledge and if chemicals other than those supplied or specified by him are used.

CHAIRMAN HARMER: We are indeed grateful to Mr. Smith for the subject that he presented, and one other thing that I think we ought to emphasize; that is the fact that Mr. Smith is an authority on this paramount subject. I think possibly there are many of us who do not know what the Underwriters' Laboratories up here in Chicago are. I think it is our duty to find out exactly the ramifications and extent

of that work so we will have that background to know primarily what we are trying to do in the prevention of fires. Tackling these things without the primary background sometimes leads us astray, or along the wrong line, and I feel if we knew exactly what the Laboratories are trying to do to give us a background, we would be able to get to some satisfactory solution.

In view of the fact that our time is so limited, there is only one other thing I would like to say just now, and that is that we, as public utility employees, ought to correlate. Our official reporter here makes a very good suggestion, he suggests that the paper just read by Mr. Smith be printed. We have already turned that suggestion over to the chairman of our Publication Committee, Mr. Keller, and I am going to pass it on to your chairman. I just want to draw to your attention the fact that our official reporter is an outside man to a certain degree, who comes in with us and comes right along with us, and helps develop our thought. I thought it was worth while mentioning that.

Mr. Opp, will you take the chair?

Classification of the Section Attendance

CHAIRMAN OPP: I have here an announcement of the classification of the entire attendance of our Section yesterday, executives 14, managers 6, claim adjusters 6, safety engineers 105, superintendents 46, foremen 40, employment men 23, insurance agents 5, and the National Electric Light Association representative, making a total of 295. It is always well to know just how we are situated, and what composes our audience, and that is the reason for this resumé of the attendance of yesterday. The attendance of today will be 298 and will be classified for presentation tomorrow.

By way of explanation to Mr. Bennett on the matter of the poster referred to this morning, I find from the chairman of the Poster Committee who did not happen to be in the room at the time, that he had sent out the posters to the vice-chairman on gas, and having had no response from him he took it for granted that the idea was O. K., and the poster was published. Hereafter we are going to see that there is an actual O. K. put through on these things, in order to avoid the possibility of printing something that will lead to a misunderstanding, and as in this instance, even harm.

I think it is a very good point for Mr. Bennett to raise, and we have gone to the bottom to find out how it occurred. We are all very much interested in the keynote struck yesterday relative to the question of safety in the employment manager's office. The idea of stopping the leak to make sure that the class of personnel that enters our plant or our line work or anything else, is of the type that is going to be safety-wise as they are working.

So, in keeping with that view, we are going to reproduce for you here, not by addresses, and not by word of mouth alone, but by real action, the matter that ties in very closely on this point, in the form of a playlet. This playlet has been presented on several previous occasions, and has been amplified to meet the needs of this particular occasion, and it gives me indeed great pleasure to introduce to you the next feature to be presented through the courtesy of Mr. C. P. Ryan.

C. P. RYAN (Northern Indiana Power Co., Indianapolis, Ind.): I might say that it was our idea in the territories where we operate, that if we ever got anywhere in the world it was due to the fact that our safety engineers would see to it themselves. Each year we held an all day foreman's meeting, and in two districts in Indiana, which brought in our foremen and managers from approximately 35 counties.

This subject has two special points, one of which is the fact that any employer

has the right to know the type of a man he is going to employ; he has a right to know his contact with the man. One thing I have in this little playlet is that this man who was a roamer, or a "boomer" lineman as you call them, never saw a real foreman until he came to this job. I think you who are employing men in any department of your work can, and have a right to, ask any questions of any prospective employee, providing you use tact and courtesy in doing it.

You should also remember that a man who is out of a job, and is in need of a job, will tell the best he knows about himself, the same as you and I; if I am out of a job I will put myself in the best light possible. That is what you would do, and that is what I would do.

I want to introduce you to the gentlemen who are construction foremen, constructing and maintaining electric lighting lines.

"An Application for Position as Lineman"

C. P. Ryan, Northern Indiana Power Co., Indianapolis, Ind., and Robert Myers and M. L. Fitzsimmons, Northern Indiana Power Co., Kokomo, Ind.

(Superintendent is seated at his desk when the applicant enters and remains standing.)

APPLICANT: Good morning. I was told that you are in the market for a first class lineman.

SUPT.: Well, yes. Take a seat. We could use a man of that class. What is your name, please?

APPLICANT: John Doe.

SUPT.: Your age?

APPLICANT: Thirty-four.

SUPT.: Where do you live?

APPLICANT: Well, my home is in St. Louis when I am there. I live with my sister. My father and mother have not maintained a home since I was twenty-one.

SUPT.: Have you a wife or children?

APPLICANT: Wife and one child.

SUPT.: Where do they reside?

APPLICANT: They stay with my wife's people in Peoria.

SUPT.: When did you see them last?

APPLICANT: About two years ago.

SUPT.: Are you divorced?

APPLICANT: No, sir.

SUPT.: How long have you done line work?

APPLICANT: Well, I think about twelve or thirteen years.

SUPT.: For whom did you first work?

APPLICANT: I think it was the Utopia Telephone Company.

SUPT.: How long did you work for them?

APPLICANT: Well, I think about three months.

SUPT.: What kind of work did you do for that company?

APPLICANT: Well, just line work.

SUPT.: Did you climb poles and do work at the top of poles?

APPLICANT: Yes.

SUPT.: Was your foreman on this job well versed in his business?

APPLICANT: Well, not very. He wouldn't take any advice from we linemen and there were several old-timers there. They didn't seem to be able to tell him anything.

SUPT.: Why did you leave there?

APPLICANT: Well, it wasn't much of a job and the wages were small and I didn't like the foreman very well.

SUPT.: Where did you next work?

APPLICANT: For the Walkerville Telephone Company.

SUPT.: How long?

APPLICANT: I guess about eight months.

SUPT.: Did you do practically the same kind of work there?

APPLICANT: Yes. Climbed poles and put on insulators and strung wire.

SUPT.: Was your foreman capable on this job?

APPLICANT: Yes, I think he was. That is, when he was around where we were working. He wasn't there very much.

SUPT.: Why did you leave there?

APPLICANT: Well, I just felt like there was a job somewhere else that would probably be better.

SUPT.: Were you dissatisfied with the foreman?

APPLICANT: No, I don't think I was. I guess I just wanted to roam.

SUPT.: Then where did you work?

APPLICANT: Well, I worked in a foundry two years.

SUPT.: Not at line work?

APPLICANT: No.

SUPT.: Whom did you do line work for next?

APPLICANT: The Gazelle Electric Company.

SUPT.: For how long?

APPLICANT: About eleven months, I think.

SUPT.: What were your experiences there?

APPLICANT: Well, I climbed poles, strung wire, changed transformers and other work that seemed to be necessary.

SUPT.: Tell me about the foreman on this job.

APPLICANT: Well, I worked under Bill Jones as a second-class lineman for about two months and one of the first-class linemen was injured and I was given his job.

SUPT.: What did the men do who were classed as second-class linemen?

APPLICANT: Well, they only let us work on dead stuff.

SUPT.: And what did you do when you became a first-class lineman?

APPLICANT: Well, I worked with two other first-class linemen and we worked on any kind of voltage and all alive.

SUPT.: What voltages did you handle on this job?

APPLICANT: 110, 220 and 2,300.

SUPT.: In what condition was their equipment?

APPLICANT: Well, it looked like bum construction to me.

SUPT.: Was Jones an experienced foreman?

APPLICANT: Well, I don't think he was as good as some I have seen. He talked a great deal and sometimes was rather insulting to us fellows.

SUPT.: Why did you leave there?

APPLICANT: Well, to be perfectly frank, they were not paying enough money and we all got other jobs.

SUPT.: Did you all quit at the same time?

APPLICANT: Well, yes; but we didn't strike.

SUPT.: How many quit at that time?

APPLICANT: Eleven.

SUPT.: How many went back to the job after the trouble was over?

APPLICANT: Why, I think six of the worst ones went back.

SUPT.: Where did you then go to work?

APPLICANT: Well, let's see. I think I worked on a railroad in a round house for a while.

SUPT.: How long?

APPLICANT: About three months, I guess.

SUPT.: Where did you then work?

APPLICANT: On a construction gang, building a hi-line from West Applegate to Podunk, about 32 miles.

SUPT.: What did you do on this job?

APPLICANT: I dug holes, set poles, put up wires and anything they told me to do.

SUPT.: How long did you work at this job?

APPLICANT: About three months.

SUPT.: Was the job done when you left?

APPLICANT: No, they had hardly got started. They had just begun to string wires.

SUPT.: What did you quit there for?

APPLICANT: I didn't like the superintendent, I guess, and I don't think he liked me any better than I did him and I thought I'd better leave.

SUPT.: What seemed to be the matter?

APPLICANT: Well, he expected me to do more than my share, I think.

SUPT.: Were you in good health at the time?

APPLICANT: Yes. I was able to do as much as anyone else and I believe I worked as hard as they did.

SUPT.: Was this foreman unfriendly to some of the others?

APPLICANT: Yes, I think maybe there were only two fellows in the gang that he showed any indications of liking.

SUPT.: Were they building this line on standard plans?

APPLICANT: Yes, I suppose so. Anyway, the boss was always looking over some blue pieces of paper he carried in his hip pocket.

SUPT.: Did that part of the pole line, which was constructed, look well-graded and straight?

APPLICANT: Yes, it didn't look so bad. We all took considerable pride in making it look that way.

SUPT.: There were no live voltages on this line?

APPLICANT: No, all dead stuff.

SUPT.: Where did you next work?

APPLICANT: At Evansville, on a maintenance gang.

SUPT.: How long?

APPLICANT: About five months, I think.

SUPT.: What work did you do in connection with this maintenance?

APPLICANT: Well, any work that was to be done.

SUPT.: Did you connect transformers?

APPLICANT: Yes.

SUPT.: What other work?

APPLICANT: Well, we unloaded poles, set poles, removed old poles and equipment and strung some new wire and anything that was to be done on those lighting lines.

SUPT.: How many men were there in the gang?

APPLICANT: Five linemen, four grunts and one truck driver.

SUPT.: Did you do such work as making taps to transformers from 2,300 volt primaries?

APPLICANT: Sure.

SUPT.: How did you determine where the primary terminals were for the proper voltages?

- APPLICANT: Well, I had that matter explained to me by the boss and I got so I understood it pretty well; however, when I first started, I kinda used the touch system. If the flash was just so, we had the right connection. Another lineman showed me about that.
- SUPT.: When connecting the secondaries, what method did you use?
- APPLICANT: Well, after connecting, we could test if there was any doubt by going to a house and turning on a light.
- SUPT.: You say you worked there about five months?
- APPLICANT: Yes. I quit there two months ago and have been visiting my sister in St. Louis.
- SUPT.: Why did you quit that job?
- APPLICANT: Well, we worked long hours and they were continually calling us out of nights, but I wouldn't have cared for that. I really liked the work, whether it was night or day, but the boss was kinda grouchy even though we favored him.
- SUPT.: How often did they call you out for night work?
- APPLICANT: Oh, once or twice a week, I'd say.
- SUPT.: Are you familiar with the standards for distribution lines?
- APPLICANT: Sure. I have been working long enough. I ought to be.
- SUPT.: Where should the primaries be located on the pole?
- APPLICANT: Well, on the top, if nothing else is up there.
- SUPT.: If other wires were there, how would you arrange for another set?
- APPLICANT: Either put on a longer arm up there or an additional arm below.
- SUPT.: You mean below the secondary?
- APPLICANT: Yes, or move the secondary down some. I don't think, though, that from some of the construction I've seen that that method would be standard.
- SUPT.: What clearances should be provided between wires on the same arm?
- APPLICANT: Well, there is usually enough clearance between the pole pin wires to allow a man space to crawl through. It's kinda dangerous though to have these two wires too close together.
- SUPT.: In the many places you have worked as a lineman, did you ever work under any rules?
- APPLICANT: Yes, the foreman made the rules as we went along.
- SUPT.: These were not printed rules in book form, were they?
- APPLICANT: Well, now I believe I did apply for a job with a company that did have a sort of rule book and after I looked it over and talked to some of the fellows there, I didn't go to work.
- SUPT.: Why?
- APPLICANT: Well, it looked to me like it would be a big job to learn all those rules and I was afraid that before I could learn them, I would get into trouble by violating them.
- SUPT.: What kind of rules were they?
- APPLICANT: Well, a sort of conglomeration that said, "Don't do this" and "Don't do that" and there was something in there about protective devices that looked like it would be a lot of trouble to use them.
- SUPT.: What did the fellows you mention say about these rules and devices?
- APPLICANT: Oh, they said they were alright and that the rules were alright, but that the superintendent and boss didn't pay much attention to them and didn't object if we didn't use the devices.
- SUPT.: What did you think of what they said about these things?
- APPLICANT: Well, I have always felt that where there are rules, they ought to be obeyed. I know you couldn't run the railroads unless their employees obeyed the rules and I didn't think much of the offer of the job when I found out that they were not trying to do what they were expected to do.

SUPT.: Were you ever injured in doing line work?

APPLICANT: Yes. On that hi-line job I told you about. I "burned a pole" when my spur cut out just above a knot. I was laid up about a week with a bruised leg. I might have broken my neck.

SUPT.: What were you doing at the time you fell?

APPLICANT: I was lifting one of the wires over the end of the arm.

SUPT.: Did you have a safety belt?

APPLICANT: Yes, but we very seldom used them on this work. We hooked one leg around the pole.

SUPT.: What caused your spur to cut out?

APPLICANT: One of the other linemen thought my spurs weren't long enough for those soft poles.

SUPT.: Did they say anything to you before you fell?

APPLICANT: No, but after I fell.

SUPT.: What did the foreman say after you fell?

APPLICANT: Oh, he cussed and said something about a safety belt. He had one on but didn't use it very often.

SUPT.: Did you get any other injuries?

APPLICANT: Yes. I got that burn on my hand there, (indicates burn) on the last job while I was making a connection to 2,300 volt wire after I had connected from cut out to transformer. I just forgot to pull the plug. Good thing I had my safety belt on then or I would have been knocked from the pole.

SUPT.: Aren't you afraid to handle 2,300 volts without rubber gloves?

APPLICANT: No; we old-timers ain't afraid of such voltages. Where it gets up to 4,400 or higher, I think I would want a pair.

SUPT.: Did you have a pair of gloves on when you got that burn on your hand?

APPLICANT: Yes, I had them on.

SUPT.: Rubber gloves?

APPLICANT: No, my cotton gloves.

SUPT.: Did you have any rubber gloves?

APPLICANT: Yes. I carried them in the bib of my overalls for hot wire work.

SUPT.: Don't you consider 2,300 volt connections hot wire work?

APPLICANT: Well, yes, I do now, and since that time I have made up my mind that a fellow ought to use rubber gloves when he has them, even though the voltages are less than 2,300.

SUPT.: Where did you get that idea?

APPLICANT: Well, I talked to a lineman over at Goshen not long ago and he said that all of their linemen would refuse to do any work at the top of a pole without these gloves.

BETTER NOT!

A chip of glass may cost you an eye

**Remove broken insulators carefully,
preferably with gloved hand.**

(All wires on this pole are telegraph and railway signal wires)

SUPT.: Were these all the injuries that you have received in line work?

APPLICANT: Yes, but I have seen other fellows injured.

SUPT.: Were any of them working directly with you?

APPLICANT: Yes. One.

SUPT.: Tell me about this one.

APPLICANT: Well, I was going up a pole with my pockets full of insulators and one of them slipped out and struck the lineman, that was following right behind me, on the head and he fell on the groundman who was working at the base of the pole, filling a bag of tools. Neither one was hurt very bad.

SUPT.: What did the foreman say about your methods in this case?

APPLICANT: Didn't say anything except laugh and say we were lucky dogs. I believe he did say that if I'd left the insulators on the ground, they could have come up in the tool bag just as well as me taking them up in my pockets.

SUPT.: Did he say anything about the other man following right behind you?

APPLICANT: Well, he said he had told all of the linemen not to do that, but I don't remember of him ever saying anything to me about it or I would have told the other fellow to stay down there until I got up.

SUPT.: You say you have had about thirteen years experience as a lineman?
APPLICANT: Oh, I expect about that.
SUPT.: What proportion of the time have you worked on live lines.
APPLICANT: Well, I think about six to eight years.
SUPT.: What degree of education did you receive before leaving school?
APPLICANT: I have only a common school education.
SUPT.: What is your impression of linemen who drink intoxicating liquors while working as such?
APPLICANT: I don't drink the stuff. Never did and won't work with any man who does.
SUPT.: What opportunities have you had to learn more about electricity?
APPLICANT: Well, of course, my principal learning as a lineman has been on how

to do line work. I never had a boss who of his own accord told me much about electricity. I'll have to admit that there is considerable mystery about it which I would be glad to know about, but a fellow naturally learns a little all the time.
SUPT.: Did you ever read about it?
APPLICANT: No, not much. I don't know that I have ever run across any reading matter concerning electricity that I could very well understand. The articles that I have read seemed to make the mystery worse.
SUPT.: Is it your impression that standards for construction and safely working on line work could be effectively followed out efficiently?
APPLICANT: Well, I expect they could. Of course, some of we old-timers are pretty much set in our ways, but I suppose where we were encouraged to get interested, I guess we could do it.
SUPT.: What would you think if a foreman would hand you a book of rules for the safety of employees and inform you that when you were thoroughly acquainted with its provisions, he would put you on as a second-class lineman?

APPLICANT: I don't know that I would care to work as a second-class lineman again after all my experience.

SUPT.: Did you ever meet our foreman of first-class linemen, Dick Smith?

APPLICANT: Yes, he sent me here.

SUPT.: Did you see him and his men doing work?

APPLICANT: Yes, I was out there about all forenoon.

SUPT.: What was your impression of him?

APPLICANT: Well, he is a sort of quiet fellow. Not much to say and when he does say it, he seems sort of business-like. He seems to treat the fellows nice, but I'll bet he is the boss when it comes to a show down. I think he knows his business. There was no loafing on the job while I was there and none of

them seemed to be in a hurry and there was no kidding or playing around about it.

SUPT.: Did it seem to you that they were accomplishing something?

APPLICANT: Yes, they seemed to get a lot of work done regardless of a lot of rubber things they had scattered around on the wires.

SUPT.: Did you notice whether they wore rubber gloves or not?

APPLICANT: Yes, they all had rubber gloves on with a leather glove over them and one of the fellows showed me his glove and showed me how it would hold air and he told me that they never done work at the top of a pole without them on.

SUPT.: Did their methods impress you favorably?

APPLICANT: Well, yes, I guess I never saw a crew work in that manner before.

SUPT.: What do you think of the working conditions here from what you have observed elsewhere?

APPLICANT: I think they are probably about the same as elsewhere so far as the men are concerned. Of course, I don't know anything about that particular thing much, but I think you have a better foreman than I have ever worked for.

SUPT.: If you were employed here in some capacity, do you think you could comply with the rules of the company and the instructions of the foreman?

APPLICANT: Yes, I think I could if you would put me under that foreman. I have a lot of respect for these quiet fellows that don't say much.

SUPT.: Why?

APPLICANT: Well, it rather indicates that they are thinkers. Too much gab never done anything.

SUPT.: If you would have to work as a second-class lineman for a few days until you had proven yourself capable, would you still desire to make application?

APPLICANT: Well, I don't know. That is a serious matter with me; however, I think I could afford to do that and do the best I could to make good.

SUPT.: You might look over the rules in this book, (*Hands him a book of rules*) especially sections No. 10, 20, 21 and 24 and see me in the morning. I would like to know your impression of the matter.

APPLICANT: Alright. Thank you.

(Returns next morning)

SUPT.: Good morning, Mr. Doe. Well, did you study those sections I referred to?

APPLICANT: I read them over, that is, three of them and then one of your linemen invited me to a movie with him and I ain't had a fair chance to study what they mean yet, but I think that can be done while I am working.

SUPT.: I am impressed somewhat with your frankness. You should realize that it is necessary for me to question applicants for such positions closely, and your frankness is a mark in your favor; however, I feel that you should give these rules of ours some little thought and study this forenoon and you should understand that we seek to employ only such men as are physically able to do our work and mentally capable to do such work in an efficient manner, which will include the prevention of any injury or damage because of such work.

You may take this blank, on which I have authorized a physical examination, over to Dr. Garr and report back here to me at 1:00 p. m. and I will advise you whether we can employ you as a lineman.

ADJOURNMENT

Thursday, September 29, 1927

The third session was called to order at nine-thirty o'clock by the chairman, George Opp.

CHAIRMAN OPP: The first subject on the program this morning will be presented by Mr. J. C. Sanderson, of Sargent & Lundy, Chicago.

Construction Contractors' Accidents on Public Utility Properties

J. C. Sanderson, Sargent & Lundy, Engineers, Chicago, Ill.

The politicians have taught us to shout "safe and sane," but neither they nor we have done much about it. We counsel caution, then praise daring men who have won by taking a chance. We insist on speed and economy and hope for carefulness. This is true not only of contractors but all of us; they are neither better nor worse than we.

The responsibility of unnecessary accidents is not with the individual alone nor any one group. The owner must take some responsibility for his insistence on undue speed; the accident insurance companies for being financially interested in the undertaking without a representative on the job; the contractor for not properly organizing his preventive measures; and the individual for his carelessness.

Speed in construction has become recognized as economically necessary. The interest charge for idle investment during construction is a very large item on most construction jobs. The rapid development of industry makes speed imperative to meet the ever increasing demands of the consumers.

Most utility companies are not only growing very rapidly, but the consumers are requiring a higher grade of service and greater reliability. With this demand for extended service and greater reliability is the ever present cry for lower rates. This condition can be met only by speed and efficiency.

As far as the writer knows, the accident insurance companies have not taken the interest in accident insurance that their financial obligations would indicate they should. Accident insurance may be a contributory cause of unnecessary accidents. The contractor may assume that with ordinary care and adequate insurance he has gone as far as he needs to go to promote safety. If he has an unusual number of accidents the insurance company increases the premium rate. Thus we establish the so-called "vicious" circle and the owner pays.

Protective Measures Should Qualify for Insurance

The accident insurance companies should require certain protective measures before insurance is granted. They should from their records be able to convince the contractors that intensive accident prevention is economical. At the end of each contract the insurance companies should send to the contractor a tabulation of all accidents with the causes and recommendations for prevention. The names and previous record of the foremen under whom the injured men worked should be given. There should be a system worked out to reward foreman with exceptional records. It would be profitable for both the insurance companies and the contractors if the foremen's interests in accident prevention could be quickened. It will be through the efforts of the

foremen that the greatest reduction in the number of accidents will be accomplished.

The contractor's responsibility is first and he should be required to employ intensive safety measures. It is not difficult to demonstrate that the jobs which are best organized for safety are also best organized for speed and economy.

In theory, all large contractors are strong for safety measures; in practice their safety rules are not strictly enforced. The principles covered in the following obvious rules suggested by the writer are included in the theoretical safety measures of most large contractors. Some of these rules are honored more in the breach than in the observance.

Safety Rules For the Contractor

1. The master mechanic is to make a careful daily inspection of all equipment on the job and render daily reports on its condition. Equipment that is in any way defective must not be operated.

2. All derricks must have extension levers so the operator will have unrestricted vision.

3. All rubbish must be cleaned from the work and piled outside the area of activity as fast as it accumulates.

This rule is usually indifferently carried out. If contractors would make a careful cost analysis they would find that by maintaining a rubbish crew they could reduce the total costs, speed up the job and reduce accidents. Men working on piles of rubbish, waste lumber, etc., are not efficient. A littered job makes men careless and indifferent and the number of accidents materially increases.

4. There should be established definite and comfortable lanes of travel over the job. These traffic lanes should be out of range of derricks or other moving equipment. The rubbish crew should maintain them.

5. There must be proper stairs, ladders and handrails where needed. These should be maintained by the master mechanic. Any injury to stair, ladders or handrails should be repaired at once.

6. All scaffolds, planked areas, etc., to be passed on by the master mechanic.

7. More care should be taken in hiring men. The physically and mentally unfit, careless and dissipated, should be rigidly excluded.

Contributory negligence of others is responsible for from 5 per cent to 10 per cent of the accidents on a job.

How Sixty Per Cent of Accidents Occur

The individual is a much more difficult problem. The mental attitude of the men accounts for about 60 per cent of all accidents. This 60 per cent may be divided as follows:

Poor judgment—30 per cent.

Contributory negligence of others—10 per cent.

Haste—10 per cent.

Inattention—10 per cent.

Correcting the mental faults of a notoriously careless people is necessarily a slow process. Posting danger signs has been suggested as a corrective measure. Their value is somewhat problemetical. As an illustration, some work was being done on a roof near a transmission tower. A handrail was erected between the tower and the roof and several danger signals posted. As a further precaution each man as he came on the roof was instructed to

keep away from the tower. On the third day a man climbed over the handrail and passed the danger signs to fasten a guy line on the tower. He was knocked to the ground by a 4,000-volt current. Fortunately he was not killed. The accident was recorded as thoughtlessness.

Such incidents could be recounted indefinitely, but it does not lead to a solution. Any material improvement must come through intelligent and experienced foremen. Each foreman should be charged with the protection and training of the men under him. The foreman should be held in some measure to blame for all accidents to his men. There should be a bonus system or some form of special recognition for foremen that have their men well trained. Handling materials accounts for about 40 per cent of the accidents. This percentage could be materially reduced by teaching the men the proper way to handle materials and then insisting on the proper method being used.

Lack of skill in handling tools accounts for 6 per cent of the accidents. We have no proper trade schools nor an intelligent apprentice system.

Lack of Skill and Haste Cause Their Quotas

Haste is accredited with 10 per cent of the accidents. As a matter of fact it is a contributory cause in nearly all accidents. An American contractor constructing a job in London applied American methods for speed with English workmen. The result was an unusual number of accidents. The job was called the "Slaughterhouse" by the workmen. The English workmen were not accustomed to working fast nor moving fast and the results were disastrous.

In this country we are keeping the speed of our operations ahead of the abilities of our men. We must use more efficient and more intensive training methods or slow down our operations to the safe speed of the men. It is hardly possible to slow down operations, therefore the only solution is to train the men. We must quicken their understanding, increase their interest in their work, and increase their skill in their trades.

It is useless to hope for great improvement in a short time. Material improvement will come only by formulating a comprehensive set of rules for taking care of equipment and laying out the work; and, more important, a systematic method of training foremen in safe methods of handling their work and they in turn teaching these methods to the men under them.

Contractors Association Taking Steps to Train Foremen

CHAIRMAN OPP: The meeting is open for discussion.

O. R. BENJAMIN (Detroit Edison Co., Detroit): Is there any method of training foremen?

MR. SANDERSON: No, but the Contractors Association is taking steps to do this.

G. F. STECKERT (Consumers Power Co., Jackson, Mich.): Do the contractors keep a record of when accidents occur, and so forth?

The only company I know of which does that is the L. E. Myers Company.

G. F. BENTLEY (Detroit Gas Co., Detroit): There are a number of accidents occurring during construction around plants due to falls. Are there any rules regarding the use of scaffolds, ladders, etc., prepared?

MR. SANDERSON: I do not know of such rules.

CHAIRMAN OPP: I would suggest that Mr. Bentley or anyone else desiring such rules communicate with Mr. W. Dean Keefer of the National Safety Council.

W. L. BRUCE (Westchester Lighting Co., Mt. Vernon, N. Y.): Isn't there some

way to encourage contractors to notify the utility company when they are going to do any work near the utility company's line?

MR. SANDERSON: I would say that this should be taken up, before the work is begun, with the architect.

R. B. INMAN (U. G. I. Contracting Co., Philadelphia): A code has been prepared in Pennsylvania on ladders and scaffolds which if followed will do much to eliminate that type of accident.

CHAIRMAN OPP: The next subject will be presented by Mr. Walter Wagner, of the Philadelphia Electric Company, Philadelphia.

Prevention of High Voltage Hazards on Customers' Premises

Walter Wagner, Philadelphia Electric Company, Philadelphia, Pa.

Although the United States leads in the efficiency of production because of the amount of power controlled by the industrial worker, I am firmly convinced that our leadership in the industrial world will be maintained only by the use of an increasingly greater amount of power under the control of the individual employee. Other countries, our competitors in commerce, are sensing this need, and in order to retain our advantage, more power will be used, with, if practicable, greater increase of safety and continuity of service.

To enlarge the fields of power application, our commercial departments are in an era where greater specialization in sales efforts are needed to secure the business, and a higher character of service required to stimulate a growth in its demand. Industries, particularly those having private plants now making use of by-products of plant energy, and those using electric baking ovens and electric furnaces, are typical of this group. The narrowing margin of profit from the sales of energy and the consequent necessity of low first costs and operating expenses require the absolute minimum of installation, operation and maintenance costs, compatible with the safeguarding of men, and service continuity.

The engineers of our industry are developing distribution systems of higher and higher voltages to the customer, and high tension interconnections between large utilities are making for more economical and satisfactory service. The manufacturer, through intensive specialization, is giving us equipment and machines approaching the ultimate in efficiency and continuity of service.

The Engineer Must Be in the Vanguard

The safety engineers, cognizant of this trend of the new industrial economic developments, must not be satisfied only to follow these changes, but must be in the vanguard, for it is only through their wise direction that the closely related, highest practicable, degrees of continuity of service and safety can be obtained and maintained. No expenditures must be made that cannot be concretely justified by the proper balance between the values of safety and continuity of service, and the cost of construction, maintenance and operation. Conversely, no unnecessary hazard either to life, limb, or service, can be tolerated through laxity or ignorance on the part of ourselves or those in our departments for whom we are responsible.

I have mentioned continuity of service as a responsibility of the safety engineer. Obviously, where interruptions directly create hazards to persons or property, we participate in the construction and operating plans for their prevention. If conditions in other customers' premises supplied from the same service might cause an

veloped, and operating companies have had to take the initiative. One company uses the terms "open" and "closed" for their markings, but recently an interruption to service was prolonged because a new man, an old steam engineer, thought that the word "open," as applied to the case of a steam valve, meant the flow of energy, and "closed" an interruption of the flow. One can readily appreciate the possible accident hazards which might occur under this misinterpretation of the markings. What do you believe should be the proper marking? I understand that manufacturers quite generally use the terms "off" and "on."

The method of grounding, consistent with the larger use and greater importance of power supply, is, in general, to have multiple grounds separated and connected by sweating to the common substantial copper bus at different points. Even lightning arrester grounds are now being connected to the common grounding network at larger substations in order to reduce the ground resistance to the minimum, but, because of the likelihood of great rises of potential during lightning discharge drainage, such practice is not recommended excepting where it is certain grounding conditions will not give rise to such hazards.

Construction

During the construction period, lack of insistence upon the removal of all but the minimum possible amount of combustible material has caused serious fires. It has been found advisable, at times, to require an extra extinguisher during construction periods.

The proper safeguarding of high tension receiving lines and equipment during periods of temporary construction may be very difficult, as indicated by the following quoted experience:

"In the case of a vault which was finished and made ready for service, the owner had some twenty electricians working in his section of the vault where the 4,150 volt circuit was switched from his bus to the various parts of his plant. He wished to get this newspaper plant running on partial service. This necessitated livening his bus at a time when there were no doors provided to keep unauthorized persons out of his vault, and while the electricians were as thick as flies doing a rush job in the vault. The wiring was open, copper rod between the bus and switch extended down to within three and one-half feet of the floor and no policing was contemplated. Although the hazards and possible consequences were of no legal concern of ours, we felt that we should render a service to the consumer by not only cautioning him, as he was not much concerned about the danger, but we even went further and insisted that proper precaution be taken before we turned on our service. After reaching the proper people in the owner's organization, we succeeded in getting a realization of the hazards and they agreed to delay the rendering of our service until hazards were corrected. This agreement was not reached until such a condition arose and was only precipitated by our refusal to render service, which seemed to impress the owner with the gravity of the situation."

What is your opinion of this method of procedure? If this company had been fortunate enough to be in a territory where the regulatory body had adopted and was enforcing electrical safety rules requiring the customer to properly protect himself, the responsibilities and efforts of the safety engineer would certainly be lessened, and I would urge that we who do not enjoy this advantage should keep everlastingly at it, locally, for the adoption of the National Electrical Safety Code rules by the regulatory bodies having jurisdiction.

Maintenance and Operation

Obviously, from the operating standpoint, our responsibilities actively begin with the introduction of current. Personal contacts with the prospective operator of the

substation, and the installation in the substation of glass covered or varnished surface single line circuit diagrams and operating rules, greatly facilitate the work. First aid prone-pressure resuscitation must be discussed, and, if practicable, a lesson given to the men in the presence of the employer. With the employers interested in this and other safety measures a labor turnover is less likely to lead to a loss of these instructions.

I believe that safety engineers are now generally making use of every employee visitor to the customer's substation—the meter reader, the meter tester, and the maintenance man, to advise of any unsafe service conditions which may come to their attention. Such advice, supplementing our own investigations during periodic visits and the receipt of periodic engineering information concerning the maintained integrity of grounds or other changes in conditions affecting the safety of operation, make for the greatest practicable degree of safety.

High Grade Padlocks Supplied

One company experienced great difficulty in maintaining the proper padlocking of customers' substations with the standard company padlock. A high grade brass padlock was supplied, and it was found that these were dropped, mislaid or otherwise lost by customers' employees, leaving the interior of the substation accessible to everyone. This company is now using the same lock with a short steel chain fastened by the manufacturer to the body of the lock, and the chain is permanently fastened to the door or gate protected. Unless an actual theft of lock exists, or the loss of a key in an emergency requires its destruction, it is expected that very few unlocked doors or disconnecting switch compartments will be found hereafter.

In testing equipment to determine whether it is alive, no maintenance work should be allowed until a double check on the dead circuit is made, and two men are concerned with this checking. The use of a Neon gas-filled tube at the end of a switch hook has been extensively used, but the necessity of opening a compartment for accessibility to a known live part, in checking the integrity of the tube, is an unnecessary hazard. One company is now installing Ford coils by which this tube can be safely lighted before and after the test of the supposed dead section, thus making certain that the tube has been operative during the test.

For the higher voltages, a metal switch hook terminal with condenser has been used to advantage. Slides of this and the preceding device will be shown.

Rules and Regulations

In order to serve best, it is of course necessary to be an authority on all safety rules required by those having jurisdiction in the territory served, and to know the trend of developments in related activities. Intimate contact, even if necessarily by correspondence, with the proper representatives of the city and state regulatory bodies is absolutely necessary. One of our problems in some instances is to ascertain the extent of jurisdiction of these organizations, and within these limits, cooperate actively in order to prevent the possibility of the introduction of drastic rules or adverse interpretations of existing provisions, and make every effort to secure the adoption of the new national standards.

Experience has shown that, in general, engineers of these regulatory bodies sincerely appreciate the practical cooperation which we can offer, and realize that only through joint effort can the greatest benefit accrue.

Many state regulatory bodies and others are waiting for the formal approval of the revision of the National Electrical Safety Code, revised under the auspices of the American Engineering Standards Committee. As you may know, this revision has covered a period of some four years of active work by representatives of all interests concerned, and I feel certain that very shortly the unanimous approval of

the revision will permit the American Engineering Standards Committee to promulgate this as a National American Standard. From my active participation, it is my impression that in so far as customers' high tension installations are concerned, there has been no serious difference of opinion in the revision of the rules. Many have been changed to meet the more modern practice, and I would strongly urge that each of you who have not already done so secure copies of these rules which have been printed by the Bureau of Standards. Make a careful study of the old rules and the revision, and if and when your experience would justify another change, send such statement, with supporting evidence, to the Headquarters of the National Safety Council for consideration in the next revision of the safety code.

Handbooks Issued by Bureau of Standards

Handbooks for each part issued by the Bureau of Standards are as follows:

Handbook No. 6—Safety Rules for the Installation and Maintenance of Electrical Supply Stations.

Handbook No. 7—Safety Rules for the Installation and Maintenance of Electrical Utilization Equipment.

Handbook No. 8—Safety Rules for the Operation of Electrical Equipment and Lines.

Handbook No. 9—Safety Rules for Radio Installations.

Of the above, Handbook No. 6 and Handbook No. 8 are directly concerned with the subject of this paper. Again I would recommend that in the absence of other rules or in the face of existing local rules, that you urge the adoption of these revised national rules.

The benefit of our experience in the application of these rules will serve to make more certain through our cooperative effort, that, throughout the whole country, our costs of construction, maintenance and operation, shall be consistently related to the proper degree of safety and continuity of service. We can meet the representatives of regulatory bodies on a common ground, and mutually make more certain of the adequacy of the present rules and of proposed revisions.

In closing, I wish to thank Messrs. Beardsley and Harmer and others for their valuable suggestions, and the manufacturers for illustrative material. May I congratulate the safety engineers of the industry upon the splendid results of their accident prevention efforts in the past? In the face of great increases in the voltages, in the quantities of energy used, and in the complexities of service—you have, throughout the country, successfully prevented a corresponding increase in accidents through your alertness and active cooperation with all parties concerned. There is still much to do, but the obstacles can be removed when once recognized and understood for you have both the will and the courage to meet them, and I trust that the discussion following the presentation of this paper will contribute materially to the progress of our work.

Safety Equipment For the Customer

CHAIRMAN OPP: The meeting is open to discussion on this subject.

A. A. RALL (Kansas City Power & Light Co., Kansas City, Mo.): What kind of equipment do you supply the customers with from the safety angle?

MR. WAGNER: It depends upon the nature of the subscriber.

MR. RALL: We will say it is a primary customer.

MR. WAGNER: It depends on the extent of the switching equipment and the disconnecting facilities accessible to the customer. A switch hook, rubber gloves and a tilting stool may be all that is required. But in general, the equipment shown

on the slide is the amount of equipment which we require the customer to have when the service is installed.

CHAIRMAN OPP: Are there any further questions you wish to put to Mr. Wagner at this time? I think it is a wonderful opportunity.

R. B. INMAN (U. G. I. Contracting Co., Philadelphia): With reference to the rubber gloves, I would like to ask Mr. Wagner what he considers is a frequent enough interval of inspection of the rubber gloves.

Periods For Careful Inspection

MR WAGNER: That again depends on circumstances. If the temperature and humidity conditions are such as to require frequent inspection, possibly the customer should be expected to look them over once a week. I would say that normally they should be inspected about once a month.

W. L. GRANGER (Superintendent Overhead Lines Dept., Detroit Edison Co., Detroit): Does your company own the entire equipment on the customer's premises, or any part of it?

MR. WAGNER: In general, the customer owns the equipment. The customer, of course, owns the safety equipment.

MR. GRANGER: Do any of your employees operate any of the equipment on the customer's premises or do they leave that entirely to the customer's employees?

MR. WAGNER: We have some places where the customer operates the equipment entirely. I would say in most cases the customer's employees operate the equipment, but in many instances they operate it under instructions for the operator to get in touch with the load dispatcher for the proper switching methods.

L. A. ZIMA (Safety Engineer, Brooklyn Edison Co., Brooklyn, N. Y.): In regard to the inspection and testing of rubber gloves, we have frequently had calls from customers requesting the company to give this service, and while we do not feel that we want to assume the responsibility we also recognize the fact that it is frequently quite difficult for the customer to get this service. Electrical testing laboratories are generally available in some of the larger cities, but in the small cities, how can we take care of the frequent inspection there?

MR. WAGNER: It has been about 20 years since I operated in a small town. It would seem to me that the principles still hold good in so far as the relation of the company to the customer is concerned, and possibly in those cases the customer would be handicapped to the extent of having to have an additional pair of gloves. As a matter of fact, I believe in all cases he should have an additional pair of gloves, and the time interval required to send a pair to a reputable laboratory to be tested and returned should not be long.

CHAIRMAN OPP: Gentlemen, if there are no further comments on this particular subject, we are advised that our Resolutions Committee appointed yesterday is ready to make a report at this time. Mr. McCulloch, as chairman of that committee, will make his report to you now.

Section Wires to Absent Members

MR. MCCULLOCH: I am sure many of us have missed some of our former leaders who have been very active in this section the past year. The recommendation of the committee that was appointed yesterday is that the following telegram or a similar telegram be sent to these men:

Harry Lucas, Secretary,
Philadelphia Electric Co.,
Philadelphia, Pa.

H. W. Moses,
Edison Electric Illuminating Co.,
Boston, Mass.

C. Howard Stewart,
Laclede Gas & Light Co.,
St. Louis, Mo.

Charles E. Morrison,
Utilities Mutual Insurance Co.,
New York City.

Merman Spoehrer,
United Light & Power Co.,
St. Louis, Mo.

"Three hundred and fifty members of the Public Utilities Section attending greatest Safety Congress ever held send heartiest greetings and best wishes. We sincerely hope you will be with us next year.

"George Opp, Chairman."

(Upon motion regularly made and seconded it was voted the telegrams be sent to the men named.)

CHAIRMAN OPP: Mr. Harmer, have you anything to add at this time?

Resolutions Are Offered

H. B. HARMER (Philadelphia Electric Co., Philadelphia): I tried to get in touch with Mr. McCulloch this morning relative to this resolution. I have a resolution that I would like to offer:

RESOLVED, That it is the sense of the section that we extend the thanks of the section to the splendid cooperation we have had from the National Head-quarter's staff.

I have another one, Mr. Chairman:

RESOLVED, That it is the sense of this meeting that we extend to the new Stevens Hotel management our appreciation for the splendid reception our delegates have received at their hands.

(Upon motion regularly made and seconded it was voted the resolutions be adopted and transmitted.)

CHAIRMAN OPP: Is there anything else along that line you wish to inject at this time? If not, let me read with deep pleasure the response to a night letter that went out to a man whom we had hoped to have here at the Congress, particularly by reason of his having been selected as your new vice-chairman in charge of electrical interests. That response reads like this:

"Will be glad to accept the vice-chairmanship. Will do everything I can to promote this work. Thanks for your congratulations. Did not stay away from Chicago because I wanted to dodge anything, but because of circumstances arising here at the last minute. (Signed) W. R. Lovd"

So there is the acceptance of your vice-chairman. Your official family is now complete. I understand from the new chairman that a meeting will be held at noon today to complete the organization of the work and to establish policies for the coming year. We have accomplished something this year which has not been done before. We are getting started before we stop. You know when it comes to accelerating after you have once completely stopped it means a considerable loss of time. This year we keep right on moving and we have the prospect of a real busy year. We are going to be working all of the time and not just work up to a peak in

advance of the Congress and have a happy Congress here and then go back and forget all about it for six months. You are going to be actively in touch with us and we with you all the year through, and if you wish to contribute anything make sure it comes to the attention of the officers by writing either to the chairman or secretary of this section or direct to the National officers. They will appreciate anything you might do in the way of contributing an idea or a suggestion.

We are asked to give consideration to this resolution which apparently originated in the Union Oil Company of California by George F. Prussing, who is Chairman-Elect of the Petroleum Section.

Action Deferred on Congress City

(Chairman Opp read a resolution to the effect that all future meetings of the National Safety Council be held in Chicago.)

CHAIRMAN OPP: What is your pleasure on a resolution of that nature, originating in another section, with the desire of continuing the Congress year after year in the headquarters city?

H. B. HARMER (Philadelphia Electric Co., Philadelphia): I think that is a debatable question and I don't think we can get a real, genuine consensus of opinion from the delegates this morning. It is one of those things on which we all have our individual opinion. I think possibly it would be a mistake if at this moment we took any definite action. I therefore recommend that we lay this on the table.

(The motion was seconded.)

MR. McLACHLAN: I would like to move an amendment, that it be handed over to the Secretary of this section for action.

(The amendment was accepted by both the maker and the seconder of the motion.)

G. M. GLIDEN (Ohio Public Service, Cleveland): I suggest the Executive Committee send letters to all the members of the section and get their action over their letter head on the suggestion.

(The amendment was seconded and accepted.)

CHAIRMAN OPP: We now have the motion with two amendment, all very good.

(The motion was carried.)

CHAIRMAN OPP: We are now going to pass on to the next subject on the program which is "The Affects of Attitude and Aptitude on Accident Prevention." Here is a new angle, gentlemen. We are injecting something a little different from what we have attempted in any previous program, and I am sure you are going to be interested in this new slant.

Mr. C. Y. Davis, Plant Employment Supervisor of the Illinois Bell Telephone Company, Chicago, will present this paper at this time.

The Affects of Attitude and Aptitude on Accident Prevention

C. Y. Davis, Plant Employment Supervisor, Illinois Bell Telephone Company, Chicago, Ill.

The discussion of any phase of accident prevention before a body of men primarily interested in the prevention of human suffering and the elimination of human waste is always an interesting assignment. However, it is a difficult one because the field has been so thoroughly covered that new ideas on the subject are scarce. On the other hand, it should be a rather simple task because one finds such sympathetic minds and attentive ears to whom old ideas in new form may be presented.

The thoughts which follow are not those of one who might be considered as a

professional safety engineer fully competent to discuss this important subject, but rather are the development of the accumulated observations and experiences of many workers in the telephone field.

Conditions Surrounding Telephone Men's Work

So that our minds may meet in the discussion of this important activity, it will be necessary, of course, because of its bearing on accident prevention work, that we keep in mind certain conditions which surround the work of telephone plant employees.

In general, the function of a telephone plant department is to construct, install and maintain the physical plant essential to the giving of telephone service. Moreover, the manner in which the physical work is performed has considerable bearing on the company's relations with the body politic.

Aside from the clerical and miscellaneous office forces, there are employed, in the plant department of the Illinois Bell Telephone Company, more than 5,000 field workmen.

In this field force occur the major portion of our accidents; therefore, it is toward their work that our principal accident prevention activities are directed.

These men usually work alone or in very small groups, and are seldom under the continuous visual supervision of a job foreman. Besides, they are scattered throughout the length and breadth of our territory, work in homes, offices, factories and along country roads, as well as in and under city streets and alleys.

The degree of success which each attains in working safely without injury to himself and others is, therefore, to a great degree dependent upon his individual conduct, his aptitude and ability in performing his assigned task, and upon his mental attitude toward his job and its safe performance. In short, he must be not only a doer, but also a thinker, and capable of adapting himself to situations as he finds them.

Although these conditions probably apply in most public utilities, they must be borne in mind in connection with accident prevention work in such organizations.

Tangible Versus Intangible Factors

In discussing accident prevention at a meeting of this kind, one is tempted to talk about what has been done in the way of providing safe tools and materials; in providing physical safeguards; in giving employees instructions in first aid treatment, etc.; and to quote statistical evidence of progress in prevention of injury to employees. Though all these and similar items are highly important, such history and statistics indicate that regardless of how carefully tools and material are designed, and regardless of the number of mechanical appliances furnished to safeguard employees from injury, the fact remains that we still have accidents—true, probably not as many as there would be without such precautions, but probably far more than is necessary. In the past, most of our attention has, of course, been focused on the tangible items referred to, but inasmuch as accidents still occur, does it not follow that there must be at least one other less tangible factor which should receive even closer attention, namely the human element.

It is impossible, of course, to list all of the known or probable causes of accidents which result in personal injury, but there is no gainsaying the fact that most accidents are largely attributable to the carelessness or ignorance on the part of the person injured or others. It is true that some injuries are caused by faulty tools and equipment, and some by occupational hazards, etc., but notwithstanding that fact a large majority involve the elements of carelessness or ignorance.

Webster defines an accident as an event that takes place without one's foresight or expectation, and whenever we think of accident prevention, we usually think of carelessness, ignorance, and foresight. Carelessness, ignorance and foresight are

the result of mental processes or the lack of them, as distinguished from the physical factors that contribute to accidents. Do not the facts in connection with fatal or otherwise serious injuries frequently indicate that the injured person was a skilled workman, expert in the technical requirements of his job, and working under reasonably safe conditions, but through carelessness, ignorance or lack of foresight by him or others, the unforeseen happened? Does this not emphasize the desirability of giving even greater attention to the mental qualities of employees?

It would be presumptuous on my part to undertake anything approaching a full discussion of the relation of all the mental qualities or processes to accident prevention; therefore, let us confine our thoughts to only two of these factors, namely, "attitude" and "aptitude."

Proper Attitude an Important Factor

What effect or influence does attitude have on the prevention of accidents? Attitude of whom? Attitude toward what? Let us assume that we mean the attitude of all those involved in our operations, namely the management; the foreman, and the workman; and that we mean the attitude of each of these toward the fulfillment of his obligation to our customers, to our employees, to the owners of the business. Do these affect or are they affected by accident prevention? Such accidents as cause personal injury frequently interfere with the establishment and maintenance of telephone service, cause pain and suffering to workmen, and increase operating costs. Consequently, such accidents affect all three of the essential members of the industrial family, customers, employees and owners. Is it worth while then to attempt to develop within our own ranks a proper attitude toward the prevention of accidents?

Attitude is defined as a position assumed to serve a purpose, or a bearing indicating action, feeling, or mood. What we are dealing with is mental attitude; in other words, the position or bearing assumed toward the success of the business, the comfort and happiness of others, the development of the mind and body, and our contribution to the social order of the community. In other words, how do we feel? What do we think about these things?

Relation of Attitude to Accident Prevention

If the management thinks of accident prevention or safety in its plant operations as a matter of general propaganda only, and is insincere in its talk about these questions to the extent that it expects the foreman to wink at short cuts to production, involving extra hazard; or

If the foreman thinks of accident prevention as a temporary stunt of the management in which he must go along with just enough to get by until the newness has worn off; if he is not personally sold on the desirability of accident prevention, but merely conforms to a prescribed policy with mental reservations; if he thinks that the responsibility for accident prevention is general, and senses no definite responsibility on his part for leadership, training, and directing his men to avoid personal injuries; or

If the workman feels that the management and foreman are interested in the prevention of accidents only so that the work may be done at a lower cost; if he feels that the observance of certain specified practices are not based on reason, but are only to satisfy the whim of some specialist;

If any of these conditions prevail generally throughout an organization, it is reasonably certain that accident prevention in that organization will fall far short of its full possibilities.

On the other hand: If the management is conscious of the real value of and thoroughly in earnest regarding accident prevention, and is willing to bear its share

of whatever cost may result from an active and continuous accident prevention or safety movement; and

If the foreman feels that the management is sincere and recognizes that the training and supervision of his workmen in safe and efficient methods is his individual responsibility and that the occurrence of an accident resulting in personal injury, caused by any employee under his direction, is a direct reflection upon his ability as a foreman; and

If the workman has a personal interest in not only doing a good job, but doing it safely, and realizes that the absence of accidents on his part is just as much an element towards the establishment of a good record, and his eligibility to promotion, etc., as is the turning out of a full day's work;

If these conditions prevail generally throughout an organization, accident prevention in such an organization will most nearly approach the full measure of its possibilities.

The question may be asked as to which factor has the greatest effect or influence on the prevention of accidents in an organization such as ours, the attitude of the management, the attitude of the foreman, or the attitude of the workman. The answer appears obvious—all are necessary, but it is quite unlikely that a proper attitude on the part of either the foreman or the workman can be secured unless the management itself has a proper attitude, because the attitude of the management is reflected throughout the supervisory organization down to the job foreman, and the attitude of the job foreman is certainly reflected in the attitude of his men.

Full Understanding of Management's Attitude Is Important

Often, the attitude of the management, although entirely proper, is not fully understood, or is even misunderstood, by the foreman, but happily the management in all industry seems to be lending its best efforts to the end that any factor contributing to a misunderstanding as to how it feels toward accident prevention is removed. As a result of this, the foreman of today has a new and broader conception of his job. Through frequent conferences, he is becoming more and more conversant with the management's attitude and policies regarding the various phases of its business, and particularly with regard to its relations with employees. In our industry there is a tendency towards small groups of workmen under one foreman. This makes it possible for a foreman to be more nearly a part of his working force. He is in a position to know his men thoroughly, and he should be their teacher, adviser, leader, and personal friend. He is in the best possible position to influence their mental attitude toward safety, toward production, and toward service to our subscribers in its fullest measure.

Development of Proper Attitude

It is my belief that the development of the proper attitude on the part of the workmen in these things depends first on his general attitude towards his job.

If he is dissatisfied with his wages, or working conditions; if he thinks there is no opportunity for self-development or for promotion; if his mind is disturbed over these or similar questions; he will not have a proper attitude towards accident prevention or anything else connected with his job.

On the other hand, if his mind is not disturbed with general dissatisfaction, or personal grievances, his attitude is probably right.

Right Attitude a By-Product of Interest

A closely related and important factor in the development of proper attitude is that of interest. Is the workman interested in his job? Is he interested in his

own advancement? Is he interested in the fulfillment of the company's service obligations, etc.? Very often, mere presence on the payroll is mistaken to be sufficient indication of interest, and most workmen if asked these questions would assert that they are interested in all these things. There is probably only one sure way, however, to determine if the employee is actually interested, and that is through his individual acts. For example, what does he do aside from what he is required to do? In what way has he demonstrated his interest? Attitude and interest seem to be so closely related that we can probably safely say that where an employee demonstrates his interest in his present job and future advancement, by actual performance, rather than by mere assertions, he will have a constructive and proper attitude toward production, accident prevention, and his entire working relations.

Workmen Should Be Selected for Their Specific Aptitude

What do we mean by aptitude? Aptitude of whom? Aptitude for what? Aptitude is defined as the natural or acquired capacity for a particular purpose. We are thinking about the aptitude of the workman on his regular daily job and its relation to his efficiency. We say that a person is apt if he is especially fitted or qualified, and quick to learn. Because of the rapid development and constant changes in telephone work, it is necessary that workmen be more than skillful; they should be apt, quick to learn. The selection of new employees with regard to their aptitude is, therefore, one of our most important functions. A workman may be skillful; however, if he is not apt, if he is not quick to learn, and his skill is only the result of long and tedious training, it will be difficult for him to acquire skill under changed working conditions. Where men are working individually or in small groups, it is necessary that they be individually able to quickly meet changed conditions; especially in this true where unexpected hazards are encountered.

Testing for Aptitude

Our local practice, in which you may be interested, is, when additions are made to our working force, to insure, in so far as possible, that only new employees who are mentally alert, and who can meet changed conditions quickly, are taken into the organization. Effort is made, by simple means, to test not only the applicant's knowledge and skill qualifications, but also his aptitude for our work. This includes his ability to absorb, memorize, and apply instructions, his mental alertness and ability to reason, all of which are demonstrable.

These preemployment tests, as well as other subsequent qualification tests given in connection with our regular occupational training, were developed jointly by the line supervisory force and the plant school. All tests and class room training are handled by the plant school, but only at the request of and with the full concurrence of the regular line organization.

Preliminary Training

Applicants successfully passing the preemployment test, if acceptable from a health and personality standpoint to the department head requiring help, are employed by him. However, before being actually placed in the working organization, the new employee is given a preliminary training course, usually lasting six days, on the particular class of work to which he is to be assigned. The purpose of this course is to provide the preliminary education and information necessary to starting the job and to enable the new employee to come into production in the shortest time possible. This course also provides an opportunity for further observation and checking up on the new employee's potential ability and aptitude, and those showing insufficient ability and aptitude are dropped at this time.

Likewise, throughout his subsequent service, the employee is under observation, periodical reports being rendered concerning his progress and general aptitude for the work to which he has been assigned.

Specific Instruction in Safe Working Methods

So that the new employee may not be entirely ignorant of safety practices, as he progresses through his preliminary training course, he receives instruction from time to time in regard to accident prevention on the particular type of work being studied. For instance, in the splicing of wire, he is cautioned against improper use of cutters, and in the danger of personal injury through careless handling of tools and material.

On the last day of the preliminary training class, the students are given a lecture on accident prevention. This reviews the instruction received at various intervals throughout the course and includes, for example, such items as:

Safe use of ladders, drills, goggles, and other tools.

Safe method of climbing poles.

Unsafe conditions, that may be encountered in the field, are cited, and ways of overcoming them suggested.

Method of reporting unsafe conditions, etc.

In addition, a bulletin showing the correct method of climbing poles is given to each student involved in this type of work. All students are given a copy of a pamphlet on Foresight and an associated questionnaire. This pamphlet is in narrative form, and is intended to induce individual thought on actual working and safety practices. Further, central office workmen are given a list of safety precautions citing specific conditions encountered in their work that will require careful handling.

Occupational Training

An employee who successfully passes the preliminary training class and who is put to work receives a copy of the occupational qualifications for the particular line of work in which he is employed. These occupational qualifications set forth the mechanical and knowledge requirements which he will be required to meet if he expects to progress in position and salary, and include specific items on accident prevention.

At this time, he is enrolled in an occupational training course and receives questionnaires from time to time covering the subjects with which he needs to be familiar to do his job effectively. Every occupational training questionnaire includes several questions on accident prevention. By this method the subject of accident prevention is kept continually in front of the employee not as something special and aside from his job, but as part of it. As these men are brought into class the questions on accident prevention which they have answered are reviewed and discussed by the entire class, a procedure which we find is particularly helpful.

Qualification Tests

Qualification tests for advancement are given to field employees, and these always include a set of questions concerning accident prevention. The employees are graded on these questions and the answers discussed with them at the end of the test.

Special classes are conducted from time to time on various subjects and new practices, and very often these subjects concern items which involve the discussion of and instruction on safe methods. Classes recently held on the use of fire extinguishers, including the carbon dioxide extinguishers, are a case in point.

Percentage of Those Selected to the Total Number Tested

Reverting to the preemployment tests and the preliminary training course, you may be interested in some figures showing the number of applicants tested and the percentage eliminated during the five month period from January 1 to May 31, 1927:

For two classes of work, namely subscribers' station installation and subscribers' station repairs, 318 applicants were sent to us by the general employment office to take our preemployment test. Of the 318, 192 failed to pass the test; four could not pass the health examination, 14 were dropped at the end of the preliminary training course as being unadapted to our work, and only 109, or a little more than 34 per cent, displayed special aptitude and actually went into production. It is of further interest to note that those applicants who took the preemployment test represented only approximately 25 per cent of the total applicants who presented themselves to the general employment office. The other 75 per cent were eliminated by that office on the basis of their general standards plus their understanding of our specifications for the positions to be filled.

Result of the Elimination Processes

These eliminative processes are designed for the express purpose of securing as capable and as apt employees as is possible under the circumstances and in keeping with the positions to be filled. It is recognized that these tests are not infallible, but needless to say, such care in the selection of employees tends not only toward a better production record, but is also a considerable factor in the consistent reduction of lost time accidents that we have experienced.

In conclusion, can we not agree that the development of a proper attitude and the securing of employees with specific aptitude for the work involved is of prime importance and has a direct bearing, not only on job production, but also on accident prevention, and all other related activities. Finally, lest I have inadvertently conveyed the impression of any belief on our part that we have wholly solved our problem of accident prevention, or even approached a solution, let me definitely correct that impression. We are merely conscious of an objective, and are earnestly seeking the most effective means of its attainment.

CHAIRMAN OPP: We will not have discussion on this paper. Shoot your questions promptly because we are trying to keep to the schedule under difficulties.

J. F. McCURDY (N. E. G. & L. Co., Boston): I would like to ask Mr. Davis, is it a fact that at the present stage of mechanical and physical perfection in plant and material, that that fact may be eliminated and the mental processes of the employee be dealt with practically as a whole?

MR. DAVIS: Certainly not. The statement was introduced merely to emphasize the importance of the human element. I believe it was Mr. Scott who first emphasized that thing. Only for the purpose of emphasis, from the standpoint of attitude and aptitude was that statement made and it wasn't meant to convey the thought that it could be ignored at all.

CHAIRMAN OPP: Is there any further discussion? If not, we will go right on then to the next topic.

A Medal For Work in Resuscitation

There is one item that we have delayed making mention of in regard to a suggestion which originated in this section last year, which was the idea of a medal to be awarded for cases of successful resuscitation not covered at present by either the McCarter Medal for the American Gas Association, or the Insull Medal for the National Electric Light Association. As vice-chairman of the Special Committee on Medals for the National Safety Council I wish to report progress to the extent of the adoption of a design and the preparation of rules to cover the award of such a medal. Within the coming year we will doubtless have an official announcement relative to the administration of this new medal. The idea originated in the Public Utility Section so you may consider it your own baby.

The attendance today, indicated by the cards already turned in, which is not com-

plete because I see some more cards need to be collected, totals 297 from 22 states and Canada.

It is only proper that you should get better acquainted with your new chairman. I know of no one in the public utility field who has taken a keener interest in accident prevention than your new chairman. No one during the past year has worked harder, more zealously, more painstakingly than has our new chairman. With keen pleasure I present Mr. Carl J. Rutland, Safety Engineer of the Texas Power & Light Company, Dallas, as your next chairman.

The Humane Attitude Toward Safety Work

CHAIRMAN-ELECT RUTLAND: Retiring Chairman, Officers, Members of the Public Utility Section: I don't know of anything that has given me greater pleasure than to be associated with a bunch of men who have as their purpose the conservation of human life. I heard Charley Scott say once that when he started in safety work he thought that he would like to make a good record. He had reviewed the past records of his company as far as fatalities were concerned and as far as accident costs were concerned, and he wanted to better that record. When he started in safety work he had that for his goal.

I didn't think until two years ago just what my purpose in safety work was until he made that statement. Then he said this: "I have attended the funerals of a lot of men in our organizations. I have been deeply impressed with the tragedy that results after an accident occurs. My viewpoint of safety has been changed entirely from that of an economic one to that of a humane one."

Sincerely to you, gentlemen, my thought, my study, and my interest in safety work is purely that of a humane one. I know that you gentlemen, having possibly looked into the humane side of this question by attending the funerals of some of the employees of your own company and seeing the tragedy that exists in the home after the accident occurs, appreciate that your viewpoint of safety is turning, and that is the only successful viewpoint in bringing safety to a happy end.

I feel that we will have a successful year.

It appears to me that you have put me on a pyramid, and I am thankful and you should be consoled that that pyramid has a heluva strong foundation, and I refer to the officers who are going to serve with me this year.

The story is told of a certain dignified English gentleman who had received a questionnaire on which he was to fill out nine questions. One of the questions was: "Where did your father die and how did he die?" This embarrassed the dignified English gentlemen very much because it happened that his father had been publicly hanged. He deliberated on the question and finally wrote these words:

"He was attending a public function when the platform gave way."

How Things Are Actually Done

I don't believe the platform is going to give way with the officers we will have this year.

A good many of you have come here for the purpose of seeing how things are actually done. In the presentation of the next paper I believe you are going to get a concrete idea that may be helpful to you in your own organization. There is nothing that makes for greater safety than that of building up a safety organization on a dignified plane in the company in which it is working and giving it all the prestige that it needs. I think the paper that is going to be presented by Mr. H. F. Webb, General Safety Director of the West Penn System, Pittsburgh, will give a great many of you a new slant on prestige in your safety organization in your own company.

Organizing for Accident Prevention in Public Utilities

H. F. Webb, General Safety Director, West Penn System, Pittsburgh, Pa.

The establishment of a safety organization in a public utility presents numerous problems which are foreign to practically all other types of industry. This is especially true of the utility operating in a number of scattered communities rather than in one large city. Where other industries house their employees under one roof or in a group of buildings, constituting a single unit, the utility has men at numerous locations, i.e., steam plants, hydro plants, substations, water works, and gas plants, often situated miles apart. In addition it has line, construction, and gas crews scattered in every direction and probably never at the same location on two successive days.

Should the company operate a street or interurban railway the problem is increased, for here employees, each operating individually, are seldom, except on special prearranged occasions, found in one group. The lack of concentration of employees at one location, which must necessarily go with public utility operation, raised barriers to organized safety work which require study and continued effort to overcome.

General Organization

Safety activities to be effective should be conducted in an organized manner, thus indicating a definite policy on the part of the company.

Director of Safety

In a large organization it is highly desirable to place this special line of work under the direct supervision of an appointed general director of safety who is responsible for executing the safety policy of the company. This would allow for the centralization of accident prevention work in one department and constitute a clearing house for suggestions and proposals and secure the adoption of safety standards. It would also promulgate information on safety, methods, and accidents, and if necessary, assist in their investigation; maintain injury and accident records and prepare tabulations and statements from them. Supply literature for posting on safety bulletin boards; conduct safety inspections; engage and train men for the safety work. The functions of the accident prevention department are wholly advisory—it has no executive authority over the operating departments or other branches of the companies.

Safety Engineer

On large subsidiary properties it has been found advisable to place a trained resident safety engineer. It is the duty of such engineer to keep in close touch with the officials regarding matters pertaining to safety; make a study of local accident statistics; furnish reports to the officials and supervisors; visit and inspect the various shops, plants, and properties; call attention to unsafe conditions; recommend proper safeguards; consider employees' suggestions; follow up orders for safety work; issue bulletins and other safety material for the instruction of employees; attend and speak at all safety service meetings and at safety committee meetings, when possible, and generally supervise the local safety activities.

This engineer, obviously, in such advisory capacity must gain the respect and active support of the officers, supervisors, and men. He will attain the best results through advice or recommendations approved by the proper authority.

Accident Records

As is true of any business undertaking, the keeping of records in organized safety work is important. These should include record of accidents and their investigation, together with details as to cause, time lost, and cost; minutes of safety meetings; records of inspections, and recommendations together with action taken in each case.

In connection with the record of accidents, it is essential that strenuous effort be made to have every accident, no matter how slight, reported. It is only through a complete record of all accidents that conditions existing on the property can be known and proper remedies for their correction instituted.

Executive Safety Committee

This committee composed of the keymen—superintendents, engineers, etc.—forms a necessary adjunct to the safety program. The executive safety committee serves as the local clearing house for the accident prevention work. In this committee, problems relative to specific hazards are discussed; lost time accidents analyzed, and safety suggestions examined and approved. Minutes of these meetings should be kept by a competent secretary and all unfinished business followed up in an orderly way.

The executive safety committee should have a regular day for meeting and should confer once a month or more often, if the occasion arises. Report of the meeting should be given to the general director of safety in order that suggestions and solutions to problems may be made available for other locations.

Mechanical Safeguarding

Mechanical safeguarding not only prevents some accidents, but is also a strong indication of the company's safety policy and determination to safeguard the lives and limbs of its employees. It proves the company's sincerity in the work in which it is asking its employees to cooperate. The safety inspector should be fully qualified to recommend and supervise the fabrication erection of mechanical safeguards in accordance with universally accepted standards.

First Aid Instruction

Knowledge of first aid among employees is highly essential. It has been found that, when employees are instructed in first aid, they become more interested in the prevention of accidents and thus cooperate more actively in the safety movement. The safety inspector should be fully qualified as a first aid instructor, as it is his duty to stimulate employee interest in this important phase of accident prevention work as well as conduct individual and group instruction.

Advertising Safety

A continuous educational campaign is essential to secure cooperation. Advertising forms one of the most effective means for arousing interest in any subject. Safety may be sold to the employees of any company by means of a definite, well-organized, advertising plan. A safety advertising campaign has been conducted continually throughout the West Penn System properties and has, no doubt, been partly responsible for keeping safety uppermost in the minds of its workers. This advertising propaganda, which is supplied at regular intervals by the accident prevention department, consists of accident prevention, health, and safe practice bulletins; posters; blotters, and many other novel ideas created to arouse and maintain employee interest.

Safety Competitions and Awards

Friendly competition is one of the greatest incentives to production and can well be utilized in safety work. A safety contest, if properly conducted, is always good. The competitive spirit engendered between groups encourages every effort to prevent accidents and keeps the idea of working safely constantly in the minds of the men. Individual awards for special "No Lost Time Accident Records" made by a department are beneficial. A bronze button, a watch fob, or any slight recognition is appreciated by the men and repays a thousand fold in good-will.

Results

The results of organized accident prevention work in a public utility are well defined and are directly in line with the aims of every executive. The elimination of accidents, in itself, is a humanitarian project and fully justifies any expenditure of time and money that may be made. This, however, although the primary, is but one of the results.

Improved morale, a finer *esprit de corps*, fewer service interruptions, better public relations, and an all around higher efficiency are the by-products of the safety movement. Producing these results, the accident prevention department may feel itself an integral part of the company, binding, as it does, all departments and divisions, employees and management into a coordinate whole, with one primary object—*SERVICE*.

CHAIRMAN-ELECT RUTLAND: Thank you for your courtesy in making your address brief and in presenting it as you did. I hope some of you have shotguns to fill this full of holes or will offer suggestions which will be helpful. Is there anybody who has any discussion?

JOHN PRICE JACKSON (New York Edison Co., N. Y.): The presentation to my mind was most excellent, and we all agree with it so fully that we have nothing to say but commendation.

There is one element which time probably prevented the speaker from bringing out, and that is the presentation of statistics to the Central Safety Committee and for various departmental committees. We have found in the work with which I am connected that tabulation in a simple chart showing the monthly accidents or accident frequencies in the several department compared with the month before and year before, was very helpful in the Central Safety Committee meeting because it enabled a bird's-eye view of the situation throughout the whole country.

A Chart For Each Foreman or Group

Another thing which we found helpful was a chart which was made up for each foreman or group in every department showing the number of accidents for which he is discredited. We find that when the foreman sees a long, black line up there against him, as compared with a short line of another foreman, it wakes him up—much more so than the figure 48 as against the figure 1.

I bring that as a thought in the getting up of statistics.

CHAIRMAN-ELECT RUTLAND: Thank you, Mr. Jackson, that is a good thought.

O. R. BENJAMIN (Assistant Construction Engineer, Detroit Edison Co., Detroit): In regard to Mr. Jackson's discussion, we have made it a practice on one of our jobs to post the name of each foreman and his accidents for a month at the time-clock so that all the men on the job can see what is going on and who the foremen are that have the accidents. Each foreman wants to keep his name off of that list.

CHAIRMAN-ELECT RUTLAND: There is a psychological effect there.

A. A. RALL (Kansas City Power & Light Co., Kansas City, Mo.): I would like

to ask one question as far as the Public Utility Section is concerned. The outline which the gentleman gave this morning was an outline of the safety organization for a public utility company. Is there such an outline in graph form for this section?

CHAIRMAN-ELECT RUTLAND: No, sir, there is not.

MR. RALL: I think we should have one. It would be a nice thing for us to go by. It gives all the various duties of each one. I worked one out for our company. Due to the fact that I had so many calls for it, I was wondering if the Public Utility Section had ever thought of making a graph or a skeleton of just what the safety organization should contain.

Part of the N. E. L. A. Serial Report

CHAIRMAN-ELECT RUTLAND: Thank you for the suggestion. Incidentally, the Accident Prevention Committee of the National Electric Light Association this year had as part of its serial report how to set up a safety organization. I think if you will write to headquarters of the National Electric Light Association at 29 West Thirty-Ninth Street, New York City, and ask for a copy, it may be helpful in further perfecting your organization.

We must close this part of the discussion. Before closing my part I want to say this for Mr. Opp:

During the past hour I have taken up a burden (I say a burden and it is one which I appreciate) which has been carried on by a man I have learned to love. I don't know of a man who has worked harder to make a year successful than he has. He has abided by every suggestion he has made. They have been practical ones and I know they have been made after a long night of study. Incidentally his wife told me that many times during the past year he has worked hard all night on these questions and difficult problems.

But I am glad to say this: He is still going to be associated with us as ~~councilor~~, and better still, you heard his name read last night as one of the Executive Committeemen of the National Safety Council as a whole. We ought to feel mighty proud that he has attained this recognition. I think we should give him a rising vote of thanks before I turn the Chair back to him.

(The members arose and applauded.)

Hard Work for the Section a Source of Pleasure

CHAIRMAN OPP: Our New Chairman, Gentlemen: I haven't prepared any swan song. I feel pretty much as does Past President King. I am stepping down, but not out; and I am willing to continue in the interest of the Public Utility Section. If there is anything I can do as an individual on top of my official capacity as councilor feel perfectly free to call on me for that.

It has been a source of pleasure; in fact, it has been about the happiest year of my life to be associated, as chairman, in the work of the Public Utility Section. The many pleasant contacts created by personal letters in the past year between certain ones of you and me; the actual personal contacts in the field in connection with Executive Committee meetings and the six or seven regional meetings that I had the pleasure to attend and participate in, have been a source of inspiration that you can't weigh by any method yet known to science. It is one of those intangible things that make you want to do all within your power. If our new chairman can just get the inspiration that comes from this personal contact I am sure at the end of next year he will be coming here with "alibis," too, on the night work, for it is a keen pleasure to be engaged in such work as this and to get the happy response that comes from each and every one of you.

I can't say anything else but thank you. I am not saying good-bye. I don't know what I would do if the whole thing were unloaded. I would probably collapse for it has been the biggest job I have ever had and I want to continue just as actively as I have in the past.

Now, we will have to hurry on to the real program, but before we do let me refer to this card which has come to my attention within the past week. It is so well worded that I can't pass it by.

Words by Roosevelt and W. S. Smith

"The test of a man's worth to his community is the service he renders to it."—Words by Roosevelt. The rest written by W. S. Smith of Milwaukee:

"Before me lies a picture of the signing of the Declaration of Independence, just ordinary men, doing what seemed to be their ordinary duty.

"There is nothing in the picture to indicate the immediate jeopardy in which their act placed them; nothing to show belief that their's was a deathless deed, or that foreshadowed the love and veneration in which they would be held by succeeding generations.

"This picture brings to mind thousands of men whose duty today is to save the priceless gift for millions of their fellowmen—the precious gift of life.

"I speak of safety men—men whose lives are consecrated to saving and protecting other men from the hazards of occupation—safety men, who, by word of mouth, by their writings, their public addresses, daily are inculcating in the minds of millions the desire to work safely, for their own benefit and for the welfare of those who work with them.

"Bludgeons of discouragement and adverse circumstances have not caused these men to falter or to surrender their ideals. They have been inspired and sustained by a never-failing hope that ultimately success would be theirs. Economic values interest these men; but it is spiritual values (not mechanics and dynamics, but humanics, if you please) that grip them.

"They are the essence of cooperation—these men. Filled with that spirit, they erect great bulwarks against the ever threatening tides of accidents. They are the heralds of a new day, whose dawn will show a minimum waste of life and limb.

"No monument is needed for these men—no marble shaft to pierce the blue of heaven. Greater is their living memorial: the millions of lives saved—the countless homes kept happy."

A Source of Inspiration for Safety Men

That is a token of inspiration for the safety man of today, and if we can just get that picture within ourselves there is no question but that we will all appreciate very keenly the job that we have to fill.

We have worked up to a real climax. We have endeavored in our program to give you something new at each and every turn. Now we are going to have "Making Light of the Mystery." Fortunately there has been made available for this occasion, through the very kind courtesy of the Commonwealth Edison Company, a model which as far as models are concerned is a "world beater." It is something which is of the keenest interest to all of us, and its very presentation here is going to make a mighty fine concluding picture for us to take home with us.

It is with pleasure that I make the comment that this model was designed by the Commonwealth Edison Company for presentation before local clubs, schools, and similar audiences to give the public a real picture of the processes of production, distribution and utilization of electricity.

We have the keen pleasure of having here to explain the model, to set its little

nerve force in operation, to show us just how it works all the way through, none other than Mr. H. E. Wulfig, Engineer of the Commonwealth Edison Company.

(In connection with this talk, a large working model (*Figure 1*), was used, this model being 24 feet long and representing the cross-section of a generating station, substation, a factory and a home, with incidental scenery in colors. Its purpose was to tell the story of the production and use of electricity from the coal mine to the home. Various parts of the model were put in operation as the story progressed. The talk was further illustrated by some 70 slides, many colored, which were shown on the screen in the center of the model. On account of the large number of slides and the many operations of the model, it is not considered advisable to report this talk in full, and a description of the talk is given instead.)

Figure 1. The working model.

Making Light of the Mystery

H. E. Wulfig, Engineer, Commonwealth Edison Company, Chicago, Ill.

You might think from the title of my talk that I am a sleight-of-hand artist about to explain some of the tricks of the trade. The fact is, I am going to talk about the most common thing in every day life—electricity.

We are inclined to think of electricity as a mysterious force because we cannot sense it by ordinary means. We fear things that we do not understand. If you could take a quantity of electricity and bring it up here and set it before you, it would hold no mystery to you.

The fact is, electricity is very common. We have it everywhere. It is in everything that we do. The food we eat, the very air we breathe contains electricity.

When I went to school I was told that the atom was the indivisible element of all matter and that beyond that we could go no further. But last night President Max Mason told us that scientists had discovered that the atom is divisible, and that the element in which the atom is divisible is the electron, the common factor for all things; and that the electron is then the element of matter and also the element of this electrical force.

Electricity as it appears in matter is not dangerous. Electricity as it is made in the power house is not dangerous, if properly controlled. In fact, electricity is a wonderful aid in your safety movement, in the conservation of human energy. It not only restores man to health when used by medical science, but to a greater degree it conserves man's energy. In former times man used to do work by the exertion of muscular power, that of his own and that of the beast, and with it was the attendant risk of life. Now electric power does the work for him with less risk and greater safety. Man now directs the force instead of exerting it.

We think of electricity as produced in a power house, as being dangerous, and you might say that to some extent it is dangerous when not properly controlled. But electric power has enabled man to produce thirty times as much as he used to with really less risk than when he worked with his hands and with hand tools.

Electric power as produced in a power house is very useful. Let us consider then

Figure 2. A coal car dumper.

how it is made, how it is controlled, and how it is finally used by our customers.

Electricity is not new. It was probably first known by our stone-age ancestors when they got courage enough to get out of their caves and view the jagged lightning in the sky. Later someone discovered that if amber was rubbed briskly it would attract small particles. That was a manifestation of electrical force. Franklin discovered that lightning and electricity are the same. But it remained for that wonderful, grand old man, Thomas Edison, to invent the electric light. Less than 50 years ago electricity began to be a servant of man, a servant that never gets tired, sick, never sleeps; it is always ready to do your work, and when not in use it retires back of the button.

Most of us know that electricity is produced in the power house, but do you realize the greatest power house of all time is the sun? The sun, through its transmission lines, the light and heat rays, has been sending to this earth electrons which have been accumulating here and are now being used by us.

Millions of years ago this Mississippi Valley of ours was covered by a dense forest. For years and millions of years the vegetation grew up and fell down until this Mississippi Valley was covered by a thick layer of decayed vegetable matter. Later earthquakes: then glaciers came down until it was finally buried under tons of earth and we now find it in the southern Mississippi Valley as coal in which are concentrated the electrons, which we call kilowatts, put there millions of years ago through the transmission lines of the sun.

The first series of slides illustrate the creation of coal from the forest to the coal at the mine, and the mining of the coal by hand, and then by the use of electric power coal is elevated to the surface of the earth, automatically dumped into conveyors, and then into sizing screens, and from there into the car, practically without the aid of human hands. The carloads of coal are shown being

Figure 3. View in the boiler room.

dumped in a huge car dumper at the rate of about one carload per minute into the hopper at the generating station. (Figure 2.) At this point the model was put into operation and the coal conveyor was started in the model, demonstrating how the coal is taken from the cars to the hopper on top of the boiler.

A series of slides then followed, showing the boiler room, chain grates, and attention was called to the fact that in a modern boiler room (Figure 3) the handling of the coal, from the time it arrives until it is burned and dumped as ash into cars, is all done automatically by the electric power, of which the coal is the raw material.

Figure 4 illustrates how enormous piles of coal are carried in storage as emergency reserve in case of failure of transportation systems, and the handling of coal in these enormous piles by electric machinery was explained.

At this point the chain grate on the model started to operate, and fire appeared to burn in the firebox, and later the steam appeared in the boiler tubes and in the pipes, connecting the boiler to the miniature turbine.

Slides were then shown illustrating the operation of the turbine, and an explanation was made of how the steam actuates the turbine wheel which drives the generator producing the electricity. The use of enormous quantities of condensing water to increase the efficiency of the turbine was explained, with the slides showing how the water is brought in to the generating station for condensing purposes. At this point the model was operated and water appeared to flow from the canal through colored glass tubes into a miniature condenser under the turbine.

A powerhouse (*Figure 5*) was described in general, with views of the interior showing the turbine room and the operating gallery, from which the operations of practically all of the equipment in the generating station is controlled. This control is by means of low-voltage electric current without any hazard to the

Figure 4. Coal in reserve piled by electrically driven machinery.

operator. Assisting the operator are many relays and meters which relieve the operator of constant vigilance, and aid him in the control of the outgoing energy. At this point the model was operated and a glass tube leading from the generator to the oil switches below the operating gallery was lit.

An explanation was made, illustrated by slides, of how the electricity is carried from the generating station by means of cables underground to the substation, and how the electricity from the generating station is converted in the substation, to a pressure low enough to be carried overhead on the streets.

Several substations were illustrated (*Figure 6*) and the various types described. At this point the colored glass tube in the model leading from the generating station to the substation was lighted, showing how the current is carried underground from the generating station to the substation. The various uses of electricity in factories and the homes were illustrated and described, and the substation in the model was lighted, and by means of colored glass tubes the flow of current through the substation and up the pole was shown. A miniature factory in the model was shown in operation, with the lights shining through the windows.

Figure 5. Power house where the modern source, electricity, is produced.

Before showing the utilization of electricity in the homes, a slide was thrown on the screen showing in outline the various operations involved in the production, transmission, and distribution of electricity, with a record of the number of fatal accidents that had occurred during the years 1923-26, and attention was called to the fact that most of the fatal accidents had occurred in that part of the equipment where automatic electrical operation had not yet been perfected or was not feasible.

The use of electricity in the home was shown on the model, by having the wires, leading from the transformer on the pole to the home, glow in a dull red, and a light shine from the windows in the house. A series of slides then followed, illustrating the use of electricity in the home, not only for decorative purposes in the living-rooms, but also its use in the kitchen, the laundry-room, and the workshop. One novel feature in connection with the operation of the model was

Figure 6. Typical substation in a residential district.

the fact that smoke was caused to issue from the chimney of the miniature house.

Passing from the home to the office building of the Commonwealth Edison Company, several slides were shown of the facilities provided for the employees of the company in the way of rest-rooms, restaurants, and a beautiful summer resort nearby Chicago, where the employees can spend their vacations at a reasonable cost.

"We of the state of Illinois," said Mr. Wulfig, "are proud of the fact that the great slave emancipator, Abraham Lincoln, lived here for many years. We, of the United States should be proud of the fact that this is the home of another slave emancipator who has liberated for our use the slaves of the coal mine and the water-fall. Thirty tireless slaves are now at the command of each man, woman, and child, and the number is increasing daily, giving us more and more conveniences and necessities of life, allowing more leisure time, and forming the very basis of our present civilization. The man who has taken the mystery out of electricity and changed it from a laboratory curiosity to a willing slave is the greatest inventor of all time—Thomas A. Edison.

"Tonight when you go home and press the button which floods the room with that pleasing light, think of it as the sunlight of millions of years ago caught in the leaves of the fern-like forest, stored in the veins of coal, and now released in the huge boilers of the powerhouse, transformed, and delivered to you as Edison service."

The President of the Council Was Welcomed

CHAIRMAN OPP: I don't know how we are going to express our thanks to Mr. Wulfig and those who have cooperated with him in the demonstration which we have just witnessed except by a rising vote of thanks.

(The members arose and applauded.)

CHAIRMAN OPP: We deeply enjoyed every bit of it. It wasn't by mere chance, I guess, that the presidency of the National Safety Council came to Chicago, because at the head of the organization of safety and personnel relations in this particular company whose work we have seen illustrated and charted here, is a man that we want to present at this time as the new president of the National Safety Council. Mr. Homer E. Niesz, with whose presence we are highly honored.

(The members arose and applauded.)

PRESIDENT-ELECT NIESZ: Mr. Chairman: Thank you very much for this opportunity to say to this group with which I have been connected for a great many years that I certainly appreciate the privilege of meeting with you. I would like to say just one thing about this particular section of the National Safety Council. It has grown so remarkably that those of us who have been following it for a number of years are amazed at its size and its following.

It is also interesting to me, as it is to those who have spent a good many years of their life in the utility business, that the men who are now running this section are the younger men in the industry. The older men are giving way to the younger men who are coming along to take their places, and this is as it should be. It keeps the interest up to a higher point, it makes for better organization and work, and it improves the sense of our safety work in the development of the younger men as they come along, because those who are still younger (and there are some who are still younger than the ones who are officers of this section) are encouraged to come along so that they, too, can be leaders in the section and in the Council as a whole.

CHAIRMAN OPP: I am sorry that the time has grown so short. I think it would be making an anti-climax for this wonderful meeting if we should now revert into a round table discussion. I know you may be disappointed in not getting an answer from the floor to queries you may have turned in, but if you will take my word for it we will see that those are answered by letter just as soon as possible; and if

in the meantime you are eager for an answer I, along with the officers of the section, will be willing to stay here for fifteen or twenty minutes or longer to go into detail with you on the particular question which you submitted, rather than keep the whole assembly, some of whom may not be interested in those particular points.

We certainly have had, without any question, the most wonderful meeting this section has ever participated in. Again, let me remind you it isn't the work of any one particular man, not the work of any particular Program Committee: it has been the united team work of the whole official family of your section.

For the final word, we would like to stay for another week at a congress like this. We certainly would like to continue rubbing elbows and exchanging ideas, but, of course, circumstances and the call of duty will not permit. We do want you to leave this Congress with the feeling that we have received something well worth while: something that is going to stimulate interest in the wonderful work we are doing. As you go out just make to yourself the pledge that you are going to come back next year, not yourself alone, but with a large delegation from your respective companies, so that we may look forward to breaking next year the splendid record we have established this year.

Good bye for this year.

ADJOURNMENT

SIXTEENTH ANNUAL SAFETY CONGRESS
NATIONAL SAFETY COUNCIL

Public Utilities and Electric Railway Luncheon

Wednesday, September 28, 1927

HARRY J. BELL, Toastmaster

Executive Director, Milwaukee Association of Commerce, Milwaukee, Wis.

The joint luncheon of the Public Utilities and Electric Railway Sections of the National Safety Council, was called to order at one: fifteen o'clock by the Toastmaster, Harry J. Bell, executive director, Milwaukee Association of Commerce, Milwaukee, Wis.

TOASTMASTER BELL: It seems to me that the morale of this meeting is great and that we are going to have a very profitable time. It strikes me also that every one ought to be pleased with the music furnished by the employees of the Illinois Bell Telephone Company.

We regret that the time is so late that the orchestra must stop playing. As your toastmaster, I regard it as an honor and a privilege to preside at this meeting. It strikes me that you gentlemen of the Electric Railway and Public Utilities Sections deserve great commendation because of your interest in this meeting, your interest in the Congress, and most of all upon the fact that you are in the safety movement, the greatest movement in the world.

To me, as one who is now on the side lines after many years actively engaged in safety, I am particularly proud to have this minor part in your program.

Perhaps I am in the position of the ham actor who was required at one point during the play when the villain shot the hero, to exclaim, "My God, I am shot." He got to the point and said in a very lackadaisical way, "My God, I am shot." The stage director became quite concerned about it. He said: "We have got to do something to fix this or we will spoil the show." They decided to load the gun, not with a blank cartridge but with rock salt, and when the ham actor received the charge of rock salt, (nobody knowing about it with the exception of the stage director and the villain in the play), he said with a good deal of gusto: "My God, I *am* shot."

Now, Dr. Stewart is alleged to have the wisdom and the wit and the philosophy of all good Scotchmen, and I feel sure that he is going to deliver to us a very interesting and profitable address. In addition to being rector of St. Luke's Parish, Dr. Stewart is a trustee of Northwestern University, and (coming from Milwaukee, I say this with unusual conviction) I think that, having addressed the St. Andrew's Society in Milwaukee, he must be a good Scotchman.

I have then the extreme pleasure of introducing to you the Reverend George Craig Stewart of St. Luke's Parish, Evanston, Illinois.

Address

Rev. George Craig Stewart, Evanston, Ill.

It is my privilege, as an ancient Chicagoan, to do my share in welcoming to this city a great many distinguished groups of men who are interested in building up the safety of human life in various forms of activity throughout the country. Those of us who have lived in Chicago for a generation (and I have been rector of the Parish of St. Leger's for almost a quarter of a century) are immensely proud of this city in which you find yourselves.

A while back, I was speaking to a distinguished Englishman. I said to him: "My Lord, have you ever been to Chicago?"

"Chicago?"

"Is Chicago so far off? It is just over night. I come down to New York every week, and New Yorkers come down to Chicago."

I then proceeded in a typical Chicago way to tell of the glories of Chicago. I pointed out that it was the greatest center of university education in the country; that we had two universities while New York had but one. I told him that we had more libraries than any city in the country with the exception of Washington. I was going fine when he interrupted with this remark: "But, how about your crime?"

I said, "My Lord, we beat the world."

Chicago is incomparable in many fields, and yet I must hasten to remark that I am proud of the fact that as a Chicagoan I live outside of the city limits.

A woman in Chicago went to the telephone to inquire how much the charge would be to call Hollywood. The reply was, \$1.00. The woman said, "In Chicago, you can telephone to Hades for ten cents."

"Yes," the answer came back, "but that is inside the city limits."

I find myself in the delightful situation speaking to a group of men, not on religion and business or the relation of the higher life to the lower life of commercial pursuits, but merely as an entertainer. The sermon will be a little later by Doctor Storrs.

So I am just going to attempt for a few minutes to tell some Scotch stories that may interpret some of our Scotch life. I suppose there are some Scotch here who are committed to the fundamental premise that the Scotch are the greatest race in the world; the greatest race in business, and the greatest race in thinking. Well, they have, as the Scotch say, a good conceit of themselves.

I remember once in Scotland upon the top of a castle in the gloaming, I fell a cracking, as the Scotch say, with an old man, and I was saying to him how unhappy I was to have to go back over the border. He lamented with me and felt a deep and serious regret; and then he told me this story of a man who came down out of Scotland into England and was cracking, as the Scotch are wont to do, about the glories of Scotland and the bonnie lasses. Finally, the Englishman got so bored that he said, "See here, if you are so crazy about Scotland why didn't you stay there?"

He said, "I will tell you why. Up in Scotland where I come from all the lads, mind you, are as clever as myself. I came down to England, and I am doing fine."

Now, the Scotch have a reputation for being tight in many ways. Someone said that an Irishman "O's" money and a Scotchman "Mc's" money. And, that is attributed to the Scotchman as if it was something of reproach. But I want to remind you that the Scotchman has a capacity for making money because he is bred in the school that makes good business men, strong capable traders, strong capable leaders, bred in the school of hardship. A Scotchman will never go under

a dentist's gas until he counts his siller. After all, I know of no virtue that is more indicative of strength than the virtue of very careful conservative administration of money.

I know this is no opportunity for me to speak on one of my favorite subjects, which is prohibition. But, if you spent as many days and evenings as I do getting people out of difficulties who got into them by bootlegging and drinking, you would understand that I regret very much the name that Scotchmen have got for being fond of the water of life.

I was attending a banquet here in Chicago some months ago when a man delivered a speech that went something like this : I am a Senator from Illinois. I come from the southern part of the state, not quite as far as Herrin, but just south of the Smith and Wesson belt. When I was a young man, I lived down there. We used to go to church, and the minister preached a good long sermon for about an hour and a half. The congregation was made up of men, their wives and children. At the close of the sermon, they would stand around and the men talked politics while the women talked something like this: "You take a pound of flour and two large pieces of butter and a little milk." You go to the same church in the same district today and you find only a few people attending. The clergyman delivers his sermon in about twenty minutes. When they get outside, the women talk politics while the men talk something like this: "You take ten raisins——"

We are, of course, living in a changing world. It reminds me of the Scotch minister who said to Sandy one day as he was under the weather, "Sandy, where have you been?"

Sandy Had Been Collecting for the Church

Sandy said, "Well, I have been about the parish collecting for the church."

The minister said, "What do you mean? Where did you get the load you are carrying around?"

"Well," he said, "mind you, I got it in the houses while collecting for the church."

The minister said, "I know very well that there are plenty of people in the parish who don't have liquor in their houses."

Sandy said to the minister, "I wrote to those."

I want for a moment or two, because there may be some men here who like the Scotch people and the Scotch tongue, to give you an example of that Scotch tongue. There are two kinds of Scotch, the highland Scotch and the lowland Scotch. The lowlanders talk like Robert Burns. The highlanders speak the Gaelic. The highland people are an entirely different group of people; they have different traditions from those in the southland. When the highlander is learning English, he learns it in a very peculiar way and has great difficulty with it, mixing sentences, and always making a "she" out of the letter "I." So, when he learns English and sees that letter "I," he can't help it, and he calls it "she." He says, "She will be very good, however." He always puts in "however," "moreover" or some such word at the end of a sentence.

There were three Scotchmen who were learning to talk English. One day while the three of them were drinking the first Scotchman picked up his glass and smacking his lips said, "This will be the greatest whiskey she will have tasted nevermore." The second one said, "So was she, however." The third one said, "Never was she, too."

The lowland Scotchman talks in an entirely different lingo, because he talks a language that is made up of Saxon, German, a little Gaelic (but very little), and that is the language of Burns. I want to give you an example of it before I sit down.

As the toastmaster spoke about the St. Andrews Society, I am going to tell you of an incident that happened there some few years ago. Mr. Forgan and I were

the speakers. Mr. Forgan was the first speaker, and he used all my stories, the stories that are common to Scotchmen everywhere, and I was driven back upon the necessity of rearranging my speech hurriedly. Being a good Scotchman, I gave the speech that wee Willie Demarest gave 25 years before. At the close of the address the pipes began to play. As the men were leaving the hall, one man jumped up and said, "A most extraordinary thing has happened: William Demarest is in this hall tonight." Up stood an old man with a long beard. He came up and shook hands with me and said, "Mind you, I wrote those five and twenty years ago and I never heard them on human lips until tonight." He is 84 years old. I hear from him constantly.

I am now going to give you a translation from the psalms. I suppose every man knows one psalm at least, and that is the twenty-third. I will give you that as rendered by Wm. Dearness, of the Orkney Islands, so you can hear the Scotch that is spoken by the lowlander, who knows his onions.

"The Lord is ma' herd; nae want sall befa' me; he louts me tae lie doon in the green howes; he airts me atowe beside the lone waters; he waukens ma' wa-gaen soul; he weises me roond for his ain name's sake intil recht roddins. Na-tho I gang through the dead mirk dale, e'en there sall I fear nae skaithin, for yersel are near by me; yer stock and yer stay haud me baith fu' cherry. Ma buird ye hae hanselled in the face o' my faes; ye hae drookit ma heid wi' oyle; ma bicker is fu' and skailin; e'en sae sall gude guidin and gude gree gang wi' me ilk day of ma livin' and lang syne i the Lord's ain howf sall I mak bydan."

TOASTMASTER BELL: I am sure that I express the sentiment of everybody in this room when I say that Dr. Stewart's address was very interesting indeed.

It is now my pleasure to present to you Mr. Lucius S. Storrs, managing director of the American Electric Railway Association, and a former president of the Connecticut Company. As the President of the United States has a Herbert Hoover, and the moving picture industry a Will Hays, so has the electric railway industry our speaker, who is about to address you.

I am sure that Mr. Storrs has a message which will be of great value to every one of us in and out of the public utility and railroad field, and it is an unusual pleasure to present him.

Address

Lucius S. Storrs, Managing Director of the American Electric Railway Association, Chicago, Ill.

The local transportation industry is an active participant in and a strong supporter of accident prevention work. It takes part in this great movement because it feels a keen sense of responsibility for its 16 billion annual passengers and also because it has been clearly demonstrated that the prevention of accidents means a direct saving of money and, therefore, is good business.

You need only to read the names of men who have been active in accident prevention work in the transportation industry to realize how sincere are their efforts. That list of names itself speaks volumes for the humanitarian side of the work. The other side, the dollars and cents angle, can best be appreciated when it is stated that approximately four per cent of the \$1,000,000,000 income of the local transportation industry is being spent every year in the payment of accident claims. Thus, you readily see, our industry has a mark of approximately \$40,000,000 a year at which to shoot. It is a saving well worth making. Concretely, it is a leak that is greater than the average net earnings of the industry during the last ten years.

This is a staggering total loss, but it would have been larger, I am sure, if the industry had not been so active in accident prevention work. There is no case on record where a company has installed intelligently and carried on actively for a prolonged period a sensible line of safety work, that it has not turned in an actual dollars and cents profit, to say nothing of the good will it has engendered.

Do not gather from this that I am saying every bit of accident prevention work which has been done in the local transportation field has been successful. That would not be true. There have been many companies which tried accident prevention work for short periods and abandoned it as unsuccessful without giving the best recommended methods a fair trial. Of course, "Failure" has been written after these tests. As you all know, there never was a safety campaign run half heartedly or sporadically which was successful.

All Members Are Urged to Be Active in Accident Prevention

Leaders of the industry for many years have been urging all members of it to become active participants in local accident prevention work. They have pointed out to managements that they, as the responsible agents who carry by far the greatest number of persons in public vehicles and as engineers and experts in traffic management, should be the natural leaders in this work. In some quarters there has been hesitancy among local transportation men in coming to the fore for fear that they would be charged with using a humanitarian movement for a selfish end. In such cases the leaders of the industry have urged companies to go along with accident prevention work and lend their best assurance even if they did not appear in it publicly. Many local transportation managements are following this plan. They are giving the services of their best engineers, traffic and advertising experts to aid in local campaigns. Whether this is the best plan or not is open to grave question. Intelligent, open and enthusiastic leadership means so much in accident prevention work that it would seem to be the best plan for everyone who is interested in it to come out in the open regardless of captious criticism.

Unfortunately, utility men are inclined sometimes to turn over the accident prevention job to the man who had the most enthusiasm, rather than the most capacity, for it. This is a mistake. No man is too big for safety work. The ideal man to lead safety efforts is one not only with enthusiasm but also with a keen analytical mind who wants first of all the reason why for accidents, and, second, insists on getting at the causes of accidents in order to prevent them.

The men who have had the most success in accident prevention work in the local transportation field have been those who were leaders in other lines of endeavor. They have organized their fights against accidents along the same definite lines that experience has taught them are successful in fighting against floods, fires, falling traffic and other incidents of their daily life. They have realized initially that they must have an objective before starting a campaign and then work directly toward this objective along well-planned lines.

An example of what I mean is found in the safety work that an American Electric Railway Association committee is doing at the present time. Some months ago leaders in the safety movement within our industry decided that great good could be accomplished by pointing out to employees the six most common accidents which happen for which the employees are to blame. An analysis of the accident records of the leading companies showed very quickly what these six accidents and their causes were. The committee at once designed

a series of posters, intended primarily for the use of employees and depicting the causes of these accidents. Then by the use of posters, talks and other means, managements went directly after the causes.

This is not a new idea in safety work, of course, but it is a very good one which too frequently is lost sight of. In other words, there are definite causes which lead to the majority of accidents and they only can be reached by a definite-minded director who uses direct methods to reach them. That, in a nutshell, is the whole story of accident prevention as it is being followed in the electric railway industry. Our efforts are specific and not general.

Too many companies hesitate to enter into accident prevention work because they say they have no expert to direct their efforts. I believe that any man who is expert enough to design and lay a track properly, erect a power house correctly, keep cars running on time, or perform any other similar duty that requires exact knowledge and clear thinking, can do constructive safety work if he will apply the same business methods to it that he does to his other work. The great trouble is that safety, like some other jobs that fall to the lot of public men, too often is assigned to some one to do in his off hours.

More and more electric railway managements are coming to realize that any leak which causes a loss of four percent in industry's gross income annually is too big to be trusted to anyone who does not think clearly and see far ahead.

Enlist and Sustain the Interest of the Employee

Of course a leader alone cannot carry out accident prevention work successfully. Particularly in the local transportation business, employees, such as conductors and motormen, must be depended upon to discharge the great part of the industry's efforts. Hence it is imperative that the interest of the employee be enlisted and sustained properly. Herein lies an assignment that is worthy of the best efforts of the biggest men in the industry.

I do not subscribe to the theory that many accidents are the results of deliberate carelessness. I believe that most of them are due to persons being preoccupied with other thoughts when the accidents happen. It would seem then to be good judgment to take every precaution to see that employees and others who are entrusted with safety assignments—and that is what it amounts to in our business every time we send a man out with an electric car or motor—are free of all worry so that he can keep his mind on his job.

This being true, safety work literally begins in the home. If an employee is pressed by creditors, if his children are sick and not obtaining medical attention, if his domestic situation is unhappy, or if he is suffering from some physical disability even as small as a tooth ache, it is not reasonable to suppose he will be able to divorce his thoughts entirely from these little irritations and apply himself whole-heartedly to his job when he goes to work. All of the safety lectures in the world, all the pamphlets, and all the rules that an industry can formulate for the bringing about of accident prevention, will take secondary place to his thought about his personal situations. This is only human nature and it can not be avoided. Therefore the employee best qualified to prevent accidents is the one who is in a calm state of mind and whose home affairs, particularly, are running smoothly.

It may be said that these are personal matters and none of the employer's business, but when such situations prevent a man from exercising the precautions that prevent accidents, then such seemingly minor personal affairs become very great public affairs. It is decidedly the duty of the employers to see that such things do not interfere with public welfare.

In a word then, is it not worth while, as a background to safety work, for the safety director either to do some home welfare work on his own time or else cooperate very closely with the person in an organization who does this welfare work?

This suggestion that the safety department dovetail its efforts into those of another, is one that should have wide application in every organization where safety work is started. The experience of local transportation companies has been that there is no department which cannot contribute advantageously to safety work and that the perfect safety organization is obtained when every department works together understandingly and enthusiastically to bring about the best results. Nor should this cooperative effort cease when all the members of one organization in a community are working toward a common end. Each unit should link up its efforts with others in the community and all organizations, both private and public, work together. Such efforts have brought the best results in local campaigns whenever they have been tried.

Keeping Everlastingly at the Safety Work

There has been much disagreement in the transportation field as to whether personal appeal to the men's loyalty or bonus systems are the best means of preventing accidents, but there is universal agreement on the theory that good safety work requires keeping everlastingly at it. It is not a job that can be done successfully if attacked spasmodically. Convinced of this the American Electric Railway Association advises against so-called campaigns of a week or a month duration. Such campaigns sometimes serve only to key up, excite and unnerve employees and occasionally result in more accidents than have been had during similar periods when no campaigns were in progress. What the association urges is that every day be made a safety day within the industry. Practical results have shown that this is good advice.

A recent survey of the industry by the association developed universal agreement that frequent meetings at which everyone, including the safety director and the employees are permitted to speak their minds, were invaluable. It has been found that unless these frequent meetings are held interest in safety work is likely to lag. Doubtless what is true in the transportation field is true in others. Safety is not a thing that you can talk about once a year and then neglect for another twelve months and hope to get good results. It must be made interesting at all times. In order to make it interesting much ingenuity must be used in getting up safety meetings, putting out interesting safety posters and doing other things that will keep the subject alive. Merely harping on "Be safe" and "Be careful" is very likely to cause men's interest to go stale.

The banquets to successful contestants have proven very attractive. One of these banquets was held at three o'clock in the morning, it being the only time that the men could get together, and it did not break up until five o'clock. An interesting feature of the occasion was the compulsory waiting on tables by the operators who had had accidents on their cars during the month. They enjoyed the banquet as much as those who sat down to eat and declared unanimously that they would run their cars so well during the next month that they would not be compelled to wait on the tables.

I have touched only the high points in some of the safety work that the local transportation industry is doing. If you are interested in further details, the association's statistical department has many bulletins which are up to the minute and which you could use advantageously. If you can, the association will gladly supply them to you without charge. The association believes sin-

cerely in safety work and it is doing its best to forward it. It believes the problem is one for national, state, community, and organization effort. Just as our transportation service keeps everlastingly at it, day and night, in sunshine and in rain, so are we going to go forward with our safety effort.

TOASTMASTER BELL: Mr. Storrs, we are grateful to you indeed for that very illuminating and interesting address.

ADJOURNMENT.

SIXTEENTH ANNUAL SAFETY CONGRESS
NATIONAL SAFETY COUNCIL

Quarry Section

New Section Officers

Chairman, D. C. SOUDER, The France Stone Company, Toledo, Ohio.
Vice-Chairman, R. E. COLVILLE, United States Gymsum Company, Chicago, Ill.
Secretary, J. R. BOYD, National Crushed Stone Association, Washington, D. C.
Poster and Slide Committee Chairman, FRED E. HATFIELD, Indiana Limestone Company, Bedford, Ind.
Membership Committee Chairman, C. ZIOLKOWSKI, United States Gypsum Company, Chicago, Ill.
Publicity Committee Chairman, NATHAN C. ROCKWOOD, Rock Products, Chicago, Ill.
Engineering Committee Chairman, R. E. COLVILLE, United States Gypsum Company, Chicago, Ill.
Statistics Committee Chairman, W. W. ADAMS, United States Bureau of Mines, Washington, D. C.
News Letter Editor, D. B. BUETTNER, JR., The France Stone Company, Toledo, Ohio.
Executive Committee, THE OFFICERS AND—
A. J. R. CURTIS, Portland Cement Association, Chicago, Ill.
N. S. GREENSFIELDER, Hercules Powder Company, Wilmington, Del.
JOHN RICE, JR., The General Crushed Stone Company, Easton, Pa.
E. D. SHERIDAN, Chico Stone Products Company, Dallas, Texas.

Retiring Officers

Chairman, L. R. CARTWRIGHT, Mid-West Crushed Stone Co., Indianapolis, Ind.;
Vice-Chairman and News Letter Editor, D. C. SOUDER, The France Stone Co., Toledo, Ohio; *Secretary*, A. C. HEWITT, American Lime and Stone Co., Bellefonte, Pa.
Committee Chairmen: *Program*, J. A. HENNEN, U. S. Gypsum Co., Genoa, Ohio;
Statistics, FRED E. HATFIELD, Indiana Limestone Co., Bedford, Ind.; *Membership*, JAY E. THOMPSON, Toledo Safety Council, Toledo, Ohio; *Poster*, R. E. COLVILLE, U. S. Gypsum Co., Chicago, Ill.; *Engineering Representative*, J. R. DAVIS, U. S. Gypsum Co., Gypsum, Ohio; *Executive Committee*, THE OFFICERS and EDWARD E. EVANS, The Whitehouse Stone Co., Toledo, Ohio.

Tuesday, September 27, 1927

L. R. CARTWRIGHT, Chairman

Vice-President, Mid-West Crushed Stone Company, Indianapolis, Ind.

The first session of the Quarry Section of the National Safety Council was called to order at nine-thirty o'clock by the chairman, Mr. L. R. Cartwright, vice-president of the Mid-West Crushed Stone Company, Indianapolis, Ind.

CHAIRMAN CARTWRIGHT: We will start right off with our program. I can't tell you what pleasure it gives me to have with us the president of my own line, the crushed stone industry. He is one who has given us a great deal of pleasure on many occasions and I am sure you will be delighted to hear from Mr. Otho M. Graves, president of the National Crushed Stone Association, Easton, Penna.

Value of Accident Prevention

Otho M. Graves, President, National Crushed Stone Association, Vice-President and General Manager, The General Crushed Stone Company, Easton, Pa.

Since the time when our Puritan forefathers landed on Plymouth Rock and since the time when under fairer skies and on more fertile soil the cavaliers of Old England established their colonies in what is now Virginia, this nation has flourished and prospered. With natural resources of almost unbelievable richness and seemingly unlimited in quantity, with a population growing in leaps and bounds, the tide of progress has continued to sweep westward. Blessed with material prosperity and success, it has seemed as though the thread of our destiny has been woven into the fabric of world affairs by the hand of a fate graciously inclined to our needs and welfare, forming a part of that design known only to the Master Weaver.

Nor is this prosperity confined to any small and fortunate class of our population; it is shared and enjoyed by the mass of our citizenry. True it is that some fortunes have been amassed which would awaken the envy of a Croesus or Nero, and these are thrown into strong relief by the dark shadows of poverty among a few as abject and misery-stricken as were the lower classes of France immediately preceding the French Revolution. But these extremes are limited in number and are the result of circumstance and opportunity seized by some and ignored by others, whether their failure be due to ignorance, laziness, drunkenness, inability or any of the other causes operating to prevent a successful grasping of potential opportunities. We have, as Gladstone pertinently pointed out, the froth and the dregs; but, thank God for the good beer in between.

With a continent stretching to the westward of the early settlers on the eastern shores, the western limit of which was not even conceived by them, it is not strange that the generations following came to believe that our natural resources were unlimited in extent. It is only in recent years when we have spanned this three thousand miles of territory and planted cities on the Pacific Coast rivaling in magnificence and in population those of the east that we have come to realize that these natural resources must be conserved and guarded with jealous care if we are to continue to thrive and prosper. It is not so long ago when the phrases "conservation of forests," "of water power," "of coal," "ore" and the other gifts of a beneficent deity sounded strangely in our ears. We have come now to accept such economy as a matter of course; and yet we have largely continued to overlook the conservation of the greatest of all material, mankind itself. Of all the material with which we have to work, there is none so vitally important nor so fascinating as the human.

Over its coffee cups the world reads the morning newspapers with horrified amazement as fatality after fatality is reported among the aviators daring the transoceanic flights and asks that laws be passed prohibiting such a useless sacrifice of life. Yet complacently we go our way without giving thought that last year in the United States alone approximately 180,000 persons suffered accidental death and 7,500,000 endured casualties that did not result fatally.

These daring aviators, risking their lives in the cause of science and human progress, bear a relation to our own age such as did Columbus, Magellan, De Soto and others of their courageous faith to an era past and gone. Our pride in achievement responds with a thrill to the accomplishment of such men, but we can see nothing more in industrial accidents than sordid carelessness on the part of the employee or almost criminal lack of interest on the part of the employer, with possible resultant poverty, misery and mental anguish to the family of the injured one.

A relatively new thought is manifestly permeating industrial activity—the recognition of the interdependence of employer and employee, a relationship which now approaches economic equality. We are beginning to recognize that the employer prospers in direct ratio to the prosperity of his employees. Industry is demanding a new type of executive, one who not only intimately knows the processes of manufacture, but who also sympathetically visions and understands the problems which confront his men, one who while directing and governing creates in those associated with him enthusiastic cooperation; in other words, a leader, not a boss, one whose integrity and qualities of judicial fairness and human sympathy awakens and holds the confidence of his men. To such an executive the physical safety of his men is of paramount importance. He is motivated in safeguarding them in their employment no less by reason of their economic value (impaired as it is by lost time from any cause), than of their humanitarian interest in their welfare and contentment of mind. A contented worker is obviously of more value than one discontented and disgruntled, whether his disturbed state of mind comes from a belief that he is underpaid, unappreciated or unduly exposed to unnecessary hazards. We have outgrown the moral crutches evidenced by such phrases as “Business is business,” “Honesty is the best policy,” and “*caveat emptor*.” We now clearly perceive that business is good business only when it is conducted along sound, ethical lines. We are honest because we should be, and the values of honesty come as by-products. The buyer is not expected to beware, but is protected, and so should be the worker.

Safety From the Economic Standpoint

Is the time and money required to promote accident prevention in any particular plant economically justifiable? The answer to this question is in the handwriting on the wall, with abundant proof of an affirmative answer in the experience of our largest industries. The evidence is overwhelming that a safe plant is an efficient one, and conversely, an efficient plant is a safe one. It is being constantly demonstrated that by giving due attention to accident prevention, insurance costs, however carried, are lowered; and, moreover, production is correspondingly increased.

The committee on safety and production of the American Engineering Council has just completed its study of the relationship between industrial safety and production. Some of its conclusions, after the most exhaustive and thorough study ever given to this subject, confirm the beliefs held by some of us and are startling to those who do not yet share them. There is detailed material in the report of the committee to support the statement that maximum productivity is dependent upon the reduction of accidents to an irreducible minimum, and that there is such an intimate relationship between safety and production that it is impossible for a plant to continue to increase in productivity unless it reduces at the same time its accident rates.

Not long ago a well-known producer of a mined material was quoted as saying that he would not sacrifice production for the sake of reducing accidents in his

mines. Such an attitude would be humorously paradoxical were it not tragic. In discussing the incident the memory whimsically came to mind of an old negro who said that on his farm in southern Georgia he used to raise horses, black horses and white horses, but that he gave up raising black horses because they ate more than the white horses. When asked why this was so, he said, "Ah can't exactly account fo' it lessin it is that ah had mo' black hosses than ah had white hosses." The logic of the manufacturer and of the old negro is equally unconvincing to the enlightened executive. It seems almost obvious that a clean, neat and safe plant, factory or mine in which the employees contentedly work under conditions as pleasant as the circumstances of the work may permit is necessarily more efficient and richer in productivity than one of which the opposite is true.

Many Savings Made Through Accident Prevention

Though it is generally recognized that a reduction in the number and severity of accidents is reflected in lower insurance costs, however the insurance be carried, this is not the only nor even the largest financial saving. The Travelers Insurance Company, of Hartford, analyzed 5,000 specific accident reports drawn at random from the claim files of that company, disclosing the almost amazing fact that the "hidden" cost of accidents is four times the direct or insurable cost. In this item of "hidden" costs such factors were considered, weighed and estimated as lost time of injured employee, time lost by other employees who stop work out of curiosity or sympathy to render assistance, time lost by foremen and superintendents in assisting the injured one, preparing accident report, attending hearings before industrial commissions, injury to machinery or property as the result of the accident, interference with production, the less effective work of the man replacing the one injured and other factors which suggest themselves but are too numerous to mention. While this ratio of the hidden cost to the insurance cost may not be four to one, as analysis of these five thousands cases would indicate, it is at least something to one, and that something is too much. It is reasonable to believe that intelligent and organized effort to prevent accidents, both as to number and severity, results in lower insurance costs, even greater reduction in the hidden cost, difficult to estimate, and increased plant efficiency due in part to the improved morale of the worker. But for such endeavor there is yet another reason, either stronger or weaker, dependent upon one's ethical conceptions, and that is the obligation resting upon each of us to do his part to prevent needless suffering and privation.

It is not the intent of this discussion to enter into the various phases of the relation of employer to employee, nor to consider the several factors tending to produce that harmonious and sympathetic accord which alone can develop the fullest potentialities of any industry. That a human, intelligent and sympathetic interest on the part of the executive of any business is a factor in creating a responsive spirit on the part of the other workers must be admitted. While the paternalistic attitude may be resented, the kindly personal interest of the executive makes a direct appeal to the heart and head of the rank and file of labor. Assuming then that accident prevention is worth while from the several points of view upon which we have lightly touched, there remains only to consider briefly ways and means for accomplishing the desired purpose.

With the thought that it would be both interesting and illuminating to ascertain the attitude of mind of quarry producers throughout the country as to accident prevention, a questionnaire was submitted recently to the members of the National Crushed Stone Association inquiring as to certain phases of this

work as conducted by them. The response was generous and prompt. Certain of the information received in that manner seems sufficiently interesting to be worthy of comment.

Sixty per cent stated they were not members of the National Safety Council, and of the remaining 40 per cent holding membership, the average life of the membership was three years. The non-members were asked to state their reasons for not joining. Sixteen per cent replied that they did not believe membership in the Council would sufficiently assist in plant safety work to warrant their joining. The membership of 35 per cent has not been solicited. The literature concerning the value of membership and the work of the Council has not been sufficiently interesting or appealing to obtain the membership of seven per cent. The other reasons were scattered, although tending toward an indication of unfamiliarity with the aims and purposes of the Council.

In reply to the question if membership in the National Safety Council was of value, and if so, in what ways, such statements were received as: "It is worthwhile being associated with others in the safety movement," "Stimulates interest in safety and keeps one informed as to accident prevention." "In securing reliable data and information as to safe practices, as well as assistance personally rendered by safety officials." "Through safety posters and magazines."

Crushed Stone Men Should Be Council Members

It may be concluded from these replies that crushed stone producers to a much greater extent should hold membership in the National Safety Council, and a fair inference is set up that the responsibility for the present low percentage of membership must be shared in part, at least, by the Council itself, due to the fact that the membership of so large a percentage has not been solicited in any manner. While it is not our intention to presume to suggest methods to the Council, it is commonly recognized that personal solicitation is far more effective than correspondence; but every member of this industry should be invited by letter at least to join the Council, even if at present personal solicitation is not feasible.

An even lower percentage of our membership is enrolled in the National Safety competition, namely, 27 per cent. Of the 73 per cent not enrolled, some of the reasons are as follows: negligence, 10 per cent; do not believe that entry in the competition would be of assistance, 14 per cent; operations too small, 17 per cent. Other scattered reasons, each having a low percentage, are: too much clerical work entailed; not familiar with it; didn't know there was such a contest; safety organization too young to compete with credit; intend to join next year; not located in the United States.

As a respectful suggestion to those conducting the National Safety competition, it is worth consideration, in view of so high a percentage reporting their plants are not sufficiently large to be eligible, that it might be well to lower the requirements in this regard, as accidents occur in small plants as well as in large ones, and also possibly to render the Canadian producers eligible, as there is a number of members of the National Crushed Stone Association located in Canada.

Of those entered in the competition, all replied that they had noticed increased interest in accident prevention as the result of the competitive spirit aroused in employees as the result of the competition.

In reply to the question, "Do you believe that accident prevention and insurance should be made a major issue in the work of the National Crushed Stone

Association." 75 per cent replied affirmatively, commenting somewhat as follows: National Crushed Stone Association can put this across with quarry producers better than can the National Safety Council; believe that N. C. S. A. at next convention should adopt vigorous policy as to accident prevention; believe that N. C. S. A. should take hold of this issue and put it over in same thorough manner in which other Association matters have been handled.

The 25 per cent which are accredited with replying in the negative modify their vote by such comment as follows: Accident prevention only, omitting any reference to insurance rates; not necessarily a major issue, but given an important place in the affairs of the Association.

One producer who voted "no" replied that with the Associated General Contractors, the United States Bureau of Mines, the various insurance companies, the several state bureaus, the National Safety Council and other bodies all working on accident prevention, the subject is becoming overemphasized and should not be handled by the Association. It is safe to conclude that there is an overwhelming preponderance of opinion in the crushed stone industry favoring the Association making accident prevention one of the major issues of its affairs.

Safe Practices Pamphlet of Value to Many

The pamphlet on "Safety Practices for Quarrying," prepared jointly by the Quarry Section of the National Safety Council and the Committee on Welfare and Safety of the National Crushed Stone Association, has been of benefit to 75 per cent of those replying to the questionnaire. Ten per cent stated they had received no benefit and 15 per cent replied that they had not received a copy. There is a correlation of thought between the 15 per cent of the crushed stone industry not receiving a copy of this pamphlet and the membership in the National Safety Council of 17 per cent not having been solicited. Both of these conditions should be promptly rectified.

The requests to "Describe briefly the manner in which safety matters are handled throughout your organization," received elaborate reply, into which it is hardly feasible to enter in detail. It is apparent, however, that those plants which have well-planned and orderly operating safety organizations have shown the greatest decrease in both the number and severity of accidents. Far too many replied in an indifferent, hazy manner, such as, "Believe in it, myself, and tell all of my men to be careful;" "Insist that any man who isn't careful be fired;" "Keep machinery in order and expect men to handle it properly," etc. One executive operating only one plant goes so far as to state that he meets personally once a day with all of his employees and talks caution. If this is actually done it should achieve splendid results, but I am somewhat reminded of three women who were talking together, one of whom said, "In all the fifteen years of my married life my husband has not said a single cross word to me." The second woman replied, "My, I wish I could say that." The third one said, "Well, why don't you? She did."

It was also requested that the results of such accident work as is conducted be noted as to the number of accidents, the severity of accidents, the decrease in insurance rates and the improved morale of employees. Practically all of those who give any attention whatsoever to accident prevention, whether in a hit-or-miss manner or by orderly planning, reported that the spirit and morale of the employees was improved. The decrease in the severity of accidents and the number of accidents, as well as the decrease in insurance rates is more noticeable in the case of those companies which devote the most time and effort

of accident prevention. Naturally this would be expected to be true and is merely confirmation of common opinion.

As to the chief difficulties encountered in conducting successful and effective accident prevention work, seven per cent replied, "Lack of interest on the part of the employees" and 11 per cent, "The difficulty of overcoming characteristic carelessness of workers." Smaller percentages stated, "Getting the men to believe that we do not want them to get hurt even though we are insured" and "The difficulty of impressing upon superintendents and foremen that accidents are costly." In the case of nine per cent the chief difficulty was the failure to secure proper cooperation from employees. This is a frank admission, but I am inclined to feel that the responsibility is the employer's rather than the employee's. Several replied that negro labor is indifferent to such efforts in their behalf, as compensation for ten days for small cuts or bruises is extremely attractive. Those who have had experience in employing negro labor will recognize the truth of this observation.

Though it would seem that the answer to the last question of the questionnaire should be obvious, namely, "Do you conduct your accident prevention work from humanitarian motives or in order to reduce insurance rates, or both?" 18 per cent replied, "From humanitarian motives only." The remaining 82 per cent stating that both were considerations. As a matter of fact, a third reason could have been included in this question, namely, "Or for the purpose of increasing plant production?" This was not done, because of my belief that the acceptance of the quarrying industry in general of the value of accident prevention work is not sufficiently advanced to readily understand and interpret such a suggested reason. It is highly probable that we do not place sufficient emphasis upon the fact that a safe plant is an efficient plant and that maximum production cannot be obtained without reducing preventable accidents to a minimum.

The Organized, Intensive Effort Pays

In reducing the number of preventable accidents, as in any other human activity, orderly-planned, intelligent effort results in greater accomplishment than loose, slipshod, hit-or-miss methods. It is far from adequate for the manager or chief executive to earnestly desire to reduce accidents with a cautionary word or two every now and again to the employees to being careful. In the crushed stone industry we have but to compare the latter type of effort with that of plants in which accident prevention is a highly organized activity to realize the value that lies therein. Those members of the National Crushed Stone Association entered in 1925 and 1926 in the National Safety competition have shown a marked improvement in the latter year over the former. In 1925 the accident rate of those plants entered in the competition was 6.7 days lost per thousand man hours of exposure, as against 6.0 in 1926; and an accident frequency rate per million man hours of 61 in 1925, as against 41 in 1926. This indicates an improvement of 10 per cent in the accident severity rate and 33 per cent in the accident frequency rate. These figures relate to 38 quarries in 1925 and 37 in 1926 and are furnished through the courtesy of Mr. Adams, Supervising Statistician of the Accident Statistic Section of the Bureau of Mines. It is to be regretted that the number of quarries entered did not show marked increase in 1926 over 1925.

Improvement equally encouraging and gratifying has been made by those quarries holding membership in the National Safety Council. In fact, it is largely true that practically all quarries entered in the National Safety competition are members of the National Safety Council.

An analysis of the questionnaire submitted to the quarry industry tends to

confirm another conclusion of the committee on safety and production of the American Engineering Council, previously referred to—that the accident and production performance of the best plants in each industry clearly shows that tremendous improvements can be achieved by the remaining plants in each industry. As a corollary, it might be stated with equal truth that the accident and production performance of one industry should encourage other industries to achieve similarly successful results.

The experience of the Portland Cement Association in the reduction of accidents is inspiring. In June of this year 164 cement plants employing 45,000 workers participated in a no-accident drive. It is almost amazing to know that accidents dropped 75 per cent during this month, as compared with June of a year ago. During the June drive this year 50 lost time accidents occurred, as against 192 during the same period last year. Only one man lost his life in June of this year, as compared with six in June of 1926. To endeavor to explain such a marked improvement in corresponding months of two succeeding years as a mere coincident is futile and absurd. Such improvement can only be attributed to the intensive drive of the Cement Association to reduce accidents.

Various Organizations are Emphasizing Safety

In other industries almost equally great improvement can be shown over periods of intensive accident prevention work as compared to similar periods during which no such campaign was in progress. For the sake of humanity in general and a lowering of production costs, it is encouraging to realize that various industries, through their national associations, are giving increasing attention to the value of this work. The Associated General Contractors of America, alert as they are to improved methods of construction and lowering of costs, are, through their association, entering intelligently into this worthwhile field.

In the transmutation of an unsafe plant or factory to a safe and consequently more efficient one, certain fundamental principles must be followed, however much the detail of their execution be varied. First, the responsible executive must recognize the several values of accident prevention effort and conceive the intention of improving conditions. Second, his recognition of such values must be transmitted throughout the organization until every man is reached. Third, the formation of a general safety committee operating through local plant committees. Fourth, the education of the employee, however tactfully it may be disguised or through whatever means it be accomplished. Fifth, through mechanical and engineering means the diminishing of all hazards and the total elimination of some.

The human spirit is adventurous: it seeks new experience, new sensations, gropes its way unflinchingly into unknown territory, both mentally and physically. The progress of civilization has largely been due to those adventurous spirits who have dared unknown dangers to blaze the way that later generations may follow in safety. It is not unnatural to believe that in many instances the lack of care and caution of the workman is attributable to this willingness to face danger and a desire to more quickly and effectively serve the ends of his employer, whom he may like, respect and admire. He must be taught to discriminate between the bravery of the hero, courageous without stint for a worthy cause, and the unnecessary exposure to danger which may be easily avoided with proper care and caution, and that in exposing himself unnecessarily to plant and factory hazards he does not serve his interest nor that of his employer, but actually is jeopardizing both.

I firmly believe that the employee, if convinced that his employer's interest in him is not hurt is prompted by good will and human kindness, will respect and admire his leader all the more for that interest in him and his welfare. He is not in a position to ask that he be protected; he would feel that it was undignified and cowardly to do so, but the responsibility is on the executive none the less. I wish that everyone who has labor under his control and who feels a proper responsibility for their welfare, could carry in his mind and heart those lines of Pope, which, though written two centuries ago, seem prophetic of their application—

Teach me to feel another's woe,
To hide the fault I see,
That mercy I to others show,
That mercy show to me.

May God speed the day when this thought shall guide and govern our conduct.

CHAIRMAN CARTWRIGHT: We are indeed grateful to Mr. Graves for this address and for going into such detail in getting accurate information. I think this statistical information will make a mighty fine record to start off for another year and if we can each year go ahead and cut down that percentage it is only a question of a little time to get it within reason.

We are next to be honored by a representative of the lime industry, Dr. E. M. Parlett from Pittsburgh Limestone Co., New Castle, Penna.

The Study of the Human Element in Its Relationship to Organized Accident Prevention

M. Parlett, Supervisor Health and Safety, Pittsburgh Limestone Company,
New Castle, Pa.

Herbert Spencer, one of the world's most profound students of human life, declared that "without health and energy, the industrial, the parental, the social and other activities become more or less impossible." Pursuing this line of reasoning a step further, the Committee on Safety and Production of the American Engineering Council has this to say—with specific reference to industry itself—"Maximum productivity in industry is dependent upon the reduction of accidents to an irreducible minimum—the weight of evidence supports the common belief that the safe factory is the efficient factory, and the efficient factory is the safe factory."

Wherefore, if the wealth, prosperity and happiness of industry itself is promoted and proven to be actually dependent upon, first the health of its units and secondly upon its behavior with specific regard to self-protection against physical danger, may we not venture to broaden the scope to include society itself? It is with this promise that I would approach the problems of industrial safety and its corollaries, industrial efficiency, social advancement, national prosperity—in a word—world progress.

Confining my chief remarks to the individual worker and not the equipment, health may be considered as normal, subnormal, abnormal.

Normal health infers physical well being, reason, sanity, judgment, energy, aptitude, clear thinking or vision, resourcefulness, self control, repressions, a willful desire to serve and advance, individually and collectively. Upon these characteristics, which are those of the higher type human, as Herbert Spencer has well said, rests the foundation upon which reposes the happiness, the power, the progress and the wealth of the country. Therefore, it may with satisfying truth be said that while a normal and healthy individual will not only in emergency and

instinctively protect himself from physical violence, he goes a step further in the desire to think, to study, to cooperate with fellow humans in developing scientific ways and means of abolishing accidents by and through the prevention of both the direct and remote causes thereof. Further, it is not only the duty but the desire of the normal or highest type human to shield and protect the individual who may through the congenital forces of nature or otherwise fall into that classification of inferior grade, be it subnormal or abnormal, and may I say that ample evidence is at hand that the normal human being is fulfilling that duty of shielding and protecting the less fortunate, as witness the ennobling ideals and efforts of the membership of this splendid and inspiring organization, the National Safety Council.

Of late years the doctrine of conservation has received a new impetus in our American system of government. The Supreme Court of Ohio, speaking in 1921, said "Originally this doctrine was largely applied to mines, forests, water power and natural resources. Later it was extended to hogs, cattle, buffalo and wild animals generally, and strange to say, lastly it was applied to human beings."

Human Losses Are Met on Every Side

In this connection and for a moment considering the matter of the destructiveness of disease itself, the world has ever been confronted by conditions, not theories, frequently local in character, sometimes national, occasionally world wide in scope. Devastating plagues have threatened communities, nations. We are proud of the glorious victories of the medical profession over yellow fever, malaria, typhoid, small pox, diphtheria and other scourges. Such achievements are both wonderful and patriotic, beneficial alike to the individual, the industry, the nation.

Students of the vital statistics, however, know that the achievements of man, no matter how wonderful or how patriotic they have been, are but half accomplished.

We are yet confronted with an appalling death rate upon our highways, in our industries, upon the seas, within our homes, beneath the earth's surface in our mines, at varying altitudes above the earth's surface in our conquest of the air, from external physical violence, the immediate effects of which produce an unending train of permanently handicapped or killed.

The medical profession having taken the lead, as it obviously should, in conquering plagues and devastating disease, it is not surprising that it should give attention to that other arch enemy of man, external violence to the physical structure of the body, and lend its aid and bend its thoughts and energies in cooperation with the leaders of industry in an effort to conquer this other scourge of the human family—accident—for it must be observed that prevention of suffering in whatsoever manner it may have been produced is the cardinal aim of medical men, of industry and all clear thinking individuals.

Health promotion and accident prevention are therefore akin and equally appealing as subject to scientific investigation, study and formula, and amenable to scientific methods of approach and application. For example, science has not only been the means of discovering weak metallic structures, as well as weak tissues, by means of the X-ray, the prevention of death from shock to the body tissues of the electric current, the avoidance of acute and permanent physical harm from dusts, fumes and gases, the prevention of infections from contaminated lubricants, polluted drinking water, metallic poisoning from lead, copper, zinc, etc., the avoidance of contact or communicable disease, and of solving the problems of ventilation, industrial cancer, anthrax, stone cutter's and other respiratory diseases of industry, but science is solving the problems of human behavior, covering a multitude of human mental traits, deficiencies, perversions, aberrations, etc., to which the industrial employee may be subject, even to an appreciable degree.

To make myself clear: Conduct is defined as the way a person acts or lives; the

idea of personal and moral responsibility is inherent in the term; an energy phenomenon. When an accident occurs involving injury to the industrial employee, the first question usually to be asked and determined is "What was the cause thereof?" "Who was at fault?" The usual answer is one of the following: "Employee neglected instructions." "Machine guard not replaced." "Employee was not wearing goggles." "Disobeyed orders." "Absent minded." "Took a chance," "Became confused." "Failed to give correct signal." "Defective tools, chain, cable, etc." ad infinitum,—a long and interesting, if sordid, list of the failure of the human element, of insufficient or sustained mental endowment to anticipate, to organize, to plan and think ahead, to safeguard, to instruct and supervise, to systematize effort both personal and collective for self protection from external violence. That we are curbing accident directly or remotely charged to human trait characteristics, the sudden failure of the human element, human deficiency causes, thanks to you industrial scientists, is to be freely confessed, but that we have only just prefaced the undertaking is evident.

Admitted that there still remains a great demand for hand or manual labor, and realizing the palpable fact that many of the laboring groups may be classified scientifically as within the moron type group, we must acknowledge that fact and face the problem of placing and utilizing the energies of this class labor in an atmosphere of protection which may be devised or provided by forethought, research and careful planning by those blessed with a higher degree of intelligence. To so organize is to instruct and to supervise to such a degree of refinement that there should remain but scant excuse for flagrant failure when these children of industry are maimed or killed, realizing as we do that many are victims of perverted thought and conduct, singular human traits, inherited or acquired, submerged or quiescent under casual circumstances. These, we, as students, must realize, anticipate, correct as far as it may be possible and regulate for the protection of the employee and industry.

Proceeding Toward Safety in the Best Manner

With the established facts in mind, how are we to proceed to the best advantage of industrial prosperity and social welfare after we have first appointed a safety and health director, put our plant in good housekeeping order and safeguarded our operations to the limit of our experience and ability, instigated and promoted by a wise, a benevolent and a cooperative management?

(a) We should by careful physical examination eliminate the flagrantly vicious in mental and physical attainments.

(b) As thoroughly instruct the new employee, as well as the old employee, in specific detail as to the hazards of individual occupation and plant operation, and to broaden the field of education as time and opportunity warrant from apprentice courses to advanced instruction in craftsmanship.

(c) Organize the man and the mass into complete units for systematic and automatic functioning. Organization means systematic concerted unit effort; a marshalling of forces for efficient orderly mass action; the management first, the direct supervising forces next in line and the subdivisions of the army of employees in the order of sequence. If you wish to accomplish certain definite objects you must proceed in a certain definite and orderly way.

(d) Supervise thoroughly and continuously.

(e) Originate and utilize every means or avenue of research possible.

(f) Make practical application of known psychological laws bearing upon human traits, human emotions, human perceptions and reactions, human limitations of intelligence, interest, sustained forces of attention and memory, human physical frailties, characteristics of race, sex and age of individual and mass temperament, as the character of toil may dictate.

(g) Promote the best working environment possible and eliminate fatigue wherever possible, keeping abreast of advanced thought relative to air conditions, light, rest periods for monotonous toil, the evils of prolonged constrained attitudes, etc., thus promoting the sustained health and indirectly the safety of the worker.

(h) Discipline when necessary. Some adults are like children in their attitude and response to discipline, involving as it does the element of fear as a guiding factor in their conduct.

(i) Promote good will, thrift, respect, cooperation, personal initiative of the worker at every opportunity by personal contact, fair play, patient instruction and friendly advice and assistance and by some welfare activities from school courses and insurance features to first aid and nursing facilities.

(j) Minimize labor turnover and seasonal occupation by all legitimate means and as economic conditions permit.

Complete Safety Organization Is Essential

k. Organize safety. The writer feels that the plant safety organization should be complete from the water boy to the president, and that each should play an active and specific part. The psychological factor of such method firstly gives prominence to the self esteem of the lowliest individual in the plant, and secondly awakens his desire to cooperate with his fellow employees and means that he will become interested to a greater degree than he would be otherwise, even though such a person makes report daily only concerning the safe condition of his tools or his work surroundings. Committee organization is paramount, and most efficient the farther down the line it operates. This does not necessarily imply that formal meetings among groups of men under each or even any of the sectional foremen, but each employee nevertheless knows that he has a daily safety report to make and that his foreman represents him as a member of permanent division of the plant safety committee. Meetings when held, be they daily, weekly or monthly, should be routinely systematized, reporting unsafe conditions and practices, should be made easy, free of embarrassment and exact, for the individual key men by furnishing them with safety booklets in which to write their findings and recommendations in advance, and by such procedure to thus keep the meeting alive and to make it possible to conduct the business in hand with snap and order, even to those discussions that follow specific recommendations. Here is where contacts are made, friendships develop, cooperation inspired, thinking stimulated, reasoning promoted. One soon learns that "He that can not reason is ignorant; he that will not reason is a bigot; he that dares not reason is a slave," that no pursuit is so important as the pursuit of facts, especially those impressive and established facts of safe and economical plant operation.

Membership of the plant safety committee is composed of two groups, the permanent and the temporary committeemen. The permanent members are foremen, the temporary committeemen are appointed quarterly from among the rank and file of employees, each operating department being represented, the representation being approximately one committeeman to every ten employees. One of the first and outstanding facts that these committeemen learn is that the management both by word and action is thoroughly and sincerely supporting safety, first for humane reasons and secondly as a necessary part of production. That is important and far reaching. When recommendations are made by committeemen or men from the ranks they are given intelligent consideration, and when original or exceptional recommendations from the standpoint of value to the greatest number of employees involved are submitted and accepted, money prizes and bronze watch fobs suitably engraved and emblematic of quarry and mine activity are presented to such employees. This is also important and far reaching.

We have organized Blaster's Schools—who meet once each month and conduct

their meetings in an orderly manner similar to those of the plant safety committee. We have recently organized Trainmen's Schools, who will hold regular meetings covering train operation, train signals and safety. We have organized Five Year No Accident Clubs and Ten Year No Accident Clubs at the respective operating plants, each member of which is distinguished with an appropriate and attractive button.

We have special foremen's meetings at which every effort is made to impress on them the value of special qualifications in their relationship to their subordinates, such as leadership, alert supervision, initiative, diplomacy, sympathy and understanding, good judgment and example by respect. Every foreman has his goggles in full view at all times, not only as an example to his subordinates but ready for instant use when the occasion arises.

Naturally we endeavor to take advantage of all advanced safety thoughts, devices and methods from the psychological realm to the machine guard and operating processes that we may utilize with advantage and without too much repetition or over indulgence. It is not unusual to surfeit to the extent even of narcotizing the employee or nullifying safety effort by too much propaganda, remembering that although you may not have given the applicant more than a cursory intelligence test upon employment, and although he may not be definitely rated a moron, that nevertheless his powers of successful mental digestion are limited.

However, we look with favor upon such modes of safety approach and application as:

Arousing the Enthusiasm of the Individual

Safety rallies, picture shows carrying safety propaganda, extensive bulletin board service, envelope slips pertaining to such matters as safety at work and in the home and upon highway, health, sanitation and personal hygiene, addresses at intervals by the local plant surgeon, attorneys, men from the ranks and officials, plant picnics, competitive contests between work sections, departments and plants, the awarding of trophies and pennants to such groups, and individual prizes as above mentioned, publication of plant accident rating as compared with other similar plants, posting the accident records of respective plant foremen, subdividing the safety committee into sub-committees and exacting a written report monthly of inspections made of chains, cables, ladders, machines, shafts, set screws, air compressors, explosive magazines, tools, falling objects, including quarry face and mine roof, fire equipment, holding routine fire drills, checking plans and specifications for safety, monthly written reports by foremen describing conditions of their respective departments with specific regard to the safety features thereof, etc.

Every accident no matter how minor in nature is reported and treated immediately. We do have infections now and then, but few indeed. Some of these I earnestly believe are the result of injuries, later claimed to have occurred on the job. To put an end to this type accident, and as a measure of protection to the company against fraud, we are arranging to have each employee at the end of the day's work mark opposite his name whether or not he has received an injury during the working hours.

Time does not permit of more detail or further discourse upon this most interesting topic at this time. Let me say in conclusion that the results in health, safety and welfare among the employees of the Pittsburgh Limestone company, Subsidiary Companies of the U. S. Steel Corporation, have more than justified the sincere efforts of the management both as to the added security of their plants and the intimate and gratifying relationships, the mutual welfare and public interest that this sound and constructive policy has inspired, and by the number and severity of injuries, the reduction to a minimum of the possibilities of death, that have been promoted thereby within the organization.

CHAIRMAN CARTWRIGHT: We thank you, Dr. Parlett, for this enlightening address. I think it inspires in us some idea of our responsibility to employees for their health as well as accident prevention.

The next paper is from Mr. Jones of the Indiana Lime Stone Company on the subject of the "Safe Handling of Rock."

Safe Handling of Rock

Areli Jones, Superintendent, Hoosier & Joyner Mill, Indiana Limestone Co., Oolitic, Ind.

Rock quarries are as many and as varied as the ships that sail the seas. A rock quarry is a place where they get out rock of any description, whether it be road rock, shale, stratified rock, or the more substantial building rock commonly known as granite, marble, sandstone or limestone. In the quarrying of building stone, all conditions of hazards are very similar.

It has only been in the last two years that the quarries of southern Indiana have taken any real interest in safety problems, which confront every quarry operation, large or small, and whether it be road rock or building rock.

Just as long as men are indifferent we will have accidents to contend with. Why do some men get hurt in the quarries more often than others? Possibly for the same reason that some men have more automobile accidents than others.

We are trying every day and every hour to solve the problem of automobile accidents, because it affects the life of every one of us. We believe the only remedy or solution is an education in safe methods, regardless of the few seconds we lose at the stop signs. We must bring order out of chaos by learning to obey all signs and signals—stop at the highway and the railway crossings; when in doubt proceed with caution. With an education in safe methods of driving the subconscious mind will assert itself, regardless of the surroundings and the humdrum of life. That little substation within you will automatically control the breakers of the mind, breaking contact at stops and red lights.

Education is the key to progress. If we do not learn to control our actions, then the State must step in and find out how much we *don't* know about safe methods of running a car—just as a trainman must know the rules of the road, and just as we know that when a train crew disobeys the rules of railroading something is going to happen. Education in safe methods has reduced accidents on railways and in many industrial plants. Why not seek to attain the same results in rock quarries?

To my knowledge, the first concerted effort to establish safety principles in the stone quarries of Indiana were put forth by the Bedford Stone Club with the assistance of The Travelers Insurance Company.

This campaign was started August 1, 1925, and was personally managed and conducted by M. J. Morgan, who was then president of the club. He was ably assisted by E. C. Walters, secretary of the Stone Club.

Committees were organized in each plant, men who could be relied upon were picked for the committees, and an enormous amount of literature was passed out setting forth the advantages of safe methods. True, we agreed with the disaffected employee that it was an advantage to the company, but we pointed out that it was even a greater advantage in a saving to the worker and his family. Posters of many designs, with which all of you are familiar, were posted, more ably illustrating the point—possibly more forcibly than the pamphlets could do. Noonday meetings were held in each plant; speakers

on safety were secured; night meetings were held in the public school buildings; the men and their families were invited to these meetings; local singers entertained all present with the singing of safety songs, many of which were original, thus adding a little spice to the movement; safety slides were used showing the operation and the progress made in other industrial plants; safety engineers were also introduced, who instructed us in the safe methods they had used and the success attained. I do not doubt that there are some men at this Congress, who remember an evening spent in Bedford or Bloomington, Indiana; and thus it was we inbibed the "Spirit of Safety."

This intensive campaign terminated with a successful issue August 14, 1925. We were all tired out, but felt the message had been put across. Future events proved this to be a fact, regardless of some of the raw material we had to contend with. For our supply of men came from the farms, many of them from the mountain fastnesses of old Kentucky—men who had heard of the law, but the word "Safety" was not in their vocabulary, men who would go about their work on the ledge with the utmost abandon when a large block of stone was swinging overhead, weighing an average of fifteen tons, and as these blocks in swinging over might cast a shadow at their feet, it was received with no more concern than a passing cloud. These men realized no danger.

Each Plant Built Its Individual Record

Yet with a foundation so well laid, it was up to each plant, each mill, each ledge, in the quarry district to contribute its part to the building of this safety structure according to the approved plans and specifications. True, there were spots where the pioneering was rough, the brush and thicket had grown dense and was hard to penetrate, and instead of the bountified yield as produced on limestone soil, it seemed that some of the seed was smothered by the dense growth of previous years. Transplanting had to be done, and the records prove that it was done successfully.

I was interested at that time with the Indiana Quarries Co., which was one of a group of quarries working indirectly through the Stone Club, which sponsored this safety movement.

After the campaign, and under the direction of N. Joyner, general superintendent of the Indiana Quarries Co., we proceeded to form our plant organizations, by first electing a Board of Directors composed of 12 men, each of whom held an official position with the company. This board then picked men from the different departments, whom they considered capable of doing the committee work, because of their influence and boosting capacity. After all the committees were organized, we began holding joint meetings of all committees one night every week, exclusive of the regular department meetings. Board meetings were held once a month. It was our desire to keep up the pep previously created, and to get thoroughly organized, so as to inculcate the lessons and principles of safety just as fast as the men might be able to absorb them. Continued interest was shown by the committees and the men, safety became a real issue and foremen took as much interest in safety as production. I have no comparison of records to show what was accomplished in such a short space of time, but I do know this: the Indiana Quarries Co. carried its own insurance, and it was more than pleased at the saving made in the insurance budget up until June, 1926, when the Indiana Limestone Company absorbed the Indiana Quarries Co.

After the merging of the quarries, Fred Hatfield was appointed safety engineer, and with his able assistants, Nevin Tovey and Wm. French, a trio of

earnest and zealous workers was enlisted, a combination that is bound to win and bring about the safe handling of rock in the quarries, which of itself is a big proposition, not so much because of the number of men employed and the various branches of industry in connection with it, but because of the scattered condition of the quarries and ledges.

One does not realize the territory that must be covered by the safety engineer. If you have never been down in southern Indiana the trip is worth while, as you pass through a country of wonderful scenic beauty. As a safety suggestion, be sure your brakes are tested before you make the trip, because you will encounter wonderful hills, with long, graceful curves and some that will be rather abrupt and winding around the hillside.

Each hill or combination of hills is composed of rock that has withstood the ravages of the glacial period and the washing and pounding of many waters, when the southern part of Indiana was covered at one time with a body of water similar to Lake Michigan. If you visit Orange county you will see a lost river which drops into the ground and disappears from the eye of man, perhaps fashioning out some cave for future generations to discover.

Handicaps in the Quarry Territory

Then we have Marengo cave with its spacious halls, rooms and passageways, all washed and worn out with the irresistible force of some previous lost river. Such are the surroundings of the Indiana limestone quarries, a stone almost identical in texture and analysis with the stone of the Pyramids of Egypt.

After a prospective stone quarry has been located and tested, it may be necessary to cut off the timber, after which the hydraulic machine is set up. This water power will certainly remove all the clay, dirt and roots of trees, leaving a nice clean ledge to work on, sometimes level, sometimes exceedingly rough and jagged, resembling very much the rock bound coast of the sea. Many and varied are the ledges of rock. Sometimes merchantable stone lies just under the surface; after cleaning off the light soil, the track can then be laid on the ledge.

The machines are set to work cutting out the rock, and the derrick is raised. Several kinds of machines are used, each with some special feature or improvement over the other, if the limestone rock does not extend to the top of the ledge. Then we have the Mitchell rock to contend with; this may extend down five to 20 feet. There are times when this could profitably be taken out and used for road rock. Taking off the top rock is an expensive and more or less dangerous proposition, because of the rough nature of the stone and the work. Blasting is done where possible, all depending upon the formation of the rock. Accidents occur. Men have tried to thaw out dynamite on the hearth of the blacksmith shop; men have used drills to remove the tamping because of a misfire, drilled too deep and set off the explosive, with the usual result; men have left powder cans open and exposed to sparks—of course the inevitable happened, because a safety law was violated; some individual decides to climb up on the pile of rock just blasted out, only to step on and release an over balanced rock, causing a slide which if not disastrous to himself may be to others. Sometimes big grout, blocks weighing five or six tons, are set on the pinnacle of the grout pile, and some one is there to release the dogs and trip the blocks over to their everlasting resting place—a hazardous job, and a man who knows how should fill that job, as a trap is very easily set, and when sprung, a slide may extend up to the pinnacle and jeopardize the life of the tripper. So much for the stripping of rock.

In getting back to our channelling machines, now that the rock stripping is complete, sections of track are laid on the floor of the ledge, similar to the laying of railway track, except that the track is fitted up in sections and fastened together with rods and braces, then laid together end to end. The track is then leveled up with blocks of wood, so that the machine can run true. The channel drill bits are clamped on the machines, the machine travels up and down the track striking a blow from the piston. Some other machines work on a leverage basis. The machine runner sits at the throttle, the fireman throws in the coal and looks after the water. If he happens to be standing with one foot on the rail when the machine runs back, and the fireman forgets his foot is on the rail—well, he is liable to lose half of his foot, or at least, some toes. Men have sat on their machines and kept them running until they went over the edge of the ledge into an abandoned quarry hole from the previous year's work, falling perhaps a distance of 50 feet. Men have stopped their machines under the same conditions at the edge of the ledge to tighten up a nut, the wrench slipped off the nut and the pull on the wrench was towards the quarry hole, with the result that some one again went over the ledge into the quarry hole. It seemed to be just a case of luck, as to how serious he was hurt. Dump boxes of coal have been set down on the upper ledge, only to slide over on some one working on the ledge below.

And so we could go on enumerating accident after accident. Was the machine at fault? Only the human machine slipped a cog. So we are thoughtless, careless, and indifferent to danger. Safeguarding machinery is worth while, and money is well spent, not so much because it makes the machine fool proof, but because of the object lesson to the man employed. It is a continual reminder of safety.

The Safe Handling of Men is Paramount

To me it is not so much the safe handling of rock at the quarries as it is the safe handling of men. There are some unavoidable accidents, but with the education of the human element accidents are bound to decrease. I wish to repeat that a foreman should feel obligated to his employers for the safety of his men, if not from the human viewpoint, then from the economic standpoint. Why not cut down this economic loss, reduce the cost of production, which would be equal to about one cent per cubic foot? And yet, a greater obligation, owed to your fellow workmen, to his wife and children, to your employers and to humanity at large, is the protection of your men in every conceivable way. Safety comes first.

If you, as a foreman, have been elevated from the ranks because you have shown foresight and skill in the handling of rock, you are to be congratulated; but there are a number of tests for qualification as a foreman. Do you believe in safety? Have you been taught that accidents decrease production and increase costs? Are you interested in the welfare of your men? Are you treating your men as you would like to be treated? In so far as you treat them on the square and show appreciation of their efforts, have you succeeded in winning the confidence of your men? This alone proves the highest type of foremanship. Someone has said, "Give no man your confidence until you have found him worthy." So, to be worthy of the confidence of your men is something worth while, and proves that you have passed the acid test. Men are just overgrown boys, and we don't have to go back very far to remember the days when we moved in a new neighborhood, or some kid moved in our neighborhood. We or he had to meet the test whereby we or he gained, or lost, the confidence of the gang. You men here tonight have passed that test also, or you would not be here, because the boy is father to the man.

To handle rock safely in the quarries, there must be leadership. Not such a big word, and yet true leadership spells success in every walk of life. Leadership at the quarries runs from the executive office down into and through every depart-

ment. Out on the ledge a one track mind cannot lead. Just as the derrick runner is capable of taking up on the boom, hoisting up on the mainfall and swinging the rock around into position on the car, all three operations at the same time, accomplishing a three-fold purpose, so it is with the foreman; he must have at least a three track mind,—the condition and security of his machinery, the safety of his men, the production of rock. Are the powers bolted down securely? Are the derricks and guy-ropes safe? Has he taken time to take up the slack on the guys, and keep the mast plumb? How about that fall rope with its strands of broken wire? Does he know the limit of its endurance? Does he make inspections regularly, or just previous to heavy lifts? Has he instructed his men in regard to the relative position of the boom when dragging in cuts or making lifts of various loads? Are the chains and dogs, cables and slings in good condition? Are the ladders in good shape? Are the steps made standard so that the men can use a regulation step in climbing up and down the various ledges?

No Human Machine Can Be Replaced in a Day

For the safety of his men, is he insisting that the men on the ledge keep out from under loads that are being hoisted and swung around overhead, even though the men are running machines and producing rock? It is dangerous practice to allow men to remain on machines when loads are passing over. Get away from the old idea that men can be replaced along with machinery. A machine can be replaced in one day to one week's time; a man's life can never be replaced, and if crippled, he can never be made new like a machine. And, remember, it takes two to four years to make a capable man in the quarries. As with machinery, so with the men, does he know where they are weak? Does he know the man capable of the heavy job? Does he know the man capable of the hazardous job?

Know your men. Remember, there is no group of workmen capable of perfect co-ordination in themselves. The powerman must change gears on the derrick hoist, so must the foreman change his men to suit existing conditions.

Then comes production. This I am putting last, because in a well organized department it comes last. It is a natural result of previous preparation. As acting foreman or superintendent, I have never thought of my work in terms of production. I rather like to plan, and combine things to work together. I do not wish to sacrifice material, just to get out some certain size blocks today. I believe in preparation, just as the athlete, who expects to win in the fight, whether it be in the ring, in the channel swim or on the field of sports. There must be preparation and it must needs be the proper preparation, if you are to get results. So it is with the farmer and the gardener, preparation comes first, then follows the production of crops. Some of you can remember when your mother or some one else's mother, made bread; perhaps you had been invited by your chum on baking day to come in and get a nice big crust of fresh, hot bread covered with butter and honey. Upon your arrival, the bread was just being taken from the oven, and right there all your anticipated joys and pleasures were blasted. An accident had happened; the bread had fallen flat; production had fallen to a minimum in that household, because something was overlooked in the preparation.

So it is with the drilling and breaking of blocks that have a rather mean grain. If proper preparation has not been made to take care of the adverse grain, the break in the block may run under and below the line, and again we lose in production.

The Indiana Limestone Company owns 6,600 acres of land in Monroe and Lawrence counties, and in order that you may realize the magnitude of their operations and the responsibility of the safety engineer, I will add that they operate 220 channelling machines, both steam and electric, 200 derricks, some of steel and some of Oregon fir, all operated by electric power; 12 hydraulic stripping pumps with a

capacity of 500 to 1,000 gallons per minute. They operate their own machine shop, boiler and forging shops, heat-treating system, acetylene and arc welding outfits, the electrical department doing all their own rewinding and repairs, carrying 75 machinists, electricians and mechanics. Also operating in the quarries, we have seven lime kilns shipping out 60 tons of lime each day.

In addition to the quarry operations, the safety engineers also supervise the safety work in the mills and stone planing shops; these are a part of the Indiana Limestone Company. So that you may get some idea of the extent of their work in the mills, I will name over the machines in operation: 101 traveling cranes, 243 gang saws, 287 planing machines, 8 diamond drag saws, 38 diamond circular saws (for ripping stone), 64 diamond circular saws (for jointing stone), 9 large column lathes, 39 baluster lathes, 29 milling machines, 4 carborundum planing and molding machines, and 5 surface and polishing machines.

The company anticipates a 12,000,000 cubic feet production this year from the quarry department based on figures of previous years. Indications are that we shall beat the schedule set by one million feet or more. I am wondering to what extent safe methods have helped to increase this production.

Our short experience in safety work has taught us that education in sane and safe methods gives a man self reliance, helps him to stand on his own feet, and creates a feeling of responsibility in that the life of other men may depend on his actions. Safety education brings to a man the realization that he is capable of taking care of himself; also gives him the ability to control what otherwise might become a dangerous condition. He will develop a keen insight as to what might prove dangerous and, if not able to control it, report to those in authority. Such a man, instead of being a liability, becomes an asset to his department, his employer and his home.

As I understand it, these are the ideals safety engineers seek to attain.

Details of the Round Table Discussion

CHAIRMAN CARTWRIGHT: We thank you, Mr. Jones, for this paper. I think it is a matter of a good deal of interest to many of us who are not closely acquainted with this particular line to have Mr. Jones go into detail.

Mr. Sanborn, I wish you would take charge of this round table. You set your own schedule of time limit and conduct that as you see fit. I think we ought to count on 30 minutes; that would give us ample time and I have appointed Mr. Soder, Mr. Hewitt, and Mr. Coville on a nominating committee and they can report immediately after this 30-minute period.

A. C. HEWITT (American Lime and Stone Company, Bellefonte, Pa.): Mr. Chairman, the nominating committee asked me to make the following recommendation for chairman. We had in mind the report Mr. Graves made you. We were hoping to go on with this work. For chairman the nominating committee recommends D. K. Soder, director of insurance and safety, France Stone Co., Toledo; vice-chairman, R. E. Coville, assistant manager, United States Gypsum Co.; for secretary, J. R. Boidsek, National Crushed Stone Association, Washington, D. C.

CHAIRMAN CARTWRIGHT: All those in favor of the recommendation of the nominating committee say "Aye."

(The nominees were elected to office.)

I shall now turn the chair over to Mr. Sanborn.

CHAIRMAN SANBORN: Gentlemen, we had better divide that 30 minutes into three ten-minute periods. First, let us consider Mr. Graves' paper. Gentlemen, what have you to say? This is your party now.

A. C. HEWITT (American Lime & Stone Co., Bellefonte, Pa.): Last year I was unfortunate enough to be elected secretary of this section, but I did not know it until

several weeks ago. I had gone home from Detroit. I hope that we won't have any such luck this year and that we will have an organization that will really accomplish something in a constructive way. I feel that the past year we have done very little and I blame myself perhaps more than any one else. I was very much surprised at the figures mentioned by Mr. Graves. Especially that figure where he said that 35 per cent of the membership of the National Crushed Stone Association were not members of the National Safety Council and had not been solicited for membership. That, indeed, is a surprise. I had assumed that the National Safety Council had solicited membership from practically every industry in the country. Evidently it has not. It seems to me that one excellent track which might be followed in the coming year, especially in view of these figures, is that the new organization make a decided and determined effort to go after the members of the National Crushed Stone Association and the members of the National Lime Association. I do not know whether there is a gypsum association or not; if there is, include that. They should go after every organization in the quarry business. I think they should be solicited for membership. I think it ought not rest with a single solicitation. If it is not possible to get new members by the first attack and the secretary is unable to get a response of the right kind, let him turn the names over to some other individual and make a second or third attempt. I feel that there is no organization in the country that can do as much for humanity as the National Safety Council, and if we don't go out and spread that good news we will not get members, and if we don't go ahead we will go back.

The Cement Industry is Represented 100 Per Cent

CHAIRMAN SANBORN: Mr. Graves, I may say for your information, we are biting into your paper for the next ten minutes.

T. L. HALPER (Marquette Cement): It might be of interest to those in attendance this morning that we are connected in part with this association, and that the cement industry is represented 100 per cent in the National Safety Council. In other words, every one of the 150 plants in the cement industry is now a member of the National Safety Council—and, by the way, the only section of the council that is represented that way. I wanted to say that if our section can in any way help at any time or give you any pointers we shall be very glad to. Unfortunately for that section, I was elected chairman yesterday, so I shall be very glad to cooperate with you.

CHAIRMAN SANBORN: That is a record to envy.

MR. CARTWRIGHT: I sent my contribution to the questionnaire. I should like to emphasize this point. Some one asked what our record was on safety. We fought it along pretty actively and had splendid results at our plants in reducing the frequency and severity of accidents as a general thing, but at one plant we had two or three of the severest accidents we have ever had. Right in the face of our active safety campaign, during the season of our heaviest production, we had two accidents to members of the safety committee. One fellow was careless and injured his finger by cutting toward him instead of away from him. Another was working on a shaft that was running. I don't know how he got pulled in but it took off the end of his middle finger. Those fellows happen to be members of our safety committee, and have to be at our meeting twice a week. They make the typewritten reports of the meetings. Their word goes if they recommend a change for the sake of safety. In spite of all that here were two members, as I say, of the safety committee who had accidents, and in one plant we had the severest accidents that we have ever had. One reason perhaps was that we got into heavy production and everybody was busy. We must get out everything we can in three months of the year. Then the trouble starts. We haven't taken the time to organize anything more than our regular safety committee. But I am thoroughly convinced that we must make

a special effort during these times of heavy production to bring our men in for some special safety meeting to instill in them the safety idea, and not do just routine work. We must give some special attention to safety work.

MR. GRAVES: I don't wish to embarrass the temporary chairman, but haven't you something to contribute, Mr. Sanborn?

CHAIRMAN SANBORN: I fully intended to have my superintendent at this meeting today, but sad to relate, he is the victim of a casualty, and we have been unable to place the blame on him or any one else. He got a little scratch somewhere (he doesn't know where), and the result is he has an infection and has had quite a serious time for a couple of days. He is now out at the plant with his hand in a sling. However, he is on the road to recovery. It is one of the perverse things of the times that the one particular man I wanted to bring up here is in such a condition that he is unable to go very far from first base.

Many Men Must Be Treated Like Children

MR. JONES: I stated in my paper that we have a number of men whom you have to treat almost like children. They don't realize the danger; and the point we have tried to bring forth is that any little scratch, the slightest accident, should be reported to the foreman who immediately sends them to the first aid department. They get that first aid service right away. We have had no cases of infection in the last twelve months. Not a case. It seems that you must get enthusiasm into the men. Everybody must be sold on safety, from the superintendent down. The superintendent must be better sold than anybody, because if the superintendent is not sold, you wouldn't get results. The foreman looks to the superintendent and, just as in production, it is how hard the superintendent presses the foreman. Just as he gets more production by pressing the foreman so will he get better results if he pushes for safety.

I think we should also look ahead to prevent accidents. We have men of that class and we are proud of them. The thing is to get the foreman sold on safety. That has been our experience. Hold your meetings for the men and tell them how necessary it is, and have the first aid man explain to them the reasons for first aid and that he wants them to come back if necessary so that they may have the proper treatment and prevent blood poisoning. He gives them examples of cases in other quarries where men have lost legs or feet through being negligent. Some of these accidents do happen off the plant, but it is better to take hold of them as soon as you can, say nothing about it, gain the good-will of the men and have them report whether the accident was in the plant or at home. That is the way we handle it, and we are getting good results. We have been in the safety work a year, but the men are all interested in the safety idea and the safety engineers and workers have done excellent work.

CHAIRMAN SANBORN: We will pass to Dr. Partlett's paper.

MR. GRAVES: It seems to me in reference to what Hewitt said about increasing membership, that it would be well to put that as a motion to commit the quarry section to such a policy.

MR. CARTWRIGHT: If the cement association can get 100 per cent membership why can't the crushed stone association? I think they are blaming the National Safety Council for something they are not responsible for. I know some of these folks of the crushed stone group have received invitations and the chances are they have gone into the waste paper basket. As a matter of fact the National Safety Council did all they could.

MR. HEWITT: We would like to get behind that motion to try to be responsible for getting every member. In order to get definite action, I move you that this section make a definite attempt during the coming year amongst all of the quarry

operators, with the possible exception of cement, which is already in 100 per cent, to solicit them for membership in the National Safety Council. I would suggest, however, that circulars not be used for this purpose, that the secretary or whoever is commissioned to handle this write individual letters. He may use it as a general letter, but he should write an individual letter addressed to the president or general manager.

(The motion was seconded and carried.)

MR. CARTWRIGHT: I think the cut stone organization generally meets at the same time the crushed stone association does and I am sure we can depend on these men to carry the thing through their organization.

CHAIRMAN SANBORN: It strikes me that Dr. Parlett had a number of very helpful suggestions and these should elicit considerable discussion. Personally, I like the scheme of having the man report at night that he has gone home uninjured, because some of the nastiest accidents we have had to contend with seemingly originated some week or ten days after they happened.

The Effect of Lime Stone Dust

J. G. HALPIN (Consumers Material Corporation, Kansas City, Mo.): I should like to ask Dr. Parlett if he has any opinions on the effect of lime stone dust on the health of the worker.

A. J. EOLES (Bessemer Lime Stone & Cement Co., Bessemer, Pa.): Dr. Parlett answered that question yesterday in the cement meeting. He said respirators were not important at all as protectors since he found that the lime stone dust was rather beneficial, particularly in the case of tuberculosis, and the like of that; and he stated that dust on an open cut has rather an antiseptic quality rather than a detrimental effect. Of course we usually say dirt is dirt and dust is dangerous. However, with lime stone dust it doesn't work that way, and our medical officer voiced the same opinion. He has been in various industries and he finds cuts heal more rapidly in the stone industry than in other industries, so the point we reached yesterday was the cut was not dangerous.

CHAIRMAN SANBORN: Did he cite authorities?

MR. EOLES: He cited some but I don't recall who.

MR. A. JONES: For the information of the gentleman I will state that the Old Indiana Company had trouble with the stone cuts, and the company sent to Indianapolis and got two physicians who examined all the employees and examined the dust and took the history of the families; this was six or seven years ago, and the results were just as this fellow stated very favorable on cuts. In fact it had been suggested by the nurse who has charge of Orange County that he would like to get men who had been working in what we call the "bug" dust plant. This is a plant where they grind lime stone for use in agricultural work, for sweetening the soil, and it is also used in glass factories, beet sugar plants and in some steel plants. This place is just full of dust. It cures up any sores on the lungs; and as a worker in lime stone myself, I know that in the old days while cutting stone with a hammer, if you knocked the skin off you could throw some stone on it and it healed up. I have also noticed among machinery having motors in our industrial plants, that this lime stone doesn't have any effect on the armature whatever.

CHAIRMAN SANBORN: I think it is now up to us to begin the discussion of Mr. Jones' paper. There are certainly some of you building stone men who are better qualified to discuss those phases than some of the rest of us. May we hear from some of you?

Mr. Jones, the building stone industry has been particularly hazardous, hasn't it?

MR. JONES: More so than the quarry.

CHAIRMAN SANBORN: There have been a number of casualties?

MR. JONES: Yes. Every year there are some fatalities.

CHAIRMAN SANBORN: Gentlemen, we ought to be able to get more round table discussion on this.

MR. JONES: We have a gentleman here from the Ohio Quarries Company.

CHAIRMAN SANBORN: We shall be glad to hear from him.

H. E. DULMAGE (Ohio Quarries Company, Amherst, O.): That is sand stone. We have the silica dust. We quarry down to a depth of 100 feet with open pit quarry, and while we are doing considerable work with safety we want to do more. I notice one fact that has been brought out, and probably other industries find it the same; that is that we haven't had an accident in several years which we could blame to defective machinery. Over 90 per cent of the accidents are due to the individual workman's carelessness or thoughtlessness. Mr. Jones spoke about channel machines running over men's feet. We have the same trouble. We employ the same methods the lime industry does and we used to have a considerable number of accidents through men not removing their feet quickly enough; but now we have a guard that will push the foot off. It might be interesting to know that in making an examination of the health of our workers it was found that men who had been turning grindstones for 40 years, which is supposed to be the most hazardous work in regard to dust, were healthier and stronger than a lot of younger men.

ADJOURNMENT.

*SIXTEENTH ANNUAL SAFETY CONGRESS
NATIONAL SAFETY COUNCIL*

Cement and Quarry Joint Session

Wednesday, September 27, 1927

R. FRAME, Chairman Cement Section
Insurance Manager, Alpha Portland Cement Company,
Easton, Pa.

L. R. CARTWRIGHT, Chairman Quarry Section
Vice-President, Mid-West Crushed Stone Company,
Indianapolis, Ind.

The joint session of the Cement and Quarry sections of the National Safety Council convened at two-thirty o'clock, R. Frame, insurance manager, Alpha Portland Cement Company, Easton, Pa., presiding.

CHAIRMAN FRAME: This session is a joint meeting. As many of you men know, the cement and quarry industry have a lot in common and it has always been the practice to have one joint session at which we could discuss the subjects pertaining to our mutual interest.

I am going to ask Major Reninger to announce the nominations of officers for the Cement Section for this coming year, and immediately following will be the elections.

H. A. RENINGER (Lehigh): There is one thing I want to bring out that I am very proud of as far as the Cement Section goes. That is in regard to the new membership in the National Safety Council. We have 13 new members, making a total of 79 in the Cement Section, with no cancellations, giving us a 100 per cent clear record, and the only section in the National Safety Council having a 100 per cent record in membership.

There were four companies who were reported as having cancelled their membership. These companies—the Pennsylvania, the Dexter, the Penn-Allen, and the Penn-Dixie—have not cancelled their membership but have all combined under the Penn-Dixie. They are all actively represented in the Cement Section.

Another question was brought up by Mr. Curtis in connection with community activities, upon which I would like to touch. What can we do in the way of helping the community? Those of you who have plants in large communities, are not up against it as much as the smaller community. Where you have a small community, as we have in a number of places—at Mitchell, Indiana, for instance, where the plant is more or less the chief manufacturing concern—we believe there is a field for our safety committees to do some good, active safety work. Perhaps it isn't so necessary that we go into public safety as we have to in other cities, unless you are on a main

highway, but I believe we have a field in the schools. There should be put into the school system a course of safety, starting with the child in the first grade and keeping on up to the seventh or eighth grade.

Years ago it was hard to do that, for the simple reason that we didn't have the material and when we came to the teacher and said we would like to put across some safety work and asked what she could give us in the way of help she would have to go and dig out stories and plays and different things; and, of course, she didn't always have the time to do it. However, with the inception of the Educational Section of the National Safety Council, we have gathered a great amount of information from cities all over the country and a course has been outlined. This course has been studied by some of the best educators. It has been worked out in detail now so that the mind of the child from six years on can absorb that information, and I believe we can do a great deal of good. Get the school authorities in your community interested and have them become members of the National Safety Council.

Let us get our school people interested in home safety and public safety. Eventually when the child has reached the age to enter into industry he will have absorbed a great deal of that safety we are trying to give him now. It will become more or less of a habit and that is what we want in safety work.

I think it might be a good plan to have one representative of every plant here and hold a meeting this afternoon or tomorrow morning and get one of the National Safety Council people here to talk to us. If we can, let us get Miss Stevenson to talk to us on school safety and what we could do. Are you men interested enough to get together after adjournment of this meeting and have a talk by Miss Stevenson or some one of those girls of the Education Section who are familiar with this work? How many of you would like to come to a meeting of that sort?

(A number of men raised their hands).

The School Children Are the Workmen of Tomorrow

We can set that meeting for four-fifteen. I know that many of you are interested in this work and have suggested that we do something of this sort. I would like to have one representative from each plant. We could go into the details and find out what we might be able to do.

CHAIRMAN FRAME: Major Reninger will be glad to answer any question in regard to this matter.

MISS M. JORDAN (Indiana): I think that would interest everyone here because the school children of today are going to be the workmen of tomorrow, and if you start in now teaching them the rules of safety and how to be careful in their play, in their household duties, if you get them at that age when they start working in your mills and plants you won't have nearly as much trouble with them.

I want to know if the procedure of that will go through the school boards.

MAJOR RENINGER: Yes. You won't have any trouble if you show them just what you have to offer.

CHAIRMAN FRAME: The average school superintendent, from my experience, will readily admit that he knows very little about the aims and the progress of the National Safety Council; and he will just as readily admit that it ought to have its beginning in the public school and he will welcome any suggestions from any community man as to what might be done.

MAJOR RENINGER: There are outstanding cases where industry could take hold of this thing. Mr. Kreglow, of the New Jersey Zinc Company, backed up this work with the schools. I am going to ask Mr. Kreglow if he won't review briefly their success.

MR. KREGLOW (N. J. Zinc Company): Most of the men who are interested in safety are members of the school boards. However, we have found the teachers very friendly toward it and also the superintendent. A number of times we took them along to our

local meeting and we got them interested. We have memberships for everyone of our school buildings. We also have the safety patrol. I think it is the right way to attack the problem and it is going on now without any trouble at all.

MAJOR RENINGER: The Nominating Committee of the Cement Section wishes to report as follows:

Report of the Nominating Committee

Chairman, T. F. Halpin, Marquette Cement Mfg. Co., LaSalle, Illinois.

Vice-Chairman, F. E. Town, Supt., Manitowoc Portland Cement Co., Manitowoc.

Secretary, A. J. R. Curtis, Portland Cement Association, Chicago, Illinois.

Chairman Membership Committee, Henry A. Reninger, Lehigh Portland Cement Co., Allentown, Pa.

Chairman Poster Committee, R. B. Fortuin, Penn-Dixie Cement Corp., Bath, Pa.

Chairman Program Committee, Russell Frame, Alpha Portland Cement Co., Easton, Pa.

I want to present these names as the ones placed in nomination by the Committee as officers for 1927-28. Signed by the Committee, Mr. White, Mr. Fortuin, and myself.

CHAIRMAN FRAME: Of course, it is your privilege to nominate any other gentlemen for the positions which are open at this time. It will now be in order to listen to any other nominations you care to present.

(It was regularly moved and seconded that nominations be closed).

CHAIRMAN FRAME: It has been regularly moved and seconded that the gentlemen proposed by the Nominating Committee be elected to serve as officers for the Cement Section for the ensuing year.

(The motion was put to a vote and carried).

CHAIRMAN FRAME: I declare the gentlemen duly elected. I take pleasure in presenting Mr. Halpin, of the Marquette Cement Mfg. Company, your next Chairman.

Mr. Curtis tells me he received a telegram from Mr. Town regretting that it is impossible for him to attend the session. Mr. Curtis will again serve as Secretary of the Section.

Now we come to the first subject on our program—"Fixing Accident Responsibility." The first question when an accident occurs is, who is to blame for the accident. We believe it would be of interest to discuss this, and I am sure it was placed in able hands when Mr. W. L. White, Jr., General Superintendent of the Sandusky Cement Company, Cleveland, Ohio, was selected to present the subject. I take great pleasure in introducing Mr. White.

Fixing Accident Responsibility

**W. L. White, Jr., General Superintendent, Sandusky Cement Company,
Cleveland, Ohio**

Fixing accident responsibility is a most serious problem. It calls for a decision, which, under any circumstances, is hard to make; one which must be carefully studied, and only a cool, clear, unbiased opinion is to be used in handing it down.

The safety movement, as we know it today, particularly in the cement industry, is really an innovation compared to the age of the industry. The year 1919 saw the beginning of extensive accident prevention work by the Portland Cement Association, and, while there were a good many individual plants and companies which paid particular attention to the prevention of accidents before that date, yet, nationwide attention to accidents began in that

year. Attention to accidents means placing the responsibility on the party directly responsible for them. Little or no attempt was made to fix accident responsibility in years previous to 1919.

It might not be amiss to state here that the first day I started with a cement company there was an accident at the plant which resulted in a fatality. but, to be honest, perhaps through inexperience, or youth, or both, it did not make the impression that an accident does today. I do not recall any attempt to fix accident responsibility in the first years of my work. The general attitude in the cement industry was to take an accident, serious or otherwise, with a shrug of the shoulders, as if it had to be, or, as if it were part of the routine operation of the plant or quarry.

There are four headings into which "Fixing Accident Responsibility" can be classified:

- (1) Executive or company policy
- (2) Plant Manager or superintendent
- (3) Plant Safety Committee
- (4) The individual

(1) It is a well-known fact that the attitude of the superior officer or executive, president or board manager, or whatever individual or group directs the policies of an organization, is reflected down to the humblest employee. If this individual, or group of individuals, is not squarely behind the welfare of the employees, and does not sanction safety work, it has a bearing on results secured by the company. This might be termed more psychological than actual, and, therefore, a president could hardly be accused of being the cause of an accident. However, careful analysis shows that he is responsible to a much greater degree than a casual glance first discloses. The mere fact that most individuals and groups look up to leaders for initiative is sufficient cause for the statement that the executive is responsible in a certain measure for accidents if he, or they, are indifferent to the safety movement.

The Modern Executive Must Be Behind Safety Work

It is inconceivable that an executive of today is not squarely and actively behind the safety movement. There are some who are passive, though, and such should certainly be held liable for at least part of the responsibility of the accidents occurring in their organizations.

(2) The second party on whom the responsibility of accidents rests, is the plant manager, or superintendent. In a great measure, the entire success of safety work depends on him. If safety is not being pushed energetically, or, as in some few cases, is not even considered, then this man is directly responsible, except, perhaps, in the rare case where his good intentions are held in abeyance through the orders or wishes of his superiors. A good plant manager includes the safety movement as part of his daily duty. I say daily because safety work is largely missionary work, and the true safety man can be likened to a missionary who toils unceasingly, day after day, without any thought of reward, gratified entirely, through love of his work, with but small visible results. He must be a keen student of human nature. His interest must never lag. He must be able to put across the idea of safety, not only to the safety committee, which should be directly under his supervision, but also able to put the idea across to the individual, through his actions and speech.

The following case occurred during the war period. The common labor at the plant was composed mostly of the rag, tag and bob-tail which had escaped the draft, and more negro than white. During a particularly rainy period, with the coal storage low, it was necessary to put a force of laborers

shoveling from the coal pile into the screw conveyor under the coal trestle. This screw conveyor was guarded with a heavy bar grating, bolted down to the concrete. The plant superintendent was in this particular department for some little time, principally with the intention of putting across the safety idea to these men, as several serious accidents in screw conveyors had occurred prior to this time. No sooner had the superintendent left the storage, than one of the negroes removed the grating, straddled it, and started to shovel in coal.

He slipped, fell in the screw, but miraculously, had only the flesh and muscles of the calf torn, instead of losing his entire leg. While he lay on the stretcher waiting for the doctor, the superintendent asked him why he did it, and he was frank enough to admit that he wanted to hurry his work up, that is, fill the coal tanks over the boilers, and then sit down and rest, which is characteristic of the negro as you know. This accident brought the superintendent face to face with placing the responsibility, and he felt guilty because he did not have the ability to read human nature better, or else was unable to sell an idea, and, from that time on, this superintendent became a better safety man.

The Functioning of the Safety Committee

The injured man was not censured at the time. He was suffering enough pain without giving him mental stress in the bargain; but on his return from the hospital, coming back to work, he became one of the best safety men in the plant.

Perhaps you have all had similar experiences, and the plant executive who is unable to strike the chord of safety, and cannot sell or put across the idea of safety, lacks one of the fundamental characteristics which will make him a success.

(3) It is no easy task to have a safety committee function properly. In the early beginning, when safety committees were first organized, while it was not the rule, yet a good many plants had a safety committee in name only. This committee might be composed of any number of men, meetings would be called at various irregular intervals. Sometimes the members of the committee were "too busy," having a small repair job to work on, and considered the operation of the mill of more importance than the safety committee meeting. Again, the spirit of the organization would be dominated by the plant executive because he took it upon himself to turn down all recommendations except those which he himself might bring before the committee, feeling that an employee was "treading on his toes," or presuming beyond his station, or overstepping his authority. In other words, the safety committee was not being handled right by the plant executive. A good executive will have a good safety committee, and this is the third group upon which the responsibility for accidents rests. It is not right for a superintendent to take upon himself the duties of a safety committee, so to speak, nor to inspect the plant at such times as he may see fit, perhaps with one member of the safety committee or alone, nor to install certain safety devices and consider good safety work being done. Such practice, in reality, is nothing but the result of egotism on the part of the superintendent.

A manufacturing plant as large as the average cement plant today needs a safety committee that consists of not less than six, and ten is considered approximately the right number for a three thousand barrel plant.

The committee itself must be made up of real safety men, whose enthusiasm must be ever to the front. The members of the committee should not

necessarily be chosen by the superintendent, as the employees know best who of their number is most interested in safety work.

The committee should meet at regular intervals, and, in addition, have special meetings when the occasion demands, such as a serious accident, and it is only right to place in its hands the fixing of accident responsibility.

A man does not have to be college bred to make a good safety man, but he should be one of sound sense, a thinker, and have a good understanding of the idiosyncrasies of human nature, coupled with unflagging interest and endless patience. When all of these characteristics are found in one man, he is a jewel well worth keeping and generally demonstrates his worth through the results obtained. However, it is not difficult to find many of these characteristics in the average plant employee. If the safety committee is properly organized, and has the shining example of a good superintendent, it is bound to function efficiently.

Bad Safety Records Pull Down the Average

The accident records of the Portland Cement Association show that there are a "vicious few" plants which apparently lack something to bring their safety records to at least normal, and this record of the few pulls down the record of the majority through an excessively large number of man hours lost on account of various kinds of accidents. On the other hand, there are a number of plants which have an enviable safety record. A major portion of the success of this record can be traced directly to the safety committees.

It will not do to appoint a safety committee and then, on the day or days specified for the regular meetings, permit its members not to attend on account of some breakdown in the mill, or other excuse which might be forthcoming; or, on the other hand to cancel the meeting until the next day, or the day after, as the superintendent may have something which he considers needs his attention. There should be, as stated before, a specified time for the meetings and the schedule should be adhered to, and, except for unforeseen, serious reasons, no member should be allowed to be absent. If there are one or two members who would rather not attend, it is usually an indication of lack of interest, and they should be removed without further consideration, and others appointed in their places.

Neither should the plant superintendent, through the authority vested in him, become a jury of one and veto valuable suggestions offered by various members of the committee, merely because they might not strike him as the right move. If the suggestion is approved by a majority vote of the committee, unless he questions it at the time it is discussed and gives reasons sufficient to vote it down, the resolution should be placed on the books and the work done as suggested. Too often a peremptory veto takes the pep or enthusiasm away from the committee, and this, in turn, is reflected throughout the organization. With what result? Either there is an increase in accidents or a failure to obtain results in periods when drives are put on, such as the recent campaign of the cement industry in June of this year. Accidents in plants can be reduced if the safety committee is functioning properly, under a good executive. If they are not reduced after the organization is started, then it must assume its share of blame for all accidents, major or minor, which occur, for it has failed to do its duty, which is, first, putting across the safety idea to fellow employees, and, second, providing the good example.

No doubt some of you have observed members of your own safety committees doing foolhardy things in the plant, or making disparaging remarks in the presence of other employees. If these failings are not corrected after a heart-to-heart talk, they should be dismissed from the committee and the

fact published throughout the plant, which, as a rule, is sufficient punishment and makes them better safety men. Sometimes one hesitates to use the big stick, but it is necessary with certain types. It is rather difficult, perhaps, to cite cases where safety committees have flagrantly violated their duties. Actually, the idea of the formation of the safety committee originated from the fact that the plant executive cannot reach each individual throughout the plant, not coming into daily contact with as many of them as the members of the committee do, and on its shoulders rests the responsibility, which is very heavy. If this idea is instilled into the minds of its members, there is no doubt that the committee will never be censured nor taken to account for accidents which might occur.

(4) Fourth and last comes the individual himself. Except in catastrophies, where many are injured, and some killed, it is the individual who is generally responsible for the accident, and that responsibility must rest on his shoulders. Only, however, after a thorough investigation. If the plant superintendent is a safety man, and his safety committee is working properly, the injured employee has had an opportunity, through observation of the actions of his fellow workers, and discussion with them, to learn about the safety movement and has been instructed regarding all hazards about the plant. If he does not benefit through these methods he is entirely to blame.

The Other Side of the Subject

There are certain individuals who seem to be unlucky and who are continually unfortunate. In one particular case it was necessary to discharge the man. He would be injured, and, a day or two after his return to work, he would have another accident. Within the course of a year he suffered ten accidents, not quite one a month. It was finally decided that he was too great a risk and he was let go. Such is an unusual condition, however.

These comprise the four headings into which responsibility for accidents can be classified, but they are only one side of the subject. There is another side, which some people have emphasized, that is, the sentimental. It is not the intention to take that up in this paper as sentiment should not be used in handling safety matters. The only sentiment which enters into the situation is this; the man, or men who are responsible for an accident, and on whom the responsibility is placed, are usually punished sufficiently through the knowledge that they are the cause of pain and monetary loss to a fellow being, and further punishment should not be meted out, except in cases of gross carelessness, other than the publishing of the fact that they were directly responsible for the accident. That is as far as sentiment should be considered in handling this matter. Nor should generosity be considered in placing the responsibility.

There is one type of accident which cannot be accounted for even after a thorough investigation, and the responsibility for such accidents cannot be placed on anyone's shoulders. Particular reference is made to a fatality experienced at a cement plant in 1926 where one man was electrocuted and two others severely shocked while pulling on a cable from a car puller. These men were in the packing department and it was their duty, in connection with packing cement, to unroll the cable from the drum of the car puller, attach it to the last car of the string, and, after this hook was attached, pull the cars in front of the packing house door. These three men took hold of the cable, after starting up the motor of the car puller; two of them were knocked ten feet, one unconscious and the other severely bruised, but the third, presumably from a weak heart, was electrocuted.

Just who should be held responsible for this death is still a question. Starting at the top, the president of the company is a safety man; the superintendent has been giving, and continues to give, all there is in him to have an excellent record at his plant; his safety committee is composed of good safety men, and the general attitude of the whole organization of the plant places it in the front ranks of the safety movement. A thorough investigation of this electrocution brought forth the fact that it was caused by a faulty electrical connection. The first deduction would be that the plant electrician, who, incidentally, is a hearty worker on the safety committee, was responsible, but, if this conclusion is reached, why should not the plant executive take his share of the blame, or, going higher, why should not the head of the operating department, or even the president be implicated? To place the responsibility on any of those individuals would be wrong, because the motor received regular inspection, and the short circuit, which was the cause, evidently happened shortly after the motor was inspected, without giving any sign of happening at that time, and it could have happened the first time the machine was started up after it was inspected. It would, therefore, be most unfair to place the responsibility of that accident on the shoulders of any one individual.

In Numerous Cases Responsibility Difficult to Place

Another fatality which a cement company recently experienced, happened to a young foreigner while stripping in the quarry. He was excavating in a pocket. A large stone suddenly slipped out of the bank. Close inspection failed to disclose the possibility of this stone moving. It fell against the man's leg, breaking it above the knee. He was removed to the hospital and the bone was set and the leg placed in a plaster cast. Examination several days later showed that the set was broken. An operation was performed, but the man died from strombosis or blood clot. Perhaps the quarry foreman should be blamed for this accident in that he did not detect the loose stone at the location where the man was injured. We all know that careful inspection does not always disclose defects, and the company feels that this man is not to be blamed for the original accident. Being a muscular fellow, the doctor claimed, was the cause of the original set being broken, and they had every reason to believe he would survive the operation. Strombosis is apt to happen to anyone undergoing an operation however slight, where blood vessels and arteries are cut. On just whose shoulders the responsibility for this fatality should rest is a difficult problem to solve, but the doctor came in for censure, perhaps unfairly.

Numerous cases where it is difficult to place the responsibility even after a most thorough and careful examination, could be cited.

There is another type of accident which occurs frequently in cement plants, which is to be most heartily condemned, that is, accidents caused through "horse-play." The responsibility can invariably be placed on one or several men, and those men should first be given a fair chance to stop the practice, and if they do not heed the warning, dismissal is called for.

One reads and hears of so many horrible results such as those of ruptured intestines through the application of compressed air, or, electrification of the drinking cup, which caused the death of an employee who had a weak heart, and, while meant as a joke, such practice can be called nothing but horse-play and should not be tolerated. This is one of the few cases where accident responsibility is easily placed, and the person condemned should not be given much consideration.

I had occasion to discuss safety with an officer of one of the cement com-

panies some time ago, and remember distinctly his making the remark that he had not been pushing safety work as he should in that year, and the record of his company was much worse than in previous years. This I took as an indication of his thoughts on the matter and have watched the record of that company from that time on, and the results obtained by it have been truly remarkable. In fact, it is now near the head of the list in the length of time during which no accidents have occurred at their various plants, where before this record gave anything but a good impression.

If all executives have safety work at heart it would do worlds of good in reducing the number of accidents in their plants, for every individual would be proud of the fact that he was doing his little bit to have a good safety record, and one of his reasons for this satisfaction is the knowledge that his superior officer is keeping a close check on the plant's accident record.

On the other hand, there are numerous cases where safety work comes from the heart of every one concerned, from the president to the humblest employee, yet the accident records are deplorable. The records at the various plants where this is a fact will go along unblemished for months at a time, except for an occasional scratched finger or other minor-no-lost-time accident, and then, suddenly be spoiled by a fatal accident.

Unceasing Effort for Safety Is Necessary

I have in mind one plant in particular which would build up a wonderful record; all the members of the safety committee and the organization as a whole were on their toes to make the record 100 per cent for a year at least, when, out of a clear sky a fatality would occur; for instance, an electrocution where a man stepped from the crane girders down to the bucket and touched the trolley cables. Part of the craneway did not have a roof over it and it was raining at the time of the accident. That he neglected to shut off the current on the trolley cables before he went to repair the bucket, was assumed. The man was worked over for hours, but without result.

A year went by with a very good record before another accident occurred. This was the electrocution previously mentioned, where a man was killed when pulling the cable on the electric car puller.

About twelve months later, an employee working in the basement of the silos, in crawling over a screw conveyor which was three feet above the floor, got caught in the screw, tearing his leg out at the hip. The man died shortly thereafter.

Such accidents as these can be enumerated indefinitely, although the general trend is toward reduction. Various methods are tried in an effort to overcome and reduce them to a minimum. Placing the responsibility for such accidents has been gone into in this paper. It is poor practice, however, to close the door after the horse is stolen, and the best way to prevent waste of time, trouble, and perhaps hard feelings due to placing accident responsibility, is to prevent accidents, or, to close the door of the stable before the horse is stolen, and this can only be done through unceasing effort on the part of every one, or, in plain words, constant missionary work.

CHAIRMAN FRAME: Mr. White has given us something to think about when we try to fasten responsibility for accidents and for deaths. I know he will be glad to answer any questions.

A. JONES (Indiana Limestone Co., Bedford, Ind.): In Mr. White's talk he spoke of an accident that occurred through a rock falling out from the face of the ledge and breaking a man's leg. I would like to ask if they ever decided what was the cause of that rock slipping.

MR. WHITE: The formation of the stone at this particular quarry was up and down. This stone slipped out of the side. Why, we don't know. There wasn't any blasting at the time. The quarry is regularly inspected by the foreman and whether there was moisture there that let go all of a sudden we don't know.

E. W. BALDWIN (Solvey Process Co., Detroit): This question arises in my mind: If a man has had ten accidents in a year, shouldn't he be let out a little before that. We let a man out if he has had two, three or four.

CHAIRMAN FRAME: You mean lost time ones?

MR. BALDWIN: Yes.

CHAIRMAN FRAME: That is one way to create safety rules.

W. R. DUNN (Vulcanite): I recall an accident some 15 years ago where the rock was of a vertical formation at the top, that looked as if the rock was about ten feet wide. You couldn't tell what it looked like when you were down at the bottom, 50 feet below. The rock tapered to about one foot at the bottom. Naturally, you would suppose the rock was ten feet wide below the same as it was at the top. Without a warning of any kind it crushed down and toppled over and killed nearly all of the men in the quarry.

P. E. SANDT (Edison): May I ask Mr. White or Mr. Dunn what time of the year, if they recall, when these slides occurred? We have a great many in the spring of the year and it is a case of constant education with our men to keep everyone on their toes in the spring of the year.

MR. WHITE: I believe there is a misunderstanding on that. This pocket proposition, as we have it down in this quarry, is not over six or eight feet. We dig the clay out to expose the limestone. This stone just kicked out and was big enough to fall against the man's leg and break it.

MR. DUNN: In that case I mentioned, the rock was perfectly dry. The accident occurred about midsummer.

CHAIRMAN FRAME: You heard Mr. Curtis report this morning on the splendid accident record which had been obtained by a number of members in the Portland Cement Association so far in 1927. He mentioned the fact that there were 23 plants which so far have a clear record. It has been said many times that one of the most difficult problems after you have gotten a fine record is how to keep it up. That will be a burning question with a lot of our members in the Trophy Club. In this connection I am delighted to introduce at this time Mr. W. H. Weitknecht, superintendent of the Lehigh Portland Cement Co., Mitchell, Ind. Mr. Weitknecht's plant is the one member that has won two trophies. He is going to take up a new angle this afternoon.

How Can a Mill with a Perfect Record Keep It Up?

**W. H. Weitknecht, Superintendent, Lehigh Portland Cement Company,
Mitchell, Ind.**

I feel that I am in the position of that writer on farm topics in a leading farm paper, who wrote splendid articles on successful farming for some years, only to have his farm mortgage foreclosed sometime afterwards.

How can a mill with a perfect record keep it up? I hope we haven't been foreclosed. I know we haven't, but we haven't quite kept it up. That perhaps calls for an explanation and we are always willing to justify our position on any question or condition.

In 1923, we had what we called a very enviable record, but we were beaten for the trophy by a few fractions of man lost-time per hundred thousand man hours. In 1924, we succeeded by having, I think, just one and a fraction lost-time hours per hundred thousand man hours. In 1925, without any other lost-time accidents, we had a fatality in November chargeable to us, and yet it did

not result from any negligence on the part of any of our employees. It was due to carelessness, rather, on the part of the railroad company. In 1926, I am very glad to say, we were one of the companies that had a perfect record and we won the trophy again. In 1927 we continued the good work until about the middle of July when, after the whistle had blown, one of our men leaving his work to go to the clock house to register out was bumped by another employee in his Ford: he fell on the concrete pavement, giving his left knee a twist to such an extent that he was unable to report the following day. He reported for work the following Monday, this having happened on Thursday night. So we have two days' time lost on our record.

Perhaps that in a way—the type of accidents and how they happened—is a justification for my being here, since we have not had any serious accident in the industry arising from the employment itself.

We believe that the knowledge of any subject is the true basis for success in that line, and we have come to know that personal injury accidents can be prevented. After what you men have heard today you dare no longer rest on a belief that it can't be done. For if 23 cement plants (cement being an industry known to be hazardous) can operate for seven or eight or nine months, employing many thousands of men, without a single lost-time accident, you know that plants can be run without personal injury accidents.

Responsibility is Preventive and Corrective

That brings to you the matter of responsibility, which is twofold—preventive and corrective. The preventive side, of course, is involved. Who can say that the employment offered to the employee was in accordance with his capacity? The employer knows more about that employment than the employee possibly can know. Instruction is required before that employee goes to work. Was that instruction competent? Did it cover the nature of the work and the performance of it sufficiently? That is a responsibility for the management, more so than of the employee, through its foreman. So that the responsibility of the management as a result of the accident to the workman extends far more than to safe places. It involves, also, to a large extent, safe practices. Have you had foremen in whose departments accidents happened because the men practiced what the foremen had practiced, what they had seen him do? Isn't that a responsibility?

The other is corrective. It deals with placing the responsibility after the accident has occurred, and that is perhaps more specific and more personal. Who is responsible for it? A responsibility, to have any effect or force, must be personal, it cannot be impersonal. That is the duty of the investigating committee which we have in our program of safety work. But you say, if you have had so few accidents, what investigation of accidents does the safety committee or the accident investigating committee engage in? The answer is it engages in preventive investigation. There are many near accidents that almost result in personal injury. There are bad practices that should be discovered, and will be discovered if you have a good safety committee and a good organization; and it is just as much their duty to investigate the possible cause of any accident before it happens and place the responsibility, as it is to have the accident happen first and then fix the personal responsibility. For it follows that if you have in your industry a number of minor accidents, not lost-time accidents, but near accidents that might have resulted seriously, you are going to have personal injury accidents that will be serious.

Now, we have come to the point where our accident investigation work deals almost wholly with those near accidents and those bad practices, as a preventive measure. We try to discover the bad practice, we try to discover the responsibility for a near accident, and place it before the accident has happened. And you will find, I think, that that will be one of the keynotes of maintaining continued interest on the part of your safety committee in the way of accident prevention.

Before the Portland Cement Association awarded those splendid trophies for the best record, our company, because of the number of mills they had, began those contests at the different plants, instituting a no-accident-month campaign; and it unified the work of the safety organization of the several plants of the Lehigh Portland Cement Company and put every safety committee, every employee, every foreman on his toes. They wanted to win the safety flag. After they won that they wanted to win the cup. It was the incentive of competition that started them. We now have so many cups and so many flags that we can decorate our entire plant with them. But every cup that we get and every flag that is sent out to the mills seems to be more appreciated by the men than the first one. They know, first of all, that accidents can be prevented. They know they are standing on a record of which they not only feel proud, but one they must defend.

We are never satisfied, we always want more. Capitalize that spirit in your organization. We want to win the trophy in 1927 and we want to win it twice in succession. Those of us who attended these meetings were told by our safety committee if we wanted to win the association trophy in 1926 that we must have a perfect record, because the progress made in the reduction of lost-time accidents is such that hereafter no mill will win the trophy unless it wins it on a perfect record.

Men Must Acquire Safe Practice Habits

In 1927 we said the same thing, and much as it has hurt to lose those two days it has served to do one thing: it has served to make the men more circumspect in the real sense of the term. They look around; they are no longer content with taking care of their own safety, but are looking around for the safety of others. That is the very thing I have been trying to impress upon our safety committee. They cannot possibly be safety committeemen and serve in the plant only. They cannot be safety men at mass meetings and not be safe men on the job. It is a matter of habit. They must develop safe practice habits. There again, if I may disgress a moment, if you instruct your men and supervise their work in safe practice habits, you will prevent accidents; and that is the chief reason why plants will get along with relatively few personal injury accidents. If they cannot minimize their accidents because of the natural deficiency and delinquency of some workmen, the unlucky fellow, as we say, let him go. Be fair to the others. Transfer him from that department to another where the work is less hazardous, but if he is a fellow who stumbles over his own feet give him a few nice talks and say, "John, if this thing happens again we will let you go; you must look for employment elsewhere."

And after several transfers from hazardous to less hazardous and still less hazardous occupations, he still has near accidents, we let him go. We recognize a responsibility not only to that man, but we recognize a responsibility to his fellow men. The wife of one of the men came to me begging for the re-employment of the man. I said, "Has it ever occurred to you what a serious thing it would be for your husband to become crippled while in our employ? You are thinking only of the immediate future. He is not safe to work in the line of employment in which he wants to work. He doesn't want to be a common laborer. He is a better grade workman, as far as mechanical ability is concerned; but we cannot continue him."

We are careful not to humiliate him by letting the rest of the employees know why he was let out. Speak to him and let him quit. It is labor's respectful resignation, just as you, an executive, do not expect to be bodily discharged in being given your walking papers, but you are politely asked to resign.

What about this spirit that pervades among the men of the plant or the safety organization? They call attention to things, they want that thing prevented. They don't want the man to get fired. It isn't a question of winning the trophy, it is a question primarily of realizing our responsibility to that man and to his fellowmen,

ment to inculcate in them before they leave. They come back to their safety committees and report to them, and sometimes they don't get through in the first meeting. We continue to have a report at the next meeting, or we call a special meeting, and in that way we continue to keep the matter of accident prevention alive.

But as I said in the beginning, the keynote of the whole thing is the fact that the men know that it can be done, and they would be ashamed today if our accident record got bad. They keep up the spirit and I, for one, believe that we have our employees at Mitchell thoroughly sold just that way.

CHAIRMAN FRAME: Mr. Weitknecht has given us a sound, sensible, well organized and conscientious method by which he controls accidents in his plant, which radiates from himself as a superintendent and, as you have gathered from his remarks, extends through every one of his foremen down to the very men themselves, who have begun to appreciate that an accident record means something to every plant. He has brought to the surface many interesting thoughts on accident prevention. Some of you, I know, have questions to ask Mr. Weitknecht.

V. ROBERTSON (Canada): I would like to ask the speaker, after they have had an accident, which, of course, is investigated, is that investigation made by the executives or by the safety committee?

Special Committees Often Appointed

MR. WEITKNECHT: It is made by a subcommittee of the safety committee, which is an investigating committee usually appointed for the occasion. We appoint a special committee for every particular occasion; it tends to distribute the work and it gets more people interested. Those people who investigate accidents are better safety men because they have served.

MR. ROBERTSON: Are the findings of that investigation made public or are they confidential?

MR. WEITKNECHT: The findings usually are made public. We have had but few, but I cannot recall an accident where the cause was not evident. The reason for the investigating committee is more to ascertain just exactly in what practice this accident had its origin. If there is any mystery attached to it, it is fully explained. Usually the matter is gone into in detail at the next meeting of the safety committee, and sometimes we have a special meeting just for that purpose. I might add this: prior to the June no-accident campaign we had mass meetings and we had departmental meetings where we got a large number of men together in our shop. These men were addressed by the foremen. The men in the quarries, which are about two miles away, were called together and we had special meetings. So we may call a special meeting at any time when some particular near accident has happened. When I say near accident, I mean some occurrence which almost resulted in an accident. We make it a point to bring it to the attention of the safety committee and they to the department committees, and that is the duty of the accident investigating committee.

CHAIRMAN FRAME: I want to emphasize that a little bit stronger if I may—Mr. Weitknecht is right after the near accident. They have gotten to the point where they have few lost-time accidents. He is transferring his activities into looking into every near accident and thus he maintains a clean slate.

MR. HEALY (T. H. Martin Co., St. Louis): Do you have any difficulty in getting the men to adopt respirators where necessary?

MR. WEITKNECHT: Yes. However, we have few places where they are necessary. We have one place in a certain part of our packing house; but we have found that there is a risk involved in their use. We haven't found a single case where inhaling of cement dust such as exists in our plant has injured anyone. I think that is a matter of record for the Portland Cement Association.

CHAIRMAN FRAME: In that connection I wish to announce to anyone who is interested in respirators, the New York State Department of Labor has recently issued a pamphlet in which it is discussed from every angle. After reading that it is my personal opinion that its practical use is limited in the cement industry. You can get that pamphlet from the Department of Labor, Albany, New York.

DR. E. M. PARTLETT (Pittsburgh): I was glad to hear you say what you just said about limestone dust, because it is so. I have interested myself in that for some years. I have some data that limestone dust is free of silicate and is harmless.

QUESTION: Do you make these men who are involved in accidents appear before the safety committee?

MR. WEITKNECHT: We have not had any serious accidents. A man was injured and lost two days' time and he was before the safety committee largely as an example to the others. We don't want these men to feel that they cannot appear before the safety committee. We want them to feel somewhat like the real honest-to-goodness boy who, while he may get into mischief, will tell the truth, but he hates like anything to face his dad.

When Responsibility Is Definitely Placed

A. C. HEWITT (American Limestone Co., Bellefonte, Pa.): There are two questions I would like to ask, one from Mr. Weitknecht, and another of more general interest. When you investigate the cause of accidents and find that the responsibility can be definitely placed on a particular individual, how do you handle that case? You say that you make public the findings. Do you make public the responsibility and cause shame on the fellow who caused the accident?

MR. WEITKNECHT: All accidents that require any investigation are like gossip in our plant. You can't keep it secret and we don't want to. It is reported and then investigated by the committee. If it is of a very serious nature we call a special meeting of the safety committee. If not, it goes over into the next meeting. The findings go to every department and become public. We even issue in particular cases notices on the bulletin board. We have had so few to issue that the practice has almost been discontinued. But that is exactly what we do if we find some fool stunt practiced.

MR. HEWITT: I would like to have some idea of how many cement plants—not companies but individual plants—have a full-time safety man who does nothing else except safety work?

CHAIRMAN FRAME: I think there are very few of them. That is my personal opinion, however, and I may be wrong. I will ask those plants represented that have a full-time safety man in their plants to please stand up.

(Twelve men arose.)

CHAIRMAN FRAME: That is better than I expected.

R. E. HOFFMAN (Atlas): The gentleman beat me to the question I intended to ask. I have heard four talks today and I haven't heard the mention of a safety supervisor except just now. I would like to know from some of the plants that have safety supervisors what part they play in their success?

G. C. HUTH (Universal): I am a safety supervisor but I don't care to talk about myself. However, I can tell you about my job. My job as supervisor of safety is a combination job. I supervise the safety men of the mill. The biggest job that any safety man has, I believe, is getting the job out of the office and putting it out to the fellows who are actually doing the work. The safety supervisor organizes and helps them along. I think ultimately the fellow on the job should carry all the work. That is the way I have been trying to work it out.

A. J. EALES (Bessemer): I don't know just how to explain this, with regard to my own personal job. I don't handle the employment of the men at all. That is done by the foremen individually. I spend most of my time around the plant, not in the quarry. But with regard to putting the safety thing over, I think the foreman is your

best man for that. The men will take more from your foreman than they will from your safety man. Your safety man can handle the foreman, but the ultimate success rests with the foreman.

CHAIRMAN FRAME: Since we have gotten into the engineering phase of this important subject I notice we have with us today an engineer associated with one of the largest cement manufacturing concerns in the United States. I see Mr. Carlson sitting there and I wonder if he won't add just a few words to the importance of engineering in regard to the prevention of accidents.

A. G. CARLSON (Universal): I am not going to attempt to tell you how to prevent accidents, but I will say something about how we prepare equipment to help prevent accidents. The Universal Company has spent thousands of dollars for safety equipment. In recent installations this safety equipment is considered part of the job and the cost of same is swallowed up in the construction work. Every job, before it leaves the office, is inspected to see that all dangerous places are properly guarded. Previously, safety features were things the companies delayed putting on until forced to do so, and this cost them more money than if they had been installed at first. I think it is safe to say, since we have installed safety devices, there have been considerably less accidents. Before we had all the safety equipment, we had considerable accidents which cost the company more money than the installation of the safety equipment.

A Month to Investigate Plant Conditions

D. ADAM (Lawrence): Our friend, Mr. Hoffman, I think, asked a question which has remained unanswered. I happen to be a safety engineer. In 1924 I took over the duties of the safety engineer in our company. I faced 1,276 lost days, some permanent disabilities and two deaths. I was told to go to it, which I did. Today we have 110 lost days and 11 lost-time accidents.

When I first started in the safety work I took a month to go around the plant with my eyes open, my ears open, and my mouth closed. In that month I learned a lot. In three months' time I realized that guards and bulletins were good, but they didn't mean everything. I realized the only way to get the men interested in the safety movement was to tell them the reason why.

Our results merit what I tried to do. I introduced a Thursday afternoon talk which I consider has been the backbone of the safety work in our plant. I get a man from each department for half an hour and sit down as man to man with him, talk from an ordinary, common sense point of view and tell him about the rules and regulations of our organization; why they were made, how they are based, the reason they were made, and the benefits that would accrue from them. In that way we eliminated all our accidents. Previous to that we had one every week.

It doesn't go home unless you have a heart-to-heart talk with the man. We can collect the ideas at this meeting, formulate them and transfer them on to the individual.

In that connection I would like to mention this: Sometimes it is not always possible for a fellow to talk and explain those things to a man. I attended the public speaking class this morning at eight-thirty given by Professor Hardy. As Professor Hardy says, the main point in a talk is to get at the fellow direct, not to shoot over his head. Don't be dogmatic about it and say they must do it. It is not a case of, "you have got to do it." Tell them why they have got to do it.

MR. BLACK (Philadelphia): I wish to say something in regard to the dangers of dust. My company conducted an informal investigation. This investigation involved going over the records of physical examinations of in the neighborhood of 25,000 men exposed to cement and limestone dust and other dusts of that nature. The evidence was definite that their average health was so high that we came to the conclusion their health was above the average of workers alongside of them.

We put those various dusts, including dusts of silicate, granite, and that sort of thing, under microscopes and we found, without exception, that where you find a

sharp dust it is dangerous, but where you find a dull dust it is not dangerous, unless there is poison in the dust itself. That was our conclusion. It would be hard to support it in a general way.

CHAIRMAN FRAME: Thank you very much, Mr. Black; we are glad to know of your findings on this important question.

Is Mr. Jacobsen in the room today? I wonder if he is prepared to tell us something about his observations on the safety engineer?

H. G. JACOBSEN (Bates Valve Bag Co.): It has been my experience, if you want to get my angle on it, that in safety work, if we have 100 plants possibly we have 100 different methods, inasmuch as we have 100 different managers, and they all work more or less differently. They all have different personalities and they attack the problem somewhat differently, although possibly along the same main lines, and generally if they use common sense, they arrive at somewhat the same results.

Mr. John this morning spoke about the difficulty that was met with during the years that we had to do the pioneer work, and I can speak freely on that subject. It was difficult to get the various companies to report their accidents and take hold of them in a real two-fisted manner. I think that period has been passed and I am certainly more than pleased to be here today, because I never have yet seen a meeting quite as well attended as this one, nor have I seen a meeting that has been attended by men of such caliber as I see here today.

Safety Suggestions Come From Everybody

CHAIRMAN FRAME: I am sure we all have a very fond recollection of our pleasant association during the years Mr. Jacobsen was in charge of accident prevention work for the Portland Cement Association, and we all know what strenuous efforts he put into the organization of the various plants and the ground work he laid for the success we have recently attained.

J. R. KLINE (Universal): I have similar lines to offer about the general safety work in our plant. We are safety men at the plant all the way down. We take suggestions from anybody in the mill on any subject and give him a reasonable answer. There have been at least 1,800 suggestions made at our plant this year and every one of them has been put on record and sent out to the departments that take care of them. Each department has meetings at least once a month. Every man attends a meeting at least once a month. I talk to them at the meetings, tell them anything and everything. I give them reasonable answers to their inquiries about plant operations, safety work, or the general topics of the community.

CHAIRMAN FRAME: Don't lose sight of the fact, gentlemen, that Mr. Kline's plant is a member of the 1927 safety club.

I would like to ask Mr. Weitknecht about a problem that has been a prominent one in the cement industry almost ever since operation began. I refer to the guarding of screw conveyors. As you men know, we have had a large number of deaths and very serious injuries caused by screw conveyors. The Alpha Company recently had a fatal accident at a location we thought splendidly protected. The screw conveyor is contained in a concrete box some 26 inches high from the floor. The sheet metal covers on the top are securely bolted down. Somehow, it seems, the pressure was so great that it warped or caused the sheet metal covers to raise up and spill out the cement into the tunnels. We had a man working in these tunnels whose duty it was to clean up the spill. There was no witness to the accident but from the best information we could gather, we think that for his own convenience this man unbolted the sheet metal cover from the screw conveyor or laid it to one side, which is contrary to our safety rules. He happened to have some other duties in one of the other tunnels and when he came back he somehow or other got into the trap which he laid for himself.

I know of two other fatal accidents that happened just recently on the screw conveyors. We have made wonderful progress along many other lines, but the

We use no methods that are different from anyone else's. Management has its own responsibilities, it is true, but we are proud that we have a loyal body of safe workmen, men who know that, outside of the loyalty to their plant, an accident means something to them. We have also tried as much as possible to do away with the word "accident". In looking through the dictionary you will find that "accident" is something for which no provision can be made, it is something that happens unforeseen, something that is wished on you. We claim that an injury is not really an accident, because it is something that can't happen. We always have shown the men where the accidents have been caused, and as soon as they understood the policy the management assumed with regard to them our accidents stopped.

Among Effective Methods Is the Plant Publication

One method we use is the plant publication. We never know whether that does any good or not. It is a humble, mimeographed thing. It is not put out as the official voice of the company. It is not an attempt to high-hat or patronize the men; it is just a medium of conveying orders or wishes or commendations from the office, from the man higher up to the man lower down; and by attempting to place all on the level in that little publication we may have accomplished something.

Which of our methods has brought about the greatest results, we probably will never know. Today we are proud to stand in rank with some of the highest in the land, United States or Canada, as a plant and a company that is second to none in accident prevention.

CHAIRMAN FRAME: Has anyone else anything to add to the meeting.

A. JONES (Indiana Limestone Co., Bedford, Ind.): I don't feel like leaving this meeting without giving you another angle of this safety work. I am with quite a large organization. We employ in the limestone industry some 5,000 men. We are closely situated to Mitchell and I just want you to know the influence of the Mitchell plant on the community it is connected with. The Mitchell plant has been doing a lot of safety work in the schools in Mitchell and I have found out that they have spread that work to Bedford, Indiana. It has come into our territory and is tying up with our safety work. It had gotten so that we became ashamed of ourselves and we attended some of their meetings at Mitchell, and it has been my pleasure to become acquainted with Mr. Weitknecht and his assistant there. Whenever they make a good record we are proud of it, because they are now helping us to organize a safety-first campaign. However, it has been through the instrumentality of the Mitchell plant that we started this work, so I want to throw a bouquet right now to the Mitchell plant while I have an opportunity.

CHAIRMAN FRAME: I don't think Mr. Weitknecht knew what was coming when he tried to beat out Mr. Jones to the floor.

MR. WEITKNECHT: No, otherwise I would have insisted on my rights and addressed the Chair first.

In connection with general accident prevention, I want to give you this by way of illustration: Some years ago I was called into a meeting that had to do with the solving of a problem, and one of the men who was there said, "Now, let's put the thing over, let's all get very enthusiastic and put the thing over." Another man said, "That is all right as far as it goes, but is it a problem that requires enthusiasm alone? We know it has to be done, we know we can do it; what we want is resolution."

I said at the beginning of my talk we have settled the matter in our own minds, not by what we have done, but you men certainly should have had it settled in your own minds by what the cement plants have done so far this year. You know the thing can be done. It isn't enthusiasm you want. Of course, you want to be proud of it, you want to be glad of it because it gives you stimulus, but what you want to do now is to go home and carry this resolution with you. Get the determination and

enthusiasm from your workers. You who are responsible for the work must become resolute and not merely enthusiastic, because you have many difficult problems and enthusiasm will soon be robbed if it has too many variations.

CHAIRMAN FRAME: I will now turn the Chair over to Major Reninger, who will conduct the discussion on school and community safety for those of you who are interested in that particular phase of safety work.

CHAIRMAN RENINGER: I have asked Miss Telford to address us on this subject. She is field secretary for the Education Division of the National Safety Council. Miss Telford has had over three years of experience in traveling over the United States, making a study of safety in the schools in cities like St. Louis, Chicago, Cleveland and Detroit; and it is through her efforts and the efforts of her colleagues, Miss Stevenson and Miss Smith, that we really have the education magazine as it is today. It is through their visiting the schools that they have been able to collect the data and give it to us in the form that the teacher can use.

Address

**Miss M. Laverne Telford, Field Secretary, Education Division,
National Safety Council**

May I first of all, before I say anything about the program that I want to present to you, define safety education? Forgetting for the moment pedagogy, forgetting technical phraseology, forgetting the important philosophy associated with the safety movement, may I say that safety education as I see it is teaching children to become conscious of the hazards which surround them, teaching them how to avoid those hazards, and in teaching them, making them anxious to do so? I am thinking of a positive rather than a negative program. We are not saying, "Don't go skating on thin ice," but we are saying to them, "What is the danger of skating on thin ice?"

It seems to me the first thing to bear in mind in a school program is that it must be positive, secondly, it must meet the needs of the group for which it is designed. If you lived in the Iron Range in Minnesota, for example, and your children went to school there, one of the things you would feel should take a major place in safety education would be the danger of percussion caps. Percussion cap accidents are all too common in the Iron Range.

So those are my first two points. Thirdly, it seems to me we have a right to present to the school people, regardless of the school's size, a safety education program. This, I think, is important, because there is a tendency on the part of people in smaller towns to say, "Safety education is extremely essential in Chicago, but we don't need it in this town." Then next I want to present the thought that safety education has a place in our schools regardless of the type of school, regardless of the size of the community in which that school is located.

What we have been trying to do along these lines, with the assistance of the school, with the assistance of the public-spirited citizens, is to develop a correlated safety program to meet present-day conditions, to be designed along the lines that school people insist present-day school programs must be designed. You will find people talking about habits, safety attitudes, and safety skill. We want a correlated program because the school program now is full, there are a great many things to teach children in the comparatively short time they spend in school. So we say to the school people, "We are not talking about an addition of a new subject to the curriculum; we aren't asking for thirty minutes from nine to nine-thirty o'clock on Friday morning; we are talking about injecting safety material into your existing subjects. Talk it in the language class, write about it in the penmanship class."

My illustration on that particular point is a personal one. When I went to elementary school I took the Palmer Method of penmanship. I don't know how many times I was at my desk writting over and over again the phrase, "This is a specimen

of my penmanship." The phrase, "This is a specimen of my best penmanship," isn't particularly important in my everyday life.

We went to the school people and said, "If that is the way you are going to teach penmanship, why don't you give children something to write that will mean something to them?" We talk about safety projects and problems in connection with arithmetic, history and geography, and in the other subjects of the curriculum. It is true that the majority of school safety work to date has been done in the elementary schools, but it is spreading to the junior and senior high schools.

Because it is a correlated program I am discussing today, because it must vary in each community, I can't bring it to you in a brief way and say, "Here is the safety education, won't you take it back to your own community and see if you can't get it across in your schools?" We can't do that; we can't give you examples of safety education, asking you to take them back to your school people and say to them, "Here is something they are developing in Worcester, Mass.; it seems to fill the need there, why can't we do something like it in our community?"

The thing I want to ask of you specifically is that all of you take home with you that little leaflet published by the Education Division of the National Safety Council, so that you will have listed and described in just a sentence or two the school material that is now available. Will you take back with you to your superintendent this little leaflet on safety teaching in the modern schools? And then will you also take a copy of *Safety Education*, a monthly publication of the Education Division of the National Safety Council, a magazine that is designed for the use of teachers and students? And will you go over this material yourself and present it to the school people in your community and say, "This seems to me to represent the type of work that is being done in our progressive schools; hasn't it a place in our own schools?"

Safety Also Taught Through Student Activities

You can't go into a school and teach safety education. I can't come into your plant and make your men safe. But you can call to the attention of your school people the fact that the subject of safety education is important enough in the school field to have become a subject of discussion at the meeting of the Society on the Study of Education.

I have talked up to this time only of safety education in the curriculum. Safety is also taught through student activities, through local safety councils and through payrolls. That may have a place also in your community. The purpose of a junior safety council is to group the children into a small organization, giving them something to do, like being in charge of the passing of the classes in the corridors. They may have charge of the condition of the playground, or the inspection of the playground equipment. At dismissal time they may see that the children, particularly the younger children, are escorted safely across adjoining streets and highways.

There are two very definite methods of presenting safety to your school people—one, safety through class instruction in the class room, and the other, safety through child activities.

I wonder if you are thinking what relation all of this has to your work? If some of you are thinking of asking that question, I will answer it by telling you this: About two years ago I went across the Iron Range in Minnesota. Shortly after I reached Hibben, a student in one of the Hibben schools had come to school with a percussion cap in his pocket. He then took it out and held it between his thumb and his fingers. Mind you, he was in school. He tapped it with his pencil, and when the excitement was over they found his thumb, his first finger and part of the second had been blown away entirely. Immediately the authorities went to every school in Hibben, to all of the other schools along the Iron Range and put up notices relative to the danger of children handling percussion caps.

Don't you suppose the safety engineer in the mining range then talked to his men about the careless handling of percussion caps, and don't you suppose some of those

men went home and talked to their families about it? There was a very effective tie-up between the subject that had been presented to those children by that accident and the man's memory of the instructions which he had received from his safety engineer.

I believe the teaching of safety must begin in the kindergarten. It must begin even before that, if possible.

The Education Division of the National Safety Council not only has certain school publications, but they have a magazine, a junior Safety Council handbook, they have a manual for teachers, various leaflets such as Safety Supervisors' programs, Safety in Women's Sports, and so forth. We are glad to offer wherever it is possible a limited amount of field service, have someone come in and talk to your school people and make an attempt to present it to them from the school person's point of view. We are glad to be of assistance by correspondence wherever it is possible.

I appreciate the opportunity of talking to you, primarily for the reason that from our small office in New York City we can't look out across the map of the United States and effectively pick out interested locations; so if you can help us find out where the interested localities are you will have rendered us a service, as well as perhaps starting a worth while thing in your own community.

The Problem in a Moderate Sized Town

R. B. FORTUIN (Penn-Dixie): We have a problem in the town of Nazareth, which has a population of 5,000 people. There are six cement plants, a brick plant, a foundry, three silk mills, and several other industries of a like nature in and around that town. Several years ago membership in the National Safety Council was given to the public schools by several individuals in the town, with this thought in mind: that after one year's membership the school board would probably feel that they were deriving sufficient benefit out of their membership, to carry it on in the future. The membership expired this past year. Major Reninger got in touch with me and asked me to look into this thing. I went to see the superintendent of schools. He said to me, "I don't want anything to do with it; what do we get out of it? We get a magazine, put that magazine in the library and nobody looks at it."

Now here's a situation where the superintendent is antagonistic to the situation from the start. He never supported it when it was a contributory membership. Now a few of us have gotten together and started proceedings for the future. We have gone to the burgess of the town. He has heartily endorsed the program we have in mind. We have gone to several members of the school board and they have assured us of backing, and we have gone to a number of leading men in industries in town and they have assured us of support. What we intend to do is to go before the Parent Teachers Association and present this idea somewhat as was outlined, and in that way force the school board to bring this membership back into the town.

CHAIRMAN RENINGER: Just as soon as you are ready to have a meeting with those people I feel that we can count on Miss Telford coming up to assist you in explaining the situation to the Parent Teachers Association and the superintendent. I feel sure that she will be glad to do that because we are trying to outline a program to have her come and check up on the Allentown and Easton schools, and I know she will be only too glad to help you out there.

MISS TELFORD: I have a postscript I would like to add. May I make this generalization, on general pitfalls that I think all of us fall into? I don't know your specific situation but you made me think of this general situation, that in all schools, particularly in small schools given over to one type of industry or two or three industries, there is a fear on the part of the school people that the safety education is camouflage cement safety program that we are calling it safety education and putting into these schools our own courses. I see no way to meet the objection of

school people on that score, other than to present it to them from another angle entirely.

If I should be talking to the teachers in your school I should say, "We all agree that the function of our schools is to teach people how to live." That is the very thing we want to do, teach them how to live. But, specifically, what does that mean? Can you teach people how to live in this age, for instance, without talking about automobile dangers and other dangers? Tell them that a certain part of the program of the National Society for the Study of Education was devoted to safety education. It was on the program of the Department of Superintendence, which I pointed out was the largest professional educational meeting in this country.

Starting the Program in a Unique Way

MR. FORTUIN: We have started our program in a unique way. Last June, I believe, was the first time we tried it. We have something like 55 foremen living in the town of Nazareth. In order to bring this safety idea into the homes of this group we had the NATIONAL SAFETY NEWS sent to the homes of each and every one of these foremen and other members of the Safety Council in the plant. Now it was brought out earlier in the day that there are a great many men who do not speak English very well or do not read it as well as they speak it. The children of these men naturally read the articles out of the magazines to the parents.

After an investigation we found that the NATIONAL SAFETY NEWS was the only reading matter outside of the *Bethlehem Daily-Globe* that went into a great many of the homes. We feel that within a couple of months we have accomplished a great deal in a small circle of 55 families. We have quite a number of men come back to us after receiving this copy of the NATIONAL SAFETY NEWS and tell us how much the family enjoyed the various articles in the magazine, and it brought out this: they asked us just how some of these articles pertain to their particular jobs in the plant.

MISS TELFORD: *Safety Education* can be purchased now in single subscriptions as well as in the school membership. Do you suppose that some of your families, the children of the families could find something interesting in that sort of thing? A poster which is a part of each issue of the magazine. I am just suggesting that you add *Safety Education* as well to your NATIONAL SAFETY NEWS.

A. J. EALES (Bessemer): You mentioned something about having difficulty in your school board in support of this safety campaign. I don't see why you should have that difficulty. We have a community of not quite 4,000. We have our schools fairly well sold on safety to the extent that we have two schools, the elementary grade building and the junior and senior high schools. We have a bulletin that we send to the schools. It is changed at least once a week. Not only that, but I get into the schools for talks at least twelve times a year.

Last year the railroads had a school campaign. The agents at both depots asked me if I would give a talk. It happened that they came a month apart and we got in on that. In cooperation with the other plants in our community we have a joint safety meeting semi-annually, with a good entertainment along with it. We had so many children attending this meeting that we decided to hold a meeting for the children in the school during the day. They were let off an hour earlier in the afternoon for this event.

In the high school in our community instead of having a daily chapel program once a week, they enlist speakers to talk to them. Quite often I get in as a speaker on an occasion like that.

Then there are things in the community that the schools are interested in and you might help them out. We had a danger sign in front of our grade school building. They wanted a stop sign on the street there. I happen to be the burgess of the community and that helps some. We got them the stop sign; and incidentally we can get more out of the school board by cooperating in that way.

CHAIRMAN RENINGER: I have asked Major R. C. Haven to come and give us a short talk on what we can do in community work in addition to the school work. After he has given us that talk, it seems to me, if it is the opinion of this gathering, that we organize a committee of half a dozen or more to work out a program of what we can do in the small community where we have other industries besides the cement industry, to put across a community program. If you people think that is a good idea we can carry it out. We could work out a program, nothing elaborate, so that we could get this problem of safety in the schools, which means home safety and public safety. Major Haven will give us five minutes on what we might do in the small community.

R. C. HAVEN (National Safety Council): I don't know why the Major asked me to tell you men and women what you can do in the community, when you have more experience than I can give you in small community work. You fellows are really doing the job. That isn't applesauce, but it is absolute fact, and there are men sitting here who haven't spoken who have done wonders in their towns, both large and small. I don't believe there's another section that has thought out this idea or grasped this idea of going out into the community. There are a lot of things I can say, but if I am going to talk five minutes I have got to get down to brass tacks.

Put the School to Active Safety Use

The school is the common ground where people meet, it is the place to start activities, and it is the place where you work out your political and a lot of other problems. So if you are going to use the schools, use them. I don't know of another place you can use to better advantage. But don't try to teach school safety entirely. I wonder if you men have gotten to the point where you have sort of analyzed the accident situation in your community outside of your own plant. When you go back to your home town, start a little research work, find out where your accidents are occurring and then concentrate. It may be in the homes, it may be through automobiles, it may be through fire, or they may occur in other ways.

Find out about the parents and teachers' home inspection blanks, where you can send a little blank into the home. Perhaps it is your automobile accidents, and really that is the thing that is causing us more concern, as far as industrial safety is concerned, than the industries themselves. What does an accident mean to your factory if a man is killed by an automobile? It affects your labor community just the same as though a couple of sacks of cement fell on him.

Then your fire prevention. You would be surprised how many little fires start in your community that might burn the town down. You will find a lot of these things.

I haven't told you very much that you can do. The Major wanted me to tell you what you can do locally. I would go back, if I were you, get the men together in the plant and sit down and tell those fellows what you have learned here, the contacts you have made; and say, "Let's get together, let's go to the burgess or mayor and tell him the seriousness of the situation." That, of course, would have to come after you have found out just what your situation is. At this meeting a course of action can be decided upon.

It is pretty hard for me to stand up here and work out the details. I would much prefer to leave just one or two thoughts with you. The first is this: Don't go back to your home town feeling, "Well, I attended the Cement Section; I can report to the boss and tell him I was there and have done my duty." Remember that you are the keyman. You are the keymen who have been sent out from your community to bring back to that community something that will help them.

Then there is just one other thought. Did you ever analyze, did you ever stop to think what an accident really means? Suppose you went out here tonight to your hotel room and found there was a telegram for you saying that mother was struck by an automobile today, or perhaps your wife, or perhaps one of your children; have

you any idea what that accident would mean to you? Well, now, that is not an impossibility when you think there are between 20,000 and 25,000 people going to be killed this year by automobiles. What if you got that message? Men, just think of what an accident means and I believe that you will go back feeling that you are something more than just an ordinary man in your community.

You don't have to do that. All you need is to go back with a little energy and determination. Find out the accident situation, get the safety men together and the people, and then work out a little plan which the National Safety Council will be glad to help you with.

CHAIRMAN RENINGER: Those of you who have local safety councils naturally are tied up with them. You can have a little safety council of your own in your own community. What do you fellows think we ought to do? Do you want the Cement Section to work out the program with the help of the National Safety Council and the Education Division? Do you think we could furnish you with some information that you could use in your villages and in your towns? I have gotten to that point where I feel that in the cement industry we have gone ahead, we have shown the people throughout the country and we have shown the executives what we can do in the industry. Don't you think it is up to us to broaden out and help our own community?

D. ADAM (Lawrence): I have tried to the best of my ability to interest the local schools in safety. Once I invited the superintendents of the schools and the teachers to an evening show. In the afternoon we invited the school patrol under the supervision of the teachers to attend the theater. It is purely a sales proposition. You try to sell the safety idea to your men at the plant. In the same way you can sell the proposition to the school.

CHAIRMAN RENINGER: Does anyone have any recommendations to make?

A Committee for More Active Safety Cooperation

MR. FORTUIN: I have had this in mind for sometime: I don't know if it is exactly up to the Council itself, but someone has got to take the lead in it and if the Cement Section does, it will demand sufficient recognition to develop it into something bigger later on. Suppose we have a committee or a group to lay out a plan of procedure to extend over a period of time. In other words, to make it sort of a campaign to institute safety in the community. This information or data can be written up and a plan organized for it and that should be sent out to the various cement districts and in the next three months or in the next six months we, in each of our own individual sections, can endeavor to accomplish what is outlined therein.

R. S. HUEY (Universal): I don't know whether the scheme that is being worked in our town would work in most of these towns or not. Our town is probably a little larger than most of these cement communities. However, the activities of the safety work have been sort of taken over by the Chamber of Commerce and they have a program on accident prevention and safety during the winter. They have a meeting every month, with sectional meetings at this general meeting, where they have metal and woodworking, truck drivers schools and so forth, with a general meeting afterwards in which everybody participates. They have a first-class speaker of national importance come and talk to them. They have been instrumental in getting the men in industry and the police department and everybody else working together on this.

They started a campaign, a safe driver's campaign, in which every automobile owner was asked to sign a pledge to drive safely and this year they have cut the accidents down considerably. They had 22 last year. They have cut them down so there have only been six so far this year. They are working together with the school board and I think practically all this work is being done in our schools. In their English classes they have the pupils write "Look to the right and look to the left," and all

such things. In their arithmetic they are given the number of accidents and such things as that. It is brought home to them in the way Miss Telford has mentioned.

If you get some sort of an organization working like that, a committee which will get the interest of the community and get them out with a good program, you will certainly get results.

CHAIRMAN RENINGER: We weren't thinking so much of that; we were thinking of towns like Nazareth, or Mitchell, or some of the smaller towns of 3,000 or 4,000 population. For the big cities the National Safety Council has its organization, but it is to get some simple program for the smaller towns. If you men are interested enough we will go ahead with this and try to work out a simple program for the cities where probably they have one teacher in the schoolroom, or maybe two or three. Let us see if the Cement Section can't be a couple of jumps ahead of the other sections in this work, as it is in accident records. Let's have it to our credit that this plant in this district has started the safety work in its community. That is what I have in mind. If you feel that it is worth while and are willing to go along with it, we can get the Education Division to work out a program with us and we will hoot it to every cement company in the country.

MR. WEITKNECHT: I make a motion that the officers of the Cement Section constitute a committee to confer with the Education Division of the National Safety Council to develop a program and submit it to the cement industries where that program would be applicable.

(The motion was seconded, but to a vote, and carried).

CHAIRMAN RENINGER: I am very glad we had this meeting, I think a great deal will be accomplished.

ADJOURNMENT.

*SIXTEENTH ANNUAL SAFETY CONGRESS
NATIONAL SAFETY COUNCIL*

Cement, Quarry and Mining Joint Luncheon

Wednesday, September 28, 1927

A. J. R. CURTIS, Chairman
Assistant to General Manager, Portland Cement
Association, Chicago, Ill.

The joint luncheon session of the Cement, Quarry and Mining Sections of the National Safety Council was called to order by the chairman, Mr. A. J. R. Curtis, assistant to the general manager, Portland Cement Association, Chicago, Ill.

CHAIRMAN CURTIS: Whether your problem is to find a substitute for gasoline, to cure an illness or meet the competition of a foreign competitor, the orderly procedure is the same. First of all you must diagnose the situation, find out what the problem really means; secondly, you must devise ways and means to meet the situation the diagnosis has revealed—you must prescribe a remedy.

This procedure is adopted by anyone, consciously or unconsciously, that elects to accomplish things in an orderly and logical manner.

In safety work many industries have been taking headache medicine—doping themselves with a “cure-all” supposed to be good for what ails them. They have taken the dosage without thought about the fundamentals of the problem and without an adequate diagnosis.

The reason we have made such startling progress in safety work in the cement industry is because we have diagnosed our case and then found remedies for specific ills. We have done this by means of a fine system of statistical records and reports. This report system, inaugurated in 1919, shows us what and where the accidents are. The records indicate what season of the year a certain type of accident is likely to occur. They enable us to measure the efficiency of this scheme or of a scheme in the promotion of safety in our plants and quarries.

Ethelbert Stewart, United States Commissioner of Labor Statistics, speaking before the Cement Section of the National Safety Congress in Detroit early this year, commented favorably on our statistical system.

“I find that statistics of the Cement Section of the National Safety Council are the very best that come to my office,” Commissioner Stewart said. “You are doing a piece of work that must inevitably result in a rapid decrease in your accident rate. Do not know whether or not you are making effective use of these figures, but they are significant and you certainly should be doing so.”

“In the first place you have an industry devoted to the manufacture of one definite product—cement. Your product does not go, as would be true in the chemical industry, into everything from lipsticks to laundry soap. In gathering your statistics

you have something definite to work on and you have succeeded in doing the basic thing, that is, finding the man-hour exposure in your industry and relating your accidents to that. Statistics cannot reduce accidents, but they can tell you where the accidents occur. They can and do tell you where to apply your precautionary measures and where to spend your money. They make it unnecessary to spend money along several lines when most of your accidents are occurring along one or two lines. Comprehensive accident statistics are worthwhile and I congratulate your industry and the many individual manufacturers who are cooperating to make this statistical work so effective.

"I have been able to show others that you have reduced your accidents. Statistics form the basis for a lot of standard jokes like the mother-in-law joke and everyone thinks he can take a whack at a statistician and his statistics; but, nevertheless, if you are going to improve the accident in your plant you must know where the accidents occur and that requires statistics.

"Your statistics have made it possible for me to show others that you have reduced your accidents. I hope to impress you with the importance of continuing and further perfecting your statistical work, not only for yourselves, but for the influence it is going to have on the other sections of the Safety Council on your own and other industries."

We are so well sold on the diagnosis theory because we can take our limited means and get excellent results. We don't have to guess—we can take one direct shot and make it tell. We are able to do this because our records have revealed a specific situation—the case is diagnosed and we can take steps to remedy a definite problem that confronts us.

All mining and quarrying industries can make the same sort of case study. The experience of the cement industry points to the expediency of this method because in our industry we face problems in both of these divisions.

Let me give an example of what statistics have done and will do for us. Our records show a growth in screw conveyor accidents at a certain time of the year. For the past nine years we can trace a growth in lost-time accidents of this type at a certain period.

Instead of spreading our funds to battle all sorts of accidents at this given period we can centralize our efforts to combat screw conveyor accidents when they are again in the ascendancy. So we gathered a large number of opinions of experts on how to eliminate conveyor mishaps.

This symposium will be sent to all mills when the time comes. Plans will be made well in advance to meet the situation when it arises.

I believe that a large portion of accident success is based, as I have said before, on the diagnosing of the problem in hand and then prescribing remedies for the specific illness.

Now, we are to be favored with a brief address by a man in a position to be familiar with the inside details of the accident situation. Mr. W. W. Adams is statistician for the United States Bureau of Mines, Washington, D. C., and he has kindly consented to talk to us from the point of view of the Bureau. I take pleasure in introducing to you Mr. Adams.

Safety in the Quarry Industry

W. W. Adams, Statistician, United States Bureau of Mines, Washington, D. C.

Safety in the quarry industry is a matter of direct concern to 92,000 men who are employed in the industry and it is also of almost equally direct concern to their immediate families. Thus between 300 and 400 thousand people are personally affected by the accidents that occur in connection with the

annual production of stone in the United States and in connection with the crushing and other work that immediately follows its extraction from the earth. From 120 to 150 of these men are killed by accidents each year, and 14,000 of them are non-fatally injured.

Through the cooperation of the producing companies, the United States Bureau of Mines conducts an annual canvass of accidents and employment covering the quarrying of stone, and such subsequent work as crushing, rock-dressing, and the manufacture of lime and cement. This work began in 1911 and statistics covering the past 16 years are now available. These statistics are based upon reports furnished voluntarily by the producing companies on blank forms supplied by the Bureau of Mines. Each non-fatal injury reported to the bureau involves disability of the employee for more than the remainder of the day on which the accident occurred. In other words, the Bureau's statistics are limited to what are known as "lost-time" accidents. While many of these injuries cause the employee to lose only one or two days, some of them involve the loss of several weeks or months. Taking them in the aggregate, they average about 15 days per injury. Any company whose temporary injuries average less than 15 days each has a relatively safe plant, or is lucky, or is doing effective safety work. If deaths and permanent disabilities are drawn into the picture and given their customary equivalent weights in lost days, the average accident in the quarry industry represented a loss of 104 man days in 1925 and 94 man days in 1924. In this average each fatality and permanent total disability is considered equivalent to a loss of 6,000 days and each permanent partial disability 800 days, the last-named figure being borrowed from the reports of the Industrial Accident Commission of California until sufficient reports of this class of injuries accumulates in the Bureau's records to develop a new average.

An Intensive Study of Quarry Accidents

In addition to the Bureau's annual canvass of accidents which is based on reports from all producing companies in all states, or as nearly all of them as we can obtain, a special and much more intensive inquiry into quarry accidents has been under way during the past two years. This study is based on full and complete reports—a separate and detailed report for each accident—from a limited number of companies. Each of these companies employs at least 25 men inside the quarry. They are the companies that are participating in the National Safety Competition which is being conducted by the Bureau of Mines. Two such annual contests have been completed, namely, that of 1925 and that of 1926. One of the purposes of the safety contest is to determine which quarry has the smallest loss of time from accidents in proportion to total man hours of exposure. The quarry that establishes the best record receives a bronze trophy or statue known as the Sentinels of Safety, which is the gift of the Explosives Engineer magazine. Credit for providing the trophy and for very material aid in connection with the contest, is due very largely to the enterprise of Mr. N. S. Greensfelder, the editor. The trophy is held one year by the winning company, and is then surrendered to the winner of the next year's contest. Each year the name of the winning company is engraved on a pedestal of the trophy and each employee of the winning quarry receives an engraved certificate of honor issued by the Bureau of Mines and signed by the director of the Bureau.

The Bureau's annual canvass of quarry accidents affords a broad picture of the accident situation as it affects the whole industry or any large portion or phase thereof; it also furnishes an annual account of the volume of employ-

ment required to produce the country's annual stone supply and of the total loss of life and limb as well as the loss in Man days that went into the cost of producing the stone. The more detailed reports furnished in connection with the National Safety Competition are usually supplied as a carbon copy of the report which the company is required to send to its insurance carrier or to the state compensation commission. In this way the Bureau is furnished with valuable detailed information on accidents with a minimum of inconvenience to the company.

It will thus be seen that the Bureau of Mines statistics of quarry accidents are collected by two methods from a common source, namely, the quarry companies. It will also be observed that the statistics differ in scope, geographically, and in the degree of detail with which the information is supplied. From these two sources of information and similar information from other branches of the mineral industry, it is apparent that quarry accidents occur less frequently and cause a smaller loss of time in proportion to number of employees than do accidents at metal mines or coal mines. In other words, quarry work is not as hazardous as coal mining or metal mining, considering each of the three industries as a whole. Moreover, differences also exist between the hazard of different kinds of quarries. Perhaps the chief distinction in this respect is between quarries that produce dimension stone and those that produce non-dimension stone. Quarries that produce crushed or non-dimension stone have higher accident rates than those that produce dimension stone. For example, the fatality rate for the non-dimension group, in and about the quarry, in 1925, was 33 per cent higher and the injury rate was 7 per cent higher than the corresponding rates at dimension stone quarries; in 1924 the rates were respectively 76 per cent and 18 per cent higher. A comparison covering all years since 1916 shows that, without exception, the group rates for both fatalities and injuries, have been higher at stone quarries producing non-dimension stone, the excess ranging from 5 per cent in 1921 to 118 per cent in 1920 for fatal accidents, and from 1 per cent in 1917 to 122 per cent in 1921 for non-fatal accidents. Moreover, possible differences in length of work day at the two classes of quarries have no material effect upon this relationship. This is shown by figures which have been compiled for quarries working uniform shifts, that is, eight hours, nine hours, or ten hours.

Increased Accident Frequency Unaccounted For

In crushed-stone or non-dimension-stone quarries, where no care need be exercised to prevent breaking the stone, it might be expected that the rate from accidents from explosives would be higher than that in quarries producing dimension stone that is intended to be used for building or monumental purposes. This, in fact, has often been the case, as shown by the annual reports which the Bureau of Mines has received from the producers of stone. It does not, however, fully account for the higher frequency of accidents at crushed or non-dimension-stone quarries. A comparison of the annual figures for the two classes of quarries during the past seven years, shows that some other classes of accidents also, as a rule, occur more often at quarries that produce crushed or non-dimension stone. Crushed-stone or non-dimension-stone quarries show higher injury rates for accidents caused by handling rock at the quarry face, also for accidents from falls or slides or rock or overburden. Haulage accidents also are usually more frequent at crushed-stone quarries. Accidents caused by falling objects, which records for earlier years showed were of more frequent occurrence at crushed-stone quarries, have been materially reduced during the past four years, and in 1925 the crushed-stone rate for this

lass of injuries was actually lower than at quarries producing monumental or building stone. A somewhat similar situation prevails as to accidents from lying objects; the rates for this type of accidents have been high for both kinds of quarries, but during the past three years the non-dimension quarries have established the better record. Machinery accidents also are among the major causes of injuries at both classes of quarries, but in the past few years the crushed-stone quarries have reduced their injury rates from this cause and since 1922 these rates for machinery accidents have been lower than at dimension-stone quarries. The net advantage, however, still lies with quarries that produce dimension stone; that is to say, the injury rate covering all classes of accidents combined is still lower for the dimension-stone quarries.

Quarrying Less Hazardous Than Other Mining

Accident prevention is a national as well as local problem. It is therefore appropriate that national associations, such as the Portland Cement Association, the National Crushed Stone Association, and others, should undertake or maintain some group action looking to the prevention of accidents. In 1925, more than forty states contributed to the production of stone in the United States, and in more than 34 of these states accidents were suffered by the men who produced the stone. To the extent that quarry accidents are similar regardless of location of plants, it would seem that the national associations might with advantage undertake a study of the accident-prevention problem. It has already been said that the quarry industry is less hazardous than coal and metal mines, both as regards accident frequency and accident severity. This, however, is no more than might reasonably be expected because nearly all quarry work is done in the open daylight, whereas most of the operations at coal mines and metal mines are conducted underground, where the light, which is necessarily artificial, is often not adequate for maximum safety; also in the underground work, there is the additional hazard of falling overhead material. The quarry industry should therefore not be content if it merely maintains an accident rate better than that for the mining industry, but should strive to lower its rate from its own previous levels. This has already been done to some extent so far as fatal accidents are concerned, but not to any material degree as regards injuries of a non-fatal character.

Of the 92,000 men working at quarries in 1925, the operator's returns to the Bureau of Mines showed 52,000 working in and about the quarry pits and 40,000 working at the outside plants. About three-fifths of the accidents occurred to the men working in and about the pits. These accidents accounted for 101 deaths and 8,632 lost-time injuries. The fatality rate per thousand 300-day workers was 2.28 and the injury rate was 195. The injury rate was the highest on record since 1915, when the statistics for inside and outside accidents at quarries were first segregated. On the other hand, the fatality rates previous to 1925 were, in four cases, better, and, in six cases, worse than the rate in 1925. These figures show that more progress has been made in the prevention of fatalities than in the prevention of injuries. A comparison of these figures with those for outside plants shows that more progress has been made outside than inside the quarries, and this fact has contributed favorably to the record for the industry as a whole.

The number of days a quarry is in operation is largely a matter of contracts and weather conditions. Perhaps choice plays little or no part. Yet it may be interesting to know that it is apparently safer for a quarry to work full time than part time. That is to say, the accident rate per day diminishes as the number of days the plant is in operation increases. A quarry that is in operation a full year is likely to have a lower accident rate per day than if it

worked only half a year. This conclusion is based on statistics which the Bureau has compiled for metal mines, which indicate a relationship between accident rates and continuity of operation which doubtless exists in quarries as well as mines.

These statistics (as yet unpublished) of metal-mine accidents show that accidents occur less often when operations are most continuous—that is, the accident rate declines as the number of operating days of the plant increases. This fact was indicated not only by the figures for all classes of metal mines combined, but also by the figures for individual groups. The combined rate over a four-year period (1921-1924) for fatal accidents among underground employees was 7.69 per thousand full-time (300-day) employees for mines operating less than 100 days per year, and it was 3.77 for mines operating 300 or more days per year. The non-fatal injury rate for the former group was 675 per thousand employees, while for the latter group it was 356. Considering mines of equal or similar size, the death rate for mines employing 100 or more men underground was 8.78 for 1 to 99 days of operation and 3.71 for 300 or more of operation. When the mines were classified according to principal product, it was found that iron mines operating less than 100 days had a fatality rate of 11.92 and an injury of 836, whereas those in operation 300 days or more had a fatality rate of 3.01 and an injury rate of 174. Similarly, copper mines had a death rate of 7.58 and an injury rate of 841 for less than 100 days of operation and a fatality rate of 4.09 and an injury rate of 435 for 300 or more days of operation. These figures for metal mines were for extreme groups in respect to operating time; rates for adjacent groups indicated the same tendency, but less clearly.

Similar figures for quarries have not as yet been compiled, but we hope to be able to prepare them in the near future.

An Exposure of Over Seven Million Man Hours

The experience of 44 plants in the National Safety Competition of 1926 was classified on a monthly basis to learn the seasonal variation in the amount of exposure and the seasonal variation if any in the accident frequency rates. These 44 plants had a total exposure of 7,815,377 man hours. The severity rates were also calculated on a monthly basis, but the occasional occurrence of a fatality, with its equivalent of 6,000 days, rendered the severity rates too variable for comparative purposes. The volume of exposure, as might be expected, reached its lowest level during the winter—in January; it increased steadily through June, and held this level through July, then declined slightly but steadily through August, September and October, and continued to decline more rapidly in November and December. The maximum exposure, in June, was two and one-fourth times that of January. The frequency of accidents was smallest during the four winter months of November, December, January and February; it was much higher in other months, the average rates being about 50 per cent higher for the months of greatest activity.

In order to form a mental picture of the field that lies ahead of any prospective safety program, it may be helpful to state that so far as quarry safety rests with the operators, it is necessary to reach only a small number of companies to encompass a large proportion of the employees. Less than 700 quarries employ as many as 25 men in the pit, and these 700 or less plants employ 80 per cent of all men that work at quarries in the United States. If 50 men inside the pit are considered necessary to entitle a plant to rank as a large quarry, then such plants number less than 300 and they employ nearly

60 per cent of the total quarry workers in the United States. These facts are referred to because the cooperation of the company as well as the employees must be obtained to make safety work effective. A relative small number of companies have it within their power to give a tremendous impetus to quarry safety work that will benefit 80 per cent or more of the entire industry.

The accident rates for the whole quarry industry are but slight indication of what individual companies can accomplish. For example, the industry's accident-severity rate for work inside the pits, as nearly as it can be computed from available records, was 8.202 in 1925 and 6.931 in 1924; the corresponding group rate for companies in the National Safety Competition was 7.599 in 1925 and 7.760 in 1926. Yet in the 1925 safety contest, seven quarries out of 102 and in the 1926 contest fourteen quarries out of 118 operated their plants the entire year without a lost-time accident. In 1925 sixty plants or 59 per cent of those enrolled had accident-severity rates of less than 1 and in 1926 67 plants or 57 per cent had rates of less than 1. Thus it is seen that the group average of 8.202 in 1925 and 6.931 in 1924 for the whole industry, and the National Safety Competition group averages of 7.60 and 7.76, respectively, in 1925 and 1926 are by no means the best that individual quarries can do in the elimination of accidents to their employees. In fact, the 1926 contest showed that 97 plants, or 82 per cent of the total number, had accident-severity rates that were better than the group average; 21 plants, or 18 per cent of the total number, had rates that were higher and therefore worse than the group average. This means that 18 per cent of the companies were mainly responsible for the group average being as high as it was. Had it not been for the many good companies, the rate would have been much higher. The record, in fact, showed that the companies whose rates were better than the average had a group rate among themselves of 2.314, while the rate for those whose record was worse than the average was 38.695; 2.314 for the good companies; 38.695 for the bad companies, an average of 7.760 for both combined. The bad companies had a rate that was more than 16 times that of the good companies.

Comparing Accident Experiences Is of Value

The purpose of these and similar statistics is to make it possible for individual quarries to compare their accomplishments in accident prevention with what has been done by other companies. Any individual company may be remarkably successful in the elimination of certain classes of accidents and equally unsuccessful in combatting other types. Neither the degree of success nor the degree of failure can be known without some standard of measurement. The National Safety Competition of 1926 has shown that while all of the quarries combined had a group rate of 7.760, yet 82 per cent of them had lower rates than that figure. The rates ranged from zero to more than 200. Rates for the individual companies have been published, but in such a way that the identity of each company is concealed. Each company has been advised of its own rate and of its relative standing among all companies. Copies of a circular containing these rates are available to any company upon request. Incidentally it may be stated that the circular also contains the rates of coal mines, metal mines, and non-metallic mineral mines. All of these rates have been calculated on a uniform basis and are therefore strictly comparable. The method of compilation is simple. Any company may easily prepare its own accident records in the same way. Those companies that see fit to do so will find that they are following a practice that has become standard not only in the mineral industry, but in other industries as well. Following such a prac-

tice, any company may readily learn how it ranks with other plants of the same type or with any other industrial unit.

It is hoped that the companies represented at this meeting may find it practicable to place their accident statistics on this standard and widely accepted basis. In the event that any company establishes a safety record better than those indicated in the National Safety Competition, the Bureau of Mines would appreciate it if the company making the record would inform the Bureau of the fact. The Bureau desires to learn of cases of this kind so that suitable public recognition may be given.

ADJOURNMENT.

Tire & Rubber Co., Akron, Ohio; E. W. BECK, United States Rubber Co., New York City; E. A. HOENER, The Firestone Tire & Rubber Co., Akron, Ohio; A. L. VILES, The Rubber Association of America, Inc., New York City.

Tuesday, September 27, 1927

W. L. SCHNEIDER, Chairman

Safety Director, The B. F. Goodrich Rubber Company, Akron, Ohio

The first session of the Rubber Section of the National Safety Council was called to order at nine-thirty o'clock by the chairman, W. L. Schneider, safety director, The B. F. Goodrich Rubber Company, Akron, Ohio.

CHAIRMAN SCHNEIDER: The reports of the chairmen of the various committees are, of course, important to every one. However, most of the Executive Committee know what each one is doing during the year, and, therefore, owing to the lateness of the morning program, I will dwell but briefly on the reports of the officers and their activities. I think it appropriate at this time to say that each one of them has served faithfully and conscientiously, and I think we all owe a debt of gratitude to every one of them who are present and those who have taken an active part in promoting the growth of the Rubber Section.

I cannot speak too highly of the cooperation which the various sectional chairmen have given me this year, and I think that each of us here can say that the work of the Rubber Section has progressed splendidly, owing to the fact that each of the members has cooperated with the other to the best of his ability. The work, as a whole, I think has progressed splendidly.

Report of the Secretary

In providing you with a report of the Secretary's activities during the past year, it must of necessity be both brief and somewhat immodest.

As you know, the work has been primarily that of routine correspondence, aside from the preparation of the minutes of the two meetings which I attended at Detroit and Akron. In addition, I have contacted with various of the Rubber Section members and through National Safety Council headquarters have written numerous letters to prospective members and likewise to two or three cancelled memberships.

Several queries relative to safety problems were provided with satisfactory answers. I, of course, should not forget to mention preparation of the docket covering one-day extra session of the Executive Committee held in New York in June.

Other than that, I have not done very much to speak of.

Very truly yours,

R. C. SALISBURY, Secretary.

Report of the Poster Committee

There were twelve safety posters issued during the past year for the Rubber Section. Most of these photographs were sent direct to the office of the

National Safety Council and in turn were sent to me for approval and suggestions for copy. You will remember that you helped me in preparing these suggestions.

Additional material for safety posters was obtained by making arrangements to have Mr. Mathieu, the staff photographer from the National Safety Council, come to Akron and take photographs of subjects at the Goodyear Tire & Rubber Company, B. F. Goodrich Company, Miller Rubber Company and the Firestone Tire & Rubber Company. The result of this trip was very successful, as Mr. Gardiner informs me that all photos taken at that time will be used for safety posters. It might be well to mention that while on this trip Mr. Mathieu also made photographs to be used for safety films at the Congress and these photos were forwarded to Mr. Lawler.

The present status of the Poster Committee is that there are sufficient posters to last until February, 1928, figuring that one will be issued each month. In addition, Mr. Gardiner has promised that the Rubber Section will be favored with a large poster, 17x23 inches, and I am going to keep after Mr. Gardiner until he fulfills this promise.

Aside from our local members, Mr. Quirk was the only outside member sending in material and which consisted of four sketches, three of which Mr. Gardiner has informed me will be used.

In regard to the posters which we were informed will be used in the regular series, I wish to advise that these posters are photographs which have been submitted to the Council by Rubber Section members at various times and are of such a general nature that they are including them under a general number instead of issuing them as Rubber Section posters. Such posters are No. 1983-B, which is the drawing that was sent by Mr. Quirk and which shows the superintendent explaining a wonderful accident prevention record to a visitor in the plant. Another one is Poster No. 1988, which is a photograph showing one workman wheeling another workman on a hand truck. This poster is being made up from an old photograph. Both of these posters will appear in the October issue of the NATIONAL SAFETY NEWS.

I wish to take this opportunity, Walter, to thank you for the wonderful aid you have been to me, not only as Chairman of the Poster Committee but also in my work at Firestone. I have been up against a lot of knotty problems which through your experience you have been able to help me solve, and I certainly appreciate your efforts and only hope that I may be able to reciprocate.

Yours very truly,

C. L. HUNGERFORD, Chairman.

Report of the Membership Committee

Number of Members in Rubber Section, 10-25-26.....	43
New Memberships During the Year.....	7
Memberships Cancelled During the Year.....	2
Total Number of Members in Rubber Section to Date.....	48

List of New Members—	No. of Employees	Date Received
The Wilson Rubber Company.....		11-30-26
Farrell Foundry & Machine Company.....	1167	12- 8-26
The Rubberoid Company.....		4- 7-27
The H. O. Canfield Company.....	347	5-31-27
U. S. Rubber Reclaiming Company.....	495	7- 9-27

Hamilton Rubber Manufacturing Company.....		8- 4-27
Canadian Johns-Manville Company Ltd.....	200	8- 8-27

List of Memberships Cancelled—

Republic Metal & Rubber Company.....	60	1- 1-27
Murray Rubber Company.....	693	6- 7-27

We are practically assured of two more new members, although they may not join before this convention is held. The Trenton, N. J., factory of the Ajax Rubber Company and the Lambert Tire & Rubber Company of Akron, Ohio, are very favorably impressed with the Council and I think it is only a matter of time until they become members.

During the month of February, 1927, the lists of members of the Rubber Section of the National Safety Council and of the Rubber Association of America were revised and copies sent to the National Safety Council and all members of the Executive Committee of the Rubber Section.

A form letter was drafted and sent to Mr. Schneider and to the Council for approval. This letter was intended to be sent out to every member of the Rubber Association of America who was not a member of the National Safety Council. A committee of three was appointed from different sections of the country, namely: E. James Glascock, of the Dunlop Tire & Rubber Corporation, Buffalo, N. Y.; J. M. Hunter, of the U. S. Asbestos Company, of Mannheim Pa., and Reed Harkness, of the Cupples Company St. Louis Mo. and it was thought and planned that these men, working with the Executive Committee of the Rubber Section, could pretty well cover every section of the country and possibly make a great many personal calls. In the meantime, we decided that we wanted to send out with this letter a copy of an article which was to appear in the Rubber Age, which dealt with Safety in the Rubber Section of the National Safety Council and rubber mills in general. It was thought at the time that the article would be published immediately, but it was delayed and was just recently published. Therefore, the form letter was never sent out.

Other form letters were, however, sent out by the National Safety Council, and I have sent out many letters of solicitation. We received favorable replies from some of the solicited companies and probably the new chairman may get these companies to become members during the coming year.

R. H. COCHRAN, Chairman.

Report of the Safe Practices Committee

The following is report of activities of Safe Practices Committee for year 1926-7:

The previous work of the committee included a rough draft of a pamphlet on Knife and Shear Accidents, together with photographs of safe and unsafe practices.

The work of the committee for this year has consisted in revising and rewriting the text of this pamphlet and preparation of a paper on this subject to be presented at the Annual Congress. The text of the pamphlet is practically ready for printing and this should be done shortly after the Congress.

Other material submitted by the previous chairman includes a paper on "Material Handling," which should make excellent material for future activities of this committee.

I wish to acknowledge with thanks the assistance of the members of the

Executive Committee of the Rubber Section in reviewing the text of the pamphlet.

Respectfully submitted,

HOWARD W. LOW, Chairman.

Report of the Program Committee

The activities of this committee are naturally summarized in the two days' session of this section and if it is a success we, of course, take the credit. However, if the meetings are a "dud"—and the chances are far remote—we say it was the fault of the chairman (W. L. S.).

Really, Walter, it is hard to give you much of a report. However, the spirit of cooperation has been excellent at all times in my contact with the various members in the Chicago office of the N. S. C.

Taking the various items on the attached program, I wish to report as follows:
First Session—

1. The appointment of a Nominating Committee in advance is, in my estimation, an excellent idea. It gives the members an opportunity to carefully analyze the situation and sound out the prospects.

2. Report of Chairman. The plan you have adopted of incorporating the reports of the various committees in yours is also an excellent idea, as it will save considerable time and you will know how to bring out the points of importance.

3. Technical Paper, "Knives and Shears," by H. W. Low. This is, as you know, an excellent paper and shows careful preparation, and I am sure it will be of interest to all.

4. Address by Mr. Paul Van Cleef. This is in accordance with our practice of having some official connected with the rubber industry give us a talk each year and as Mr. Van Cleef's reputation is well known, we are sure to receive much valuable information from his address.

5. Pictures of Rubber Plantation. This is a departure from our usual program and I am sure it will interest all, as these pictures not only show important phases of our industry, but I believe it is intended that some reels will be shown that will have a close reference to health and sanitation.

Second Session—

1. Report of Engineering Committee. This is one of our most important committees, and I am sure Mr. Congdon will have very good facts to present to the members.

2. Report of Statistical Committee. We all know Mr. Mansfield's problem in procuring statistics, but in spite of this he has always given a very worthy report, and we are sure to have the same at this time.

3. Technical Paper, "Health Hazards of Compounding Materials." This is of vital importance to all of us, and through two men of the caliber of Dr. Shirley and Mr. Healey we should secure some very valuable information that will be of interest to all of us.

4. Safety Kinks. We have submitted to Chicago for reproduction 27 photos and sketches which, I think, will be more than ample for this share of the program. In addition, we have the motion picture showing the rallies at the plant of the U. S. Rubber Company, which Mr. Beck will have available in case we have time to put it on. I certainly have received wonderful cooperation in securing the material for this subject, as all of the members to whom I have appealed have come across in fine manner. The subjects are excellent and in most cases they have photographed equally as well and we should all get some very good information from their presentation.

I do not know if you consider from the above facts that this is the proper

type of report. However, it gives you an idea of just how I feel about the various subjects on the program.

As to future programs, I think this subject should be held in abeyance until after the Congress so we may secure the comments of the members and also by attending the meetings of the other sections get new ideas.

E. R. LAWLER, Chairman.

CHAIRMAN SCHNEIDER: We will now have as part of our program the paper mentioned previously, which has been prepared by Mr. Low, chairman of the Safe Practices Committee. I would ask Mr. Low to give his talk at this time.

Safe Practices With Knives and Shears

Howard W. Low, The Miller Rubber Company, Akron, O.

Purpose and Scope—Knives and shears in the Rubber industry are a constant source of accidents, mostly minor but occasionally of a serious nature. My purpose is to describe and illustrate simple methods which have been found effective in reducing accidents from this cause. No attempt has been made to cover machine knives or power shears as the hazards presented are different from those encountered with hand tools.

Accidents from Knives When Not in Use—One of the most common causes of knife wounds is brought about by the careless carrying of the knife in the operator's pocket with point up and blade exposed. All employees using knives should be provided with sheaths and their use made compulsory. Workers may have a receptacle secured to the bench or machine in which to keep sharp edged or pointed tools. Carelessness in laying knives down on the table or bench where they may roll or be brushed off is another accident maker, as they are liable to strike somebody on the foot or fall to the floor and be stepped on.

Mill Knives—Milling is an operation common to all rubber plants and the safe handling of mill knives deserves the careful study of every person desiring to reduce accidents in the industry. In cutting stock off the mill operators may receive cuts on the hands and arms. They should be taught to cut off with either hand, using the knife in right hand when cutting from the left end of roll and in the left hand when cutting from right end. Sheaths should be used for carrying the knife when not in use, as knives laid on the mill housing are very likely to fall due to the vibration.

Operators should be warned repeatedly not to grab for the knife if it should be caught in the stock and jerked from their grasp. Pull the safety, instead of grabbing for the knife, and there will be no danger of the hand being drawn into the rolls. The practice of loosening the adjusting screw with another knife blade has caused many painful cuts and should be prohibited. A screw driver of the proper size should be used and the handle of the knife placed on a bench or other rigid support. At the end of the shift knives should be placed in sheath before being put into tool bag, which will prevent puncture wounds caused by the point of the knife protruding through tool bag.

Cutting Rubber with Template—Many cuts are received in this operation by the knife being drawn up on to the template and into the other hand, or by the fingers being allowed to extend over the edge. Operators should be taught to cut away from the hand holding the template. In some plants a flange is placed near the edge of the template, which has greatly reduced the number of cuts formerly received on this operation. For cutting thin goods a roller knife may sometimes be used to good advantage.

Skiving with Knives—This operation is extremely dangerous unless extreme care is used. Never attempt to skive toward the hand holding the work, or toward the edge unless absolutely necessary.

Knives in the Calender Room—Calender operators whose work requires the use of a knife to cut samples of sheeted stock for gauging, etc., should be warned against careless handling of the knives. The operators should train themselves to overcome the instinctive desire to grab for the knife if it is jerked from their grasp, since many cuts, some of a serious nature, have been caused in this manner. When two men are picking strips from the calender roll with their knives they should be very careful not to injure each other. When not in use knives should be carried in a sheath, as the nature of the work, requiring several men to work in close proximity, greatly increases the chance for cuts from an unprotected knife blade.

Butcher Knives—Crude rubber and batched stock are often cut with long bladed butcher knives which are liable to cause very serious injuries unless proper precautions are taken. There are three types of guards to prevent the hand from slipping off the handle onto the blade. One is made by slotting a piece of sheet metal, sliding it over the blade and fastening to the handle with wood screws. A second is a safety handle which may be secured from manufacturers of knives; and the third is a ring placed at hilt of knife, secured to the tang and under the handle. The ring should be large enough to accommodate the index finger. Of the three types described, the first has been found to be the most satisfactory for all around service; the second has the disadvantage of breaking under severe usage where the blade narrows down to form the tang. This is dangerous as well as undesirable from a production standpoint. The ring type is not recommended for rubber workers. Especially around the washing mills or tank washers, so called, as it would cause an added hazard in case the knife is caught in the rubber and is pulled between the rolls. In this case the employee would be liable to have his hand drawn into the rolls before he could release his finger from the ring.

Routine to Insure Guards Are Supplied

If a guard of type first described is used and the guards applied after the knives are purchased, a routine should be established whereby the knives go from the receiving department to the shop to have the guards applied before going to the store room.

A sheath should be attached to the table or work bench and the knife kept in it at all times when not in use.

An ingenious guard for smaller knives can be made by fastening a hooked piece of sheet metal to the bottom of the handle, the hooked portion extending down where the handle joins the blade, preventing the fingers from slipping off the handle onto the blade.

Round Handled Knives—Knives with round handles have a tendency to roll off the table or bench if not laid down with care. This can be avoided and the comfort of the round handle retained by flattening the lower half of the handle into a V shape.

Sharpening and Grinding Knives—Many accidents have been caused by improper methods of grinding on wet stones. The knife should be grasped firmly in one hand, index finger parallel to and resting on the blade, the thumb on the other hand resting on the blade and close to the index finger of the hand holding the knife. The grindstone should be turning away from the employee.

When grinding knives on an emery wheel a glass shield should be provided over the wheel or goggles should be worn. The glass shield will be found superior to goggles for this work, as it is always in place and does not require the employee to spend any time in adjustments, which is frequently the case with goggles.

Severe cuts are sometimes received while sharpening knives on hand stone. The

stone should be firmly secured to table, bench or some rigid support and never be held in one hand or laid across the knee while sharpening the knife. Hand stones similar to meat cutter steels are sometimes used, and unless the correct method of usage is understood, very serious cuts are liable to result. This type of stone should have a guard at the hilt to prevent the blade of the knife passing too far down and cutting the hand holding the stone. The proper method of using this type of stone is to place the hilt of the knife at the top or point of stone, then draw the blade down towards the hilt, at the same time drawing handle of knife away from the stone. In this manner the entire length of the blade will pass across the stone.

A Cause of Many Serious Accidents

Trimming Tires—Trimming tires with a V-shaped knife has been the cause of many painful and serious accidents. Puncture wounds from these knives may be decreased and the severity reduced by rounding the points. Proper receptacles should be furnished in which to keep the knives when not in use. In trimming the tire it should be grasped back of the point at which the knife is cutting, and the thumb should be kept well down on the side wall of the tire. The cutting edge of the knife should be sharp and wet.

Shears—Shears are used extensively in the rubber industry and their use is attended with the hazard of cuts and puncture wounds, of a sometimes very serious nature. The general safety rules on carrying of knives and laying them on tables and benches apply equally well to shears, as the hazard is much the same.

Shears should never be carried in the hand while carrying other material, as this practice may cause the loss of an eye or other serious injury to fellow workers. The points of shears should be rounded where this does not interfere with the operation.

Lack of attention on the part of employees is a frequent cause of cuts from shears. Holding material in one hand and cutting this material with shears held in the other hand while watching or talking to some fellow employee, are things which cannot be done with safety.

Tossing of shears from one employee to another should be absolutely forbidden, as many serious injuries have resulted from failure to catch them and having them fall point down on the feet.

Grabbing for falling shears is another extremely dangerous practice which can be largely avoided by making the use of a sheath or receptacle compulsory.

Summary—Nine-tenths of all accident prevention in connection with knives and shears comprises, proper safety instruction, constant vigilance, providing proper receptacles and the compulsory use thereof.

Supervisors and inspectors should be firmly impressed with the fact that it is their duty to insist upon operators handling tools in the safest possible manner.

A Paper Worthy of Careful Study

CHAIRMAN SCHNEIDER: I am sure we all enjoyed the paper so efficiently prepared by Mr. Low. I think every one in this room can carry home some worth while idea. It proves that we can produce good safety methods, and it is simply a matter of correlating ideas. I think we all feel very highly indebted to Mr. Low for his paper and he is to be congratulated.

We have with us a gentleman who needs no unusual introduction. He is a man who commands the respect of every one, not only in the rubber industry, but in other industries, as a leader in safety work. I take great pleasure in introducing Mr. Paul Van Cleef, vice-president, Van Cleef Brothers, Chicago.

The Important Place Safety Holds in the Rubber Industry

Paul Van Cleef, Vice-President, Van Cleef Brothers, Chicago, Ill.

The Rubber Section of the National Safety Council had its beginning in October, 1919, though the safety movement itself was inaugurated somewhat earlier. In the Akron district this probably occurred along in 1910 or 1911. It indicated a growing consciousness for safety but lamentably a slowly growing one.

That the conditions in the rubber industry require serious consideration is amply demonstrated. Fluctuations in the frequency and severity rates have appeared from year to year. During 1926 the frequency rate was four and one half points above the average for all the industries reporting although fortunately the severity rate was three quarters of a point below. A good idea of the periodic change in the frequency and severity rates for the years 1921 to 1926 inclusive can be gained from the following table:

	Frequency	Severity
First half 1921.....	24.80	.65
First half 1922.....	34.75	.67
First half 1923.....	35.83	1.50
First half 1924.....	25.96	.814
All of 1925.....		
All of 1926.....		

	Frequency	Average	Severity	Average
Last half 1921.....	37.60	31.20	1.15	.90
Last half 1922.....	37.18	35.97	1.07	.87
Last half 1923.....	26.73	31.28	1.15	1.33
Last half 1924.....	28.87	27.42	1.337	1.08
		29.15		1.11
		30.09		1.17

There has never been a better record than in the first half of 1921, but the year ended badly, for there was never a worse record than the last half of that same year. The year 1924 had the best general average, although the past two years have not differed greatly from it.

Are we to be satisfied with the figures shown, and would they still apply if every rubber manufacturer had turned in a report on his accidents? It is, of course, hopeless to expect in such a highly mechanized industry as the rubber industry to see a zero frequency or severity rate. Even leaving aside the accidents caused by machinery, this statement still holds, for it is said that of all accidents in industry 66½ per cent are not caused by machinery. Nevertheless, the rubber industry is confronted with the fact that the past three years have shown an upward trend in the accidents occurring. When one stops to consider that only 32 firms reported their accident record in 1926, although this was a gratifying improvement over the 22 of the previous year and the 16 in the year of 1924, it is worth while estimating the situation in the whole trade.

Since there are no data for arriving at the position in non-reporting plants, we may venture a guess at it. Suppose that the plants reporting represented about as much as half of all the rubber workers. On this basis the grand total averages would stand for 1926 as follows:

Average No. Employees	Number of Accidents—Disability				Total All Causes
	Total Hours Worked	Deaths	Permanent	Temporary	
156,566	322,446,048	20	172	9,690	9,882

Deaths	Number of Days Lost—Disability		Total All Causes
	Permanent	Temporary	
120,000	143,078	137,512	400,590

Comparisons might be made of these figures with those of other industries. It would be both for and against the rubber industry. They suffice to show, not in index figures but in real terms, the facts. A casual examination will convince anyone of the importance of the need for safety work in the rubber industry.

Why isn't there a more general affiliation with the movement? Is there some sort of mental complex which deters firms from boldly facing the safety problem? Do they fear learning something so unpleasant it might stir them to inescapable action? You know the tendency to follow the lines of least resistance. At that I believe the record quoted favors the trade as a whole. I am convinced that only the more progressive organizations have contributed to the records. Doubtless some exceptions will be found because there may be some firms outside of the National Safety Council which are fully aware of their safety problems. But if the truth were known, would the industry be able to make as good a showing?

An Industry with Many Hazards

The rubber industry contains, without doubt, as many possible sources of accidents as almost any other. We are dealing with highly powered equipment. We handle dangerous chemicals, hazardous solvents, electric currents, etc. Many parts of equipment cannot possibly be guarded without interfering with operations. There is an immense amount of handling which cannot be mechanically performed. Yet some factories are indifferent to it. Some feel that the insurance company will take care of their losses. Some believe accidents inevitable. Some give the matter no thought at all. They don't sense this important modern trend. I could enumerate in detail the various causes for accidents in the rubber industry. I could show perhaps how conditions in each case could be remedied, but much of this is already in the records. What I want to show is that the problem can be solved by forcing a realization of its necessity on the whole industry.

Do you know that there are 468 manufacturers in this country that can be classified basically as rubber manufacturers? Yet the Rubber Division of the National Safety Council has only 48 members, four of whom are not rubber manufacturers—hardly a tenth of all. Surely it is not because of the cost of membership, which is nominal. It must be because of actual neglect of the principles of safety in their own plants, for association is one of the best means of fostering an ideal. I have heard of places where the firms thought their duty towards their employees was complete when they paid them well. Any other effort was thought of as expense.

For the sake of argument, consider for a moment in passing what safety work would mean in cash outlay. Take, for example, a firm capitalized at \$750,000 and earning \$100,000 per annum. Suppose it spent \$2,000 a year on safety work. Do you think that amount would make any real difference to the owners? If the business were held by several stockholders they would perceive the difference even less. Smaller or larger firms would feel the cost only proportionately. The considerations of financial expense, it is obvious, must be left out of the picture almost entirely. What is left, then, is the personal element as involved in the relations existing between employer and employee. The safety problem is greatly simplified when there is a better mutual understanding, and this is within the reach of every company. It is expressed by the firm in the form of personal consideration.

This matter of personal consideration has a direct bearing upon the importance of successful safety work. By this term I have in mind welfare in its broadest connotation, which omits the dollars and cents idea. It is not just sufficient to put mechanical contrivances on equipment and feel that that is sufficient—or to pay some recognized wage scale and from there hope responsibility ceases. The best part of the work yet remains. Safety work must be done for its own sake, and be a part of the general welfare work which every organization should do. It must have the support of management and be a part of it. If it is half hearted, if it treats safety work solely as an experiment to determine whether it “pays” or as a necessary evil, success in this field is a will-o’-the-wisp. If management can see the underlying benefits from safety work and enter whole-heartedly into the spirit almost immediately the whole organization will become permeated with the same feeling. Once the latter realizes that safety is not a selfish force applied by the employer for his own good, the interest in safety becomes a vital factor in accident prevention.

The Plant Morale Registers in Safety Work

As I have said, it does not always take a direct expenditure of money to do safety work. What is required in any plant is the building up of a general interest in safety. Even the office boy must learn that it is wrong to leave a waste basket where someone may trip over it. The management must not only take a sympathetic interest in the subject but an active one. When meetings are held it must be present. If there are stockholders they should also be present. Make everyone in the organization feel the importance of the subject keenly by having every official of the company as well as every employee present. Perhaps officials will object by saying there aren’t enough accidents to justify their presence. The answer to that is the standard phrase: “One accident is too many.” Possibly they will say: “Our presence may emphasize the subject so much our employees will become scared and we will drive them away.” This is a false position. On the contrary, I know of one place where operators refused to work because of its hazards until the firm became personally interested in solving the problem. This is the thing that inspires confidence. This is the sort of thing which costs the least and does the greatest amount of good. You will recall that I stated 66½ per cent of accidents were not caused by machinery. This is the group that will be most helped by the personal interest method. It is through safety conferences with committees and direct contact with the workers discussing matters freely that safety becomes a living matter. There are many ways of stimulating interest in safety and in all of them the plant owners must take an active part. Safety work cannot successfully be imposed from without. The National Safety Council can be the means of interchanging safety knowledge. It can be the starting point for safety work and its inspiration, but fundamentally the safety problem is something which must touch the heart of plant management.

We have seen the figures showing the record of the rubber industry during the past few years. We have regarded with regret the relatively few firms affiliated with the safety movement. It was pointed out that the rubber industry has as grave problems in safety as other industries. The monetary cost was shown to be negligible. It has been indicated that in so important a work as this the management must be active in arousing an interest in safety. There is still another approach which will show why safety work in the rubber industry, or for that matter any industry, is important. It is justified solely on humanitarian grounds.

It is really a mistake for safety workers to be constantly endeavoring to

defend their departments by the savings in plant operation which they effect. What if not a penny were returned in increased efficiency? There are other considerations. I am not a sentimentalist, but it really pains me whenever I witness an accident. I know it hurts the real sufferer more. I don't think you are different from me or the men in the 400 rubber plants not members of this great organization. Isn't it up to us to try to reduce the hazards of daily life just for the sake of the distress it will save? Are we to stand in awe of those "ogres" the stockholders? They are just plain people like ourselves, only waiting to be directed. They are not a whit more callous. We only imagine they are mercenary. But what if they were? Some must show the way and be bold enough to stand up for a better understanding.

They must be made to see that accidents are not matters of fate, though of course there are some unavoidable accidents. The indifferent factory foreman and superintendent must be won to the cause by making them more sensitive to the happiness of others. The worker must be made to understand that it is all for his personal welfare. We must talk less of the cost of accident prevention and more of the good it will do. We must make apparent that the safety movement is cooperative in which every participant derives gain. Since we of the rubber section are few in comparison to the rest of the rubber manufacturers, we must hold up the light for the rest to follow. We must inspire others with the necessary zeal. We must talk and write safety until we have their serious attention. We must try to have them enroll in the National Safety Council, where they can derive the good that comes from direct contact with established safety interests. We really ought to have the vast majority of rubber companies as members. It would be good for the industry as a whole, making it a more wholesome place for men to work and justifying a belief that rubber manufacturers have a true love for their fellow-men. Then we could say our industry realized the importance of safety.

Lack of Statistics a Vital Point in Safety Work

CHAIRMAN SCHNEIDER: I am sure we all enjoyed Mr. Van Cleef's talk. I think it is something that should lend us the zeal of which he speaks about in our work. I also think he has done a great deed in giving us his time and has devoted a great deal of attention to this paper. I know he has his heart and soul in safety, both industrial and public.

It is to be regretted, as Mr. Van Cleef states, that there are not more reporting members of our Section. We have earnestly endeavored to secure other members. I am sure that the officers of the coming year have a task on their hands because there must be a greater proportion of reporting members than we have at the present time although we have secured a much larger proportion this year. The number of members, of course, is not as great as it should be, and most of the active safety work is done by a comparatively few members. We hope that every one here will lend their support to the work which the Rubber Section is doing and endeavor to secure more members. After we have secured them, I think we can sell them on cooperating and taking a real active part in our programs.

At this time, we will endeavor to show some very interesting moving picture films, and we are also indebted to Mr. Beck, of the United States Rubber Company, for bringing them here. They are very interesting and I am sure you will all enjoy them.

(Motion picture film was run.)

CHAIRMAN SCHNEIDER: I have an announcement to make. The council asks if there is any one who wishes to make any plant visitations to mention the fact on the back of the registration card.

Mr. Van Cleef suggests that if there are any questions regarding his paper he will try to answer them.

R. C. SALISBURY (The Fisk Rubber Company, Cudahy, Wis.): Mr. Van Cleef the safety problem has always been a difficult one to introduce in the smaller plants. I believe your plant employs about 150 people.

MR. VAN CLEEF: Not quite.

MR. SALISBURY: Have you some definite form of safety organization that you deal with?

MR. VAN CLEEF: Yes, we have, as a subsidiary to the organization I mentioned. We have in this organization the safety and social club. We have a number of committees, and they are, principally: A committee on safety, committee on fire prevention, and committee on personal welfare. The committee on safety brings in various suggestions.

This committee has sub-divided itself still further into a group consisting of a representative of each room in the plant, making about 20 who are called captains. and each one wears a pin designating him as a safety captain; and this safety captain has the authority, which comes from the house itself, to speak to any one he sees committing something against safe practices, and that has worked very well.

Members of the Committee Rotate Monthly

This committee rotates. Once a month there is a change. Of course, the safety committee puts on contests from time to time and makes a study of such accidents as we have and makes recommendations. In fact, the safety committees keeps one busy in trying to keep up with them in the way of correcting things around the plant that are likely to cause accidents.

I noticed among the pictures given here on "Knives and Shears," there was one covering a problem that we have, that is, how the calender and mill men should carry their knives. We ran into some difficulty there. We supplied the men with sheaths which were made out of leather, and were to be fastened with a string around the waist. It appears that the men do not like to wear them, they say they are too unhandy. We have to overcome that in some way. Does that answer your question?

MR. SALISBURY: Yes. Do you make periodical inspections?

MR. VAN CLEEF: Yes, the safety committee has one man who makes a trip around the factory once a week, examines all the fire equipment, and the chairman of the safety committee turns in to me a weekly written report, which is a form furnished by one of the insurance companies, indicating that all parts of the plant are in satisfactory shape, or otherwise; and then each one of these captains turns in a report about once every two weeks. The reports of the captains go to the safety committee for its consideration and are then brought to my attention.

E. W. BECK (United States Rubber Company, New York City): I would like to talk about the figures which Mr. Van Cleef gave this morning. What he says regarding the small plants is very true, and I think it is best illustrated from the figures which he showed.

In 1921, 1922 and 1923, we had a very good severity rate. That is, our days lost per thousand hours worked were fewer than for the years 1925 and 1926. A layman might presume that our safety work is going backward, that we are twice as bad as we were in 1921, 1922 and 1923. That is not so.

A careful analysis of those figures will show back in 1921, 1922 and 1923, the factories and companies that were submitting their statistics to the Statistical Committee of the Rubber Section were the larger companies, like Goodrich, Fisk, Goodyear and United States Rubber Company. Those larger companies, as Mr. Van Cleef stated, were pretty well organized in safety work and they were doing a pretty good job, judging from their severity figures.

We added other companies to those submitting figures. Naturally, they were the smaller companies, and their frequency and severity rates were terrible. When you look at the figures and see .65 as a severity rate, and then 1.11 and 1.17, there is an experience twice as bad; but it does not give you the picture of how much worse the smaller companies are than the larger companies.

I had occasion to consider our own factory. We had 30 factories represented in all those years, and when divorced from the hours worked, I got a picture of our own experience. I have done that each year, and I find it is the smaller factory that is pulling down the average. If you could see the severity and frequency rates for the small rubber factories you would be surprised. There is the big job, as you have stated. There is where we have to get out, roll our sleeves up to our elbows, and do some work. I feel it is our job to show those fellows the light. We can show it as a paying proposition from financial and economic points of view. It is not often that I mention the financial. So often, they are just looking at the dollars and cents. When they have insurance, they feel that is the insurance company's job, they are paying for it and paying a high rate.

I think you gentlemen should know that the experience of the industry, as a whole, is not as bad as it might look, because if you could take the larger companies which represent the large number of workers, I think you would find a much lower rate than that average of 1.11 and 1.17.

CHAIRMAN SCHNEIDER: I am sure Mr. Beck has outlined a true picture of that situation. The officers have known of that condition for some time. It has been discussed individually and collectively by our group, and we have also discussed it with insurance representatives, and I believe that is a true picture of the situation. So, as Mr. Beck says, we must roll our sleeves up and get to work. I think the smaller plants have a definite need for safety work, particularly in the rubber industry.

A Word in Defense of the Small Organization

MR. VAN CLEEF: I want to say one thing in defense of the smaller organizations when it comes to statistics. You take a small organization and it has one accident during the course of a month that causes a loss of a whole day. That ratio will seem very high because it is figured on the same man-hour basis that the larger organization is. The small organization might have a broken arm, and lay a man up for three weeks, and I think there ought to be something done about that phase so as to encourage the smaller organizations a little bit when it comes to statistics.

MR. BECK: What you say is true. I think that is due to the fact that you are using a severity or frequency rate that is more or less equalized. While our company has 30 or more factories, our best experience is in our smaller factories, because they haven't the exposure. Our larger plant, where Mr. Quirk is located, has a terrible time with new developments, new construction. That happens to be the tire end of it, and you know what has taken place in the tire industry. The Department of Labor in Washington, said the tire industry is the worst in the United States. I do not believe it. They used these figures that we have shown this morning, and these smaller plants are the ones that are pulling down this severity and frequency rate.

CHAIRMAN SCHNEIDER: I think what Mr. Beck says is true. I have to cooperate with him on that. It is true that the smaller factories are pulling down our rates, and, as he states, the method of computation is unfair, because the exposure is so much greater. The method of computation is also by an approved method, and approved by the Bureau of Labor. We have recently revised our method of reporting to make it more simple. Consequently, I believe we are getting as accurate reports as it is possible to get.

M. A. QUIRK (Morgan & Wright Plant, United States Rubber Company, Detroit, Michigan): I believe Mr. Van Cleef spoke about handling their knives. Some of our plants have a receptacle at the side of the mill for the men to put their knives in, or a sheath, with a metal clip, and hung on their belt. It fits on their belt and in that way, it is hung there without any trouble. Maybe, somebody else has some other method.

CHAIRMAN SCHNEIDER: Any other methods used?

DR. J. NEWTON SHIRLEY (Hood Rubber Company, Watertown, Mass.): The idle knife, from the medical viewpoint, is not the trouble-maker; it is the used knife. If there is a holder on the side of the machine, as a rule they use it, and we do not have the accidents when they do use it.

R. A. BULLOCK (Corduroy Fire Company, Grand Rapids, Michigan): We have the apron, without the bib, and the pocket where the carpenter usually keeps his ruler, a fabric lining is put in there and the man keeps his knife in that pocket. Some have a sheath made out of friction fabric and strap it to their belt, and it makes it real handy, out of the way, and no danger at all of any one being punctured with a knife.

CHAIRMAN SCHNEIDER: I think that is very interesting, indeed, for the reason that it makes it a part of the wearing apparel. However, I doubt if you could compel the workmen to use a certain garment.

MR. BULLOCK: Our men seem to approve of that garment, that way of wearing the knife.

Appointment of the Nominating Committee

MR. BECK: I would like to say that at the meeting of this Section, tomorrow, Mr. Congdon, chairman of the Engineering Committee, will give the report of his committee, and as secretary of the Rubber Code Committee, I would like every one to be present who possibly can be here, because you know the outstanding hazards in the rubber industry are the mill and the calender, and we have been successful in getting the unanimous approval of the entire Safety Code Committee in drawing up the code. I would like for you to be present to hear what Mr. Congdon has to say, and possible receive a copy of the Code that has been published.

CHAIRMAN SCHNEIDER: It might be well to announce, to save time, that the Nominating Committee has been appointed to select the officers for the coming year. The Nominating Committee consists of: Mr. H. T. Martin, The Fisk Rubber Company, Chicopee Falls, Massachusetts, chairman; Mr. E. W. Beck, United States Rubber Company, New York City; and Mr. E. A. Hoehner, The Firestone Tire and Rubber Company, Akron, Ohio. The Nominating Committee will render its report tomorrow morning.

Are there any questions any one would like to ask Mr. Beck before closing the meeting? I would like to ask Mr. Beck if he has any means of telling just what type of accidents they have on these plantations? I notice they are doing some wonderful health work, and I would like to know something about the accidents.

MR. BECK (United States Rubber Company, New York City): You asked me a question that I cannot very well answer. I have reports of all accidents in this country, but do not get many report of accidents at our plantations. I think those of you who are in the safety field can well imagine the nature of accidents that you get with employees working under the conditions they are working.

I am sorry that it was necessary to confine the exhibits to only four reels. Last year, we had two young men go to Sumatra to take these pictures. They spent several months over there and took 27,000 feet. You have seen 4,000 feet. You have seen very little. You have only seen a small portion of the medical reels, and I might say that the physicians and surgeons, not only in this country, but abroad, have

shown a great deal of interest in the work of the plantations, and we have had the films printed in foreign languages for their use.

As I say, I am not familiar with any of the accidents of the plantations. I do not go over there every month as I do to my factories. If any one goes there, I understand they make a complete trip around the world? I have seen a great many colored pictures of the plantations, and it is certainly a beautiful country.

CHAIRMAN SCHNEIDER: In closing, I just want to thank every one who has contributed toward this program, and I think and hope that next year we will have even a more successful program. Do not forget tomorrow's program. We have another portion that is just as good, if not better, than we had this morning.

ADJOURNMENT.

Wednesday, September 28, 1927

The second session was called to order at ten o'clock by the chairman, W. L. Schneider.

CHAIRMAN SCHNEIDER: The first matter on the program is the election of officers. As most everyone here knows, the duties of carrying on this work rests on individuals, who are elected and appointed each year for carrying on this work of the Rubber Section.

I would like to ask the chairman of the Nominating Committee, Mr. H. T. Martin, to render his report.

H. T. MARTIN (The Fisk Rubber Company, Chicopee Falls, Mass.): Your Nominating Committee wishes to submit the following report:

Chairman, R. C. Salisbury, The Fisk Rubber Company, Federal Division, Cudahy, Wisconsin. Vice chairmen, M. A. Quirk, U. S. Rubber Company, Morgan & Wright plant, Detroit, Michigan; Paul Van Cleef, Van Cleef Brothers, Chicago; E. A. Hoerner, Firestone Tire & Rubber Co., Akron, Ohio. Secretary and Chairman of Publicity Committee, E. R. Lawler, U. S. Rubber Company, Hartford plant, Hartford, Connecticut. Posters and Slides, H. W. Low, Miller Rubber Company, Akron, Ohio. Program, Harvey Willson, The Rubber Association of America. Membership, R. H. Cochran, Kelly-Springfield Tire Company, Cumberland, Maryland. Statistical, R. B. Harkness, The Cupples Company, St. Louis, Missouri. Health, Dr. J. Newton Shirley, Hood Rubber Company, Watertown, Massachusetts. Advisory, H. T. Martin, The Fisk Rubber Company, Chicopee Falls, Mass.; E. W. Beck, United States Rubber Company New York City; W. L. Schneider, The B. F. Goodrich Rubber Company, Akron, Ohio.

CHAIRMAN SCHNEIDER: You have heard the report of the Nominating Committee. What is your pleasure?

V. L. MEARS (Aetna Rubber Company, Cleveland, Ohio): I move the adoption of the report.

CHAIRMAN SCHNEIDER: The motion has been made to accept these nominations. Do I hear a second to that motion?

(Motion was seconded and carried.)

CHAIRMAN SCHNEIDER: The next on the program will be the report of the Engineering Committee, Mr. Congdon.

The Engineer's Opportunity for Safety

**J. E. Congdon, U. S. Rubber Company, New Haven, Conn.,
Chairman Engineering Committee**

The term "engineer" today is somewhat broad and to indicate the field of work the term "engineer" must be qualified. We have in the rubber industry all classes of engineers, including designing engineers, development engineers, safety engineers, plant engineers, etc. Each of these plays a contributing part in the advancement of safety.

The designing engineer in the drafting of a machine should include in the design safety guards properly placed and so arranged that they do not interfere with production and may be easily removed for overhauling the machine.

We all know that even today in some cases safeguarding is an after-thought and after two decades of propaganda there is considerable chance for improvement.

However, as illustrations of the advance in safety, I would mention the design of safety treads for stairs, the various safety locks on elevators, the use of safety trip-bars on mills and calenders, all of which are common enough today but a development of recent times.

The development engineer in the invention of new and untried processes and equipment should consider carefully whether or not there is being introduced hazardous conditions with which he is not familiar, and should guard against same not waiting for sad experience.

The safety engineer, or supervisor, a product of the last few decades, has not yet come into his own. Often he is limited in his sphere of work by not knowing what is being done until it is done. In this respect a closer cooperation between the various engineering branches of an organization would be of benefit to all. In fact, every engineer should be a safety engineer.

The plant engineer, superintendent of engineering, master mechanic, or man in actual charge of the mechanical operation of the plant, is the man who, if he will, can play a large part in the program of safety. Why do we say this? Most accidents are physical not mental. It is true that a great many accidents can be prevented by education, but modern inventions and developments have introduced conditions which still more than in the past require the attention of the plant engineer. Just to mention a few of these, pulverized fuel with its attendant explosive hazard, high tension electric current with the necessity of proper insulation, high pressure steam boilers with their greater need for watchfulness, the use of various new ingredients in compounding and the necessity for better ventilation, and so on through a long list.

Each Condition Must be Studied Individually

How is the engineer to safeguard the constantly appearing new conditions? Each condition should be studied by itself. Sometimes the mechanical fails, sometimes the human fails. On railroads accidents have occurred by the locomotive engineer not seeing signals, due to various reasons, and running by the signal set against him. In this case the human fails. To overcome this and similar accidents various systems of train control have been developed and are being installed at the present time so that if the human fails the mechanical would safeguard, thereby reversing the age-old adage of "the power of mind over matter," and showing the superiority of matter over mind in a specific case.

Grade crossing accidents in which automobiles are wrecked by locomotives are of common occurrence. We understand that magnetism has been used to stop an automobile automatically in case it approaches too close to a railroad track. Why not use this method for preventing a collision of automobiles?

The use of the radio and electricity are yet in their infancy. The passing of a hand over a tube starts a large steel plant operating miles away. Who shall say that it may not be possible in the future to stop a line of mills by thought waves?

But to get back to our daily task, what one thing has done the most to prevent accidents? Inspection—thorough inspection by a competent man and if a hazardous condition exists the correction of this hazard. It is true that we have a great many inspectors now, boiler inspectors, building inspectors, fire insurance inspectors, and through a long list, but do we have a competent safety inspector or inspectors of our manufacturing equipment?

It may be true that it is more difficult to inspect for safety on special manu-

facturing equipment than it is on standard equipment common to all, such as buildings, elevators and boilers, but such things as belts running so that they jump off the pulley, gear teeth becoming so badly worn that there is possibility of topping, the links on chain hoists becoming worn so that there is a possibility of breakage, and so on. These are generally inspected very casually, if at all, by some mechanic. Would it not pay, from a safety and financial standpoint, to employ a thoroughly competent and experienced Safety Inspector who would inspect regularly and thoroughly and be a Safety Inspector actually as well as in name?

During the past year the Committee has endeavored to spread the safety idea from an engineering standpoint to the various members of the National Safety Council rather than to write a paper on a specific engineering subject. In this way it was the thought that the most good could be done for the largest number.

As you know we have circulated letters giving information regarding the Safety Code for elevators, the suggested rules for the care of power boilers, the method of operating vulcanizer doors safely, guards for the protection of breaker caps, etc.

We regret to say that we have received no inquiries for an engineering investigation into any specific subject. It would seem that the large experience represented in the Rubber Section could be utilized to good advantage on engineering subjects through the Engineering Committee, and it was our thought in our last circular letter to emphasize this point and to see if during the coming year this could not be utilized.

The new Rubber Machinery Code is of vital interest to the Rubber Section and this code will be discussed at the meeting following this one.

The writer wishes to thank all those who have cooperated with the Engineering Committee for the past year and trust the same and more cooperation will be given to the chairman of the Engineering Committee of the coming year.

Further Cooperation is Emphasized

CHAIRMAN SCHNEIDER: I think Mr. Congdon has covered this subject very well. There is a very close need for cooperation between the engineer and the plant safety man. We all have our ideas, I think, in that respect. I know that the machine begins on the drawing board and the building begins on the drawing board, and the engineer usually specifies the materials that go into that machine and into the building. I think after the engineer has designed the machine and the building and it is built, it requires constant watchfulness by the safety inspector or plant inspector. I believe that the plant engineer is becoming more sold on safety each year.

The Section itself and the Council are carrying on very constructive work, editing pamphlets of all characters for the engineer, as well as the safety man, making the engineer a safety man.

Any remarks in connection with this subject that any one would like to make?

DR. J. NEWTON SHIRLEY (Hood Rubber Company, Watertown, Massachusetts): There is one thing that came to my mind, you mentioned safety appliances being inspected before being put into operation. How many people have a safety man inspect machines before they are put into operation to see that appliances are properly installed? That seems to me a fairly important question. I have seen several accidents where if proper inspection had been made before the machines were used they would, undoubtedly, have been avoided.

CHAIRMAN SCHNEIDER: Can any one qualify that question? Mr. Beck, I would

like to ask you what your method is in taking care of the new machine before being placed in operation.

E. W. BECK (United States Rubber Company, New York City): We fortunately have a development Department that makes an inspection of our equipment before being used, and those matters are watched in a safety factory all the time. Only last week, I had occasion to find a certain machine where the rolls when running idle were not far enough apart to allow a person's finger, if he got caught, to pass through, and I had occasion to bring the fact to their attention.

I think all developing engineers and all engineering departments when designing equipment should design it so that all moving parts, when they do come near a shoulder, that shoulder will be wide enough so that it will not pinch. I am speaking now of footwear machinery, where ladies are working on the small operations in connection with the making of shoes. I have found that our different departments, development, engineering and chemical, are always glad to accept those suggestions, and try to work them up.

I think if we safety engineers pay a little closer attention to those departments, before the equipment gets into the factory to see that it has the proper guards, we are going to make our job much easier. We are also going to help the person who operates that particular machine. I know the machine I have in mind now was slowing up production materially, the rolls had to be cleaned, it was not practical to stop the machine, and it would have been a simple matter to have a smaller roll, or to have had them a little farther apart. I feel, as Mr. Congdon does, that it begins on the board, for a great many other problems come into observation when the equipment gets into production. We have to work with the development engineers.

Inspect the New Equipment for Safeguards

CHAIRMAN SCHNEIDER: Any more remarks in connection with this question? I would like to hear from Mr. Martin.

MR. MARTIN (State Department of Ohio): I would just like to leave a thought with you which I know is in practice in some of the plants that I visit. That is, where new equipment is installed in the plant, that it be kept out of production until the Safety Division has approved this machine. They check the machine thoroughly as to safety appliances and proper method of operation. I think that will answer the doctor's question more than the other discussion that was brought up.

I understood the doctor to inquire what methods are practical and should be taken. Is that right, doctor?

DR. SHIRLEY: Yes.

MR. MARTIN: I think if the safety inspectors in the various plants are given the authority to hold up the machine until such inspection has been made, you will find that the machine will be in good condition.

R. C. SALISBURY (Fisk Rubber Company, Cudahy, Wisconsin): What do you advocate for small plants, where there is no safety department?

MR. MARTIN: I do not know. I would like to answer that just for the state of Ohio. Now, our state has a Division of Safety and Hygiene and any representative of that division is available to any of the small plants that have no safety division.

CHAIRMAN SCHNEIDER: I think the condition that Mr. Martin mentioned, in the first place, is an ideal one, when every one has to see that every piece of machinery or equipment is properly guarded before being placed in operation. When I say "ideal," it is not always possible. It is the goal that we are all reaching for, but we cannot always secure it.

The proper method is, no doubt, to see that the machine is fully equipped

in so far as possible to do so. Some hazards exist which we cannot foresee on the drawing-board and, perhaps, by inspection they would be discovered before being put into operation. Does that fully answer your question, doctor?

Dr. SHIRLEY: Yes.

H. T. MARTIN (The Fisk Rubber Company, Chicopee, Massachusetts): Just another step in there. I dislike to talk about what our company does, that we do so and so, but you cannot always avoid it.

The engineering department, in the organization with which I am connected, keep the safety division advised from the moment an authorization is made out to purchase a machine until it is installed. That gives the safety inspector an opportunity to keep in touch with it from the very beginning and the production department is not permitted to place any machine in operation until the safety inspector has said it is safe for operation.

CHAIRMAN SCHNEIDER: I think that condition is also ideal. The cooperation between the maintenance department, drafting department and production department is very necessary, so that there is no possibility of a machine being put to use unless it is fully guarded.

Opinions From the Smaller Companies

MR. SALISBURY: We have considerable representation of the smaller companies, and I think it would be well to hear from some of the members of the smaller companies. We are not reaching them, as evidenced by the fact that we have not a large membership in the Section of the smaller companies, and I would like to hear from some of the companies other than U. S. Rubber, Fisk, Goodyear, and so on. Mr. Mears, of the Aetna Rubber Company, might have something to say, Mr. Schneider.

V. L. MEARS (Aetna Rubber Company, Cleveland, Ohio): I think it is a very good idea to have the foreman of each department held responsible for any accidents that occur after a machine has been turned over to him. Here is a loophole and caused this to occur in our plant a few weeks ago. We bought a new machine under the guarantee to do the job, and we set it up, checked it, and it had all the guards on, so we turned it over to the department.

The operator of the firm from whom the machine was bought came along and had to make a few adjustments, took several guards off. I walked past the machine two days later, it was running and all gears exposed. That foreman heard a few things, and hereafter the foreman in each department is going to be held responsible for guards taken off in his department.

J. E. CONGDON (U. S. Rubber Company, New Haven, Connecticut): I think we can offer many helpful suggestions to the makers of machinery. I have in mind the tuber machine. It has a large gear, and I know it was three or four years before we could get the makers to make a solid guard. A man could not stick his hand through the guard. It was pointed out to the manufacturer repeatedly that the design of the guard was wrong. That applies to a lot of the machinery.

CHAIRMAN SCHNEIDER: I think Mr. Congdon has brought up a very important point. The machinery manufacturers do not, in all cases, comply with the best safety requirements. In some cases they do not even comply with the codes of the various states. We know it is a tremendous task to get the machinery manufacturers to comply with our codes. Prices on machinery alter the construction of the machine, and very often when they comply, the guards are very weak in structure and practically useless. I have seen any number of them with only a small piece of tin over the face of the gears when they arrived at the plants. We hope that the engineering field, which I think is largely responsible for that, will

bring about a better condition with regard to the safeguarding of machinery before it enters the plant.

MR. MARTIN (State Department of Ohio): May I just say a word in connection with this phase of properly safeguarding your equipment that comes into your plant, new. The discussion has brought out the fact of the necessity of cooperation of the engineering, manufacturing and production departments. One vital factor has been overlooked, and that is your purchasing agent of the plant.

Now, if your purchasing agent specifies that the new equipment which is purchased and is to be placed in your plant must comply with the requirements of the code of Safety Appliances as specified in the state in which it is to be used, you will get your equipment properly safeguarded to conform to said code. But the trouble is that your purchasing agent asks for bids on a certain machine of various companies, and he does not specify that this machine must comply with the safety requirements of the codes in which state it is to be used. If that were included, you would get your machine equipped properly.

I have heard those stories time and time again. I get into plants where they make specific machines used in our home state, and I asked the manufacturer, "Why don't you manufacture these machines to conform with our code?" And he replied, "If I did, I would lose one-half of my business." So it is the purchasing agent who must be included in the cooperative line.

CHAIRMAN SCHNEIDER: It is true that the purchasing agent has a direct bearing on the purchase of machinery in regard to specifications. On the other hand, the safety engineer should see that those requirements are embodied in the quotation.

There is one point that may be debatable in that connection, that is, the quality of the guards and accessibility of the machine itself. While we might say that a manufacturer should comply with the requirements of a code, some other firm may have some particular reason for guarding that machine in a different manner from the manufacturer. It may be more convenient and may find some particular reason for mounting certain motors or some other added equipment to it which may make it better for the manufacturers to guard the machines themselves.

Any further discussion? If not, we will proceed with the program.

The next item on the program is the report of the Statistics Committee. Mr. Mansfield is unable to be here, so Mr. Kidney, of the Goodyear Tire & Rubber Co., will read the report.

Report of the Statistical Committee

We have often read statements regarding the number of industrial accidents and the economic losses due to them. Accident costs, operation of hospitals, compensation expenditures and loss in production all form a very important item in the cost of doing business. The everyday citizen may read in a paper or magazine that statistics show that over three million accidents, of which approximately 24,000 proved to be fatal, occurred last year in our industrial plants and mines.

The above figures to a certain extent may be a bit misleading to the average person who may not understand the methods of tabulation. Industrial accidents are not only applied to industrial plants, but to each and every gainful occupation. The word "accident" does not necessarily mean that an employee was seriously injured, but accidents as tabulated by the Sections of the National Safety Council, may be comparatively slight and of only two or three days' disability. For this reason we list accidents by frequency and severity.

Ten years ago it was almost an impossibility to get satisfactory accident

data from industrial concerns. Now we see a marked progress in the keeping of records, the tabulation of minor and major injuries, and a more friendly spirit of cooperation in the safety movement in the industry.

Some three years ago it was suggested that a more lengthy form should be used in tabulating accidents for the Rubber Section; a form whereby one could read how the accident occurred, the nature of injury and the cause of the accident. Such forms were made up and put in use. On account of the length of time it required for the completion of this form, we were unable to increase our list of reporting members and it seemed advisable to make a change to a form which would be a one page affair, with the necessary information to render a good report of our accident experience for the year. For the past year we have been using the regular printed form prepared and furnished by the Council, and in use by the majority of the other Sections.

In our summary report for the last year we have three divisions under the following headings: Footwear, Tires and Miscellaneous. We were able to get reports from 32 members as compared with 22 of the preceding year. This is an indication that the shorter form is more satisfactory. We are looking forward for a gain in the reporting of members for 1927.

Fewer Employees But More Hours Worked

The average number of employees in 1926 is somewhat lower than in 1925, which is no doubt due to more efficient methods of production, installation of conveyors, etc. The number of hours worked has increased considerably which may be due to a more steady business condition and less labor turnover in the Rubber Industry. There is a slight increase in temporary injuries amounting to 259, which of course has a tendency to increase our days lost. The percentage of frequency for 1925 was 29.15 which has increased to 30.09 in 1926. The percentage of severity also shows a rise from 1.11 in 1925 to 1.17 in 1926.

Taking into consideration the fact that the above figures include ten additional plants, some of which do not have a safety organization, we feel that the work of the Rubber Section has progressed in every respect. With the hearty cooperation of each member we can have a more complete report for 1927, which will be due after January 15, 1928.

Due to the vast difference in the products and working conditions in the different Sections of the Council, we can make no real comparison in the Sectional reports. For the benefit of those who have not received the annual report of the statistical division of the Safety Council, we have copied the following figures relating to severity:

Textile	.64
Rubber	1.17
Automotive	1.37
Power Press	1.39
Food	1.40
Packers and Tanners	1.75
Paper and Pulp	1.95
Chemical	2.28
Metals	2.44
Petroleum	2.47
Cement	3.97
Public Utilities	4.32

Woodworking	4.51
Construction	5.44
Quarry	7.04
Mining	8.47

S. MANSFIELD, Chairman.

MR. J. KIDNEY (Goodyear Tire & Rubber Co., Akron, Ohio): I am going to take this opportunity to talk a little safety myself. This is my first attendance at any Safety Congress, and I have been very much interested in it. I do feel, also (not wishing to brag), that we have the best organization in the country. In spite of that, our frequency still stays up, and I am going to try to talk with all the rubber men here in the hope of finding out what runs that frequency up. Having been on the job only three months, I get a lot of impressions that, maybe, you fellows who have been in it a long time do not get, and I have been listening with a great deal of interest to all that has been going on.

I think that the educational program of safety is the most important. I think it is more important than engineering or guards or anything else, and I think that we should have some discussion on that. I am not going to take up any more of your time.

Satisfaction With the Section Standing

CHAIRMAN SCHNEIDER: I think we all enjoyed the remarks of Mr. Kidney and the report of Mr. Mansfield. I know that Mr. Mansfield has given this job considerable thought and study, and he has also worked on the committee.

I do not believe that it will be necessary to discuss this further, with the exception of the fact that the gain from 22 to 32 reporting members, as mentioned yesterday, I think had some bearing on the increase in severity, for the reason that we feel that there have been a number of plants that do not have a full safety organization. At least, they are young in the field. I have reason to believe, myself, that that has a tendency to bring up our severity rate slightly.

I think, however, every one here should feel proud of the Rubber Section which according to the figures which the Council has compiled, ranks second highest of all the industries covering a period of over six billion hours. I think that is a very favorable comment and we should be proud of it.

J. KIDNEY (Goodyear Tire & Rubber Co., Akron, Ohio): I would like to ask what is the secret about some of the accident figures that some of the companies won't report.

MR. BECK: I am probably as much interested as any one in the question of statistics. I think that if we analyze our statistics properly we can get a lot out of them.

To answer Mr. Kidney's question, there are some companies that do not like to accept the standard of time losses for permanent disability. They do not like to say a death is responsible for six thousand days, the loss of an eye is responsible for so many thousand days. They like to feel that a death is no days lost, because the next day they put a man in his place. When you have factories figuring severity and frequency rates that way you cannot get very far. You have to have all factories using the same scale of time losses.

There are some factories that have a very good hospital, and a staff of doctors and nurses connected with their organizations. Those doctors and nurses like to feel they can get the man back on the job quicker than anybody else. For that reason, they feel they should be given credit. I do not agree with them.

I have been the one who opposed the complicated reports on statistics. If we are going to get more companies to come in on this question of statistics, we have

to make it simple, cannot give them a complicated form to fill out, and expect them to do it willingly. We have to start in a small way and get them interested.

To come back to the question of a large factory, when a man loses a finger, no infection sets in, and he only loses seventeen and one-half days, that is all they should be charged with. We charge the scale for the loss of that finger. A loss is exactly the same in Ohio as a loss in Massachusetts, Connecticut or any other state. The fact is that you are not going to get anywhere unless you agree that the loss of a finger is the loss of a finger, regardless of the state in which it takes place. That is the reason some of the factories have not come in with their reports.

Mr. Congdon asked me to say a word about the number of factories reporting. You stated there was an increase. Some of you may not know in the past the large companies have been reporting all their figures from all their plants as one severity rate and one frequency rate, and the National Safety Council is now trying to get United States Rubber Company, Fisk, Goodyear, Goodrich, and so forth to submit their figures for each unit, rather than for the company as a whole. Their idea being, of course, to show more factories and give a larger spread. I know in our company, where we have over 30 factories, you would probably not get the picture that you wanted if we gave you a severity rate of .75, because in our company we have all kinds of factories, making even hardware, regenerating, footwear, mechanical and tire. So I think our statistics should go farther, the rate for the industry, might break it down into groups, the groups that I mentioned might be a good break at first.

I feel that we should take these statistics more seriously and see if we cannot get something out of them. The only way I justify my existence is by my statistics. If I could not prove my work with statistics, I would feel I was not doing my job.

CHAIRMAN SCHNEIDER: We all have a big job ahead of us. The statistical field has only been scratched. I think the Statistics Committee has a life-size job ahead of them. The fact that we have 32 reporting companies instead of 22, last year, does not mean a great deal if we are not getting the meat out of it. It is getting the meat from these statistics that we require. It is true that they must be necessarily simple. We must have a standard method of reporting these figures.

The next item on the program will be "Health Hazards of Compounding Materials." We have with us today, Mr. Healy, of the Fisk Rubber Company, who has spent a great deal of time in the preparation of this paper. It gives me great pleasure to introduce Mr. Healy.

Compounding Materials Used in the Rubber Industry— Their Classification and Health Hazards

L. J. D. Healy, Fisk Rubber Company, Federal Division, Cudahy, Wis.

The object of this paper is to bring before this Section of the National Safety Council the nature of some work which the Health Hazards Committee is now engaged in carrying out to provide authentic data on the hazards and proper handling of compounding ingredients used in the rubber industry. With the rapid strides being made in safety work to safeguard the health and lives of the nation's workmen, we find that the more obscure type of hazards is being brought to light. The early endeavors of safety work were largely along the lines of mechanical safeguards to protect workmen against injury from exposed machinery. This was natural in view of the fact that accidents from this cause were usually violent and made rapid and deep impression upon the minds of victims and witnesses. The causes of such accidents as well as results were well defined. In many of the cases the

cause of accident was due to exposed machinery; in others it was carelessness or both. The remedy for exposed or poorly constructed machinery was apparent to both operative and employees and in most cases the hazard could be overcome by some protective mechanical device or guard.

The question of carelessness was a problem which required more thought and could be attacked only by a process of education, a process which required time for its accomplishment, but which, thanks to the intensive work of the National Safety Council, is making rapid headway.

Hand in hand with the elimination of mechanical hazards and the eradication of carelessness, we have had the development of sanitary protective measures. This is another process of education. An attempt to have the workman use his head to think before he acts, to take inventory of himself, to realize the value of his health and to protect his body against disease and injury. This is a slow process of education and evolution but has already borne much fruit as can be attested to by our accident and health statistics and by the adoption of intelligent compensation laws. The work of the National Safety Council becomes more and more a fight against ignorance and the proper education of both employer and employee.

The Obscure Hazard is Most Dangerous

The more obscure any hazard, the more insidious and dangerous it is, especially if it be of a type to slowly affect one's health. This slow insidious burrowing from within is a monster to be feared—its presence is often unknown until irreparable damage has been done or even death occurs. There are many hazards of the latter type still present today in our industrial processes. Many substances are in use which neither the manufacturer nor employee recognizes as being dangerous. This is especially true in smaller industries where technical advice or medical services are lacking. These substances are to be feared and rightly so inasmuch as contact with or improper handling of them may cause a slow breaking down of the body structure which cannot be corrected if allowed to continue for too long a period. How often have we witnessed a case where a man's health has been impaired in early life by some toxic compound, often to the point where disease has fastened its deadly grip upon his emaciated body. A life sacrificed to ignorance.

These are the problems to which we must also turn our attention. Much good work has been done but there is still more to do. It is a process of investigation and education. We must first ferret out these insidious substances and educate both employer and employee as to how to handle them with safety.

The rubber industry is one in which a great many and varied types of compounds are used. An inventory would probably reveal several hundred different compounds in use for compounding rubber, many of them in quite general use. Amongst this large number we know that some are very dangerous to the health of those handling them unless precautionary measures are taken. There are others about which comparatively little is generally known. Some manufacturers are apparently absolutely ignorant about the properties, toxic or otherwise, of many of the substances they are using. With the increasing use of organic substances for vulcanizing rubber there is an ever present danger of health hazard unless the toxic and irritating properties of these substances are known. There is a tendency for many manufacturers of chemicals to place rubber accelerators and compounding ingredients upon the market under fancy trade names. This may be done to disguise the true nature of the substance, especially if the latter has toxic properties. It is a practice to be discouraged unless the producer is

willing to state the exact chemical nature of the compound. If he is unwilling to do this, he should at least stand back of his product and guarantee it to be free from toxic and all other properties injurious to one's health.

The manufacture of rubber, while requiring heavy machinery and the use of many and varied chemicals, should be no more hazardous than any other line of manufacturing where heavy machinery is involved. In fact, it should be and can be made less hazardous than most lines of manufacturing if proper precautions are taken. The machinery used is mostly slow moving compared to many industries and is adaptable to being well protected to safeguard the operatives. The chemicals used can all be handled in a safe manner provided their toxic and chemical properties are understood and efficient methods of handling are employed. Many poisonous chemicals used in the past are fast being replaced with non-poisonous compounds and there is no reason why the manufacture of rubber goods cannot be carried out under the safest and most healthful of conditions.

To Stimulate Interest in the Industry's Poisons

It is with the hope of stimulating more interest along these lines that this paper has been prepared. Until very recently there has been an utter lack of definite data concerning many of the compounds used in the rubber industry. At best, information pertaining to nature of these compounds is widely scattered and in many cases very meager. In a few outstanding instances the ground has been very well covered especially in the handling of certain lead compounds and benzole. The splendid work done by the combined Rubber & Chemical Sections of the National Safety Council on Benzole is an excellent example of what can be done to educate the manufacturer in the proper handling of these chemicals so as to prevent injury to those using them.

This paper is more in the nature of a proposition for classifying and describing the nature of the various compounds used in rubber manufacture.

In preparing this paper the writer has endeavored to compile in a compact and correlated form such data as will be useful as a reference and which will indicate the hazards to be avoided in handling the materials used in the rubber industry. For this purpose the rubber compounds have been divided into four groups:

- 1—Accelerator and Dry Organic Compounds.
- 2—Dry Inorganic Compounds.
- 3—Gums, Resinous Materials and Waxes.
- 4—Liquids and Gases.

Each compound is classified alphabetically and cross indexed where different names are used for the same material. Under this grouping, each compound or chemical is described:

- 1st—As to its origin, identification and chemical characteristics.
- 2nd—Its general use in the industry, especially as to its use in the rubber industry.
- 3rd—Its health hazards in the rubber industry and any suggestions, if necessary to reduce or eliminate such hazards.

This material has been condensed as much as possible for quick reference work but is complete enough to show the chemical nature of these compounds and the care with which these should be handled to prevent an impairment of health. References are appended so that more detailed information may be obtained where necessary, especially in the case of the more toxic substances.

A considerable number of the organic accelerators under Group 1, and two in organic compounds of Group 2, have been completed and the data attached hereto. These will give a general idea of the way in which we propose to compile this data.

GROUP I

Organic Accelerators and Dry Organic Compounds

Aldehyde Ammonia
Alpha-naphthylamine
Anhydro-formaldehyde-aniline (See Methylene Aniline)
Anhydro-formaldehyde-paratoluidine (See Methylene paratoluidine)
Aniline
Beta-naphthylamine
Dimethylamine-dimethyl-dithiocarbamate
Diorthotolyl-guanidine
Diorthotolyl-thiourea
Diphenyl-guanidine
Diphenyl-thiourea—(See Thiocarbanilid)
Ethylidene Aniline
Formaniline—(See Methylene Aniline)
Formaldehyde-aniline—(See Methylene Aniline)
Heptaldehyde Aniline
Hexamethylene-tetramine
Lead oxidation product of dimethyl-dithio-carbamic acid
Methylene aniline
Methylene-dianilide—(See Methylene-diphenyl-diamine)
Para-phenylene-diamine
Methylene-ditolyl-diamine
Methylene-para-toluidine
Mercaptobenzothiazole
Ortho-toluidine
Para-nitroso-dimethylaniline
Para-phenylene-diamine
Para-toluidine
Phenyl-tolylguanidine
Piperidine-pentamethylene-dithiocarbamate
Quinoidine
Tetramethyl-thiuram-disulphide
Tetramethyl-thiuram-monosulphide
Thiocarbanilid
Toluidines—(See Ortho and Para Toluidine)
Triphenyl-guanidine
Zinc-butyl-Xanthate
Zinc-ethyl-Xanthate
Zinc-isopropyl-Xanthate
Zinc-oxidized salt of dimethyl-dithio-carbanic acid

GROUP II

Dry Inorganic Substances

Aluminum Flake
Ammonium Carbonate
Antimony—(See Antimony Sulphides)
Antimony Sulphides

Asbestine
 Asbestos
 Barium Dust—(See Barium Sulphate)
 Barium Sulphate
 Blank Fixe—(See Barium Sulphate)
 Barytes—(See Barium Sulphate)
 Beckton White—(See Lithopone)
 Blank Fixe—(See Barium Sulphate)
 Blue Lead—(See Lead Compounds)
 Cadmium Yellow
 Calcined Magnesia—(See Magnesium Oxide)
 Calcium Chloride
 Carbon Black
 Carbonate of Ammonia—(See Ammonium Carbonate)
 Carbonate of Magnesia—(See Magnesium Carbonate)
 Caustic Soda
 Chalk—(See Whiting)
 China Clay—(See Clays)
 Chrome Green
 Chrome Yellow
 Clays
 Crimson Antimony—(See Antimony Sulphides)
 Diatomaceous Earth—(See Infusorial Earth)
 Emery
 Fossil Flour—(See Infusorial Earth)
 French Chalk—(See Talc)
 Fuller's Earth
 Golden Antimony—(See Ant. Sulphide)
 Graphite
 Ground Glass
 Gypsum
 Hard Rubber Dust
 Heavy Magnesia—(See Magnesia Oxide)
 Hypo—(See Lead Compounds)
 Iron Oxide—(See Red Oxide)
 Infusorial Earth
 Kaolin—(See clays)
 Light Magnesia—(See Magnesia Carbonate)
 Lamp Black
 Lead Compounds
 Blue Lead
 Lead Thiosulphate
 Hypo
 Lead Oleate
 Lead Oxide
 Litharge
 White Lead—Sublimed
 White Lead—Basic
 Lime
 Litharge—(See Lead Compounds)
 Lithopone
 Magnesia Carbonate
 Magnesia Oxide
 Mica

Oxide of Magnesia—(See Mag. Oxide)
Oxide of Iron—(See Red Oxide)
Paris White—(See Whiting)
Plaster of Paris—(See Gypsum)
Plumbago—(See Graphite)
Pumice
Prussian Blue
Red Oxide
Red Ochre
Rotten Stone—(See Infusorial Earth)
Silica
Slate Flour
Sodium Hypo Sulphite
Soapstone—(See Talc)
Sulphur
Talc
Tripoli—(Infusorial Earth)
Ultra Marine Blue
Umbar
Venetian Red
Vermilion
Whiting
White Lead Basic—(See Lead Compounds)
White Lead Sublimed—(See Lead Compounds)
Yellow Ochre
Zinc—(See Zinc Oxide)
Zinc Oxide
Zinc Sulphide
Zinc Yellow

GROUP III

Gums, Oils, Resinous Materials and Waxes

Asphalt
Balsam—(See Canada Balsam)
Beeswax
Bitumen
Brown Sub
Burgundy Pitch
Canada Balsam
Carnauba Wax
Castor Oil—(Sub)
Ceresin
Coal Tar Pitch
Colophony
Corn Oil
Cotton Seed Oil
Degras
Gilsonite
Glucose
Glue
Guayule
Gutta Percha
Hardwood Pitch

Hydrolene
Lard Oil
Latex
Linseed Oil—(Sub)
Mineral Oils
Mineral Rubber
Montan Wax
Naphthaline
Oil Substitutes
Organic Dyes
Ozokerite
Palm Oil
Paraffine Wax
Petrolatum
Pine Tar
Pine Tar Oil
Pitches
Pape Seed Oil
Rosin
Rosin Oil
Rubber
Shellac
Stearic Acid
White Substitute
Wood Tar
Wool Grease—(See Degras)

GROUP IV
Liquids and Gases

Liquids:

Acetic Acid
Alcohol
Ammonia
Benzole
Carbon Bisulphide
Carbon Tetra Chloride
Chloroform
Coal Tar Naptha
Ethylene-di-chloride
Gasoline
Glycerine
Sulphuric Chloride
Sulphuric Acid
Toluol or Toluene
Turpentine
Xylol

Gases:

Chlorine
Hydrogen Sulphide
Sulphur Chloride
Sulphur-di-oxide

Aldehyde Ammonia

Origin & Constitution:

Aldehyde Ammonia belongs to that class of compounds known as the amine-aldehyde group and has the formula C_2H_5O, NH_3 . It is prepared by the action of dry ammonia on acetaldehyde. It can be crystallized from an ethereal solution. When pure it is a colorless crystalline solid with a melting point of 70° - $80^{\circ}C$. It is quite stable in closed containers but rapidly turns brown and becomes resinous when exposed to the air. The commercial product varies from a fairly white powder to a dark brown viscous, resinous mass and is liable to show considerable variation in composition. On heating aldehyde ammonia, it readily decomposes into ammonia and acetaldehyde.

Uses:

Formerly Aldehyde Ammonia was quite extensively used as an accelerator for vulcanizing rubber. It was one of the early organic accelerators to replace aniline and gave quite satisfactory results although the commercial grades could not always be relied upon for uniformity. It belongs to the class of moderately powerful accelerators but is fast being supplanted by the more stable and powerful type of accelerators. From one-half to one per cent on the rubber is the amount ordinarily used for accelerating purposes. It is added to the rubber, during the mixing operation on the mills.

Health Hazards:

Aldehyde Ammonia gives off a small amount of fume and a disagreeable odor during the mixing and calendering operations. This odor is quite nauseating to some workers, but is one to which the operatives become accustomed. Where used, it is advisable to use suction hoods over mixing mills and calendars. At no other place in the factory is the odor noticeable and beyond this disagreeable odor in the mixing and calendering operations, no harmful effects of its use have been reported. (Hamilton P. 432). Its health hazard is not serious and no precaution need be taken other than to remove by suction the small amount of fume thrown off during the mixing and calendering operations.

Alpha-Naphthylamine

Origin & Constitution:

Alpha-Naphthylamine is a white crystalline powder having the composition $C_{10}H_7NH_2$ with the aniline radical in the alpha position. It has a melting point of $50^{\circ}C$ and a specific gravity of 1.223. Upon exposure to light and air it discolors, turning to a purplish gray. It is almost insoluble in water, but is readily soluble in alcohol, ether or aniline. It has a characteristic unpleasant odor.

Uses:

Alpha-Naphthylamine is used in the manufacture of synthetic organic compounds. It has been used in a small way as an accelerator for rubber goods. Its accelerating powers are comparatively weak and it finds but little application in the rubber industry due to its disagreeable odor.

Health Hazards:

Alpha-Naphthylamine is relatively non-poisonous, although it is capable of producing symptoms characteristic of Anino compounds. No serious cases of poisoning have been reported even in chemical industries where the substance is used in much larger quantities than in rubber manufacturing. (See Hamilton, 1924—P. 510.) For rubber work, small amounts equal to approximately 1 or 2 per cent of the weight of the rubber are used. This is weighed out in the Compound Room and thrown onto the mills with the other powders during

in mixing operations. Being a powder, it is easily handled and worked into the rubber. It is not used to any extent in the rubber trade today and its health hazard is very small.

Aniline

Origin & Constitution:

Aniline also known as Aniline Oil, when pure is a colorless oily liquid. Upon exposure to light and air, it turns to a reddish brown color. The commercial product is usually of a light brown color and has a characteristic aromatic odor. It has a formula $C_6H_5NH_2$ and is prepared by reducing nitro-benzene with nascent hydrogen. The latter is carried out by heating the nitro-benzene in the presence of iron filings and hydrochloric acid. The excess acid is then neutralized with milk of lime and the resulting product steam distilled.

The commercial product often contains impurities such as traces of water, nitrobenzene hydrocarbons and toluidines. It has a specific gravity of 1.027 and boiling point of $184^\circ C$.

Uses:

Aniline plays an important part in our chemical industry. It is one of the basic raw materials used in the synthesis of many chemical compounds, including many dyestuffs and organic rubber accelerators. It is probably best known in connection with the aniline dye industry. It was the first organic accelerator to be used commercially in the vulcanization of rubber and was used extensively for quite a number of years, being at its peak a decade ago. Its use in the rubber industry, however, has steadily fallen off the past ten years, due largely to its toxic properties, and the advent of more powerful and less toxic accelerators.

The use of Aniline brought about a revolution in the rubber industry, its use being the greatest improvement in vulcanizing rubber since the discovery of vulcanization by Goodyear.

Aniline is a relatively weak accelerator when compared with the accelerators of the present day. However, it has valuable properties as a softener in mixing and imparts excellent ageing properties to the finished goods. Were it not for its strongly toxic properties, its use would no doubt be very large even today.

Health Hazards:

Aniline is exceedingly toxic. It is a volatile poison, affecting the nervous system and acting destructively upon the red corpuscles. The poisoning may be absorbed through the skin by direct contact or from saturated clothing or inhalation of the vapor given off during mixing and calendering, and also by way of the digestive tract.

The first symptom of aniline is pallor, which soon changes to a striking bluish color, especially in the lips. There is usually severe headache and general weakness, and if the exposure to the fumes continues, loss of consciousness, which may be prolonged alarmingly. It is not necessary that the exposure to aniline fumes be long continued or intense for serious symptoms to ensue.

While comparatively few deaths from aniline poisoning have been reported in the rubber industry, there have been many serious and chronic cases. Where death has occurred, it has usually been through absorption of the poison through the skin, this occurring where the worker has had his clothes become saturated with the oil.

The oil is received in drums which are opened in the weighing room. Here the oil is weighed out in tins and carried to the mixing mills. The weigher is in danger of getting the oil on his hands or clothing. He should wear a rubber apron and rubber gloves. The latter should be kept clean both inside and out.

It is advisable to have a suction in order to draw vapors away from the weigher, since the oil is volatile at a room temperature. The oil is added to the rubber on the mixing mills by pouring it slowly onto the rubber as it is being masticated between the rolls. Considerable fuming occurs here, due to the heat of the rubber batch volatilizing the oil. The mill should be hooded and provided with powerful suction, since aniline fumes are heavy and are difficult to remove. Hence, the mills should be completely enclosed except for the space where the operator works. Under the best conditions, there is still danger of inhaling some of the fumes, as well as absorbing the aniline through the hands, while cutting the rubber on the mill.

At the warming and calendering operations, a great deal of fume arises and it is here where some of the most serious cases have been reported. The calender temperatures are relatively high, causing excessive volatilization of the accelerator. The calenders should be well hooded and provided with powerful suction. It is more difficult to hood the calenders than the mills, and for this reason calender operators are in considerable danger of exposure to the vapors.

The use of alcohol, even in moderation, increases very much the susceptibility to these fumes. Hot, muggy weather also increases the dangers of aniline poisoning.

The aniline is added only in small amounts to the rubber, usually in the proportions of from 1 to 3 per cent. Hence there is comparatively small danger of poisoning throughout the subsequent operations. If proper precautions are taken in weighing out and during milling and calendering operations, the hazards are reduced to a minimum, although they cannot entirely be overcome. It is for this reason largely that aniline is being fast replaced by the less toxic accelerators.

Because of the secrecy which formerly shrouded the rubber compounding processes, it was very difficult to properly diagnose the earlier cases of aniline poisoning. Aniline poisoning in rubber factories has been thoroughly studied during the past ten years and very complete data has been tabulated. This will not be dwelt further upon here, but complete data may be found in the following:

U. S. Bureau of Labor Statistics—Bulletin 179—Industry Poison Used in the Rubber Industry.

Hamilton—Industrial Poisons in the U. S., 1925.

Kober & Hayhurst—Industrial Health, 1924.

Beta Naphthylamine

Origin & Constitution:

Beta Naphthylamine is a white crystalline powder having a composition $C_{10}H_7NH_2$ with the aniline radical in the Beta position. It becomes brown upon exposure to light and air. It has a melting point of $112^{\circ}C.$ upon a specific gravity of 1.06. It dissolves in hot, but only sparingly in cold water.

Uses:

Beta Naphthylamine is used in the manufacture of synthetic organic compounds. It is also used to a small extent as a rubber accelerator. It is, however, only slightly stronger than aniline and suitable only for the dark colored goods, since light rubber goods are discolored by the use of this compound.

Health Hazards:

Beta Naphthylamine is relatively non-poisonous, although, as in the case of Alpha Naphthylamine it is capable of producing symptoms characteristic of amino compounds. According to Hamilton, men coming in contact with Beta Naphthylamine in chemical factories have been known to suffer from both cyanosis and micturition. No cases of poisoning have been noted in the rubber industry,

no doubt due to the small amount used and on account of but little danger of exposure.

The material is weighed out as a powder in the Compound Room and mixed with the other powders upon the mill. Only about 1 per cent is used. The powder has very little tendency to fly, and the health hazard, when used in the rubber work, is negligible. The material is no longer used to any extent in the rubber manufacture, having given way to the cheaper and more powerful accelerators.

Hamilton, 1925—P. 510.

Dimethylamine-Dimethyl-Dthiocarbamate

Origin & Constitution:

D. D. D. is a reaction product of dimethylamine and carbon disulphide. It is a white crystalline solid readily soluble in water and having the formula— $(CH_3)_2N.CS.SNH_2(CH_3)_2$. This accelerator belongs to the class known as ultra accelerators, which are very active at low temperatures.

Uses:

D. D. D. is used as an accelerator for vulcanizing rubber. It is one of the most active accelerators known, but requires a small amount of Zinc Oxide to promote the reaction. It is used in extremely small amounts, only a fraction of 1 per cent being required for vulcanization. Using larger amounts, vulcanization has been found to take place at room temperature over a period of several weeks.

This accelerator has attained only limited application in the rubber industry due to its very powerful action and the low temperature at which it works. The latter is too low for the usual milling and calendering operations. It may be added to the rubber in the solid form by means of a master batch or the salt may be dissolved in water and the solution used for soaking the rubber.

Health Hazards:

D. D. D. has been used to a very limited extent and to date no ill results have been reported. Its toxic properties are small and the material can be so handled in the form of master batches, that the health hazard should be negligible.

Di Ortho Tolyi Guanidine

Origin & Constitution:

D. O. T. G. is a white crystalline powder, having but slight odor, with a specific gravity of 1.10 and a melting point of 171° to 175°C. For rubber work it should be ground to approximately 200 mesh. It is slightly soluble in rubber, is quite stable when exposed to air and light, and does not readily volatilize. D. O. T. G. is insoluble in water and does not readily absorb moisture from the air. It is prepared by the action of ammonia upon di-ortho-tolyl-thiourea, in the presence of a lead compound and has the formula, $(CH_3.C_6H_4.NH)_2C:NH$.

Uses:

D. O. T. G. is used primarily as a rubber accelerator and is one of the most popular accelerators used at the present time in the manufacture of tires, tubes, mechanical and non-blooming rubber goods. It is one of the most active of the so-called high and medium temperature curing accelerators. D. O. T. G. is ordinarily used in the proportion of from ¼ to 1 per cent on the rubber, and at temperatures ranging from 270° to 320°F. The accelerator is practically odorless, does not readily volatilize during mixing and calendering operations and can be handled without danger of scorching the stocks. It is for this

reason, as well as its low curing cost, that this accelerator has become popular.

Health Hazards:

D. O. T. G. is weighed out in the compound room as a dry powder in small amounts, usually not over $\frac{1}{2}$ of 1 per cent on the rubber. It is practically odorless, does not absorb moisture and is non-poisonous and non-irritating to the skin. The powder is mixed on the mill with the other ingredients, being quickly absorbed by the rubber without fumes. It is one of the safest accelerators to use and no ill effects from its use have been reported.

Di Ortho Toly Thiourea

Origin & Constitution:

Di orthotolyl thiourea is a white crystalline powder having a specific gravity of 1.25 and a melting point of 144° to 148°C . The commercial salt may contain, as impurities, small amounts of mixed toluidines and aniline. It is slightly soluble in rubber and insoluble in water and does not take up the moisture readily from the air. Di orthotolyl thiourea is prepared by the action of carbon disulphide upon ortho-toluidine and has the formula $(\text{CH}_3\text{C}_6\text{H}_4\text{NH})_2\text{C}:\text{S}$.

Uses:

Di orthotolyl thiourea is used chiefly as a rubber accelerator, but its use is not very great except for a few special lines, such as rubber shoes, mechanical goods and specialties. It is very similar to Thiocarbanilid in its characteristics, being, however, somewhat more powerful. The presence of zinc oxide seems necessary for proper acceleration. This accelerator scorches on both mills and calenders at very low temperatures, and for this reason it is not practical for many purposes. It is a comparatively cheap accelerator and can be used for white goods to good advantage where scorching difficulties are not encountered.

Health Hazards:

Di orthotolyl thiourea being a dry, white powder, can be readily handled in the compound room without danger. It is weighed out in the usual manner in small amounts up to one or two per cent. During the mixing and calendering operations there is some decomposition resulting in vapors having a very pungent odor. Mills and calenders should be headed to remove these vapors. During vulcanization decomposition products are evolved in the form of obnoxious vapors which are objectionable to the operatives.

The same precautions should be taken here as noted on Thiocarbanilid. No serious hazards are involved with proper precaution.

Diphenylguanidine

Origin & Constitution:

Diphenylguanidine is a white crystalline powder, having a specific gravity of 1.13 and a melting point of 144° to 147°C . It is insoluble in water and does not readily take up water from the air. For rubber work, it should be ground to approximately 200 mesh. D. P. G. is slightly soluble in rubber, has no perceptible odor and is very stable when exposed to light and air. It is prepared by the action of an ammonium salt upon thiocarbanilide in the presence of a weak base such as zinc or lead oxide and has a formula $(\text{C}_6\text{H}_5\text{NH})_2\text{C}:\text{NH}$.

Uses:

D. P. G. is used largely as a rubber accelerator. It is a very active accelerator at ordinary curing temperatures, and is one of the most widely used at the present time. Until quite recently, it was probably the most widely used

of any of the accelerators. It is gradually being supplanted by lower temperature accelerators.

D. P. G. is an ideal accelerator for nearly all classes of rubber goods, including white and colored goods. It has no perceptible odor and does not volatilize during the milling and calendering operations, and is non-poisonous. It is used in the proportion of about $\frac{1}{2}$ of 1 per cent on the weight of the rubber and is especially well adapted for low sulphur and non-bloom stocks. It imparts good ageing qualities to rubber goods.

Health Hazards:

Being a dry, non-hygroscopic and non-irritating powder, D. P. G. can be easily handled without hazards. It is weighed out as a dry powder in the compound room in small amounts and is added to the rubber directly on the mixing mills. It does not readily fly or volatilize, does not fume and rapidly disperses into the rubber. Due to its non-toxic properties, it is a safe accelerator to use, and the health hazards are nil.

Ethylidene Aniline

Origin & Constitution:

Ethylidene Aniline is a brown, viscous, resinous material with a melting point of about 80°C. Commercial varieties vary in composition from a viscous liquid to a low melting resin. It is prepared by the action of acetaldehyde upon aniline. A number of resinous substances having various trade names, belong to this type of accelerator. They are reddish brown resins of low melting point and their activity depends largely upon the proportion of the reacting agents. Their general type of formulae are $(C_6H_5NH)_2:CH. CH_3$ or $(C_6H_5N:CH. CH_3)$.

These types of accelerators are very active in vulcanizing properties. They may be used with or without zinc, but are more active in the presence of zinc oxide. Furthermore, they are readily soluble in rubber and disperse easily during the mixing and aiding in the softening action. They are insoluble in water, do not take up moisture from the air and are quite stable upon storage. They have no objectionable odor.

Uses:

Ethylidene Aniline and resinous accelerators of this type are used extensively as rubber accelerators. They impart very desirable properties to rubber and may be used in all types of rubber compounds with the exception of white and highly colored stocks which are somewhat darkened.

Various types of these accelerators are sold under different trade names and are very popular with the rubber trade.

Health Hazards:

Ethylidene Aniline, whether in liquid or resinous form, is added directly to the rubber mix or put up in the form of master batches. The material is soluble in rubber and disperses quickly without decomposition and with but slight volatilization. A slight odor is given off during the mixing and calendering, but is not offensive or toxic. Hoods over mills and calenders are desirable but not necessary. The material is non-poisonous and as far as we have been able to discover has produced no dermatitis.

Heptaldehyde Aniline

Origin & Constitution:

Heptaldehyde is a brownish liquid accelerator prepared by condensing heptaldehyde with aniline. It is a powerful accelerator and especially adapted to high-gum stocks. Carbon Black, Clays and certain acid oils have a negative

influence upon it. It has a slight odor and incorporates readily with the rubber. It has the formula $(C_6H_5N:CH.C_6H_5CH_2)$.

Uses:

Heptaldehyde Aniline is used primarily as a rubber accelerator. It is a very active liquid accelerator, giving excellent results with gum stocks. It also has a softening action upon the rubber, which is beneficial for many purposes.

Health Hazards:

Heptaldehyde is classed as non-toxic and no ill effects from its use have been reported. It is often diluted with an inactive oil such as mineral oil to better mixing conditions and aid in dispersing the accelerator uniformly. The accelerator is weighed out in the form of a liquid and incorporated with the rubber at the mixing mills by slowly pouring the liquid over the rubber. It does not fume or produce obnoxious odors and can be handled with safety. It is advisable to handle all liquid accelerators in the compound room with rubber gloves. The latter must be kept clean inside and out.

Hexamethylene Tetramine

Origin & Constitution:

Hexa is a white, odorless, crystalline powder. For rubber work, material should be ground very fine to pass a 160 mesh. It has a specific gravity of 1.20 and is soluble in water. It is a stable product, but should be stored in airtight containers until ready for use to prevent taking on of moisture. Hexa has no definite melting point, as it decomposes with heat. It is prepared by the action of ammonia on formaldehyde and has the formula $(CH_2)_6N_4$. The exact arrangement of the groups is somewhat in question.

Uses:

Hexa is used extensively in medicine, in the manufacture of synthetic resins, for gas masks, and as a rubber accelerator. Up to a few years ago, it was one of the most widely used accelerators in the rubber trade and is still in quite general use. It is an excellent accelerator and produces stocks of high tensile strength and great resiliency. It has a tendency, however, to produce a disagreeable skin rash, which has caused it to lose its popularity as an accelerator. As a result, the use of Hexa has greatly fallen off in favor of more powerful and more easily handled accelerators.

Health Hazards:

Hexa is a dry, white powder, easily handled in the compound room without trouble or hazard. It is weighed out from sealed containers in the usual manner and is added directly to the rubber on the mixing mills, where it readily disperses in the rubber without odor or fume. While perfectly safe to handle from the toxic standpoint, Hexa does cause a troublesome dermatitis with some individuals. This takes the form of a disagreeable rash (sometimes called "rubber itch"). It very seldom causes trouble, either to the weighers or mixers, but is more likely to develop among those operatives who handle the warm, raw stock subsequent to the mixing operation, such as among the warmers, calender operators and sometimes the tire builders. The rash usually begins on the wrists, extends up the forearms, sometimes extending to the face and neck, and in a few cases spreading quite generally over the body. In some ways it resembles ivy poisoning and is inclined to itch violently, especially at night. The rash is not obstinate, however, and disappears in a few days with change of occupation.

Some individuals are immune to attack, while others are very susceptible. Hot, muggy weather and profuse sweating are conducive to this rash. Accord-

ing to Shepard & Krall, the rash is probably caused by the water soluble Hexa entering the skin, where it is first decomposed and then oxidized in part to formic acid, and the latter being the real cause of the rash. A saturated solution of bicarbonate of soda is recommended as a curative treatment. The severity and frequency of Hexa cases are largely proportional to the amount of Hexa which is used in the rubber stocks. Where only very small quantities (say under one-half of 1 per cent), are used, very little trouble is usually experienced. Due, however, to this disagreeable feature of Hexa, it is fast losing ground as a rubber accelerator.

Methylene Aniline

Origin & Constitution:

Methylene Aniline, also called formanilin, formaldehyde aniline and anhydro formaldehyde aniline, is a white powder having a melting point of about 133° to 137°C., and a specific gravity of 1.14. It is prepared by the action of formaldehyde on aniline. Two products are formed, depending upon whether one or two molecules of aniline enter into the reaction. If one molecule of aniline is involved, methylene aniline is formed having the formula $(C_6H_5N:CH_2)$. If two molecules of aniline enter the reaction methylene-diphenyldiamine is formed, having the formula $(C_6H_5NH)_2CH_2$. Methylene aniline is only very slightly soluble in water and does not take up moisture readily from the air. It is very soluble in rubber. For proper dispersion it should be ground to about 100 mesh. It is fairly stable, although it turns brown when exposed to air and light, due to slight oxidation. It should be stored in closed containers.

Uses:

Methylene Aniline is prepared for use in the rubber trade as an accelerator and as a softener. It is a mild accelerator, being slightly more powerful than aniline and requires about 2 per cent upon the rubber for use as an accelerator. Zinc Oxide is desirable, but not necessary for proper acceleration.

Methylene Aniline probably finds its greatest use as a softener, and secondary accelerator in conjunction with the more powerful accelerators, especially of the guanidine types. It has a softening effect upon rubber and decreases the scorching tendency when used with the more powerful accelerators. Commercial Methylene Aniline often contains traces of uncombined aniline or formaldehyde.

Health Hazards:

Methylene Aniline is weighed out in the compound room as a powder and mixed directly on the mills in the usual manner. The powder does not fly and no special precautions need be taken in weighing out, since the material is non-toxic if pure. It is advisable, however, for the weighers to refrain from handling the material with the bare hands, since the commercial product invariably contains traces of aniline.

During the mixing and calendering operations, some volatilization takes place, producing a pungent odor and causing irritation to eyes and respiratory organs. Mills and calenders should accordingly be hooded with suction to remove these vapors. The material is not poisonous, except as traces of impurities, such as aniline or formaldehyde are present. It has been claimed that susceptible persons have contracted slight dermatitis, probably due to the presence of formaldehyde. Such cases, however, are not general and the material can be used with safety, provided precautions noted above are taken.

Methylene Diphenyldiamine

Origin & Constitution:

Methylene diphenyldiamine, also called methylene dianilid, is formed when two molecules of aniline react with formaldehyde, and has the formula $(C_6H_5NH)_2CH_2$. It is a yellowish, white, mealy compound, being rather difficult to grind, due to the fact that it has a tendency to roll up into a ball. It should, however, pass a 20 mesh screen, and be free from hard lumps. It turns brown upon exposure to the air and light and is inclined to cake if stored in a warm place. It should be kept in sealed containers and stored in a cool room. It has a specific gravity of 1.15 and a melting point of approximately 45° to $60^\circ C$. It is soluble in water, does not absorb moisture readily from the air and is very soluble in rubber. It disperses very readily in the rubber, giving a decidedly softening action.

Uses:

It is used both as an accelerator for rubber and as a softener in conjunction with other accelerators. It has relatively mild accelerating properties, being only slightly greater than aniline and about equal to methylene aniline. Its greatest use is as a softener for rubber and has an anti-scorching ingredient in connection with the use of more powerful accelerators.

Health Hazards:

Methylene diphenyldiamine is weighed out as a dry powder in the compound room and added directly to the rubber during the mixing operation. It does not fly and is easily handled without danger. The commercial product usually contains traces of aniline, and weighers should therefore avoid handling the material with bare hands.

During the mixing and calendering operations, considerable vapors are given off which are irritating to the eyes of those not accustomed to its use. The vapors, while quite irritating, are not seriously poisonous. Traces of aniline and formaldehyde may be present, and the mills and calenders should be hooded with suction to remove the vapors. Applying the precautions noted above, the material can be handled with safety.

Mercapti-Benzo-Thiazol

Origin & Constitution:

Mercapti-Benzo-thiazol is a yellow, amorphous powder, having a melting point of 174° to $179^\circ C$. It has a sweetish odor and a somewhat bitter taste. The material is prepared commercially by heating aniline, sulphur and carbon disulphide under pressure. The reaction product may be dissolved out in caustic and precipitated in an acid solution. It has the formula $C_6H_4 \begin{smallmatrix} N \\ S \end{smallmatrix} C_2SH$.

Uses:

Mercapti-benzo-thiazol is prepared primarily for use as a rubber accelerator. It is one of the very powerful low-temperature accelerators, working best at temperature of about 260° to $270^\circ F$. It requires the presence of a small amount of zinc oxide for proper activation. It is a very stable accelerator and has but slight odor. It also imparts good aging properties and gives excellent cures at low temperatures. For these reasons this type of accelerator is becoming very popular at the present time. It works well in most all types of rubber goods.

Health Hazards:

Mercapti-benzo-thiazol is a dry amorphous powder, has but slight odor and is classed as being non-toxic. It is easily handled in the compounding and milling departments. Only very small amounts are used, averaging less than one-half

of 1 per cent on the rubber. It can be weighed directly into the rubber or preferably put up in the form of a master batch. The substance does not fume on mills or calenders and can be easily handled without disagreeable effects. No cases of skin irritation or poisoning have been reported and the material may be handled with safety.

Ortho Toluidine

Origin & Constitution:

Ortho Toluidine is a colorless to yellow, thick refractive liquid which turns to a reddish brown upon exposure to air. It has a boiling point of 198°C . and a specific gravity of 1.01. It has the general formula $\text{CH}_3\text{C}_6\text{H}_4\text{NH}_2$ with the methyl and amino groups in the ortho position.

Uses:

Ortho Toluidine is used in the manufacture of dyes, intermediates, various chemicals and rubber accelerators. It is a weak accelerator and finds but little application in the rubber trade directly as an accelerator. It is, however, used quite extensively in the manufacture of other accelerators.

Health Hazards:

Ortho Toluidine is poisonous and should be treated with the same care as aniline. Operatives must not be allowed to get the oil on their flesh and mills and calenders should be hooded. Its toxic properties are quite similar to aniline, causing some cyanosis and affects the nervous system. Its use in actual rubber work is nil, since more powerful and non-poisonous accelerators are available. In such factories, however, where it is used to prepare other accelerators, due care should be exercised in its handling. (See Hamilton 506.)

Para Phenylene Diamine

Origin & Constitution:

Para Phenylene diamine is a colorless, crystalline powder which readily turns grayish-brown upon exposure to air. It has a melting point of 1.40°C . and a boiling point of 287°C . Its specific gravity is 1.14 and it has the formula $\text{C}_6\text{H}_4(\text{NH}_2)_2$. For rubber work the material should be ground very fine and be free from lumps. It is a rather difficult substance to grind and should be examined carefully for hard, crystalline particles.

Para Phenylene diamine is soluble in alcohol, ether and water. It takes up the moisture readily and is quickly oxidized upon exposure to air, and for this reason must be stored in sealed containers.

Uses:

Para Phenylene diamine is used extensively in the dye industry for dyeing hair and furs. It is also an excellent and powerful rubber accelerator, imparting very desirable properties to rubber goods. It cannot be used for white or light colored goods, since it discolors the same. It would be a very popular accelerator but for the fact that it is decidedly poisonous. It has been used for many classes of rubber goods, including soft cures, semi-hard and hard rubber compounds, but due to its toxicity it finds but little application in the rubber industry at the present time.

Health Hazards:

Para Phenylene diamine is decidedly poisonous and should be handled with extreme care when used for rubber work. In the compounding room the operatives weighing it out should wear rubber gloves and respirators. The powder is soluble in water and if it comes in contact with the hands it will partially dissolve in the perspiration and discolor the flesh badly. It is also conducive to dermatitis and in the case of some individuals causes bronchial asthma. (See Curt Gerdon, Zentral bl f. Gewerbeyg, 1920, VIII—183.)

C. W. T. D.

Since the material is unstable in air it must be incorporated with the rubber immediately upon opening the sealed containers. There is slight fuming during the mixing and calendering operations, and both mills and calenders should be hooded, since the fumes are injurious to the eyes and respiratory organs.

In spite of its poisonous properties, it has been used successfully in rubber work with no serious results. It requires careful supervision, however. The writer has found that by breaking the seal of the container and immediately submerging the dry powder under oil in an enclosed mixer, the material can be incorporated with rubber without danger of oxidation or handling on the part of the operatives. Using this method of mixing, a suction at the calenders or tubers reduces the hazards to a negligible point. Unless properly equipped to handle this material, the rubber manufacturer should shun its use.

For Toxicity (See Olson J. A. M. A.—1916—66—864). Hamilton 528.)

Para Toluidine

Origin & Constitution:

Para Toluidine is a white, crystalline substance, having a specific gravity of 0.973 and a melting point of 45°C. The material has a flaky appearance, the crystals being in the form of leaflets. When exposed to the air, it turns yellow and then brown. It has a burning taste and a characteristic odor quite similar to aniline.

Para Toluidine is one of the three toluidines, all having the general formula ($\text{CH}_3\text{C}_6\text{H}_4\text{NH}_2$), and being homologues of aniline. They are prepared by the reduction of nitrotoluene in the same way as aniline is obtained from nitro benzene. The crude product consists of about 35 per cent of para toluidine, 63 per cent of ortho toluidine and 2 per cent meta toluidine. The para and ortho are the only ones used in the rubber industry.

Uses:

The toluidines are used in the manufacture of various chemicals, dyes and intermediates, including accelerators for the rubber trade. Para toluidine was formerly used quite extensively as a rubber accelerator. It is considerably more active than aniline and imparts desirable qualities to the rubber. It is, however, no longer used to any extent on account of its toxic properties and comparatively weak accelerating power.

Health Hazards:

Para toluidine is decidedly toxic and similar to aniline in many of its effects. It is weighed out in the compound room as a powder and care must be exercised to prevent workmen from handling it with their bare hands. Rubber gloves should be used. It can be handled safely in this department with reasonable precautions. In the milling and calendering departments, however, it gives off toxic vapors. Mills and calenders should be hooded with suction. According to Treitenfeld (Stuttgart, 1911,790), toluidines have an effect upon the central nervous system and cause some cyanosis, but to a lesser extent than aniline. (Also see Hamilton, 491-497-506 for toxicity.)

Considerable hazard is present in connection with the use of para toluidine and it can readily be replaced with other non-toxic accelerators.

Piperidine Pentamethylene Dithiocarbamate

Origin & Constitution:

Piperidine Pentamethylene Dithiocarbamate is a white, crystalline substance readily soluble in water and having the formula ($\text{C}_5\text{H}_{10}\text{N}.\text{CS}.\text{SH}.\text{NH} \text{C}_6\text{H}_{10}$). It is formed by the reaction of piperidine and Carbon di sulphide. It also

forms a zinc salt having the composition $(C_4H_8N.CSS)_2Zn$, which is insoluble in water. Both the piperidine and zinc salt are very powerful accelerators, belonging to the class known as the ultra accelerators and are active in low temperatures.

Uses:

Piperidine Pentamethylene Dithiocarbamate and its zinc salt have been prepared for use as powerful, low-temperature accelerators. They have acquired only limited application, due to their extreme activity and susceptibility to scorching.

Health Hazards:

Piperidine Pentamethylene Dithiocarbamate has been used to a very limited extent and to date no ill results have been reported. From its general use, its toxic properties should be negligible, although no definite information has been obtained on this matter.

Thiocarbanilid

Origin & Constitution:

Thiocarbanilid is a white crystalline salt having a specific gravity of 1.29, and a melting point of 152° to $154^\circ C$. The commercial salt usually contains as impurities small amounts of aniline, triphenylguanidine or sulphur. It is quite stable, not being seriously affected by light or air. Thiocarbanilid is slightly soluble in rubber, but insoluble in water, and has no tendency to absorb water from the air. It is prepared by the action of carbon disulphide upon aniline and has a formula $(C_6H_5NH)_2C:S$.

Uses:

Thiovarbanilid is used chiefly as a rubber accelerator and in the manufacture of Diphenylguanidine. It is one of the oldest organic accelerators, following closely upon the use of aniline, and has probably been the most widely used accelerator covering the past 12 years. It replaced aniline in many factories, due to its less toxic properties. Its most serious disadvantage is its decided tendency to scorch during the mixing and calendering. It is only a mild accelerator and its use has greatly fallen off in recent years in favor of more active accelerators. Thiocarbanilid requires the presence of zinc oxide for proper acceleration, but it cannot be used to advantage in the presence of lead salts. It still finds a limited use in mechanical goods, shoe stocks and colored goods. It leaves a residual mustard oil odor in the finished goods, which is undesirable for some classes of goods.

Health Hazards:

Thiocarbanilid is a dry, hygroscopic powder, non-poisonous and non-irritating and can be handled, readily, in the compound room without danger. It is weighed out in the usual manner and mixed on the mills with the other ingredients. It readily incorporates with the rubber during mixing. However, during both mixing and calendering operations, the heat often causes slight decomposition in phenyl mustard oil, which is irritating to the eyes and mucous membrane. Mills and calenders should be hooded to remove any fumes or odors.

During vulcanization, the thiocarbanilid decomposes and liberates toxic gases which are very offensive and irritating to the operators opening the molds. Eyes and mucous membrane are usually affected. These gases, liberated during curing are largely phenyl mustard gas and some free aniline, both of which are toxic. (Hamilton, Page 525).

The amount of aniline fumes formed is usually small and the phenyl mustard oil causes only slight cyanosis. The obnoxious and irritating affects upon the operators, however, are such as to warrant attention. Cooling of molds where

possible and proper ventilation will help these conditions. Other accelerators are available and should be used in such press rooms where workmen cannot be properly protected from the fumes.

SUGGESTION OF HOW GROUP II WILL BE TREATED

Mica

Origin & Constitution:

The name "Mica" includes a number of closely related mineral substances characterized by the ease with which they split into thin laminae that are flexible and somewhat elastic.

All Micas are complex silicates, containing aluminum and potassium, generally with magnesium, but rarely with calcium. Lithium and iron are also sometimes present in certain deposits of Mica. The micas of commerce come mostly from India, United States and Canada. Large sheets of sufficient purity to be profitably worked are of rather limited occurrence. They are usually found in veins of pegmatite or giant granite where the constituents crystallize on a large scale. The two commonest varieties of Mica are Muscovite and Phlogopite. The former is the variety common in the United States and is a potash mica $H_2K Al_3 (SiO_4)_3$, and the latter is found largely in Canada and is a magnesian mica $H_2K Al Mg_3 (SiO_4)_3$.

The general analyses of micas will run about as follows:

Silica Di-oxide	40 to 46%
Aluminum Di-oxide	20 to 35%
Iron Oxide	Trace to 11%
Magnesia Oxide	Trace to 25%
Potassium	8 to 10%
Water	3 to 5%

Chemically speaking, the micas are very inert. The rubber manufacturer is interested only in the ground product. Color, state of fineness and absence of grit are the prime requisites for rubber use. The specific gravity should run approximately 3.00, and the product should be ground sufficiently fine to pass a 160 mesh sieve. It should also be free from grit and free silica. A satisfactory mica for rubber work should show only a slight loss upon ignition (about 4 to 5%) and be very slightly soluble in dilute acids (not over 5 to 7%).

Uses:

Mica is used primarily for windows and lining of stoves and furnaces, for ornamentation of wall papers, for heat insulating mixtures, in electric insulating materials and in the rubber industry as a dusting powder and dry lubricant. In the rubber industry mica is used in the ground form. It is usually of a fairly pure variety being the waste from the industries mentioned above. The waste material is screened dry, ground wet, settled clear of water and dried in pans at 100 lbs. steam pressure. The dried material is then bolted over wire and silk and packed in bags. Properly prepared, it should be fairly light in color, have a silvery sheen and be free from silica and gritty material. In the rubber industry mica is used but very little in compounding, but it is used largely as a mold lubricant and for dusting purposes. It is also used to a considerable extent in making a paint for painting the inside of tire casings to prevent chafing of the tube. In the latter case, it is usually mixed with either water or a very dilute rubber cement.

Health Hazards:

Due to its inert nature, mica is not a poison. Taken internally, even in

considerable amounts, it would have but a slight affect, due to its insolubility. Its chief hazard would be as a mechanical irritant. Considerable dust is raised during some of the dusting operations, due to the fineness and light gravity of the substance.

Upon being inhaled, no harm would result from swallowing, but irritation of the respiratory tracts might be possible.

Rhinitis or bronchitis constitute the most common result of inhaling dusts of this type. All dusts in excess tend to lower the resistive power of the lungs against tuberculosis, but it is only in the cases of gritty dusts where serious results have been encountered. Mica should not be classed with dusts containing silica. A good mica is soft compared to silica and is not gritty. It does not cause silicosis.

Much more care is exercised now-a-days than formerly in all dusting operations, both for cleanliness and for saving of material and with due precautions to prevent unnecessary dust and adequate ventilation, mica should cease to be a hazard in the rubber industry.

SUGGESTION OF HOW GROUP II WILL BE TREATED

Talc

Origin and Constitution:

Talc often referred to as "Soapstone," "Potstone," "French Chalk," etc., is a hydrous magnesium silicate of the formula $H_2Mg_3Si_4O_{10}$. It is characterized by an extreme softness of touch and has a peculiar greasy or soapy feel.

Talc never occurs as distinct crystals but only as folia or scales which possess a perfect micaceous cleavage, and which have a pearly to silvery luster on their surfaces. The folia are flexible. Talc is extremely soft and can be readily scratched with the fingernail. It is considered probably the softest of the common mineral substances used in the rubber trade. Talc is found widely distributed through the United States, England and Bavaria. The term "Steatite" is restricted to the compact, massive variety of talc. Soapstone and Potstone are more impure forms of Steatite, in which the talc is probably in combination with more or less soft minerals and produces soapstone of darker shades of color. The color of the good grade of foliated talc is silvery white or often a delicate shade of green. The material used for the rubber trade is the natural product, pulverized and air-floated.

The general analyses of talcs run as follows:

Silica di-oxide	45% to 62%
Aluminum (Oxide)	Trace to 9%
Magnesia (Oxide)	25% to 35%
Water	4% to 8%

The chemical analysis of talc is of secondary importance to the rubber manufacturer. The color, state of fineness, softness and absence of grit are the prime requisites for use in the rubber trade. The specific gravity should run approximately 2.60, and the product should be so ground that 99½% will pass a 200 mesh sieve. On the other hand, the talc should not be too fine for dusting purposes, otherwise the dust scatters too readily. Material should be free from grit and free silica should be absolutely smooth to the touch with no indication of harshness.

Chemically speaking, talc is very inert. It is only slightly soluble in dilute acids and shows a loss upon ignition of only about 6%.

Uses:

Powdered talc is used largely for preparing toilet powders and as a dry lubricant, for foundry facings, for adulterating soap, in the manufacture of

paper and paints, as a non-conducting material for steam and hot water pipe covers, in the production of electrical insulating materials and in the manufacture of rubber goods.

Its principal uses in the rubber industry are as a dusting powder and as an imbedding medium for rubber goods during the vulcanizing process. To a limited extent it is used in the manufacture of gaskets and in acid-proof stocks.

Health Hazards:

Due to its inert nature, talc is not a poison in the toxic sense. Taken internally in small amounts, it would have no serious effect due to its insolubility. Its chief hazard would be as a mechanical irritant, and the latter would be slight, due to the smoothness of the particules and absence of grit. Upon being inhaled, no harm would result from swallowing, but some irritation of the respiratory tracts might be possible where large amounts are present in the air. Due, however, to the smoothness of the particules and absence of cutting surfaces, it is doubtful if any lacerations of the respiratory mucosa would be produced.

Certain workmen are subject to rhinitis or bronchitis as the result of inhaling dust of this type. All dusts tend to lower the resistive power of the lungs against diseases but danger of this sort from talc is small in comparison to the dangers of gritty and abrasive dusts.

With modern methods of rubber manufacture, much less soapstone is used in comparison to what was used a few years ago. This is due to a determined effort on the part of the rubber manufacturers to keep down the dust as much as possible, inasmuch as excessive dust often results in defective goods. The campaign for sanitation and cleanliness in factories has also contributed to the effort to eliminate dusting operation wherever possible. The extreme, fine dust probably of five microns or less, can be reduced if necessary by air floatation, where extreme exposure to fine dust might be encountered. Where reasonable care is exercised and adequate ventilation installed, there is no serious health hazard from talc in the rubber industry.

Commendation For a Valuable Piece of Work

CHAIRMAN SCHNEIDER: There is no doubt but what Mr. Healy has contributed a very valuable paper to us. I think this can be used for reference, and as he so stated, even though it is preliminary, it is very valuable as it is, and I think we owe him a very deep debt of gratitude for his work in this connection.

We will now proceed with the discussion by Dr. Shirley, of the Hood Rubber Company.

DR. J. NEWTON SHIRLEY (Hood Rubber Company, Watertown, Massachusetts): I prepared what I considered a slight discussion of this paper, but I don't know that I will go ahead with it.

We should be most thankful to Mr. Healy for the paper he has prepared. In starting a preparation for a discussion, I thought that in the course of two or three days I might collect information to adequately pull this paper to pieces, if I could. I found, after trying for three days, that I had very little. Information available in reference work is practically nothing. All of these compounds have been used, some have shown toxic systems, but there is very little information in medical literature regarding their use in the rubber industry.

I believe Mr. Healy deserves a most hearty offering of thanks for what he has done. The other day I was called to a meeting, a conference of certain doctors in the rubber industry. They had looked at his list and said, "Are these all hazardous?" I said, "No, possibly five substances, we feel, are, perhaps, injurious to

the life of the individual, and possibly a dozen more which will produce certain re-actions."

The most toxic, of course, is aniline, and this is a hazard for the mill men and calender men, as well. Its replacement by other substances is desirable, and usually possible. If not, the worker should be protected by rubber gloves and apron in handling and exhaust ventilation should be installed on mills and calenders. It is fairly treacherous.

Associated with aniline are certain other aniline derivatives, reasonably safe except for traces of aniline which are present at times. These are Thiocarbanilid, Di Ortho Tolyl Thiourea, Ethylidene Aniline, Heptaldehyde Aniline, Methylene Aniline and Methylene Diphenyldiamine.

These may readily be handled by the master batch method, and thus the slight contamination becomes negligible, provided the weigher and master batch mixer are protected by gloves, while handling the accelerator. Right here it must be stated that the proper use of gloves demands that they be kept clean, especially inside, lest a part of the accelerator get in and become more hazardous through confinement and perspiration.

Certain para groups tend to be sources of danger. Para-nitroso-dimethylaniline, Para-phenylene-diamine and Para-toluidine. All these have had occasion to produce symptoms, more especially in the rubber than chemical industry. Further than that, I did not plan to discuss his paper. I felt it was most complete.

I have prepared a little paper on other substances. I attempted to make this as practical as possible from the viewpoint of the general safety man.

Compounding Ingredients and Their Health Hazards

J. Newton Shirley, M. D., Hood Rubber Company, Watertown, Mass.

Mr. Healy has given a very complete resume of the common organic accelerators, and their common uses and dangers.

I think we have been very fortunate in having so capable a chemist as Mr. Healy in preparing this work for us. Of course there are on the market many trade preparations which are merely forms of those noted and the derivatives of them. I feel that the manufacturers have endeavored to avoid known toxic substances. Some may be detected by color, but most are not distinguishable except by delicate tests. As you have noticed, most of these substances are used in relatively small amounts and the hazards are thus largely confined to the compound weigher handling them directly.

I have chosen to mention the other substances used and their general hazards we meet in the compounding and mixing rooms, rather than attempt to discuss further a paper which I feel is most complete.

I will attempt to be as practical as possible and present these as they may come up to the general safety man.

The first is, of course, Lead—most commonly used in form of the yellow or orange oxide, litharge.

We first meet this friend in the opening of the kegs, which is practically always accompanied by considerable dust. I have never seen a workman use care here. The end is smashed in with a bar and of course the blow carries wood into the powder, causing a fair amount of dust to rise. This keg may be emptied into a bin or the weighing out may be done direct from the keg, probably this is the safer way because of less dust.

The weighing process may be well safeguarded by the proper use of respirator masks and, if possible, by an exhaust hood placed at the rear of the weighing stand

or table. The compound weigher handling litharge should be particularly careful.

His respirator will protect him from the dust if he will use it and cleanliness of person before eating and after work will keep him free from any dangerous amount of lead. One company rotates the compound weigher on this work so that any one man is not on lead oftener than once a month. This weighing may be done into a batch pan or scale pan and put directly into the large batch pan, thus contaminating all the dust with lead, or into a small paper bag, keeping the batch free of lead until this substance is added directly on the mill by the mixer. Several companies are using a "master batch" for their lead compounds; this exposes only the litharge weigher and the mixer, mixing the master batch to the dust. This is quite a task in a large plant where several kegs of litharge are used in the course of a day. After the batch pan containing litharge with other substances reaches the mill practically all lead hazards disappear if the mill is properly hooded. I have heard it said that if master batches are used for lead, no exhaust hood is necessary. This is not true.

We then immediately reach the question of other dusty compounds and fumes from such substances as may break down on the mill. Lead once added to compound and worked in becomes less hazardous but is still capable of producing symptoms if handled carelessly. I once heard it said that the whiting used in dusting stock in bins can pick up enough lead from the stock to become quite a material hazard. Personally, I feel that some other source of lead must exist.

General Rules for the Compound Room

The general rules to observe for lead in the Compound Room are:

1. Handle lead with as little dust raising as possible.
2. Protect weigher with a respirator of proper type.
3. Exhaust the dust away from the weigher if reasonably possible.
4. Rotate compound weighers where possible.
5. Require strict hygiene on the part of the workers by
 - a. Clean clothes furnished by employer daily.
 - b. Shower bath after day's work.
 - c. Careful cleaning of hands and face before eating.
 - d. Lunch room should be provided.
6. Institute periodic medical examinations of these men every month. The mixers and floormen handling the batch pans on the mills should be required to take a shower after the day's work and wash carefully before eating. Medical check-up of mixers and floormen should be done occasionally, but I feel that once every two months is sufficient unless some suggestive findings are noted. It has been my experience that a group of mixers examined in the late winter, when the windows and doors have been shut and the exhaust systems on the mills are functioning properly, show a better blood picture than in the late summer when the doors and windows are open and the cross currents of air are interfering with the exhaust hoods over the mills.

The question of the type and thoroughness of the medical examination may be asked. I believe the man should be fairly carefully looked over. Leading questions attempting to bring out symptoms of absorption should be asked; such as indigestion, diarrhoea, constipation, cramps or colic, tired feeling, uneasiness, loss of weight or loss of color. We should then note the general appearance, color, condition of mouth, especially gums for lead line and tongue for coating from constipation. Then note heart and lungs. In any case where a suggestive story is obtained or suspicious signs are noted, further study to rule out lead should be done.

As for laboratory work, I believe a hemoglobin test should always be made and a smear for stippling taken in every case where there is a suggestive symptom or the hemoglobin is low. A positive diagnosis is made on the finding of a lowered

hemoglobin and stippling with suggestive symptoms and exposure. We are constantly told that stippling is found in only 65 to 70 per cent of positive cases. Therefore the absence of stippling should not cause a diagnosis of lead poisoning to be passed up. This brings up a very important question: is lead absorption a better term than lead poisoning?

The body is capable of ingesting and excreting lead up to a fairly definite amount. Anything above this is stored in the various organs of the body and will give rise to gradually increasing symptoms. This is so-called lead absorption and I believe that all cases in our industry should not get beyond this level; detection and transfer will keep these men on the job without any loss of time or pay, as a rule. At times you will see a case where a man becomes the victim of an acute infection such as "grippe," in which the increased body metabolism with elevated temperature will free a part of this stored lead in sufficient quantities to cause acute symptoms, usually noted only as a slow convalescence from the illness.

Problems For the Workers in Lead

We have yet to determine just how much effect this continued exposure to small amounts of lead may have on later developments in body pathology. It has been stated that in towns where work in lead is the major industry, (1) the presence of a higher percentage of hypertension, arterio-sclerosis and chronic nephritis and chronic heart conditions are noted in late middle life. But I believe that all those men were exposed to more marked doses of lead than men in the Rubber industry. It may also be true that the result of lack of precautions at earlier dates may influence the figures.

Should tobacco be chewed by workers in lead? This is a serious problem. You will find most foremen telling their workers to chew, and perhaps rightly. As the entrance of lead is largely through the digestive tract, any procedure causing the collecting of dust in saliva and expectoration may be very important in cases where proper ventilation removing the dust is not possible. But remember the plug of tobacco soon becomes covered with lead and other compounds.

Zinc has become a very important ingredient in connection with organic accelerators, as several will not function except in the presence of zinc. Recent investigations have shown that "metal fume fever" may also come from the inhalation of a sufficient quantity of zinc in the form of fine dust, usually zinc oxide.

Zinc oxide taken into the body in sufficient quantities (2) produces general malaise and chills accompanied by an elevation of temperature. This is followed by a leucocytosis and an apparent immunity to zinc after the first twenty-four hours. This reaction is dependent upon the inhalation of a sufficient amount of fine zinc oxide dust. It is doubtful if the worker in the ordinary compound room would have a sufficient amount to produce symptoms, but this may be covered up by the fact that a new man on the job develops his immunity unnoticed and the older worker has no symptoms, and shows no signs. We have no information which shows any physical evidence of permanent changes in the body. Adequate ventilation on mills should remove the hazard here and care in handling zinc in compound room should remove all hazard there.

Lime—Hydrated lime is used to a limited extent in compounding. This is essentially harmless as it rarely contains any lime other than the hydrate or carbonate. The dust does produce a conjunctivitis if it enters the eye in any appreciable amount and is irritating to the mucous membranes of the nose and throat. The drying effect on the hands and exposed skin may be quite annoying to some workers. Absorption into the body is not great and will produce no harmful effects; I am tempted to say it may be beneficial to many workers.

Carbonate of lime or whiting is used in large quantities as a filler and for certain qualities it produces in the finished product it is used in great quantities

as a dusting powder. The exposure to the dust by workers is great, but I can see no hazard. In fact, there is evidence to show that the original stone cutters (3) working in limestone knew nothing about stone mason's disease nor a process now known as silicosis with tuberculosis. This did not appear until they used mill-stone or hard sandstone which contain quantities of free silica.

Magnesia appears in the form of silicate in talc, soapstone and asbestos, and also as the oxide and carbonate. This is used largely as a filler and dusting powder. The material is usually very fine and has a rather low Sp. Gr. 2.2 to 2.7 and will fly rather easily, causing a rather high percentage of dust in and about the mill room and storage bins. Workers exposed to this dust are apparently not affected to any appreciable extent. The ordinary product contains a small amount of free silica and theoretically should show evidence of changes in the lungs if exposure is carried on for a period of years. This does not seem to appear. The dust will produce symptoms in those individuals who are affected with faulty nasal passage, causing a mild chronic rhinitis, due to the drying of the nasal secretions and will require a change from this type of work. Men suffering from chronic bronchitis will also find work of this nature undesirable. The absorption of magnesia is essentially nil and we have no evidence of poisoning.

Any Possibility of Silicosis Worthy of Note

Aluminum is used in the form of silicates largely as fillers. We have aluminum flake, a silicate and oxide compound; clay, largely an aluminum silicate; mica, the complex silicate of aluminum; potassium and magnesia with occasionally calcium; pumice stone; silicate of aluminum, potassium, magnesia, calcium, iron and sodium. These all may contain small amounts of free silica, but the quantity is relatively low. It might be said here that with the increasing incrimination of dust with reference to destructive changes in the lungs, that any possibility of silicosis is worthy of note. It seems that a recent case of pneumoconiosis (4) was judged as occupational in which the exposure was to substances containing very small amounts of free silica, if any. Reference is made to definite cases of silicosis (5) occurring in workers making brick from clear sand or essentially pure silica, while a neighboring community manufactured brick from a sand containing 16 per cent clay or organic matter showed essentially no changes. Did the organic matter or clay reduce the effect of silica, or was the free silica in the rust much less? If clay will decrease the effect of silica then we in the compound room may feel safe, as the percentage of free silica in material used is comparatively small.

Barium is used both as the carbonate and the sulfate. It is in both cases very fine, but not particularly dusty. It is essentially non-absorbable and thus non-toxic. We consider that there is no hazard to health.

At times rather large quantities of infusorial earth or Stoughton's earth are used as fillers. This is a fine white to pinkish or brownish powder. Sp. Gr. 1.66 to 1.95. The best grades are very nearly pure silica and thus we must consider a slight risk from the silica. If it takes 12 to 15 years to produce definite changes in the lungs from free silica in South African gold mining districts, (6) how long will it take to produce similar changes in our compound rooms where the dust concentration is much less? It is undoubtedly true that the size of the particles of dust are capable of producing symptoms eventually, if the exposure is sufficiently great. Many dusty substances are used for coloring. We will first mention

Carbon Black. This is one of the most objectionable substances used in compounding. It is practically entirely a pure carbon product as used today, and no known hazard is reported insofar as ingestion is concerned. Taken into the lungs it of itself is harmless. Externally it is a very dirty, oily substance to handle, and a worker can rarely get cleaned up after his day's work even with a warm shower

bath. It may contribute to the formation of disturbances of hair follicles, but no definite information is at present available to substantiate this.

A few companies are supplying their carbon-black workers with a thin soap paste which is applied before going to work and readily comes off later with a warm shower bath. This removes the objectionable factor to the worker.

Red Oxide of Iron is largely used for red colors. This dust is fairly finely divided and will fly in ordinary handling. I can see no danger other than the quantity of dust inhaled. I believe this is essentially negative.

Antimony is used as the Golden Sulphuret for golden yellow. Antimony pentasulfide—for red colors. Its use has been closely associated with both lead and arsenic; as a result the symptoms supposed to be due to antimony poisoning may be caused in part by lead or arsenic, but we accept the following as definite symptoms. It is irritating to the skin and may cause a form of eczema or dermatitis. It first appears as vesicles and pustules and may even ulcerate. It is doubtful if such could occur in our industry with ordinary use. It is irritating to the mucous membranes, producing mucous discharges from the nose and small ulcerations about the mouth and with marked gastro-intestinal symptoms, loss of appetite, abdominal distress, cramps and diarrhoea. It is doubtful if absorption causes any central nervous system lesions. I believe that the use of antimony is much less than formerly because of the fear of poisoning and production of dyes which are less toxic and will readily give satisfactory results in much smaller quantities. The precautions necessary are: care in weighing out compound and cleanliness in hygiene of worker.

Care in Handling Is Sufficient Protection

Chromium is used in three colors, all of which may be a source of symptoms. Chrome Blue, a chromate of potash; Chrome Green, a sesquioxide of chromium; and Chrome Yellow, usually the chromate of lead. Chromate of zinc and strontium may be used. Chromate of lead is probably the most toxic, because of the possibility of lead poisoning, but the others are capable of producing an irritation of the mucous membranes and ulcerations. No definite internal poisoning has been made out. Therefore care in handling the relatively small amount of chromium used in the ordinary plant would seem to be sufficient protection.

Cadmium Sulphide is used for yellow in rubber to a limited extent. Cadmium is capable of producing irritation of the mucous membranes and a gastritis, but since the cost has limited its use in rubber, it is not considered a serious hazard. It must depend upon absorption.

Yellow Ocher sometimes used, but it is not a hazard. It is a combination of iron oxides in clay.

Certain amounts of so-called mineral rubbers are used in compounding. These are bituminous substances, all having some amount of plasticity. I have been unable to find any reference to toxicity, and consider them harmless.

Various oils are used as rubber softeners. Most oils are vegetable oils, but we find a few mineral oils. I have failed to find any reference to toxic symptoms due to oils. They are naturally soothing to the skin, but may produce skin rashes if contaminated with pathogenic bacteria.

Kerosene is considered an oil and produces a fairly marked erythema to the skin of some people, but this may well be set aside.

A few acids are used in the rubber industry, but very few in compounding. I am going to mention Stearic and Oleic acids for a reference (?) is made to their use in connection with litharge. It seemed that the fatty acid-lead compound produced marked skin changes when used. If this is to be used, gloves to protect the worker should be furnished.

We next come to the resins and pitches. These are essentially semi-solids and practically free from health hazards. This group contains tar and we are hearing a lot about the possibility of skin cancer from tar. I feel we are essentially free from this because of the relatively small amount used and the fact that it is neither in fine particles nor sufficiently hot to give off fumes.

We last come to what is probably a fairly dangerous group of materials—solvents. These have been very adequately considered in recent meetings and I feel that as their use is elsewhere than in the compound room, mention should not be made here other than to say that there have been five cases of chronic benzol poisoning treated at the Massachusetts General Hospital in Boston during the year 1927. We are thankful that none were in the rubber industry, but one is attributed to the use of Goodyear's Wringfoot Cement. (8) (B. M. & S. J., Vol. 197, No. 8). This warrants our careful attention to all our processes using benzol.

Reference was made to certain coloring materials. Today many aniline dyes are coming into use. Insofar as I know, these will introduce no appreciable hazard to the workers. The quantities used are relatively small and care in handling by the worker is all that is necessary.

In general it must be said that the question of health hazard is inversely proportional to the following factors:

1. Plant—planning and department layout.
2. Plant—cleanliness, sanitation and ventilation.
3. Employee protection: 1. protecting clothing; 2. washing facilities—showers, etc. 3. employee education.

Lest you misinterpret the purpose of this paper, it should be said that all substances listed are not Health Hazards. In fact, there are less than half a dozen substances used which are capable of jeopardizing an individual's life. This list was compiled for the purpose of making available a source of information which might account for certain symptoms and skin rashes which at times will occur in rubber workers. Early diagnosis and protecting of the employee will result in less lost time from work and fewer controversies over cases which may be considered of industrial origin. The industry today is essentially free from lost time caused from substances used because we have attempted to avoid known toxic substances and protect the worker wherever it has been possible.

CHAIRMAN SCHNEIDER: There is no doubt but what we are highly indebted to Dr. Shirley for his splendid report and discussion of Mr. Healy's paper. As he so states, he gave the committee a copy of the paper and they pronounced it a very efficient piece of work. I have reason to believe that Dr. Shirley had quite a task to discuss Mr. Healy's paper. However, the matter is open for discussion now, and we would be very glad to hear from any one who would like to ask any questions in regard to these papers.

E. W. BECK (United States Rubber Company, New York City): I had the pleasure of reading Mr. Healy's paper before the meeting, and I think both Mr. Healy and Dr. Shirley have made an excellent contribution.

I would like to make a motion that they continue with their work, together with one other suggestion. I happen to know that the Correlating Committee of the National Safety Council is desirous of tying in the work of the different industrial sections, so as to have joint sessions. Probably you remember several years ago, when our good friend, Charles Durand, was president, that we did have two or three joint sessions with the Chemical Section. This is a subject that might well take on a discussion with the Chemical Section. I know that our organization has a chemical factory and our research checkers are doing excellent work in reducing the hazards, and I would like to see the committee enlarged and strengthened by a representative of the Chemical Section, working with these two men from this Section.

They have gone one step farther than Mr. Durand did with his excellent paper on "Health Hazards in the Rubber Industry," by covering other factors in the handling and contents of the compounds. If that meets with your approval, I would like to make that as a motion.

CHAIRMAN SCHNEIDER: Will you restate your motion, as briefly as possible, Mr. Beck?

Correlating the Work of Two Sections

MR. BECK: My motion is, in view of the wish of the National Safety Council, to correlate the work of one section with that of another section, and inasmuch as the work of this committee is tied in with the work of the Chemical Section, that this Rubber Section ask the Chemical Section to appoint a member of their Section to work with the two gentlemen who have presented their papers this morning, and continue the work further with the object of having a safety practice pamphlet on the hazards of rubber compound accelerators and other material, and next year have a report from that committee.

CHAIRMAN SCHNEIDER: You have heard the motion. What is your pleasure? I would like to hear from Mr. Healy, first, as to his attitude.

MR. HEALY: Personally, I would be very pleased to work with this committee, Dr. Shirley and myself and this other member from the Chemical Section, and I think it would work out very satisfactorily. I would be very glad to do anything I could.

CHAIRMAN SCHNEIDER: I would like to hear from Dr. Shirley as to his part of the contribution.

DR. SHIRLEY: I have hardly anything to say. It has been largely a question of Mr. Healy's contribution so far. I do not know whether Mr. Healy has contact with the Chemical Section or not. I thought, perhaps, he might have.

MR. HEALY: No, I have not.

DR. SHIRLEY: In other words, it will be necessary to get a third member from them. Personally, I feel Mr. Healy is doing very well in the preparation of the work. In fact, I feel very few can reach the same point of efficiency. I second the motion.

(Motion carried.)

J. KIDNEY (Goodyear Tire & Rubber Company, Akron, Ohio): I would like to ask Dr. Shirley a question. Of course, anything is liable to happen in Boston. Is there any publicity on the fellow who died?

DR. SHIRLEY: I had a talk with Dr. Manlin the other day, and I think he could give you a copy of it. I believe it is the week of August 25 or thereabouts.

that it appears in black and white. As far as I know, it has not reached much publicity outside of that. I did go to the State Hospital and tried to get further information.

C. L. HUNGERFORD (The Firestone Tire and Rubber Company, Akron, Ohio): When I approached the mysterious chamber of our chief chemist with Mr. Healy's paper he was very glad to review it. There was only one question that he brought up at the time and it was to this effect: Has the degree of toxicity been determined by actual experiment on animals, rather than finding it among human beings?

MR. HEALY: I would prefer to refer that to Dr. Shirley to answer, as I think it should be answered from the medical side rather than from the technical side.

DR. SHIRLEY: I am sorry to say I feel that it has all been obtained from references either in chemical papers, medical papers, or some experiences of that sort on human individuals.

MR. HUNGERFORD: This was just a wonderful example of what we meet with in our plant. Somebody will come from the compound room and say they have a poisoning pigment they are using because they had a nose-bleed or something. I will ask the Chemical Department about it, and they will say, "We don't know, you had better ask the doctor." I will ask the doctor and he will write to the chemist and ask him for a complete analysis, and then peruse the different elements and see what he can find. I think it is a wonderful example of what vital importance the result of the work of Mr. Healy and Dr. Shirley will mean to the rubber industry.

Tests Made Upon Animals Are Encouraged

MR. BECK: Mr. Chairman, talking on that subject further, our research laboratory always conducts a test on mice in all these materials mentioned, and I have even gone down there to see the test. It is not a very difficult thing to make such a test, is very interesting to a layman to watch this test being made, very conclusive evidence, and I would suggest that those companies that are large enough to have research laboratories encourage the running of tests on animals.

CHAIRMAN SCHNEIDER: I would like to ask the Doctor whether that presents a true picture of the toxicity as in human beings?

DR. SHIRLEY: I feel that it is a fair measure of the toxicity. It is the only method that we have.

MR. KIDNEY: We have this experience on some lead press operations: We will examine the man and find some absorption and sometimes the man might get suspicious and be examined by an outside physician, and he tells the man that he has lead poisoning. When is it dangerous?

DR. SHIRLEY: It is a delicate question. I think if we have any worker with suggestive symptoms and any evidence to back it up, we should remove that worker from exposure to that. It is doubtful if he is disabled.

R. A. BULLOCK (Corduoy Fire Company, Grand Rapids, Michigan): We had a case of analine poisoning in the early part of the summer. I would like to ask Dr. Shirley whether analine poisoning comes from absorption or ventilation.

DR. SHIRLEY: It may be both, or either.

MR. HEALY: My observation is that I think I have seen the worst cases from absorption, that is, from actually handling it. Of course, you get it both ways, through handling it.

MR. HUNGERFORD: I just have one suggestion which might be of interest. We had a certain compound which was used in amounts of 25 pounds to a master batch. We had complaints from men in the compounding room and our findings were that it was not poisonous, but that it tasted bad, smelled bad, so we arranged with the purchasing department, and the manufacturer of this certain substance is now sending this compound to us in 25 pound paper bags and it is not touched. It is

broken open and put directly on to the mill, and it is a fine way of removing any contact at all. It has not only resulted in the elimination of complaints but in the actual saving of dollars and cents to the company.

MR. BECK: We were buying in bulk and found that by buying in bags it was easier handled and removed the hazard. The purchasing department was a great boon in that.

CHAIRMAN SCHNEIDER: I think we can readily agree that it is a comparatively safe method and leaves the purchasing department open again to cooperate with us on these problems. A good many plants that I know of bag their material.

Is there any further discussion? If not, we will proceed to the next subject, which is "Safety Kinks in the Rubber Industry," by E. R. Lawler, U. S. Rubber Company, Hartford Plant, Hartford, Connecticut.

(At this point Mr. Lawler showed a group of lantern slides which illustrated various ingenious safety kinks of value in the industry.)

CHAIRMAN SCHNEIDER: We are certainly indebted to Mr. Lawler. I know he has worked hard in preparing those slides; also, the members who contributed to this cause. The Council is making every available slide in the film, and these can be secured from the Council direct. If you wish any information, get in touch with your Section and the Council. They will be glad to supply you. Even a machine will be placed at your disposal at a very nominal fee for rental.

I am now going to ask Mr. Quirk to tell us about the Safety Contest conducted by his company.

Outline of an Interesting Plant Contest

M. A. QUIRK (U. S. Rubber Company, Detroit, Mich.): I was not responsible for this contest, but I might give you a resume of how it was handled. Safety contests had always been conducted, but up to last year it was thought that, perhaps, a little more interest could be stimulated if a contest was held among all the plants, that is, conducted in sort of a written way.

The central safety committee decided to conduct a contest with the 30 plants and the contest was based on the percentage of improvement over the previous years, and the written contest.

The men were asked to write what they thought these two men were talking about, this party on the right talking to the man on the left, and on the reverse side, what the man on the right was saying to the man on the left. A committee of judges were appointed: Walter Kingston, President, Arthur Young and a Mr. Scott were the deciding judges on the best written contest.

Out of the 30,000 employees in the U. S. Rubber Company, 87 per cent replied to these blanks, as well as the Hartford Plant. And this contest showed at the end of six months a 42 per cent improvement over the previous years, and we feel that safety contests are an added advantage to stimulate interest in safety work.

We find that safety contests have materially reduced our accidents in the U. S. Rubber Company. The first prize was \$75 in gold; second prize, \$20 in gold, and third prize, \$5 in gold. After the prizes were issued a booklet was printed by the company and sent out to all plants. I have that booklet here, showing the pictures of all the men who sent in replies and winners. Here are the pictures of the judges and the winners in this folder, and they were sent out to 30,000 employees, as well as a message from our President, Mr. Seiger, right after the contest.

CHAIRMAN SCHNEIDER: Before proceeding with the motion pictures, I think it opportune that every one here be acquainted with the officers of their Section.

Heretofore, a good many of us have been strangers to one another. We are all working, as a Section, for the common good of our industry and I think we ought to know who our officers are. I take great pleasure in introducing Mr. Salisbury, our new chairman.

R. C. SALISBURY (The Fisk Rubber Company, Cudahy, Wisconsin): I appreciate this honor very much, and am particularly fortunate in having selected for me a group of men who will make my chairmanship over this Section a very marked success.

There is considerable to be done in the Section, and I know with the cooperation of the balance of the Executive Committee that we will render a very good service. I shall endeavor to serve you to the best of my ability.

CHAIRMAN SCHNEIDER: I would like to ask that the officers rise and give their names and affiliations while they are here.

(The following men arose:)

M. A. Quirk, U. S. Rubber Company, Detroit Plant.

E. R. Lawler, U. S. Rubber Company, Hartford Plant.

C. L. Hungerford, The Firestone Tire and Rubber Company, Akron, Ohio.

H. W. Low, The Miller Rubber Company, Akron, Ohio.

R. H. Cochran, Kelly-Springfield Tire Company, Cumberland, Maryland.

Dr. J. Newton Shirley, Hood Rubber Company, Watertown, Massachusetts.

MR. MARTIN (State Department of Ohio): I would like to move that a rising vote of thanks be given the retiring chairman and officers for the year 1926-1927, for the very good work they have done in the accident prevention line in the past year. (Amended to read rising vote to chairmen.)

(Motion put by Mr. Salisbury and carried.)

CHAIRMAN SCHNEIDER: I cannot say very much. I think my heart is pretty full. I have received wonderful cooperation from every one of the officers, and I feel highly gratified for the reason that I know every one has had his heart and soul in the work. I have benefited by my association, and in retiring, I leave my best wishes with the succeeding officers.

J. E. CONGDON (U. S. Rubber Company, New Haven, Connecticut): You will recall a year ago that we had a meeting of the Code Committee and there were some changes made in the Code. Since that time, we have received unanimous approval of the Code by all members of the Rubber Section, National Safety Council. It has been approved by the American Engineering Standards Committee.

The Code has been published by the U. S. Department of Labor, which Mr. Beck will give out. If you have any criticism or suggestion to make kindly send them in to the secretary, as this has been approved unanimously. When you want to find out whether a mill is properly guarded, look at the Code and study that carefully. You will probably see some difference in opinion.

I might say in publishing this Code that Mr. Beck, as secretary, sent a typewritten sheet to the Department of Labor, but credit was not given to Mr. Leveridge, as Mr. Leveridge as chairman of the sub-committee, has since died.

Additional copies of this publication may be procured from the Superintendent of Documents, Government Printing Office, Washington, D. C., at five cents per copy. When making your request ask for Bulletin No. 447—"Safety Code for Rubber Mills & Calenders."

ADJOURNMENT.

SIXTEENTH ANNUAL SAFETY CONGRESS
NATIONAL SAFETY COUNCIL

Steam Railroad Section

New Section Officers

Chairman, E. R. COTT, The Hocking Valley Railway Company, Columbus, Ohio.
Vice-Chairman, J. E. LONG, The Delaware and Hudson Company, Albany, N. Y.
Secretary, C. F. LARSON, The Missouri Pacific Railroad Company, St. Louis, Mo.
Past Chairman, J. D. WHITE, Illinois Central System, Chicago, Ill.
Accident Causes and Remedies Committee Chairman, T. H. CARROW, The Pennsylvania Railroad Company, Philadelphia, Pa.
Poster Committee Chairman, L. G. BENTLEY, Chesapeake and Ohio Railroad Company, Richmond, Va.
Publicity Committee Chairman, A. B. HOFF, Erie Railroad Company, New York City.
Prevention Highway Crossing Accidents Committee Chairman, C. T. BAILEY, Oregon Short Line Railroad Company, Salt Lake City, Utah.
Public Relations Committee Chairman, J. L. WALSH, Missouri-Kansas-Texas Lines, Dallas, Texas.
Program Committee Chairman, D. G. PHILLIPS, Wabash Railway Company, St. Louis, Mo.
Special Committee Chairman on Present and Future Activities of the Section, T. P. BRENNAN, The Long Island Railroad Company, New York City.
Membership Committee Chairman, A. V. ROHWEDER, Duluth, Missabe and Northern Railway, Duluth, Minn.
Engineering Committee Chairman, W. L. ROLLER, The Hocking Valley Railway Company, Columbus, Ohio.

Retiring Officers

Chairman, J. D. WHITE, Illinois Central System, Chicago, Ill.; *Vice-Chairman*, E. R. COTT, The Hocking Valley Railway Co., Columbus, Ohio; *Secretary*, J. E. LONG, The Delaware & Hudson Co., Albany. *Committee Chairmen*: *Program*, C. F. LARSON, Missouri Pacific Railroad Co., St. Louis, Mo.; *Membership*, FRED W. MITCHELL, New York, New Haven & Hartford Railroad, New Haven, Conn.; *Poster*, HARRY GUILBERT, The Pullman Co., Pullman, Chicago, Ill.; *Accident Causes and Remedies*, THOMAS H. CARROW, The Pennsylvania Railroad Co., Philadelphia, Pa.; *Publicity*, D. G. PHILLIPS, Wabash Railway Co., St. Louis, Mo.; *Prevention of Highway Crossing Accidents*, C. E. HILL, New York Central Lines, New York City; *Public Relations (U. S.)*, E. R. SCOVILLE, The Baltimore & Ohio Railroad Co., Baltimore, Md.; *Public Relations (Canada)*, W. A. BOOTH, Canadian National Railways, Montreal, P. Q. Canada; *Train Service Accidents*, C. T. BAILEY, Oregon Short Line Railroad Co., Salt Lake City, Utah; *Engineering Representative*, F. HARTENSTEIN,

Lehigh Valley Railroad Co., Bethlehem, Pa.; *Executive Committee*, The OFFICERS and L. G. BENTLEY, Chesapeake & Ohio Railroad Co., Richmond, Va.; ISAIAH HALE, The Atchison, Topeka & Santa Fe Railway System, Topeka, Kan.; H. A. ROWE, The Delaware, Lackawanna & Western R. R. Co., New York City; A. V. ROHWEDER, Duluth, Missabe & Northern R. R. Co., Duluth, Minn.; ROBERT SCOTT, Atlantic Coast Line R. R., Wilmington, N. C.

Tuesday, September 27, 1927

J. D. WHITE, Chairman

Superintendent of Safety, Illinois Central System, Chicago, Ill.

The first session of the Steam Railroad Section of the National Safety Council was called to order at nine thirty-five o'clock by the chairman, J. D. White, superintendent of safety, Illinois Central System, Chicago.

CHAIRMAN WHITE: It is appropriate that we open our meeting by giving thanks to Almighty God for the many blessings we have enjoyed the past year, and I will ask our good friend, Mr. L. F. Shedd of the Chicago, Rock Island and Pacific Railway, to offer up our thanksgiving and invoke divine blessings upon us and upon our work.

MR. SHEDD: The Lord is in His Holy Temple. Let all the earth keep silent. Almighty and everliving God, Maker of Heaven, earth, the sea and all that in them is, immortal, immaculate and immutable, Thou to whom Almighty only applies, into Thy presence we come this morning with grateful hearts and with thanksgiving upon our lips for this added privilege of again meeting with this great body of Christian railroad men, assembled here to do those things that we trust Thine approval and Thine aid and assistance might lead us to do, something more for humanity and to raise the standard of our fellow beings.

We are not unmindful that Thou hast dealt mercifully with us. We thank Thee for it all. We thank Thee for the privilege of meeting. We thank Thee that Thou hast spared our health and strength and our fortunes and those of our families and those dependent upon us that we might come here together. And while we enjoy all of these things and open our hearts in grateful thanksgiving to Thee, let us stop just a moment to pause and think of those dear fellows, those lovely companions, those God-fearing men about whom Thou hast thrown a mantle in Thy great and Holy way, Thy wonders to perform. They are afflicted, we know not why, but we pray, our Heavenly Father, that Thou wilt lighten their burdens. Some of them may come back, we trust they all may, but we especially pray that Thou wilt be with them, guide them, love them and bless them. We are glad to see that some of those who have been absent have come back, and while we are mindful that Thou hast done much for us, we hope that Thou wilt do a great deal for them.

It is a privilege, dear Father in Heaven, to meet here, called together that we may do something for the safety of our fellow men.

We thank Thee for it all. We ask that Thou wilt be with us in our deliberations. Give us wisdom in our counsels and give us valor and determination in our field of endeavor to overcome those things that rend and seek only to tear down, to destroy and to degrade.

Be with us as we are assembled here. Go with us when we go to our homes, and at last save us for that place in the sky, give us a habitation in that house not made by hands but eternal in the Heavens.

We ask it in the name, for the sake of Thy dear Son, Jesus Christ our Lord and Savior. Amen.

CHAIRMAN WHITE: We have with us this morning the Missouri Pacific Diamond Jubilee Quartet. This quartet has a splendid reputation for high class entertainment, being in great demand for radio singing and on the Orpheum Circuit. I am sure we are all going to enjoy and appreciate their presence here with us during our meetings.

I will ask these men to come forward and give us some songs.
(Selections by the Missouri Pacific Diamond Jubilee Quartet.)

Opening Address

J. D. White, Superintendent of Safety, Illinois Central System, Chicago

It is most gratifying to the officers and committee men to have such a representative gathering here this morning. I extend to you all cordial greetings and a hearty welcome. With your cooperation we can make our part in the Sixteenth Annual Safety Congress an outstanding success.

Our program is replete with well-known speakers, and I know every member of this Section appreciates having them with us. Their presence here proves that they are devoted to the safety movement. After listening to what they have to say, we shall be better prepared to go back to our work and continue the promotion of safety with more skill and enthusiasm than ever before.

If there are any announcements any one wishes to make during the sessions, I shall be glad to accommodate him if he will give his name to the secretary. I may say, in passing, that I am going to try to carry out our program on time both in starting and in closing.

As chairman of this Section and as a representative of a railroad which is earnestly engaged in seeking to reduce hazards and promote safety practices, I am deeply interested in safety work. I consider it a privilege to be engaged in such work because, in my opinion, the conservation of human life and well being is one of the most worth-while activities to which one's efforts could be devoted, and I am always glad of opportunities to participate in furthering the cause of safety.

It affords me genuine pleasure, therefore, to be present at this Congress. Such gatherings are a most effective means for the dissemination of information on safety matters, and I am confident that much benefit will be derived from the several sessions. Moreover, I want you to know that I heartily appreciate the compliment of being elected to serve as your chairman the past year. I have done my best to be worthy of the honor, and I am going to do my best to give my successor the same loyal, enthusiastic support which you have accorded me and for which I am deeply grateful. It has been a most pleasing experience for me to have been so closely associated with you men, most of whom I know personally and am proud to call my friends, and I want to express my sincere thanks to the entire membership of the Steam Railroad Section for the cooperation and the assistance they have extended the officers and the chairmen of the various committees.

We men assembled here, representing the safety departments of various railroads, have an important duty to perform—one that demands from us the best of our hearts and minds. It is for the purpose of better fitting ourselves for our tasks that we meet in these conferences to exchange ideas and discuss our problems so that all may have the benefit of our individual experiences and viewpoints.

The promotion of safety offers a broad field for activity. Changes in equipment and in methods of operation are constantly being put into effect by the

railroads, and not infrequently these changes give rise to new safety problems to tax our ingenuity. It is often the case that such problems can be solved satisfactorily by some small adjustment of practice which though simple in its application is highly important in its results. I want to urge that we cooperate fully among ourselves for reciprocal benefits along this line. If any railroad puts into effect a plan for preventing accidents which proves effective, the safety officers of other railroads ought to be fully advised of the details of the plan so they can take steps to obtain its adoption on their respective railroads. The promotion of safety is an undertaking common to all railroads, and it will be of material benefit to us all if we pool our information concerning the best ways to further this undertaking.

The value of safety work is conclusively evidenced by the steady increase in the safety of steam railway operation that is reflected in the statistics compiled by the Interstate Commerce Commission and other organizations. In spite of the gratifying results already accomplished, however, there is yet plenty of room for improvement. So long as preventable accidents occur, no matter how infrequently, we must continue to strive for the attainment of perfection. There is a twofold incentive for us to do this; good safety work results not only in safeguarding life and limb, which is the primary consideration of humanity, but it results also in greater efficiency among employees, more favorable public sentiment toward the railroads, and, as a corollary of these other factors, improved railway earnings.

Many Broad Reasons For Interest in Safety

For this reason, I want to suggest that in promoting safety work among railway employees we should not confine our arguments exclusively to its benefits to the individual concerned. We must endeavor to get the employees sold on the idea that regard for safety precautions is both a duty they owe to themselves and their families and an essential part of the loyalty and efficiency expected of them by the railroads as part of their employment. When we have succeeded in getting railway employees to understand and to accept enthusiastically this idea of their dual obligation to practice safety, we shall have advanced a long way in the prevention of accidents on the railroads.

I think there is a close relation between discipline and personal injuries. We all know something of the difficulties involved in the administration of discipline. I believe the best, if not the only way, to overcome these difficulties is for us to strive to bring about a more general understanding among employees that the proper administration of discipline is always of benefit to themselves. In other words, it should be impressed upon employees the fact that discipline is imposed not so much for the purpose of punishing the guilty party for his past derelictions as for the purpose of emphasizing the necessity of correcting carelessness and unsafe practices, which offer the hazard of accidents and which often jeopardize the safety of others as well as the guilty person. Seen in this light, discipline really is a form of protection for the careful workers against recklessness and disregard for rules on the part of fellow employees who might be disposed to take chances in their work unless restrained by the prospect of incurring disciplinary penalties for so doing. It is part of our job to bring about a general sentiment among employees in favor of the proper administration of discipline in their own interests.

Employees are now being disciplined for instances of carelessness or indifference which result in train accidents, damage to equipment in yards and other similar losses to the railroads. However, I believe that not enough care is being taken to apply discipline in cases where personal injuries or risks which might cause personal injuries alone are concerned.

In passing over such cases without disciplinary action it is frequently said, "This man has had his lesson and will never be guilty of such conduct again." That argument has force when applied to men who have honestly tried to comply with the railroad's rules and regulations and have simply made an error of judgment. But the men I have particularly in mind when I refer to the need for more frequent disciplinary action are the reckless chance-takers and the frequent violators of rules and instructions which are intended to procure their own safety and the safety of their fellow workers. Let us withdraw lenience from such men and impose disciplinary action as often as they violate safety and other rules, and either they will leave the service voluntarily or they will be forced out by the accumulation of disciplinary penalties, or else they will change their ways and become careful workmen.

While supervisory officers should always be careful that discipline never works an injustice, I believe that when it is rigorously applied to employees who are careless of the safety of themselves or of others our personal injuries will quickly take a downward trend.

Wise Selection of Employees Promotes Safe Operations

We must not overlook the fact that by the wise selection of men for employment, our division officers can do a great deal to promote progress of safety work. Care must be exercised when employing men to give the preference at all times to men who apparently can be relied upon to carry out their duties in a safe, painstaking, efficient way and to endeavor to follow out the rules and instructions under which they are to work. In order to maintain a high standard among our employees by recruiting men of this type only, there must be close cooperation between the employing officer and the examining physician so as to exclude at the outset men who are physically, morally, mentally or temperamentally unfit for the safety requirements of railway service.

I also want to refer to the foreman. He is the man to follow the new men taken into service and teach them in the beginning the requirements of safety. He should make them understand they are on probation to meet the requirements for safe operation.

The foreman is the medium of communication between the management and workmen and his attitude toward safety is that by which the official is judged by the men. If safety is to become a habit, naturally this attitude of mind must first be with the supervising forces whose duty it is to arouse and maintain the enthusiasm of their men. Operations of any kind without safety are inefficient and if properly stressed, all ambitious foreman will guard against accidents which betray their inefficiency.

Often the excuse is given that increase in accidents is due to increase in business, but we should not accept explanations of this character because in my opinion the handling of a heavier business with a smaller number of fatalities is a barometer of railway efficiency, and that is the very thing our managements are striving to accomplish. Therefore, we should make it plain that a foreman who is lukewarm on the subject of safety is a liability and if in our opinion we are burdened with any such men on our respective railroads we should not hesitate to make it known to their superiors.

There are certain classes of railway accidents which chiefly affect persons who are not employed by the railroads and consequently are not subject to their control. I refer to accidents to trespassers and to persons on public crossings, especially to automobile accidents at highway crossings. I am sure that all of us are keenly conscious of the awful toll of life and limb being enacted by such accidents and are mindful of the importance of doing everything possible to solve the problem they present.

The railroads are making strenuous efforts and are spending thousands of dollars to reduce the number of accidents of these classes, but in order to prevent them entirely we must have the whole-hearted support and cooperation of the public. Our people in general need to be aroused to widespread realization of the fact that they can utterly overcome all hazard of such accidents by a proper regard for their own safety. I believe the continuation of our efforts through publicity and education with the encouragement of suitable legislation will be efficacious in bringing about this sense of personal responsibility on the part of the public and thereby enable us to make progress in diminishing the frequency of these accidents.

In order not to take up too much time, I have tried only to indicate in bare outline the more important scope of the work, as I see it, which confronts the Steam Railroad Section of the National Safety Council. It is work that both humane and economic consideration require shall be accomplished as quickly and as thoroughly as possible. So far as the railroads are concerned, it must be admitted that we have had and are continuing to have too many preventable accidents. A study of the reports shows that the great majority of such accidents are due to causes which could be remedied by a proper attitude toward safety on the part of our employees. Therein lies both our opportunity and our responsibility for service which will greatly benefit the railroads, their employees and the public generally. Consequently, I hold out to you the ideal, which I firmly believe can be realized, of the complete elimination of preventable accidents on our railroads. I know I speak for every member of our gathering in saying that our best efforts will continue to be devoted toward the attainment of this goal.

Various Reports of Committees

ROBERT SCOTT (Atlantic Coast Line, Wilmington, N. C.): Before you proceed, Mr. Chairman, with the program, may I have just a word here? Fellow members of the Steam Railroad Section, we have been meeting for a good many years and we have listened to some wonderful messages from the presiding officer. It seems to me, however, that never in all these years have we had such a straightforward, such a conscientious, such a message with a real punch in it as Mr. White has given us today. I think, gentlemen, in view of the difficulties under which our chairman has been laboring during the past year, we ought to show our deepest gratitude for this wonderful message that has reached the heart of every man here. While it may be rather early in our session to start with rising votes of thanks, I cannot refrain from asking you to show your appreciation to Mr. White for this wonderful message, and I ask you all to rise.

(A rising vote of thanks was extended to Mr. White.)

CHAIRMAN WHITE: I now come to the reports of committees. The first upon whom I shall call for a report is Mr. Larson, chairman of the Program Committee. I am sure he will give us an idea of the proper way to go about getting up a program for a meeting of this kind, and also will furnish us a forecast of the good things the meeting has in store for us. I take pleasure in introducing to you Mr. Larson.

C. F. LARSON (Missouri Pacific Railroad, St. Louis, Mo.): The only report that I can make is simply to place in your hands the finished product of about one year's hard labor on the part of the chairman and his co-workers. We have endeavored in our labors to present to this organization a worth while program. As you see it printed in this pamphlet and as you will hear it unfolded as the various speakers will appear before you, you may think that it is a very easy matter to prepare such a program, that all you have to do is to suggest to some person whom you want to speak or prepare a paper and he quickly jumps at the opportunity; but that is not

true, my dear friends, with my committee. We have worked diligently, we have sought speakers of note in our organization, and all I have to say now in conclusion is that as this program unfolds itself it is open to commendation or condemnation as you may see fit. I do hope that we have given you a program that will enlighten you and instruct you on the principles of safety.

CHAIRMAN WHITE: I am not going to call on our good secretary for his report just yet, but I am going to ask him to announce the appointment of the Committee on Resolutions.

Committee on Resolutions Appointed

SECRETARY LONG: I suggest that Mr. L. G. Bentley, of the Chesapeake & Ohio Railway, Mr. L. F. Shedd of the Rock Island, Mr. N. L. Satchell, of the New York Ontario & Western, and Mr. M. T. Fulton, of the Kansas City Southern, be asked to serve as the Resolutions Committee for this Section.

CHAIRMAN WHITE: We all know that when we cast around for new memberships we are attacking a difficult proposition, because this same casting has been going on for several years. We are fortunate, however, to have as chairman of the Membership Committee a man who has been successful in this casting, as several of us know what the chairman of the committee did in casting last year for wall-eyed pole. This man is none other than our genial friend and co-worker, Fred W. Mitchell of the New York, New Haven & Hartford.

Report of the Committee on Membership

Your Membership Committee communicated with all Class I railroads, not members of the Safety Section, making special effort with those formerly members (Southern Pacific, Northern Pacific, C. M. & St. P., Great Northern, and D. & R. G. W.).

October 1, 1926, there were 100 members. Four railroads, viz., Millstead Railroad, Cumberland & Manchester Railroad, Spokane, Portland & Seattle Railway and Texas Pacific Railway and one individual member discontinued their memberships. As a result of efforts made, six railroads applied for membership, viz., Panama Railroad, New Orleans, Great Northern, Lake Superior & Ishpeming, Mississippi Central, Spokane International Railroad and Per Marquette. Summarized, we began with 100 members, lost five, gained six, and on September 22, 1927, we had 101 members.

Much credit is due Mr. W. A. McGonagle, president of the Duluth, Missabe & Northern, for his very active part of our endeavor.

Automobilists and Others—Take Heed

CHAIRMAN WHITE: You have heard the report of the Membership Committee. What is your pleasure?

CHARLES E. HILL (New York Central Lines, New York, N. Y.): I move its adoption, with thanks.

(The motion was seconded and carried.)

CHAIRMAN WHITE: Next we will have the report of the chairman of the Committee on Prevention of Highway Crossing Accidents. Charlie Hill, like our famous Herbert Rowe, needs no introduction. He has been talking on this subject for several years, and if automobile drivers would follow his advice, many casualties would be avoided. In common with all the rest of us, I have been looking forward to his report with much interest and pleasure.

Report of Committee on Prevention of Highway Crossing Accidents

Your chairman begs leave to submit the following report:

During the past year, through the auspices of the local safety councils, working in conjunction with the National Safety Council, there were distributed 27,000 copies of the American Railway Association crossing poster. This number, doubtless, is quite low, from the fact that in many instances orders were transmitted by the local council, and we have no tabulation covering these shipments. The local councils, however, in the main, have been quite active in making distribution of these posters, and other literature in connection with our Careful Crossing Campaign, among the citizens and the industries in their particular localities.

The National Safety Council has issued a large size poster entitled "Let the Train Pass"—a facsimile of this poster appearing in the September issue of the NATIONAL SAFETY NEWS. This poster is used as a follow-up of other activities along these lines.

The May issue of the NATIONAL SAFETY NEWS gave prominent display to an article on the 1927 Careful Crossing Campaign prepared by Mr. H. A. Rowe, chairman of a similar committee of the Safety Section of the American Railway Association.

The National Safety Council has a mat service that is sent to more than 225 daily papers in various cities. The press service also goes to all of the leading press syndicates, to news associations, daily papers, trade, technical, and class periodicals throughout the nation. Through this medium references from time to time have been made as to the necessity of carefulness at grade crossings along with other public hazards.

Through the medium of the radio—which service covers approximately 80 different broadcasting stations—this vital subject is also touched upon occasionally.

Public Safety, which is a magazine that has been published monthly starting the early part of this year, and is sent to all officers, superintendents of police, motor organizations, and others who are in any manner interested in public safety, has given space also to the subject of safety at railroad highway crossings.

Carefulness at grade crossings is also covered in the various school publications in our local council activities. In fact, it is quite generally included in all our educational work as one of the important hazards to be avoided.

The foregoing very briefly outlines the scope of the work that has been done by the National Safety Council and local safety councils in cooperation with our committee. In addition, your chairman is also a member of the committee on Prevention of Highway Crossing Accidents of the Safety Section of the American Railway Association, and has worked in conjunction with Mr. Rowe as chairman of that committee, and in this manner many of the duties that would ordinarily be assumed by the committee of which I am chairman are handled by the A. R. A. Committee and in this respect there is no duplication of the work.

Your chairman has individually spoken to a large number of public bodies, and has in all instances not failed to stress the importance of the crossing problem. Our remedy lies almost entirely in the cooperation that we may hope to obtain from the motoring public, and this feature has been stressed wherever occasion permits. We have also, the same as all other railroads, been following many channels which would serve to create a better understanding as to the

causes of this character of accidents, and the methods that can be employed to prevent them.

Based upon reports to the Interstate Commerce Commission covering the first five months of this year as compared with the same period of 1926, there was an increase of eight deaths and a decrease of 120 injuries. There was also a decrease of 37 accidents during the 1927 period. Mr. Rowe has canvassed ten of the principal railroads located geographically in various parts of the United States, and obtained information showing the number of deaths and injuries during the first six months of this year as compared with the same period of 1926, and based upon the information he has secured, on these ten railroads during the 1927 period there was a reduction of 19 deaths and also a reduction of 190 injuries, which means a reduction of a little more than 4 per cent in the number of deaths and 12 per cent in the number of injuries. When we take into consideration the continued increase in the number of automobiles, together with the increased mileage of improved highways, which eventually means a vast increase in the volume of traffic on such highways and over railroad crossings, we can take courage in the fact that even though the decrease in casualties has been slight, that we have, at least, brought about a check in what had been an increase previous to the time that our special campaigns became effective. Your chairman merely wants to suggest that every railroad in the country make liberal use of the safety material that is supplied by the Safety Section of the American Railway Association and that they individually continue to do all they can to educate the public as to the crossing hazard, at the same time impress upon the traveling public the realization of their responsibility so that if this is assumed, the hazard of passing over railway tracks at grade will be materially lessened and the number of accidents, of course, will be greatly diminished.

Charles E. Hill, Chairman.

CHAIRMAN WHITE: You have heard the report of the Committee on Prevention of Highway Crossing Accidents. What is your pleasure?

(A motion was regularly made, seconded and carried that the report be accepted.)

CHAIRMAN WHITE: Next comes the report of the chairman of the Committee on Publicity. We all know Duff Phillips. I don't think he will be up here very long until you know he is connected with the Wabash Railroad, and he is about one of the best advertisers the railroad has. I take great pleasure in presenting Mr. Phillips.

Report of the Committee on Publicity

D. G. PHILLIPS (Wabash Railway, St. Louis, Mo.): As chairman of the Publicity Committee during the last year I have tried to make public some of the doings of the railroads through the newspapers and by other means. I think I have learned something about publicity during the last year. I am going to tell you what I think I learned.

In the first place, I found out that a general item or a general report would receive very little recognition from newspapers. If I wrote and told them what the railroads as a whole were doing, I didn't get anywhere with it; but if I would single out some railroad, say the Wabash, for instance, and write and tell them what the Wabash had done, I had no difficulty in getting those articles printed from coast to coast. I tried it, and I know it is true, because the articles were returned to me from the Atlantic and Pacific Coasts. It caused me to think a while. I found out that the kind of publicity that spurs you and spurs me to action is when some fellow stands up and says, "My road has done this, or my road has done that." We hear that. But if I were to get up here and say, "The railroads as a whole have done this or done that," we would all sit here and pay very little attention to it.

A statement has been made recently that the railroads as a whole are reducing the number of crossing accidents. Of course, that is good publicity. We were all interested in it; but when a railroad came out, as the Southern Pacific did—I hate to mention any other railroad, but I will—and stated they reduced the number of fatalities in eight months from eight to two, that was the publicity that attracted our attention, and many of us, I know, wrote to that railroad to find out just what they had been doing to make that kind of reduction.

I know that Mr. Hale has made some very caustic comments on fellows tooting their own horn; but after all, it is this horn-tooting business that makes you and me jump out of the road of the automobile; and when I begin to think on the Wabash (I will name them) that we are making a good record in our mechanical department, and I hear Johnnie Long over here on the Delaware & Hudson tooting his horn, I don't know whether it is just ahead or just behind me—it certainly makes the men on the Wabash move.

It is these identical statements, publicity, if you please, that causes each one of us to know just where we stand.

Just one more illustration and then that long speech I said I wouldn't make is over. A railroad (I mustn't mention any names, you know, longer than the Wabash) reports to me that they have only had three fatalities among employees in eight months. There is some publicity for you. We thought we were making a wonderful record in fatalities. I have to tell you, no matter what you think about it, that we have killed six in eleven months, and we were pretty well satisfied; but, gentlemen, when I heard that statement yesterday that this other railroad (Warfel is connected with it) had only killed three men in eight months, I heard a horn toot, and I am going back on the Wabash and tell them we haven't started yet. Let's let the other fellow know what we are doing on the railroad—that is if it is something good—then you have got publicity that is going to make every one of us do something for safety.

CHAIRMAN WHITE: You have heard the report of Mr. Phillips. What is your pleasure?

ROBERT SCOTT (Atlantic Coast Line, Wilmington, N. C.): I move it be received with thanks.

(The motion was seconded and carried.)

CHAIRMAN WHITE: I am certainly very much pleased with the attendance here this morning. It seems to me this is the biggest crowd that I have seen at any of our opening meetings since I have belonged to this Section.

Our next report is that of the Public Relations Committee, to be made by our good friend, Mr. E. R. Scoville of the Baltimore & Ohio, and Mr. W. A. Booth of the Canadian National. Both of these gentlemen represent big railroads and I am very much pleased to present them this morning to you for their reports.

Report of the Committee on Public Relations

Your committee begs to report that a number of railroads have organized committees which perform the same duties as public relations committees, while they may not all be given titles as such.

The plan usually followed is to establish a committee composed of employees in each county, through which the railroad operates. The work performed by these committees is to keep the public informed as to matters pertaining to policy, shipping or difficulties under which the railroads are laboring, which the public can assist in minimizing, etc., and from information gathered it is thought that the personnel, organization and functions of these committees are along the same lines as those on the railroad which I have the honor of representing.

During the year 1923 these public relations committees were organized in each county through which the railroad operates. The membership of each of the committees was about ten and composed of employees located in the county. In those counties where division headquarters were located the division superintendent, and in other counties the local attorneys, were selected to act as the chairmen. The members of the committees were local agents, trainmen, if any located in the county, track foremen or other employees that were suitable and available. There are 158 of these committees with a total membership of 1,415. They are called together once each month. The reason for the organization of those committees was that at that time there was a feeling of unrest and questions in which both the public and the railroads were vitally interested. Information intended for the public was sent to these committees in order that they might be in position to discuss it intelligently at every opportunity and to address chambers of commerce, civic clubs, churches and schools on the subjects of interest. The matter of greatest importance was settled during the Presidential election in 1924. However, as there were other matters of importance, such as a proposed amendment to the Transportation Act, it was decided to continue the activities of these committees, so that at this time they are given any subjects in which both the public and the railroads are interested. At present, they are being kept posted on loss and damage, proper packing of shipments, etc., and also highway crossing accidents, and these subjects are now being discussed by them as the principal topics. However, they at all times cultivate the proper mental attitude toward the railroad, and to assure them of the desire to serve them promptly and properly and to be considered a good neighbor and one to be called upon for assistance in times of disasters by flood, fire or other similar emergencies—in other words, to look upon the railroads as a friend and not as a heartless corporation which it is not and never has been. They also discuss these matters with other employees with whom they come in contact and to urge upon them the importance of passing the information to the public with whom they work or deal and to personally advertise the service of the company by whom they are employed, in the hope that where the service afforded is equal to or better than that of other roads in the vicinity, they may travel or ship over the railroad which gives them employment.

In all of our dealings with the public, we wish to impress upon it the "will to please."

The above is a brief outline of the organization and duties of a public relations committee.

Respectfully submitted,

E. R. Scoville, Chairman.

The B & O Pageant in Baltimore

MR. SCOVILLE: Mr. Chairman, while I am here I should like to make a little announcement. I don't want to advertise the Baltimore & Ohio Railroad, but as many of you know, the Baltimore & Ohio is celebrating this year its centennial. They have been working on a pageant or exposition. At this time and continuing until October 8 they are having a pageant each day at a suburb of Baltimore. It starts from earliest history of transportation, and leads on up to the latest locomotives. Not only the Baltimore & Ohio itself, but a number of other railroads have assisted by sending to that exposition the oldest and the latest locomotives they have.

The Baltimore & Ohio have rebuilt completely from the first locomotive that was built in the United States on up, each successive engine has been built there and is operating under its own steam at each one of these pageants.

Any of you gentlemen who can do so should not miss seeing this. It was the greatest thrill of my life to see those old engines operating under their own steam on that circular track. If you can come to see it, do so. It is free for anybody to come and see.

W. A. BOOTH (Canadian National Railroad): Mr. President, Ladies and Gentlemen: I am very glad to take the cue from our friend Charlie Hill to come before the pulpit.

We in Canada rather take our tip from the rules laid down by this Congress, and in so far as our work is concerned I don't know that I could do anything better than just dwell a few minutes on a little skit that we got up a short time ago in connection with some brackets that were placed on each corner of these motor cars that run along the railroads.

I have had inquiries from Mexico, Alaska and everywhere else. We are pleased to give you any information today or during the Congress. It has come in for a wonderful lot of publicity. Not boastingly do I say it, but it is a bracket that is well worth trying out.

Ten Radio Stations Used in Canada

In our work on the Canadian National Railways, we use ten different radio stations and get our talks over the radio.

We have with us today a few of our notorious Canadian characters. Shall I mention W. H. Jones of fame? He should be here this morning. We have George Kell. Everybody knows Kell. He handles a part of the American business, as well as the central region running from Chicago to Quebec City. Then we have Bill Kauk this year. He is a newcomer. He comes from Nova Scotia. He is a most outstanding character. He stands about six feet high and weighs as much as Bill.

I don't know that I have anything more to say in so far as this Public Relations Committee is concerned, except that we work hand-in-glove with our dear friend Mr. White and his committee.

I am delighted to be with you again. This audience at an opening session speaks very highly for you.

(A motion was regularly made, seconded and carried, that the report of the Public Relations Committee be accepted.)

CHAIRMAN WHITE: I understand that our attendance at this time is 347 on the opening morning of our session.

We now come to the report of a committee that has been added to the committees during the past year. I am going to make the suggestion that everyone in this room take note of the report, because it has to do with a subject that deeply concerns all of us. I am confident the very efficient chairman has given a lot of time and study to it. I take great pleasure in presenting Mr. C. T. Bailey, of the Oregon Short Line of Salt Lake City, who is chairman of the Committee on Train Service Accidents.

MR. BAILEY: Before going into the report of the Train Service Accident Committee, I should like to direct your attention to the chart that is before you outlining the causes of train service accidents with their resultant injuries. Statistical data shown covers a spread of seven years, which should present a fairly representative picture.

It will be noted that the totals at the bottom of the chart do not include highway grade crossing accidents. However, they are tabulated as one of the causes on the chart. I wish to direct, also, your particular attention to the increasing percentage of highway grade crossing accidents as to the whole that have mounted from 11.35 per cent in 1920 to 19.22 per cent in 1926. It is true that the percentage of increase in registered motor vehicles for the same period is largely in excess of these per-

centages and is some encouragement to carry on an intensive campaign continually against this type of accident.

As the report is read, clause by clause, your committee suggests that safety officers visualize the conditions on their respective railroads and leave this conference with the determination to carry on a campaign for a reduction in accidents attributable to the causes outlined.

Report of the Committee on Train Service Accidents

C. T. Bailey, Chief Safety Agent, Oregon Short Line Railroad,
Salt Lake City, Utah

CLASS		1920	1921	1922	1923	1924	1925	1926	Total

**Exclusive of Highway Grade Crossing Casualties.

The Train Service Accident Committee, as composed at the last Steam Railroad Section of the National Safety Council, has reviewed the Train Service Accident records of the American railroads, studied the causes contributing to such accidents and beg to submit the following report.

Train Service Accidents, as are no doubt understood by all, are those accidents that arise in connection with the operation or movement of trains, loco-

motives or cars that result in reportable casualties to persons, but not in damage to equipment or other railroad property in excess of \$150.00. Train Service Accidents are divided into ten major causes which will be treated separately as they are tabulated by Interstate Commerce Commission reports. A study of Train Service Accidents forcibly impresses one with the enormity of the problem confronting a committee in making an adequate recommendation to control such accidents. The recommendations embodied in the following report should be given serious consideration by all operating officers, and such means taken to correct as local conditions warrant.

Coupling or Uncoupling Locomotives or Cars

During the period 1920 to 1926, inclusive, records indicate that there were 1,613 persons killed and 12,163 injured, which were directly or indirectly attributable to this cause. Of the total reportable casualties listed as Train Service Accidents, 3.89 per cent are chargeable to this cause covering the 7 year period, 1920 to 1926. Of all the causes for this particular class of accidents, approximately 75 per cent were chargeable to the following practices:

1. **Adjusting coupler.**

Unexpected movement of cars due to slack.

This type of injury can be avoided by adjusting couplers on that part of train or cut of cars from which end a slack movement will naturally start.

2. **Adjusting coupler.**

Unexpected movement of cars due to other causes.

A better understanding between train and enginemen as to the work to be performed will tend to reduce accidents attributable to this cause.

3. **Adjusting coupler when cars are nearing each other.**

Strict observance of rules forbidding employees from going between moving cars for the purpose of adjusting couplers.

4. **Adjusting coupler with foot on moving cars.**

Trainmasters, yardmasters and conductors should supervise the work and insist on strict compliance with the rule forbidding adjusting coupler with foot while cars are moving. A strict rule prohibiting this practice and supervision for its enforcement will stop this type of accident.

5. **Part of coupler falling out, striking person while adjusting coupler.**

Close inspection by department charged with the responsibility for proper maintenance of operating parts of couplers should be consistently required.

6. **Uncoupling without uncoupling lever.**

Proper inspection of lift levers and lock pins, making it unnecessary to lift lock pin by hand and where necessary to uncouple cars in this manner cars should be stopped before going between them for such an operation and care used in uncoupling cars in this manner.

7. **Manipulation of uncoupling lever.**

Employees performing this class of service should take all precaution possible to safeguard the position they occupy while manipulating uncoupling levers and be prepared for any slack action in cuts of cars that would tend to result in jerking employees from cars they are riding.

8. **Coming in contact with objects, material or locomotives while coupling or uncoupling.**

Strict adherence to maintaining proper side clearance of all material and the enforcement of the rules requiring proper clearance of locomotives and cars on adjacent tracks will materially assist in reducing accidents attributable to this cause.

9. Stumbling, slipping or falling.

Proper maintenance of grounds, walks, runways, etc., where pin pulling is done in yards. A liberal use of salt, sand, cinders, etc., to prevent slipping in freezing weather.

A consistent campaign of education among all train service employees and the strict supervision by supervising officers to see that rules covering all subjects above mentioned are adhered to will contribute largely to a reduction of accidents due to coupling or uncoupling locomotives or cars.

Coupling or Uncoupling Air or Steam Hose or Safety Chains

There was a total of 164 persons killed and 3,218 injured during the period 1920 to 1926, inclusive, which constitutes 1.03 per cent of the total number of Train Service Accidents.

The practice of attempting to manipulate air or steam hose, angle cocks or safety chains while cars are moving should be absolutely prohibited. Care should also be taken to see that angle cocks are properly turned in air hose manipulations and care exercised in parting hose to see that sudden release of air will not cause injury. Where it is known that steam hose have to be manipulated by car forces or others, and in large terminals or any other point, steam pressure should be shut off and pipes and hose drained before attempting such operations. Care and understanding as between employees engaged in these operations will eliminate to a large degree this type of accident.

Operating Locomotives

During the 7 year period, 1920 to 1926, inclusive, there occurred 144 deaths and 46,420 reportable injuries chargeable to this cause, which constitutes 14.18 per cent of all Train Service Accidents.

The hazards incident to operating locomotives are many, which emphasizes the necessity for employing men in this class of service qualified physically and mentally to sense these hazards and be prepared to protect against any unnecessary risks. I. C. C. tabulations indicate that the following are some of the prominent causes of injuries in this class of service:

Levers slipping off shaking grates or while dumping ash pans.

Slipping or falling, or striking hands or body against other parts of locomotive or objects while shoveling coal.

Slipping or falling, or striking hands or body against other parts of locomotive or objects while shoveling coal.

Using other fire tools.

Unexpected movement of locomotive, causing slipping or falling while operating water plugs.

Operating reversing apparatus.

Careless handling of squirt hose valves.

Slipping or falling on locomotive or tender, not otherwise classified.

Struck by locomotives or cars on adjacent tracks.

Unexpected movement of locomotive or tender.

Coal falling from overload tanks of engines onto employees and others on the right-of-way, in roundhouses and other places.

Employees being injured by escaping steam and hot water when testing fire fighting apparatus on locomotives so equipped at terminals. (If locomotive injectors are properly operated by enginemen, injuries of this kind can be avoided).

Slipping and falling from engines as a result of snow and ice accumulating

on side steps and footboards, which should be kept free from snow and ice by applying salt or sand.

These are some of the prominent causes of injuries to employees engaged in operating locomotives, which are largely contributed to by the failure of the employee to protect against the hazards incident to the particular operation engaged in. A very small percentage of these accidents can be charged to defective equipment, which fact indicates that a consistent course of instruction and education by road foremen of engines, district foremen, traveling engineers and firemen is necessary to bring about an improvement. Employees in this class of service should be instructed to make inspections of tools they are required to use and to see that they are in first class condition, particularly so with grate shaking bars to see that proper fit is obtained over shaker lugs.

On the Union Pacific System, a unit of which I have the honor to represent, a plan of holding progressive examinations for firemen is effective. All firemen are required to pass these examinations from time to time. These examinations cover many subjects pertinent to the duties of locomotive firemen, such as mechanical efficiency, air brakes, fuel conservation and safety. Under the subject "Safety", the examiner usually deals with the many safe practices that will prevent injury and the necessity for careful examination of tools and other appurtenances to see that they are in safe condition for use. These men are being trained in the matter of safety from the time they enter service until having passed final examinations and are thoroughly conversant with the safety rules and regulations.

Operating Hand Brakes

During the period 1920 to 1926, inclusive, there were 229 persons killed and 15,518 injured while engaged in operating hand brakes, which constitutes 4.79 per cent of all Train Service Accidents.

Injuries caused while engaged in operating hand brakes are about evenly divided as between defective conditions and unsafe practices. The following list indicates some of the prominent causes for accidents occurring to employees engaged in this operation:

Brake chains or bolts breaking or giving way.

Brake chains kinking, twisting, overlapping or too long.

Broken, loose, or defective brake shaft or brake wheel.

Defect in or failure of pawl or ratchet.

The slipping of brake club in brake wheel or struck by brake club when wheel flew around.

The sudden stopping, starting, lurch, or jerk of train while engaged in setting or releasing brakes.

Slipping or falling, or losing hold while engaged in setting or releasing brakes.

Employees engaged in the operating of hand brakes must be alert to the unexpected movement of train or cars they are employed upon. It is advisable for them to be conversant with the switching movements contemplated and effect a plan of team work as between members of the crew to perform the work efficiently and safely. Approximately 75 per cent of accidents occurring to employees while engaged in operating hand brakes occurred to yard service employees. Congested switching terminals with the risk incident to such congestion makes it imperative that this class of employee should be given special attention by supervising officers in their employment and assignment to this class of service. Proper maintenance and frequent inspection by mechanical department employees placed with that responsibility should be effective to see

that no defects exist in air or hand brake appurtenances, and when such defects are noted cars should be carded or chalk marked where plainly visible by operatives, indicating nature of defect and immediate steps taken to see that cars so marked are placed for repairs.

Accidents to Employees While Operating Switches

During the years 1920 to 1926, inclusive, there were 12 killed and 7,422 injured while operating switches. This constitutes 2.26 per cent of all Train Service Accidents and were charged to the following causes:

Switchstand levers flying up.

Switch lever or ball falling on or catching hand, foot or other part of the body.

Slipping or falling on ice or snow on tracks or elsewhere.

Caught between locomotive or car and switch lever or stand.

Struck by locomotive or cars while operating switches.

Foot, hand, or other part of body caught in or by mechanism of switch.

Injuries occurring due to these causes can be largely traced to the carelessness of the individual. Employees engaged in the class of service requiring the operating of switches should be cautioned by supervisors to the risk incident to these operations and advised against undue haste in manipulating switches and to take proper position while engaged in throwing switches. Maintenance of Way department should make frequent checks of switchstand mechanism to see that switchstands are in proper condition and that walks or runways around switches are kept in good condition and as free from ice and snow or other obstructions as possible. Care should be exercised by employees operating ground throw switches to keep their feet and hands free from coming in contact with ball of switch lever when being thrown in either direction. Injuries occurring due to this cause can be rightly charged to the human element, and employees engaged in the class of service requiring the operation of switches should be constantly warned by supervisor against indulging in any unsafe practice while manipulating switches.

Coming in Contact With Fixed Structures

Interstate Commerce Commission tabulations indicate that for the years 1920 to 1926, inclusive, there were 365 persons killed and 5,928 injured, caused by coming in contact with fixed structures above or at side of track. This type of injury comprises an average of 1.91 per cent of all Train Service Accidents.

Many of the structures which contribute to this type of accident are: water, oil and mail cranes, coal chutes, stock chutes, cattle guards and other fences, side and overhead bridges, tunnels, retaining walls, overhead wires, poles, platforms and other buildings. Responsibility for accidents of this kind may be grouped (a) presense of the objects, and (b) fault of the employee to take cognizance of its presence.

It is doubtful whether any structures over which the railroad has control are now being built with insufficient clearances. In most states the railroad or utility commissions have specified standard clearances and maintain inspection to see that new structures do comply with their rules and that old structures where feasible are moved or cut back to provide greater safety; although this is unnecessary due to the whole-hearted efforts on the part of the railroads to see that no accident hazards that can be removed are permitted to remain.

It is also true that in most states the commission's regulations or legislation requires the placing of signs where ample clearance does not exist, and even

where this is not required by law warning signs have been placed by the railroads.

But even after the taking of these precautions there is something else necessary to prevent the occurrence of accidents due to fixed structures alongside of and above tracks. This is that men working on and about trains and engines be constantly alert with their minds focused on their whereabouts and the things they are doing. With the number of fixed structures that are a hazard constantly decreasing, and with no additional hazards of this nature being added, with warning signs being placed where required, the remedy seems to lie with the men themselves. They must keep posted as to where these hazards exist and be alert to avoid contact with them.

Getting On or Off Locomotives or Cars

This cause of accident is one of the most prolific causes of accidents coming under I. C. C. tabulations. There were 933 persons killed and 59,202 injured during the years 1920 to 1926, inclusive, which contributes 18.31 per cent of all Train Service Accidents.

Many conditions and practices are the causes of such accidents. Among some of the most prominent items of these contributing causes are:

- Missing or losing hold of hand hold or grab irons, stirrups, footboards.
- Slipping or falling due to ice or snow on ground or on locomotives or cars, or while train is starting or stopping.
- Striking or being struck by locomotives or cars on adjacent tracks.
- Sudden starting, stopping, lurch or jerk of locomotive, car or train.
- Jumping from equipment in anticipation of an accident.

Stumbling, tripping or slipping in their many forms are the largest items under this cause. Ice and snow on the ground, as well as stones, rubbish and other loose refuse, cause a good proportion of this type of accidents, and emphasize the necessity for Maintenance of Way Department constantly being on the alert to improve these conditions. In other words, good housekeeping will help. Trainmen should exercise exceptional care in alighting from trains or cars. Education of employees to the hazards involved in this operation is very necessary. Supervisory forces should be on the alert for any unsafe practice indulged in by employees, and corrective measures taken to see that such practices are not repeated. Interest of train and engine crews should be maintained in matters of this kind.

A plan evolved on one of our large railroad systems on portions of their territory appears to have been effective. A series of letters were sent to conductors, devoting the first three letters to the number of accidents occurring to all trainmen on railroads, after which one letter was devoted to each of the causes of Train Service Accidents, endeavoring to impress upon the conductor his duty along accident prevention lines and soliciting his aid in sustaining interest among trainmen on his division and educating the members of his crew in the safe performance of their duties, as well as warning them of the hazards existing on their division. These letters were sent to all active conductors at periods of 25 to 30 days, were each typed separately and signed personally by the superintendent. In many instances, the letters were placed in caboose cars and were a constant safety reminder to all members of the crew.

Supervisory forces should keep constantly before train and enginemen the hazards in connection with getting on or off locomotives or cars and impress upon them the necessity for exceptional care in performing this duty. This type of accident is largely within the control of the employees themselves to carefully guard against the hazards incident in getting on or off locomotives or cars.

Highway Grade Crossing Accidents

This type of accident which comes under the general classification of Train Service Accidents, and which constitutes 16.22 per cent of all Train Service Accidents covering the years 1920 to 1926, inclusive, is one that has been efficiently dealt with through activities of the Highway Grade Crossing Accident Prevention Committee of the Safety Section, American Railway Association, with the able assistance of a like committee in the National Safety Council, and your committee urges your fullest support to recommendations and activities of the afore mentioned committee. Any attempt on the part of this committee to supplement the reports emanating from such authentic sources is deemed inadvisable.

Struck or Run Over by Cars or Locomotives at Places Other Than at Highway Grade Crossings

During the period 1920 to 1926, inclusive, there were 5,181 persons killed and 8,245 injured, or 4.09 per cent of all Train Service Accidents are classified under this heading. These accidents are occurring to:

- Persons walking along tracks.
- Private crossings.
- Crossing tracks not at crossings.
- While working on or about tracks.

In congested terminals where employees are required to pass through yards, either open track level crossings or viaduct or subways should be maintained. Stringent rule, where these conditions prevail, should be enforced requiring employees to use them at all times. Train and enginemen going to and from trains in checking cars or other duties in large terminals should be constantly alert to cars or locomotives moving on adjacent tracks. Sufficient room between track centers should be maintained to provide safety for employees required to work between tracks. Where regular assigned foot walks through yards are maintained, sufficient distance should be cut in strings of cars to permit safe passageway, and positive instructions should be issued to switching crews to guard against closing up these crossings without having a man stationed at the crossing to warn employees. Car inspectors and repairmen should be cautioned constantly of the hazards in connection with their duties and not crawl over or under cars at other than designated points where crossings are provided unless positive blue flag protection has been provided. Supervisory forces should see to it that employees understand and comply with such instructions.

Miscellaneous Train Service Accidents Not Elsewhere Classified

Under this heading it is found that during the years 1920 to 1926, inclusive, there occurred 2,851 fatal injuries and 106,597 non-fatal injuries, which constitutes one-third of all Train Service Accidents.

It is apparent in analyzing the many causes of accidents that have been listed under this heading that sufficient analysis by reporting agencies has not been developed.

A thorough investigation should be developed on every injury resulting in a reportable casualty and sufficient detailed information furnished in such investigation so that employees required to make reports of accidents and their classification would not be left in doubt as to which group such accidents should be classified.

An attempt to recommend adequate measures to prevent the class of accidents coming under this heading would be extremely difficult. Your committee

realizes that the list of causes of Miscellaneous Train Service Accidents is available to all lines through I. C. C. Bulletins and suggests that safety officers review the accidents classified under the many causes outlined in such bulletins for the purpose of utilizing such information to conduct any plan of instruction or education necessary to cover local conditions. A careful study of the causes of Train Service Accidents as classified by I. C. C. Bulletins should be the guide by which safety officers could conduct a campaign of education among employees to overcome such accidents. Taking the whole Train Service Accident classification and analyzing the many causes of such accidents, it is apparent that the failure of the human element is by far the greatest contributing cause, which obviously indicates that a more intensive plan of education and instruction be carried on by the railroads.

Train Service Accidents should be discussed at safety and staff meetings and the contributing cause given serious consideration by supervising officers to remedy if possible. Where safety rules are effective and investigation develops responsibility rests with an employee, disciplinary action of some kind should be seriously considered. Unless and until carelessness on the part of train service employees, which causes accidents, is severely dealt with, educational efforts will be of no avail.

In conclusion, I wish to take this opportunity of thanking my colleagues on this committee for their very able assistance and advice, and hope this report will be the starting point of an intensive campaign among all safety officers of the American railroads in an effort to reduce personal injuries coming under the classification of Train Service Accidents.

CHAIRMAN WHITE: I am sure that all members of this Section appreciate the very thorough manner in which Chairman Bailey has gone into this subject. I think it is of great interest to everyone in this room to carry back to his railroad and try to put it over. What is your pleasure on this report?

MR. HILL: I move the report be accepted with thanks for the very able work. (The motion was seconded and carried.)

CHAIRMAN WHITE: We are now going to have the report of the chairman of the Committee on Accident Causes and Remedies, to be made by Mr. Tom Carrow. It is unnecessary that I say anything about Tom Carrow, because we all know him and love him. We also know that a meeting without Tom Carrow would not be complete.

Report of Committee on Accident Causes and Remedies

**T. H. Carrow, Superintendent of Safety, The Pennsylvania Railroad,
Philadelphia, Pa.**

I have sat here this morning and I have literally seen the children of my imagination take off their swaddling clothes and put on long pants. I think it will not be necessary or probably it would not be advisable for me to continue after this term as chairman of the Committee on Statistics, because I can see that the thing I have dreamed about all these years is coming to pass. This chart is the first comprehensive exposition of the Interstate Commerce Commission statistics that I have ever listened to, and I have no doubt that other railroad men, taking the cue of our esteemed friend, C. T. Bailey, will go and do likewise.

While I am making this observation, I want to make an additional one, and that is, the engineers of the railroad have always developed their facts and figures before they undertook to carry on a project. In safety work we have depended almost exclusively upon generalities. The time has come for the development and the application of specific information, such as has been presented here this morning.

It is difficult for me to make a report in the common acceptance of the word. It seems to me that the function of a statistician, or what more properly may be called an actuary, would be the crystallization of the thought and the effort, the knowledge, the information, that is developed from year to year.

I trust that I shall be able to do that this morning, speaking under the caption, "Education for Safety."

It is a great world in which we live, and a wonderful world, but, my friends, it is not the world in which we who have reached the meridian of life were born. The changes that have taken place are almost unbelievable.

We have the same instincts, the same faculties, the same aspirations, the same ambitions, and the same ideals, but the whole structure of human society provides new and additional means for giving them play.

Modern Life Is Kaleidoscopic

The whole fabric of human experience is woven from different thread today compared with our childhood. It is of a different texture, and it has a different coloring.

We lead what might be called a panoramic existence. We see things on the go, and we go while we see. Twice daily we are presented with graphic outline of what is going on throughout the entire civilized world, and even into the jungles of Africa and other foreign countries.

From supper time until bedtime we hear the best in music, literature, sermons, and we are literally flooded with oceans of jazz, razz and blazz.

We devour the news on the trains, in the homes, in the clubs, on the street cars; indeed the daily newspaper is as essential to our mental digestion as our breakfast food is to our physical digestion.

There is no end of subject matter. There is production and distribution, immigration and foreign relations, tariff and war debts, political corruption, burdensome taxation, railway transportation and motor transportation, inland waterways, bootlegging and prohibition. Down in Philadelphia the other day a boat hove into the dock with \$2,000,000 worth of liquor, a boat valued at a million dollars, and nobody knew what it was. Think of a problem like that being introduced into our life today.

Then we have the extension of the highways, trans-Atlantic aviation, Tunney and Dempsey, Lindbergh, Chamberlain and Byrd, the suicide wave, Rudolph Valentino, Teapot Dome, numberless highway accidents, low necks and high skirts, the new Ford car, and a multiplicity of other things that attract our attention day in and day out. And last but not least we have the continuous report of railway, street and highway accidents, the one subject that never ceases to be of interest, the one subject that never ceases to appear in any issue of any metropolitan paper which you may look at on any day.

Of all these subjects, accidents lead in the frequency of appearance and volume of space occupied in the newspaper, notwithstanding the fact that our good friend Lindbergh occupied 27,000 columns of space the first four days after he arrived in this country.

Why is it that accidents are of more interest, appear more constantly, more frequently than any other subject? Because they are of the greatest importance and lead in human interest, because the loss of life is the supreme tragedy of life, and well do we know it, because every year, 90,000 people meet an untimely death in this country, and because every year 4,000,000 are maimed or otherwise injured.

And the tragedy of it is that three-quarters of them are preventable. We walk across the streets in the midst of moving vehicles without looking in either direction. We get on and off trolley cars without regard to whether the car is moving fast or slowly or whether it is still, and as a result we are crushed under the wheels. Our children play on the railroad tracks as if they were public parks.

Machines are operated without guards provided for the purpose, and our hands are mutilated. Eye-hazardous work is performed without goggles. The result: we lose sight, which is the finest blessing that we enjoy as a physical being. We cross with our automobiles at intersections at high speed without looking in either direction and pay the toll in untold numbers of deaths.

As my friend Herbert Rowe would say, we approach highway crossings, although the shimmer of the rail is in sight, without paying the slightest attention to the danger involved and we also pay the penalty, often with death.

What is the antecedent of all of this casualty list? As I said before, we are living in a different world. Beginning about the middle of the last century, or sometime previous to that, somebody discovered that we could move with steam, and from that date on the whole genius of the human race has been directed toward the development of machinery and electricity and the application of steam; and comparatively little attention has been paid to the question of developing our minds to ward against the dangers that thus develop.

When the engineers of the United States of America devote as much attention to the human element as we so often say, when we begin to study psychologically, physiologically and otherwise, the problem of getting the mind adjusted to this present civilization, as to mechanical detail, we will then be as safe as our forefathers were in their rural communities.

Figures Prove the Value of Safety Education

How do we know that safety education will work? How can we prove it? We can prove it by cold figures, and the railroads, my friends, stand out as a shining example of safety education. The railroads have been constantly developing a set of operating rules whose purpose was primarily directed toward the prevention of accidents. In our later days we know that personal injuries have been prevented on a corresponding scale, injuries to employees, which is the important part of my report. I received the statistics Saturday morning before I left my office, from my good friend down at the Interstate Commerce Commission. Injuries to employees, dropped from 24 casualties per million man-hours in the first six months of 1926 to 20 casualties in 1927. And 50 or more of the best railroads in the country have a better record than that.

In order that you may carry this home with you, you tell your boys that in 1926 the casualty rate, to be exact, was 24.32 as compared with 20.33 in 1927. That represents roughly a reduction of 17 per cent in casualties to employees.

How was that brought about? By safety education, cooperation, persuasion and training, by intelligent effort directed toward the prevention of accidents to employees.

Now I want to illustrate how we fail, lamentably fail, in the direction where we should have made the most progress. Back in 1915 and previous to that year, 5,000 people were killed and 5,000 were injured as trespassers on the railroads of the United States. Last year, and previous to that for two or three years, that number had been cut 50 per cent. Instead of a total of 5,000 fatalities, we had only 2,500; but the first six months of this year shows an increase of 160 killed and 176 injured, while trespassing on the railroad tracks. I will venture to say that 80 per cent of that increase was made up of little children who didn't appreciate the danger with which they were confronted.

Collisions on our railroads decreased 13 per cent in the last six months. Deaths from collisions decreased 51 per cent, and injuries decreased 17 per cent.

I have something to say that will tickle you all; it will demonstrate that Deff Phillips was right when he said, Toot your own horn. Toot it like hell and then toot it some more, because if you toot it right and you have it harmonize with all the music and symphonies of human society, you will get an audience. What am

I going to tell you? I am going to tell you that highway grade crossing accidents for the last six months in our country (I got the figures before I left my office), show a decrease of four-tenths of one per cent in the number killed and seven per cent in the number injured, notwithstanding an increase of 2,000,000 automobiles, an increase in the popularity of touring and an increase, I am certain, of 25 per cent in the average mileage per car.

What are the antecedents of that magnificent record? It started back in Boston in 1921 when the Committee on the Prevention of Grade Crossing Accidents was appointed. And it was continued through the efficiency and capable effort of our friend Rowe until this present day, through the divisions along all the railroads that have solicited cooperation of the newspapers which have and always will publish matters of human interest.

The Modern Newspaper Has Great Influence

On our own line in Williamsport, Pa., a town of 50,000 people, for 30 consecutive days the editor carried a block advertisement to prevent highway crossing accidents. If there ever was an illustration of influencing the public mind, it has been in the careful crossing campaigns, in the persistent and unrelenting effort that the railroads have put forth to prevent highway crossing accidents. I don't think that I exaggerate in saying that we have no more than scraped the surface. I am sure that Mr. Rowe would say that. In 1928, if we put our shoulders to the wheel, we can even accomplish 15 or 20 per cent more than we have thus far accomplished.

The United States Steel Corporation, the Bethlehem Steel Corporation, the International Harvester Company, the wood pulp companies, the cement companies, and many others that I could mention have all made remarkable reductions, and they have made reductions not only in their accident frequency but in the cost of accidents.

The cities of the United States where organized safety has been in effect for some time, show marked reductions. In Detroit, I recall, a year after the Safety Council was inaugurated, they cut the fatalities to children in half. On the highways, it is true, as almost any citizen could point out, there is an awful lot of carelessness, but anybody who has the eye to see can determine that a very large proportion of the people who drive automobiles are careful and cautious. You see the signs on the roads, there is everywhere evidence that public safety is being felt all over the United States of America. Witness the Hoover Conference. My friend, Mr. Singleton, of the Indianapolis Public Utilities Commission is here, a man who is devoting his untiring efforts to cautioning and educating the people of Indiana to use greater care. Public education along safety lines is not any more in the experimental stage, it is beyond that, it is a positive fact.

I could tell you something about my own railroad, but I would rather not count my chickens before they are hatched, and besides, pride goeth before a fall. Maybe somebody else will tell you that some later day.

I want to conclude, however, with the reasons for safety effort. What are the reasons? If you were to go to your boss and tell him that you want to put a spur at some place, you want to put an extra track in a yard, you want to have more cars in a train, you want to get a larger locomotive to replace the little one that you already have—why do you want it? If he is an intelligent manager he makes you produce the evidence. Well, the time has come when we safety men ought to take this question of ours right out of the realm of uncertainty and put it on the rock foundation of specific figures. Why? What are the reasons for better safety on American railroads, for more safety on the American highways, for greater safety in the American industries? I will mention the first one: It is economic. No investment in time and effort will bring such marvelous returns as a scientific accident prevention campaign. You are glad to invest your few dollars in a

reputable stock company to get six per cent; for every dollar that you properly invest in safety you will get a dollar back.

First of all, safety is economic and if you have no other reason for it, the economic reason is sufficient.

What is the second reason? Reputation. Character is what a man is, but reputation is what a railroad is. It is what the people think a railroad is that it is. But people think of a railroad based on its performance and the railroad that puts forth a good performance can't help being high in the estimation of the people. Reputation, friends, is a mighty fine thing to have when you want to get something that is right and reasonable put over with the public. The public will go along with you, the public is nearly always with you if they understand you and if you can present your proposition to them in the proper light. But, believe me, you have got to come clean and you have got to have some reason for going to them and asking them to do the thing that you want them to do.

So reputation among the other things is a reason for safety.

Human Happiness Is the Final Goal

Now I come to the end of the reasons, and the end of my talk. There is one other thing to me that transcends in importance every other reason for safety. I so often state it that it is becoming an obsession with me. I think it, I write it, I talk it, and I sleep it. I want to contribute a little to the sum total of human happiness. I know that you want to do it, and of all the fields of human endeavor there is not one that compares to safety in proportion to the amount that you can contribute to human happiness. Happiness, my friends, is the greatest thing in the world. It is the thing that you begin to seek from the time you are born until you die, and unless you are physically qualified to be happy you don't know what happiness is. A maimed man, a man who is debilitated from any cause, is not happy; and oh, think of the thousands of people who are leading miserable lives because they were involved in preventable accidents, accidents that could be prevented. Isn't it a beautiful prospect to think that instead of a hundred thousand accidents on the American railroads in 1926, we can have 50,000 in 1928 or 1929? If there were no other object in safety, if there were nothing else than merely to make this a better world to live in and our railroads better upon which to travel, that alone would be sufficient for me to carry on.

There is one other point that impresses me as being wonderfully attractive to work to, and that is, our job is never done. You can work out a scheme right here in your imagination this moment that will be bearing fruit for ten years to come. As long as we are subject to natural law, as long as we have moving equipment operated by human beings, we will have a certain minimum of accidents, but until we reach the position where we continuously do everything that is reasonable and right to be done, we can never reach that irreducible minimum. And my friends, that is a tremendously big job. We can't do it with a flash in the pan, we have to formulate principles and continuously apply those principles from year to year. We must be actuated by the philosophy contained in those lines that I have so often repeated to you:

Heights of great men reached and kept
Were not attained by sudden flight,
But they while their companions slept
Were toiling upward in the night.

CHAIRMAN WHITE: I am going to ask my friend Mr. Robert Scott to tell us what we will do about this wonderful talk made by Tom Carrow.

ROBERT SCOTT (Atlantic Coast Line, Wilmington, N. C.): Mr. Chairman, you perhaps know something about the friendship that has existed between Mr. Carrow and myself a good many years. I fear that if I should undertake to tell you what

to do with that report it might embarrass Mr. Carrow and it might embarrass me. Therefore, I am going to ask you to call upon Mr. Hale to respond to Mr. Carrow's address on this subject.

ISAIAH HALE (Santa Fe Railway, Topeka, Kansas): That is the time dishonored practice of passing the buck. I really don't know. I have before used the expression, I am tempted to use it again, it is futile to attempt to paint the lily. Tom always has something worth while, and if on my recurring visits to this and the A. R. A. Convention I did nothing else but get the inspiration which I do from Tom Carrow's irrespressibility and enthusiasm, I would be well paid for coming. I have nothing to say for his report because it speaks for itself. He has said something that you and I should await in its published form and sit down and give very serious thought to. That you will do it I feel very sure. For one I feel very greatly indebted to Mr. Carrow as I have so many times before for the inspiration he again gives me. He is a magneto. He always has a shock with him.

CHAIRMAN WHITE: I want to say just a word about our secretary. You all know our secretary, and I want to tell you he has been a real secretary. If it were not for the fact that we want to use him for bigger and higher things, I would be in favor of making him permanent secretary of this Section.

I am now going to call on John Long to make a brief report as secretary of the Steam Railroad Section. Mr. John Long, superintendent of safety, the Delaware & Hudson Company, Albany, N. Y., will make his report.

Report of the Secretary

SECRETARY LONG: A speaker yesterday said that the grossest flattery was good enough for her. I am a bit embarrassed this morning because, being an old railroad man, I am not accustomed to having nice things said about me. Ordinarily, if we do our work, that is what we are paid for. If we don't do our work—well, there are ladies present, but you know what happens.

I do not believe you need a report from your Secretary. I have been making that report to you for the last twelve months. However, complying with the wishes of our honored chairman, it might be well to say that during the year I attended most of the Executive Committee meetings, and at such meetings that it was impossible for me to attend, the Secretary's work was very ably handled by my good friend and your vice-chairman, Mr. Cott.

I want you all to know how much I have enjoyed working with you during the past year. It has been a real pleasure, and it has been an especial pleasure to work with our beloved chairman and vice-chairman and the other members of the Executive Committee.

I have endeavored during the year to get out to you worth while news letters to the best of my ability. During the year I have succeeded in getting a number of letters to you which I hope you have enjoyed and profited by.

The credit, my friends, for these letters, is not due to your secretary, but rather to the fine cooperation of the many members of this Section who have sent in interesting news notes.

I have endeavored from time to time in these letters to express my grateful appreciation for this assistance, and today I want again to thank all of you for the very fine support which you have given me.

In conclusion, I want to urge upon each and every one of you to send to the new secretary, whoever he may be, any items of interest, any successful method of putting over your work, any unusual safety methods that you employ, so that at the end of this coming year he will be able to express his gratitude to each and every one of you.

CHAIRMAN WHITE: I believe this completes all the committee reports.

Before I pass on, I want to ask Mr. Hartenstien of the Lehigh Valley, who is our engineering representative, if he has any report or any remarks he wishes to make.

FRED HARTENSTIEN (Lehigh Valley Railroad, Bethlehem, Pa.): I very much regret to announce that I have not taken any part in the activities of the Engineering Committee from the sole fact that I have not had the time. I believe they have a meeting here on Thursday afternoon which I intend to attend, but I have not had the time to devote to the action of the Engineering Committee and I beg to be excused from making any further remarks.

CHAIRMAN WHITE: You all understand that our Executive Committee for the past year embraces some of the past presidents for this Section, including Mr. Bentley of the C. & O., Mr. Hale of the Santa Fe, Mr. Rowe of the D. L. & W., Mr. Rohweder of the D. M. & N., and Mr. Scott of the A. C. L.. All are due grateful thanks from me for their helpfulness when I needed assistance and called on any of them.

We now come to another interesting part of our program. It is a safety playlet by our good friend Mr. Cott of the Hocking Valley. While I have never had the pleasure of seeing this playlet, yet I have heard that it is up to the standard and is something that we will all enjoy. You all know Emerson Cott. He has a reputation, among other things, of having the most costly, the best fishing outfit of any member of this Section, and catches the fewest fish of any member.

While Mr. Cott is getting ready for his playlet, I am going to ask the Missouri Pacific Quartet to give us a song.

EMERSON COTT: I hope you folks will bear with me for a moment. I will give you a word of explanation of what I am going to try to do. I have heard, as you have, a great many safety men make safety talks. During a series of two years' rallies, while we had many able speakers, some ten or eleven (I was one of them so there were eleven), I learned that after all was said and done there was considerable duplication in what safety men said in safety talks. A certain amount of statistics, a certain amount of what we might call sob stuff, appeals to the ladies present, etc. It seemed to me that we needed some new method, perhaps, of introducing the safety idea to railway employees. So out of that thought was born a safety playlet. The use of the safety playlet in introducing the safety problem is not new. But it is, however, difficult to arrange a cast and train them and to carry out the plan that you have in mind. It takes time and money. I am going to try to do what some of you can no doubt do better than myself. I do not pose as an actor, but those of you who do have dramatic ability can take this germ of an idea that I am going to give you today and perhaps can use it on your own lines. I give it to you for what it may be worth. It is not a finished product, but there are possibilities, I believe, in it. Our paraphernalia here is not complete. You will have to use your imagination a little bit. I am going to try to take several characters and I hope and trust you will like it.

Safety Playlet

E. R. Cott, Supervisor of Safety,
Hocking Valley Railroad Company, Columbus, Ohio.

ACT I

Hello, Mother. I will not be home tonight.

Put in some new lights down here in the yard and I am going out to see how they work and then I am going up to the safety rally.

What's that? (*Lighting a cigar.*) That isn't fair. I got to eat over to the

greasy spoon. Save that chicken until tomorrow night. How are the kiddies? To school all right? Fine. I will be home as early as I can, Mother. Good-bye.

(Calls party on telephone.) George, what is the matter down in that yard? Can't you handle cars down there? Now listen, George. You have got the bottle neck down there, now get out and get into the game, get right behind those boys. Stir up their interest. Tell them we need that room. We need tracks down there . . . That's the way. Go right after them. You work with those men and they will work with you. Now you give us some room in ten and eleven. We are going to have to have . . . Look out for that manifest . . . All right, all right . . . Thanks. You will do it.

(Rises and greets visitor.) Hello, John. How are you, sir? I am glad to see you. Sit down . . . Well, yes, I suppose I ought to feel good over my promotion to trainmaster, and I do; but there is a lot of responsibility with this job that makes a man lay awake nights and think about it. I have got a good many men whom I am responsible for. My actions make or break them and one has to weigh his actions . . . Yes, I know, we all appreciate it, and I am not trying to get out of it, but at the same time I realize my responsibility, and I am going to try to live up to it.

Thanks, thanks, come again.

(Telephone rings.) Hello. Now listen. We have got to have better inspection in this yard. Too many penalty defects getting by those men. You know what our accident record is here, and if we have any more trouble of this kind we are going to lose it. I want you to get out among your men and teach them the importance of 100 per cent inspection in this yard—100 per cent inspection. Nothing else will do here. That is right, that is right. You follow that up. What is your night man doing? Is he staying in the shanty or getting out among the men? You get that night foreman out. That is where we are having a little trouble. Watch that blue flag. I have got a report (I will send it down to you) on 14 last night. They failed to put up blue flags. I know it is not my responsibility if my men get in there, but that doesn't make any difference; it is an accident. That's right, that's right, get the night foreman out and get an explanation on this blue flag last night on 14.

What's that? Well, I'll call him for you. I'll call him.

(Calls another party.) Supervisor there? Harry, I was just talking to the general car foreman and he tells me your men are not getting these drawbars out of the yard like they should. They have got a hook down here. Every man should come in in the morning and they know where those drawbars are. If our men are failing to report them I want to know it. I will take the proper steps. But in the meantime you get out and get on it. Come on, we have all got to work together up here. Yes, sir; yes, sir; down 27 and 19 and 11. Yes, had a car man stumble over one of them last night. He is not hurt bad. He will be back to work all right today. He has the right kind of spirit in him. Somebody else would have been off five or six days with a reportable accident. In the meantime you fellows want to prevent anything happening like that last night. All right.

(Calls somebody else.) What is that delay on 97? Well, now, listen; why don't your men find defective bells and headlights before they get them out? That's what they are down there for. No, we are not going to run any engines out without good bells and electric lights, but find them in the first place. We have got to account for this delay. All right, all right, thanks.

ACT II

Yes, sir, come in. What is your name? I. B. Newman?

Well, I see, young man, the doctor has passed you. You still think you want to go to work on this railroad?

Young man, you never had any previous experience, did you? I am not going to preach and talk to you a great deal, but there are a few words that I want to say to you, as a new man going to work in my territory. I want to tell you in the first place that we have got good clean men working on this railroad, and that is the only kind we want here and it is the only kind we are going to keep.

Another thing, we have a safety record on this division, of which I am train-master, of which we are proud. There isn't any accident about our safety record. It is because you and the men you are going to work with and the foremen and the supervisors and the engineers and all the people on this division have been proud of that record and have worked to maintain it. I want you to learn something about safety as you go out on this job, and I am going to send a conductor to you who will talk safety to you, the man I am going to put you to work with.

I want you to listen to what he says and take his advice. Just a minute.

(Exits. Re-enters as conductor.)

Hello. Are you the new fellow that is going to work? Uhuh. Ever had any experience? Fireman? What is the idea of going to work on a railroad? Oh, want to be president? Well, what is your name? That is a good name, I. B. Newman. Now listen, buddy, you are going out to work for me. The old man sends all new fellows out on my crew. Now, I want to tell you, we got a crew that you are going out with, and it does the work. Believe me, we handle cars. But I want to tell you one thing, that the crew that I be runnin' ain't had an accident for four years, and we ain't going to start having any right now. Now listen, kid, don't go out there and try to hit the ball. I am not going to step on your tail, I want you to come along as fast as you can, but don't be trying to do tricks.

You watch me and the other boys in the crew and get on to what they are doing and do what they do, and if you don't know it, don't guess. And if you don't know what switch to throw, find out, or by God leave 'em alone. I had one fellow that didn't know what to do so he did something and I came pretty near breakin' my record. Keep your feet and fingers away from drawbars. They got couplers on 'em. The men fought for 20 years to get 'em and half of 'em don't know how to use 'em, after they fought 20 years to get 'em.

Don't think that you don't have to do anything. You do. But you use the noodle while you are doing it. That's all there is to this game. Come along.

ACT III

Get the house for me. Hello, I'll not be home tonight. Naw, naw, can't get home for supper. Yard's shot to hell, everything else wrong on the road. No, no, no, send the kids to the movies and g'wan yourself. No, I'm not going to any safety rally. That's where this dumb bunch of men we got ought to go. If you'd see these reports on my desk! I'll be home when I get home. All right, good-bye, good-bye, good-bye!

For heaven's sake, what is the matter with that yardmaster down there?

(Calls yardmaster on telephone.)

Hello down there, George, what are you doing, sittin' on your tail down there all the time? How do you expect me to run a yard down there and you balling everything up? Now you get down there and get 11 and 14 out. You get on the tail of those men! You got the bottle neck of this yard, damn it, and your men got to come across or I'll put somebody down there that can do it. That's the idea! You get out there. I'm not coming down there and run your yard for you, that's why I got you down there. If you can't deliver the goods I'll find somebody else in this yard that can. Naw, I'm not going to talk any more about it.

(Calls roundhouse.)

Give me the roundhouse. Say, what's the matter with 97 engine? Bell missin'?

Who in the hell cares whether they got a bell missin' or not? Don't nobody miss a bell these days? Get that engine out and get it on the train, you got twenty minutes delay now. Never mind the bell, never mind the bell! Make your light test, make your light test.

Huh. Look at that. (*Calls operator.*) Get the car foreman for me. Say, what do your men do down there after they put up the blue flag, play ring around the rosey? Don't they ever inspect them? Do they put up those blue flags and forget them? Aw, I heard there was one that wasn't up; thank God we had one man that inspected a train and didn't spend all his time puttin' up a blue flag. We have got to get trains out. Get your night man out. Never mind the blue flag so much. I know you got safety inspectors. Yes, I know, you've always got them. They come and they go. Oh yes, they write a letter. Don't worry about letters, let's get the trains out. Nobody is going to kick as long as we have performance in this yard. You get that night foreman out and find out what those fellows are doing. Inspect cars instead of putting up blue flags. For God's sake, don't forget to take 'em down if they do put 'em up.

Yes, what's that? You weren't through with me? Some drawbars in the yard, huh? Well, your men have got eyes, haven't they? Oh, well, they have lanterns at night. Whadayou want, to wet-nurse all these guys? Pretty soon we will have to have a helper for every man to go around and look for him.

(*Calls supervisor.*)

Oh, Harry, some bird fell over a drawbar last night; please pick it up, yes. Uhuh. By God, I like to see drawbars in the yard. I think we are doing business. If a man can't get one around here once in a while I don't think they are moving any engines. Pick it up. We gotta keep 'em satisfied. Yes, uhuh.

(*Enter new employee.*)

Well, who are you? Oh, Newman. What's your initials? I. B. Newman. Doctor's passed you? Young man, I think you had better stayed on the farm. You know when you work in this yard and on this division, young man, you hit the ball. I am one man that demands performance. And I get it! And I am going to have it! (*Lighting a cigarette*)

Now if you want to work I got a job for you. If you want to come around here and have a whole lot of esthetic dancing in this yard you are in the wrong place. I was raised in the old schools; do or die. Some of 'em do and some of 'em die.

I got a conductor out here you are going to work for. I'll send him in and let him talk to you. (*Exits.*)

ACT IV

(*Enters as conductor, taking a chew of tobacco.*) Hello. (*Puts the trainmaster's cigarettes in his pocket. Expectorates.*) You the new guy that's going to work, huh? Had any experience? Farmer! By God, the old man must think I am runnin' a kindergarten. Wonder where he's gittin' all these guys, farmer guys. I suppose you think you'll be runnin' a railroad 'fore long, eh? I don't know what he sent me in here for. But they ain't much for me to tell you kid, but to git out here in the yard and hit the ball.

Yes, yes: well never mind, you don't get this stuff out o' books. You git in here and go to work and you will know a hell of a lot more about it after while. They ain't anything I can tell you but keep your eyes open and follow me. I know how to handle cars and I know how to handle you. But one thing, you are working for an old man and you either hit the ball or the ball hits you. Now, you might as well learn that to start with, and you ain't going to be president o' this railroad in three weeks, either. You come on out here and I'll give you a job and we will go to work, and when I say work I mean it.

ACT V

Henry. Bring in those newspapers, will you? Thank you. Send Newman in. Newman, sit down a minute. Newman, you have made a good man. I am pleased to tell you that, beginning tomorrow morning, you are taking the conductor's rate on this road. You have learned the game. In the first place you started right. You started with the right kind of a man. You kept your eyes open. You have kept your body and your mind clean. You have learned the game. You are the kind of a man that we are proud of on this railroad. You have been free from injury, and that is an index to a man's character, to some extent, on the railroad. And it is an important thing. Newman, because of this fact: that it doesn't make any difference how capable a man may be, what his possibilities are, what he

may mean to this railroad and can be to this railroad, if his chances are cut off with an accident. The money we have spent and the time we have spent in training that man and making him of value to the railroad is wasted.

You have got a future. I have seen your work on the safety committee and I am going to see you are back there again. I have liked your work. You are connected up with the organization in a good way. That is the kind of men we want in the organization. Generally speaking, that is the kind of men we have in the organization. We want men of your character and type active workers in the organization.

I want to thank you for what you have done and bring this good news to you, and you go out and keep up the game as you have before. Good-bye, Newman.

ACT VI

Ohum. Tried to beat the train. It can't be done. Another nice one. (*Answers telephone.*) Well, hello. What's that? My God! Wait a minute! Wait a minute!

Henry! Call the ambulance and get hold of the doc on the 'phone, quick. Yep. Down yard C. Right up by the hump crossin'.

Now tell me about it. What in the hell did he mean by going in there? Ugh! By God, it's nobody's fault but his own; nobody's fault but his own; I'm not going to shed any tears about it. All right, I have called the ambulance. Go ahead, yes, yes. (*Hangs up receiver.*) Well, I suppose every passenger train in the next ten hours will vomit safety inspectors. They will want to hold me responsible. What have I got to do with men on this railroad? By God, they got eyes the same as I have; they got feet the same as I have; they got brains the same as I have. I hire 'em and fire 'em; I can't nurse 'em out in the yard. Oh, there will be the usual inquiry and a fatal—thank God, it isn't that, but they will all be here, and I will have to sit around here and look sweet.

(*Telephone rings.*)

Hello. What was that? All right. Henry, never mind that ambulance and the doctor. Get me that fellow's address, will you? Well, I gave him a job, that's what he wanted. That's all I can do about it. Get me Mrs. I. B. Newman at 426 Rose Avenue, Bay City. Make it snappy.

That is all part of the game. Some do and some don't. Hello, this Mrs. Newman? This is Mr. Noman of the XYZ. Mrs. Newman, we had a little accident in our yard today. Yes, your son. Yes. Your son is dead. Yes.

MR. COTT: Gentlemen, we have heard a lot about safety and perhaps not so much about efficiency. You saw two trainmasters, you saw two conductors. Which of those four men were the better railroad men? Who of the four were the better producers? Who of the four did the most work and did it safely and efficiently? And following that, of the four who were the better, safety men? Safety is a by-product. It is a thing you cannot order. It is a thing you cannot achieve, it is the product of the character of the man. And with efficiency and the milk of human kindness and interest that every man should have in his heart for his fellows, along with that and as a product, comes safety. Stress efficiency, stress production, stress kindness, and if you can accomplish those things safety is the result that will follow.

CHAIRMAN WHITE: I am quite sure you all enjoyed Mr. Cott's playlet. I want to say, from my experience out on the road, that there is more truth in that than poetry.

I want to express my appreciation to the ladies and gentlemen for their good attention and the large attendance here this morning.

ADJOURNMENT

Wednesday, September 28, 1927.

The meeting convened at nine-ten o'clock, with the chairman, J. D. White, presiding.

CHAIRMAN WHITE: We now come to that part of our program well and happily known as executives' day; and it means a great deal to all of us in this section.

The gentlemen on our program are so well-known that it is scarcely necessary for me to mention anything but their names when introducing them.

I do not believe any greater compliment could be paid to the Steam Railroad Section than to have these gentlemen come here and talk to us about safety. We all know that safety must start at the top and go all the way down to the bottom.

I exceedingly appreciate the compliment they have paid to us by coming here, and I consider ourselves honored in having them with us. They have all had many years experience in railroad matters generally, and I am sure what they have to say to us will encourage us to such a degree that we will all go home to our respective railroads with more vim, more energy to promote safety among our people than ever before.

The first gentleman on the program, whom it gives me a great deal of pleasure to introduce, is Mr. L. C. Fritch, vice-president of operation, Chicago, Rock Island and Pacific Railway Company.

L. C. FRITCH: Mr. Chairman, Members and Guests of the National Safety Council:

I esteem it a great honor and a privilege to address this gathering. The safety movement, particularly on railways, is one of the most important elements of our operation. The railways have been considered as being among the most hazardous of occupations, but through the efforts of the rank and file and the officers and due very largely to the safety movement, railroading has become comparatively a very safe occupation.

There is, however, one thing that still remains as great menace to the safety of life and limb, and that is the railway highway grade crossing.

A speaker yesterday made a reference to the cost of eliminating all the railway grade crossings in this country at a sum of approximately \$20,000,000,000. Now that is approximately the valuation placed by the Interstate Commerce Commission upon the railroads. It is hardly conceivable that the railways could raise the funds necessary to eliminate all highway grade crossings. There will be much more progress made in this direction if the attitude of the public authorities is changed toward the railroads.

Years ago it was commonly understood, or taken as a matter of fact, that the railways were responsible for everything; that when any improvement or any change was made necessary by the existence of the railway the railways had to bear the entire cost. But that time has changed. The introduction of the automobile has brought a problem which is one of the most serious confronting the American public. That is the large number of casualties which occur at grade crossings. There is scarcely a day on our railway that we do not strike from one to three automobiles somewhere on our system. Ninety-nine per cent of these accidents are due to the carelessness of the drivers. We have many instances where automobiles run into the side of our trains. This problem is becoming so serious that something must be done about it. As I said before, if the attitude of the public authorities with reference to the elimination of grade crossings will be changed and they will cooperate more fully with the railways, a great deal more will be accomplished.

I mean that the railways cannot stand the major portion of the expense of elimination of crossings; it would be impossible for them to raise the money to do it.

In many states now the railways are being met on a very fair basis, and in those states more progress is being made than in those states where the authorities do not cooperate with the railroads. This subject is one of very live interest at the present time among the railways of Chicago. There is in Cook County alone, the county in which Chicago is located, a program of some \$32,000,000 of highway improvement. That means that a great many railways and crossings are to be affected; they must either be eliminated or protected. That is only one county in this state. The same large programs of highway improvement are going on all over this country, and it is getting to be such a stupendous thing for the railways to meet that it is almost staggering. The railways are called upon every year to spend millions of dollars in the separation of grade crossings. There is a limit to the extent to which they can go, and the public must make up its mind that in order to eliminate this danger they must meet the railways half way, they must cooperate with them, they must bear their part of the cost. The railways are not responsible for the introduction of the automobile. It is an element that has been brought in without their instigation. The railways are willing to meet the situation and in many cases are meeting it successfully, so that I say the public authorities must change their attitude in this matter and make up their minds that the public must pay a very large part of the cost of eliminating these grade crossings.

If that is done, one of our greatest menaces to life and limb as far as railway operation is concerned will be removed.

The Safety Movement on American Railroads

L. C. Fritch, Vice-President, Operation, Chicago, Rock Island & Pacific Railway Company, Chicago, Ill.

The safety movement is at once a humane and intensely practical and economic proposition.

Organized safety movement on American Railroads has long since passed the doubtful or experimental stage and for many years has been recognized by management and the rank and file of employees generally as an essential in the proper, efficient and successful handling of the transportation industry, and as a part of its systematic and orderly procedure.

The United States Steel Corporation was in fact the real pioneer in organization and successful promotion of the principle of modern safety as applied to men in industry and, it is stated, that as early as the year 1906, that corporation expended one and one-half million dollars to better the working conditions of their employees through improved safety conditions, sanitation and welfare.

The railroads were close followers and the growth of the safety movement on the railroads of America is almost phenomenal. Simultaneously with the organization and attempted promotion of organized safety on the railroads, there came with the "Positive Thinker" who was willing to accept and assist, the opposite type—"The Negative Thinker," who could see nothing sincere or honest in the desire to promote such a worthy and needed cause as the conservation of life and limb, but saw rather in contrast an ulterior motive or—"Something up the sleeve." He doubted and held aloof. However, the life of the negative thinker was short as far as his ideas were concerned, and soon he changed his viewpoint and began to see that HE would be individually benefited if the safety movement were successful, and with this idea possessing him, he becomes a convert and a real advocate and the march of progress continued.

Practically every railroad of any considerable mileage in this country now maintains a safety organization or department under the direction of an officer who devotes his entire time, or practically his entire time to the study and handling of

those features that are necessary to carry on the safety work and produce positive results.

Like every other business, there are two angles from which the safety organizations on the railroads must be viewed and considered, namely, the humanitarian and the economic. It is but a delusion to believe that either of these two considerations can "Go it alone," as it were—they must be co-ordinated. There is no business activity that can be conducted in this day and age without giving consideration to the benefits that will accrue to the human agency and bring financial reward to the investor as well—the safety movement is no exception.

The safety movement generally is, today, one of the most important, widely known, openly discussed and seriously considered subjects before the American people. The complexity of our modern civilization has introduced hazards into our daily life never before known. The speed craze of the present day is responsible for untold thousands who annually lose life or limb in the mad attempt to realize a thrill. The automobile in the hands of reckless drivers has made the life of pedestrians, as well as that of the motorist, a weapon more deadly than firearms. The public generally, therefore, is vitally interested in the safety first movement and it is but proper and just that it should be so, for next to his belief in Deity, SAFETY represents and reflects man's highest ideal—conservation of human life and limb.

To practice safety, earnestly and whole heartedly, is but to observe and obey "Nature's First Law," to assist others to do so demonstrates our unfeigned belief in the "Brotherhood of Man."

The Individual Employee Must Cooperate

To carry on this work, requires time and money. The management of the railroads are willing to furnish the money necessary to make their properties safe, to guard machines, establish and maintain suitable and proper avenues for travel in and about the buildings and grounds, maintain proper and safe lighting and the many other things so necessary to make the working conditions and surroundings, not only safe but attractive so that the environment with which the workers are surrounded will appeal to their finer sensibilities. But, after all this is done, safety results will not be assured unless the individual employee willingly and conscientiously accepts his full responsibility, and does his part, adding his personal assistance and endeavor as far as possible to enlist the aid and assistance of his fellow workmen.

Safety, in the final analysis is a personal proposition and must be so looked upon and accepted.

Personal contact with and education of those who handle the every day work of the American railroad is the needed agency through which success will most surely come. Management and supervisory forces must realize this principle and lend support to its acceptance and advancement.

Lectures, employee meetings, public safety gatherings, literature and statistics, are all beneficial, but personal CONTACT between representatives and those who must be interested, is more important than these other agencies. Men must be WON to the cause.

Through safety committees, we believe, the greatest interest and cooperation of employees, and the best results can be obtained. On the Rock Island, our safety committees have done splendid work. We have always looked upon such committees as our allies, in principle and in fact.

At the present time, we have localized our efforts to obtain results through the organization of safety committees, sufficient in number and geographically located to have each important point on our railroad properly supervised and the committee at such points guided and directed by the man in charge as the chairman. We find that this distribution of responsibility and leadership is productive of greater interest and better results.

The success achieved by the railroads generally through their efforts to reduce loss of life and to prevent injury to employee, passenger, patron and neighbor is a matter of common knowledge, so well known and so obvious as not to need specific mention in these remarks.

However, exercising the privilege of reference to the particular property with which I am associated to say that in our safety work and efforts, we have been generally successful, the most attractive accomplishment lies in the reduction of 62.70 per cent in employee fatalities, 1926 compared with 1912, the year our safety department was organized.

Our railroad has taken an active part in every campaign in which the co-ordinated efforts of the railroads have been sought to give the greatest impetus to the advancement of safety education in the most forceful manner.

The railroads are ready and willing to do everything they consistently can to prevent accidents on railway highway crossings, but the driving public must recognize that the real responsibility for the prevention of such accidents lies with them and not with the railroads. Drivers of motor driven vehicles must be held to account for their wrongful acts. They must assume their full share of responsibility and if they do so, accidents at railroad highway crossings will be materially decreased.

Safety Campaigns in the Public Schools

Education of the public is the recommended medium through which the highest degree of success may be attained. To teach safety in the schools is but to embrace and to employ modern means and methods to assure the rising generation (our boys and our girls) being more thoughtful and considerate for their own personal safety and a manifestation of that same interest towards others.

Safety campaigns in the schools have always been a part of the Rock Island Lines' safety program. We have done an extensive work in the past and have definite outlines for the future. Safety talks, or lectures, by railroad men in the schools find welcome response from management and scholar alike, but it is an absolute essential, if we hope to merit and maintain such receptions, that such speakers confine themselves to the subject—SAFETY—and make no attempt to commercialize or otherwise take advantage of the kindness and hospitality accorded by the school management through the introduction of other subjects.

The school bus, thousands now operating in the various states, must be seriously considered in our safety educational work. The elimination of the small school house and the building of Consolidated schools in their stead, increases the hazard of the children who are transported in them to and from home and school, because of the numbers assembled in one vehicle rather than to have them scattered, either in vehicle or on foot as was formerly the case. We must see to it that school management becomes interested and insist that drivers of school busses take no chances when crossing the tracks of a railroad, that a positive STOP be made before attempting to cross, and a view of the track in both directions obtained by the driver, to know that it is safe to cross before he attempts to do so. At grade crossings the positive STOP, regardless of conditions, objection or criticism is the only way to insure SAFETY to life and property.

The Rock Island was a pioneer in the safety movement, we have actively and energetically pursued a program in our safety work prompted by a desire to be leaders, not followers, originators, not imitators, and we are of the firm conviction that those who enlist in the cause of safety and who lend their unstinted assistance to the advancement of that noble work are "Building for the Future of America and Its People."

CHAIRMAN WHITE: Mr. Fritch, I want to assure you that I appreciate having you with us today. In order that you may know how much the section appreciates it I am going to ask Mr. Charles E. Hill to please make a response.

CHARLES E. HILL (New York Central Lines, New York, N. Y.): To be privileged to respond to this interesting and instructive address of Mr. Fritch, Vice-President of the Rock Island Railroad, is I assure you, an honor. It shall not be my purpose to undertake an elaboration of the points he has so well covered, but rather to emphasize our appreciation of the wonderful addition he has made to our safety program.

For 13 consecutive years, the Steam Railroad Section of the National Safety Council has met in convention to discuss the railway accident problem. Each year we receive renewed inspiration which serves to increase our efficiency and stimulate our efforts, thus augmenting our progress in the field of accident prevention. Accident prevention along scientific lines is comparatively a new feature. Twelve years ago accident prevention work was not recognized by the railroads as being of any great concern.

The American people are rather prone to be skeptical of new theories until through practical demonstration they have proved their value, and safety work along scientific lines at that time was an undeveloped theory.

We have now reached the point, however, where safety is recognized as an integral part of railroad operation. We have seen the number of employee casualties materially reduced during the period in which organized safety has been functioning upon the American railroads.

This reduction does not only apply to accident frequency, but also to accident severity as well. Our experience teaches us that this has not just happened; it has been due to the carrying out of a definite plan of procedure, for our success, after all, lies in the carrying out of certain fundamentals.

The great interest that chief executives of railroads of this country are now taking in safety is indicative of a further downward trend in accident frequency.

Therefore, Mr. Fritch, you can readily understand why we not only feel honored in having you with us here this morning, but we are glad to know that a busy railway executive is willing to give his time to come here and testify as to the efficacy underlying the great fundamentals we are pursuing to reduce accidents and thus preserve life and limb.

The Practical Side of Safety Emphasized

Therefore, upon behalf of the American railroads, and particularly those assembled here this morning, I want to acknowledge our indebtedness to you for your presence here, the inspiration it lends and for your splendid address which shows a keen appreciation of the problems confronting us, and which will better enable us to meet these problems as they arise. It is our hope that we will have further opportunity to know you and that you will honor us with your presence again.

ROBERT SCOTT (Atlantic Coast Line, Wilmington, N. C.): I have no idea, gentlemen, of undertaking to emphasize anything that Mr. Hill might have said about Mr. Fritch's address. I should like to emphasize just one thing that Mr. Hill touched upon rather briefly, and that is that part of your address which dealt with the practical safety which the railroads are undertaking to carry on. If safety is not practical, it is of very little use. I want to assure you as an operating vice-president of one of the leading railroads of this country, that we safety men are trying to put it over in a practical way.

I thank you for your splendid testimony to that phase of our work.

CHAIRMAN WHITE: As further evidence of our appreciation, I think it would be entirely appropriate that we give a rising vote of thanks to Mr. Fritch for his presence here this morning.

(A rising vote of thanks was extended to Mr. Fritch.)

CHAIRMAN WHITE: It gives me a great deal of pleasure to introduce Mr. R. C.

White, Assistant General Manager of the Missouri Pacific Railroad, St. Louis, Missouri.

The Purpose of the Safety Organization

**R. C. White, Assistant General Manager, Missouri Pacific Railroad Company,
St. Louis, Mo.**

What is the real purpose of the "Safety Organization," and why should we be interested? Every employee would, without question, like to hear his railroad spoken of as the best railroad. An important factor, if not the most important, in bringing about a reputation for being the best, is safety. If we, by our performance, establish a reputation for being the safest railroad, we will at the same time have gone far in establishing a reputation for being the best railroad, as service with safety will make our railroad what we want it to be. I do not mean by using the term "our road" to restrict the application to the road that I have the privilege to represent, but use it in the broad sense. The dominant thought in the mind of every employee on every railroad should be that he wants his road to be "A Service Institution"; the best, the safest.

It takes something more than tracks, locomotives, cars, roundhouses and station buildings to make a railroad; it takes man power, and all that this implies. The thinking unit must be constantly at work and constantly alert for at the basis of every action or activity there is thought.

Without substantial work by the thinking unit we cannot hope for maximum results; without being alert we cannot be certain that our thinking is being directed along and into basic channels. In other words, without thought we would have complete collapse of our activities; with thinking of the proper kind and giving it proper direction we finally obtain proper action and therefore proper results. Hence, thinking is basic.

In the minds of the public that we serve, we officers and employees are the railroad; and with our thoughts and efforts properly coordinated, the result will be safe, dependable and satisfying transportation service. Proper coordination, however, cannot be brought about without creating and sustaining enthusiastic interest on the part of each and every one of us. This interest must spring from the desire to do good, and this desire only obtains when mutual understanding of "The purpose of the Safety Organization" obtains; thinking, constant thinking, right thinking and contact bring about that mutual understanding. This interest must, of course, be manifest from the head of the railroad, and from the head it must work down through every avenue where it can and will reach the man subject to error and injury, and none are immune to the dangers that are ever present in railroad operation, hence it naturally follows that every officer should have an interest in the safety organization and through every known mental and physical channel create and sustain individual and enthusiastic interest in promoting safety.

In order to obtain maximum results in any undertaking, we must give thought as to what we desire to do or accomplish, and then go about making plans and devising ways and means for carrying out those plans. We have made up our minds that we are going to be the safest and best railroad. One of the problems of the directing, thinking units is to convince each and every railroad employee that we have made up our minds, and that because of the desire to do good individually and collectively; further, that this desire or conclusion follows closely in the channels of universal right thinking; this thought must be sold to each employee, and he must be shown that the bargain is a good one for him individually.

The first step in formulating plans and devising ways and means for accom-

plishing our objective, was the creating of what we term our "Safety Organization." Its primary function is to keep in touch with every phase of accident prevention; to disseminate information and to educate all employees, particularly officers, in the principles of accident prevention. This is carried on by various methods, the scope and extent limited only by the capacity and ingenuity of the director of safety. The efforts of the "headquarters" organization must be intelligently and persistently directed; activity must be such as to obtain the enthusiastic interest of the individual; ingenuity must be such that this individual interest will become a co-ordinated force gathering momentum with experience and opportunity.

It is very apparent and necessary that the "headquarters" organization be outstanding in leadership and direction to preclude the possibility of inefficient or ineffective use of any substance upon which the safety movement feeds and lives.

Since the superintendent of an operating division is responsible for the safe, economical and dependable operation of his division, there must be a divisional organization or division safety committee; the division safety committee is a unit in the system organization for safety. The function of the division committee must be constructive—the making of plans and the devising of ways and means for creating and sustaining individual interest in promoting safe methods, correcting hazardous conditions and unsafe practices, and creating safe practices in producing transportation. Carrying the organization further, we have sub-committees among the maintenance of equipment and maintenance of way and structures departments, whose functions are to educate the man on the job in the principles of safety.

Functions of the Safety Organization

I have indicated in a general way the function of a safety organization, and what I have said has not been worth while unless I have caused the question to be asked: "What can I, as an individual, do?" There are many things, but I shall mention only a few; and in mentioning them before the directors of safety as well as operating officials of the railroads of our country, I will refer to them as a function of the safety organization, and addressed to the whole organization.

First—If you observe an unsafe practice and have the opportunity, tell the individual right on the spot. Tell him both how and why, in language that he understands—in doing so, you will have transmitted a thought that he can never get rid of; whether he likes it or not, you have put into him being something that is good; and have done him a real service. At the same time, make a mental or pencil note, and before the day is over make a memorandum, giving the chairman of the division safety committee the benefit of your observation.

Second—If you observe an unsafe condition and you are not in position to personally correct, do not turn in for the day until you have made out and mailed a safety card, and, in addition, advised the supervisory officer by telegram if the circumstances seem to warrant, this in order that the condition may be corrected before, rather than after, causing an accident. The saying of the philosophers, while very old, is very true; and, being the truth, we can always afford to repeat it: "An ounce of prevention is worth a pound of cure."

By following these two suggestions, it will make possible immediate handling for correction and, further, will make it possible for the division committee at the monthly meetings to devote its time to the working out of constructive plans. It is neither interesting nor constructive—in fact, it is a positive imposition on the intelligence and good nature of the members of the committee and interested visitors to be forced to sit in a meeting and listen to statements or reports as to unsafe conditions or practices observed thirty to sixty days previously, with nothing done to correct. If each individual will promptly report unsafe conditions and unsafe practices, these reports promptly gotten into the hands of the proper supervisory officers, and then promptly corrected, and record as to report and correction made, this information

can be written into the minutes of the meeting, together with subjects to be carried over for further discussion and consideration, and copies of the minutes distributed in advance to all members of the committee.

It is not my purpose to suggest here how safety meetings should be conducted or how the safety work should be carried on. However, I desire to leave this thought with you that safety meetings be conducted in such a way as to cause each and every individual present to tell the other fellow what is being done to promote safety and how he, as an individual, can be helpful. In this way your educational work will spread among the rank and file of the employees.

Essentially this is a matter of education; the transmitting of thoughts of a kind, and in a way that the individual will understand: with understanding comes confidence; with confidence comes action; with action comes results; with results comes gratitude; and at that time we find the individual an agency of interest and enthusiasm under the well-directed thought of what we are trying to do, which, in the last analysis, is so basic and essential in any field of action.

Each Safety Rule Is a Constructive Thought

Another thought I would like to leave with you is this: the operating book of rules has been compiled literally one rule at a time; each rule is constructive thought tempered with experience, and reduced to a written rule for our guidance. A rule fails in its purpose unless all have an intimate working knowledge as to its provisions. Every employee, particularly those involved in train service, must know the rules, understand and appreciate their real purpose and uniformly observe them. At this point I would like to call attention to the thought that the Golden Rule and the Book of Rules are the safe guides in every railroad man's life: without the Book of Rules we would not safely understand each other; without the Golden Rule we would not care for each other.

The purpose, therefore, of the safety organization is to inspire thought, with its impelling co-ordinated action, and I have tried, without going into detail, to show, in brief outline, how we should go about it.

The safety organization has still another aim, and that is, helping solve the grade crossing automobile accident problem. Education of the public to the dangers growing out of carelessness in the use of the automobile with particular reference to the duty they owe themselves when crossing a railroad crossing at grade. It is the function of the organization to disseminate appropriate literature, and to go out among the public and address them at all kinds of gatherings and vividly portray the dire results growing out of failure to make sure that it is safe before proceeding upon the track—to go into the schools, seeking the opportunity to do so, and in proper language impress the children with all phases of safety and especially the safe and sane use of the automobile, for the foundation for successfully teaching the principles of safety, the ethics of fair play and the value of co-ordinated action—cooperation, lies in the schools and in the homes of the nation.

I subscribe to the thought that a thing of great importance is for the chief operating officer to recognize his own responsibility, appreciate how far his interest and influence will reach, and then emphasize his own interest by inaugurating such follow-up as will enable him to know that all supervisory officers accept their responsibility for the safe conduct of the employees, working under their supervision. However, we must all recognize our interdependence in this great co-operative effort, affording safe and satisfying transportation service.

CHAIRMAN WHITE: Mr. White, I assure you that your message on the promotion of safety has been a wonderful inspiration to the members of the Steam Railroad Section, and in order that you may further understand how much we appreciate it, I am going to call on Mr. Warfel of the Union Pacific Railroad, to make a response.

Discussion of Mr. White's Paper

**G. H. Warfel, Assistant to the General Manager, Union Pacific Railroad,
Omaha, Neb.**

I have a grievance against this program committee. Sometime ago they asked me if I would participate in the discussion of a paper by Mr. White, and I replied that I would. I was then notified that my discussion should be extemporaneous and must be brief. Now I see they have my little talk billed as a response. I have always understood that a response was something offered in reply to a toast or a prayer.

When I received a copy of Mr. White's paper a day or two ago, of course I immediately sat down to read it, and the first thing that greeted my eye, as you have heard here this morning, was this: "An important factor, if not the most important, in bringing about a reputation for being the best, is safety. If we, by our performance, establish a reputation for being the safest railroad, we will at the same time have gone far in establishing a reputation for being the best railroad." Now this had a very familiar sound to me, and I had to look back at the title to assure myself that the writer of such a statement was connected with another railroad.

It goes, without saying, however, that I must certainly subscribe thoroughly to the sentiment which Mr. White expressed, even though it be a carbon copy. I would like to call attention to this statement in his paper: "With thinking of the proper kind and giving it proper direction, we finally obtain proper action and therefore proper results." I feel somewhat inclined to suggest that two words in that statement should be reversed, and say—"With action of the proper kind in the proper direction, we finally obtain proper thinking, and then proper results."

I wonder if many railroad managements realize that one of the most valuable by-products of an aggressive and intensive handling of accident prevention work is the much greater amount of thinking done by employees than would be the case if no such campaign were conducted.

It has been our experience that when a man feels that an accident is going to endanger his standing with his employers, he will devote a much larger part of his time to careful thinking, and practical thinking, than he has ever done before, in an effort to avoid that accident.

I believe it will be found that the general intelligence of the entire personnel of a railroad will rate decidedly higher where an active and continuous safety campaign is conducted, than on a railroad where this has not been done. Inevitably, this incentive to think leads to a higher efficiency along all other lines of progress as well as in accident prevention.

In regard to interest in safety work Mr. White says, "This interest must spring from the desire to do good." Here again I should like to suggest that it is a debatable proposition whether more people are moral from a desire to do good, than from the fear of punishment for doing evil. We have found it well worth while to play upon both incentives in the human mind—the desire to do good, and the fear of the result of wrong-doing. We believe in the Evangelistic side of safety work, but we have also secured some remarkable results by emphasizing the punishment that will follow from doing wrong. I agree with the speaker when he says: "This interest in safety work must be manifest from the head of the railroad and from the head it must work down"; and I repeat what I have said in other meetings that the casualty rate among the employees of a railroad may be regarded in a general way as an

index of the effective interest taken by the management of the railroad in accident prevention. I believe it is even possible that more spectacular results could be obtained in some instances by one honest-to-goodness safety meeting held with the chief operating officer of the railroad, than by a hundred so-called safety meetings held among the rank and file of the employees. We have not yet sold the conservation idea properly to some managements.

An element too often lacking in safety organizations on railroads, is the element of authority, and that element must be supplied by the head of the organization. The voice of a safety agent or inspector may be honeyed with persuasion, may be filled with the milk of human kindness, but it will accomplish much more among the personnel of a railroad if it rings with the tone of authority.

Mr. White says: "We have made up our minds that we are going to be the safest and best railroad," and he continued, "one of the problems of the directing and thinking unit is to convince each and every railroad employee that we have made up our minds." I submit that the most effective way in which to convince the employee that we have made up our minds is through the judicious use of impartial discipline for the employee who knowingly or carelessly violates the safety rule.

A Judicious Use of Discipline Often Necessary

Now, I would not have you get the idea that on the property I represent, the officers and the safety agents are hard, stern, and cruel, seeking every opportunity to thrust the iron of discipline into the heart of an employee, for that is not the case.

But when we have set up a comprehensive code of safety rules for the guidance of our men, and have educated them thoroughly in that code of rules, a judicious use of discipline proportioned according to the hazard involved in the violation is the most effective means for securing uniform observance. A code of rules is not effective unless it is uniformly observed. I would be inclined to substitute a different sequence than that which Mr. White arranged, as to the stages through which the education of the employee is accomplished. I would state it this way: essentially, it is a matter of discipline. This requires taking action of a kind and in a way that the individual will understand. This action gets results in the saving of life and limb. The results inspire confidence; with confidence comes understanding, and with understanding comes gratitude; then we find the individual an agency of interest and enthusiasm in the work we are doing.

The purpose of the safety organization on railroads is to save lives, to keep the clouds of sadness from darkening the homes of our people; and the measure of effectiveness of the organization is the amount by which we decrease the casualty rate on the railroad. A gratifying progress in the reduction of the casualty rates on American railroads has been made in the last few years, but we have not even approached the reductions that most of us feel are entirely possible. Perhaps, one reason is that we have been too prone to present accident prevention on the basis of its humanitarian appeal, rather than upon the hard, cold basis of economic gain.

I am as strong an advocate of safety for humanitarian reasons as any other man in the work, but I suggest to you that the cause of humanity might well be served by presenting to our managements in dollars and cents, the cost to the stockholders of the failure to thoroughly and aggressively enforce safety on their properties. If this great waste could be accurately presented for their inspection, the action which they would take might be the greatest boost which

humanitarianism has received in a long time. It would be a strange thing to see the casualty rate tabulated on a dollars and cents basis rather than on a man-hour basis; but it might be a very effective way in which to present the real value of safety work—the saving of human life, and the prevention of needless suffering.

(Mr. E. R. Cott took the chair.)

CHAIRMAN COTT: It has been suggested by the Chair that we ask for a rising vote of thanks for Mr. White's paper.

(A rising vote of thanks was extended to Mr. White.)

CHAIRMAN COTT: We have a number of railroad executives with us today. I am going to ask the safety representatives of the various railroads here if they will introduce their executive officers. I will first ask any safety representative, who has a president with him, if he will introduce him to the assembly. Mr. Rohweder, will you start, please?

(Mr. A. V. Rohweder, Superintendent of Safety and Welfare, D. M. & N. Railway Company, introduced Mr. W. A. McGonagle, President, D. M. & N. Railway Company; Mr. H. Johnson, President, D. & I. R. Railroad Company, and Mr. Clarence Howard, President, Commonwealth Steel.)

CHAIRMAN COTT: Are there any other safety representatives here with their presidents today? If not, we will ask the safety representatives of the various roads to introduce their vice-presidents.

L. G. BENTLEY (General Safety Agent, C. & O. Railway): I take great pleasure in introducing Mr. J. B. Parrish, assistant vice-president of the Chesapeake & Ohio, in charge of all personnel activities.

CHARLES E. HILL (General Safety Agent, New York Central Lines): I want to present Mr. T. W. Evans of Chicago, vice-president of the Indiana Harbor Belt and Chicago River and Indiana Railroads.

(Mr. M. Dailey, vice-president in charge of operation of the C. & I. M. Railroad, was also introduced.)

CHAIRMAN COTT: We are now coming to another number on our program which I am sure many of you are anticipating. The president whom it will be my pleasure to introduce in a moment, is a president of a railroad with which you are all familiar, due to the contact we have as safety officers with our co-worker, Mr. Rohweder. It will be my pleasure at this time to introduce Mr. H. Johnson, president of the Duluth and Iron Range Railroad.

MR. JOHNSON: Mr. Chairman, may it please you gentlemen, the few remarks that I have to make are entitled, "The Spirit of Safety," or "The Safety Spirit," whichever way you wish to put it. It is, in my opinion, one of the great underlying factors of accident prevention. While it is true that volumes might be written on this subject, the short time is too valuable to listen to such an extended discourse. I have only tried to touch on one or two salient points which to the best of my experience and my knowledge are very valuable in producing in the minds of the individual a state of affairs, a state of mind, which will be very helpful to him and to his associates in surrounding his work with a safety zone.

The Safety Spirit

By Horace Johnson, President, Duluth & Iron Range Railroad Company

The Safety Spirit now well implanted in the operation of the American Railroads was brought about by the realization on the part of the managements of the necessity of curtailing the frequency and severity of accidents to employees and to the public.

It was rather a startling realization to the managements of the railroads to find that after the order went forth "Let There Be Safety" it required more than an order. They realized that it was necessary to bring forth the mechanical and educational abilities of the management, supervisory officers and employees, looking for the solution of the problem of accidents on their properties.

The problem of safety on a railroad, as compared with that in an industrial establishment enclosed between four walls, varies in a great many ways. A railroad has a wide expanse of territory to cover, a great number of things that are impossible to foresee; the effect of climatic changes upon its operation and the action of the entire populace along its line.

The solution of the railroad safety problem has resolved itself, in my opinion, into several fundamental phases:

Fundamental Phases of the Problem

First—The manner of mechanically protecting machinery, cars, locomotives, docks and structures, is one that was easily solved, as it dealt with the clear-cut problem of engineering.

Second—The most complicated problem facing the managements of American Railroads today is the problem of human engineering. I like to refer to this problem as the bringing about in the minds of our supervisory officers and employees a state of what I term "safety consciousness." How can such a state of mind be developed?

We now have on our railroad under our educational work such items as a Safety Magazine, Safety Bulletins, Safety Lessons, Safety Slogans, Safety Schools, Safety Committees—all co-ordinated and working out the ideas and plans developed on our railroad in conjunction with such agencies as the American Museum of Safety, the Steam Railroad Section of the National Safety Council, and the Safety Section of the American Railway Association.

At this point I would like to express my full appreciation of the work of the Educational Section of the National Safety Council, in carrying on both directly and indirectly, through such organizations as our railroad, the work of teaching the youth of our country, from the kindergarten through the various stages of school life, the matter of protection of life and limb.

I believe that through such efforts we will eventually have in the railroad business, men who have had from their childhood the Spirit of Safety fully instilled in their mental make-up.

In studying the manner in which the Safety Spirit can be instilled into the mind of the railroad employee, it is well to remember the fact that it is a comparatively easy matter to sell the safety idea to the president, the superintendent, the chief engineer, and undoubtedly down the line to the supervisory officers, but the big problem is to sell this same idea, through the executive and supervisory officers, to the mass of employees in the rank and file, bearing in mind that these are the men who suffer the injuries. A willing cooperative state of mind brings about the ideal situation for the accident prevention program.

A great deal of importance is attached by most authorities and students to the foreman in charge and directing the energies of a unit of employees. In fact, by some thinkers and writers the bulk of the onus of securing accident prevention is attached to the foreman, without much regard to the material comprising his force.

The mental attitude of the foreman toward safety measures undoubtedly influences his effectiveness. The secretary of the Industrial Commission of Minnesota sums up his conclusions in these words:

"The particular subordinate upon whom the responsibility for effective safety first methods devolves is the foreman. His mental attitude toward safety measures determines the enthusiasm and skill with which he will work among his men to create for them and with them a sane, safe atmosphere, that most powerful weapon against accidents."

While granting that the management imbued with the safety spirit is an absolute necessity, and that it finally focuses on the foreman (having eliminated all of the things that can be eliminated mechanically), it brings us then face to face with the material with which the foreman has to work. That is, the men who are really doing things and are surrounded by danger in some form or another—danger that must exist in the established order of things.

In dealing with the mental causes of our accidents, there is a great difference of opinion as to whether carelessness is the cause of most accidents. Authorities disagree as to whether or not carelessness causes a large number of the preventable accident. No doubt a part of the seeming divergence of opinion arises from the difference in definition of terms. What one man calls carelessness the other regards as a psychological condition, due undoubtedly to unfortunate working, home or health conditions, or to a limited mental capacity.

To my mind the attitude of the worker at his daily task is largely dominated by psychological conditions and is determined to a large degree by the environment by which he is surrounded. I would refer you particularly to the fact that a clean, orderly shop is conducive to a satisfactory mental attitude. I would suggest to you that the man who is interested in activities of the company, such as baseball, basketball, bowling, swimming, and employees' association, usually is inclined to be satisfied with his lot and to work along with a keen sense of appreciation and a keen mind, ever watchful for the welfare of himself and others. The development of women's athletic activities as promoted by the Duluth & Iron Range Welfare Department creates another approach to the employee by surrounding him with a feeling of satisfaction that some real consideration is being given his wife and family. All this tends to promote a state of mental co-operation.

The Man With the Proper Mental Attitude

Along this same line, let me suggest to you that a man who is a good citizen, who is interested in the solution of the problems of the community in which he lives; the man who tries to raise his family under proper environment; the man who tries to keep up a good order of things about his home, is a man who has developed a proper mental attitude which is conducive to safety.

I am thoroughly in accord with the recommendations of the Medical Section of the American Railway Association, suggesting that railroads require a proper physical examination of all men in their service. A thorough study of these examinations, made by competent doctors, will indicate to a very large extent the physical and mental condition of the employee, and will necessitate careful consideration on the part of the management in placing employees in occupations where their health will permit them to work with safety.

The mind and body of a man is not always synchronized, thus causing unnecessary and improper movement which is the primary cause of accidents. The synchronization of mind and body resolves itself into the elimination of accidents through mental training and through the increase in efficiency by eliminating unnecessary movements.

The question of habits of employees when not on duty is a matter that is of vital importance in the accident records of our company. It is necessary to be temperate. By temperate I do not refer alone to the matter of being temperate in the use of those things that are prohibited by the Eighteenth Amendment but to being temperate

in all matters of life. I refer you to the matter of over-indulgence in sports; the over-indulgence in recreation of any kind, that brings about the lack of proper rest.

I would also call your attention to the fact that the spirit of safety goes beyond the property of the railroad because of the fact that a large number of our employees are killed and injured as citizens in various communities. Along with the training of our employees to a safety consciousness in connection with our operation we must go beyond the line of our railroad into the community and the home, thus bringing about a fuller realization of the true safety spirit.

There are several things in which an executive officer should assume a personal interest. First of these is the matter of investigating personal injuries.

Recently we had an accident on the Iron Range in which a man was injured by the return blow of a steam hammer without an apparent cause. The usual procedure, I presume, on most railroads is to accept the report of the investigation and let it go at that. In this case an expert from the company that built the machine was brought in from the works in Pennsylvania to the source of the accident and after a careful investigation determined that the operator had been operating this hammer in an erroneous manner for a period of four years. The hammer operator was not to blame, due to the fact that the entire Mechanical Department personnel did not understand the proper operation.

This is a typical case of what can be developed through a personal investigation by the executive office.

Comparison of the Rates

1923	1924	1925	1926			1926 vs. 1923
Cas.	Cas.	Cas.	Total	Man-hours	Cas.	Percent Red.
Rate	Rate	Rate	Casual's	(000)	Rate	or Inc.
10.93	6.75	5.99	18	4,065	4.43	59.47 Red.

You will note that the Duluth & Iron Range Railroad has contributed approximately 60 per cent towards the goal, and during the first eight months of 1927 has had a reduction of 66 $\frac{2}{3}$ per cent in the number of accidents over the same period of 1926, which will contribute a still greater percentage towards this goal.

In the year 1926 you will note that there were 18 casualties for 4,065,000 man hours worked, or one accident per 225,833 man hours, indicating theoretically that an individual could have worked on this basis on the Duluth & Iron Range Railroad for a period of 92.2 years without an accident. The Duluth & Iron Range Railroad Company has operated for more than thirty-nine months without a death to an employee or passenger; and without the loss of an arm, leg, hand, eye or foot. In addition the road has operated from 1853 to date without an accidental death to a passenger.

A summary of these thoughts embodying the responsibility of directing accident prevention work on the American Railroads would include:

- 1st. The necessity of seeing that the mechanical problem of safety is well cared for on your property.
- 2nd. An assurance that the executive department of your railroad fully develops its responsibility in furthering the work of the safety department.
- 3rd. Careful attention must be given to the injection of the Safety Spirit through the medium of educational facilities and through the realization that the development of the mentality of your railroad organization along safety lines will produce the results desired.
- 4th. A great deal of stress should be laid on the subject of safety education in the public and parochial schools throughout the country.
- 5th. A thorough system of physical examination should be inaugurated and utilized.
- 6th. All accidents and their causes must be fully investigated and remedied in so

far as practicable, not only by the department responsible, but by the executive department of the railroad.

7th. Full consideration should be given the welfare of your employees insofar as their recreational hours are concerned.

8th. It is my prediction that the Duluth & Iron Range Railroad will set a standard for all Class 1 railroads of the United States in accident prevention work for the year 1927 which will be accomplished by the safety spirit which has been instilled into our employees.

In conclusion I would like to extend my appreciation for the recognition that has been given in the past by the Steam Railroad Section of the National Safety Council to the superintendent of safety and welfare of our railroad, Mr. A. V. Rohweder, and to say to you that if at any time he or any member of our organization can be of service to you, they are at your call.

I wish to thank you for the privilege of attending your most interesting convention, and also for the opportunity of meeting with you to discuss the subject of saving human life and limb.

Earnest Study of the Paper Recommended

(Chairman White resumed the chair.)

CHAIRMAN WHITE: Mr. Johnson, I am sure every member of our Section appreciate having you with us today. As a further testimonial of our appreciation I am going to ask Mr. Larson of the Missouri Pacific to make a response.

C. F. LARSON (Missouri Pacific Railroad, St. Louis, Mo.): Before I respond to this splendid paper of Mr. Johnson's, may I take a few moments to explain to my good friend, Mr. Warfel, who has something to say about the discussion or response, that I think a long time ago this Section decided not to have discussions of papers, but merely a short response thereto, and to make it short. I also would like to say that I believe all of the railroad safety workers are in agreement with my good friend, Mr. Warfel, that his railroad has set a very high example for us to follow but we do not, I believe, agree that we have had to borrow the thunder of his general manager in the preparation of the paper by Mr. White of the Missouri Pacific Railroad.

Just a few comments on Mr. Johnson's paper, and I hope when the printed minutes are in your hands you will read them very carefully and use them.

He says, "In fact, by some thinkers and writers the bulk of the onus of securing accident prevention is attached to the foreman, without much regard to the material comprising his force."

Let us enlarge, just a moment, upon the foreman question. All of the employees on a railroad who are subject to error and injury are not under the supervision of a man who is called a foreman. Our train service employees are under the direction of trainmasters and road foremen of engines, and therefore the onus attaching to the foreman as referred to by Mr. Johnson also attaches to the trainmasters and road foremen of engines who have jurisdiction over train service employees.

We had depicted for us yesterday, by Mr. Cott, that wonderful playlet showing us the qualities of two kinds of trainmasters and two kinds of conductors who had charge of brakemen. I think the onus is attached to that other character depicted by Mr. Cott, the man who bullied his men into their duties, rather than that other trainmaster who showed so conclusively that he had interest in the welfare of his employees.

I would refer to another paragraph of Mr. Johnson's most instructive paper where he says: "I would refer you particularly to the fact that a clean, orderly shop is conclusive to a satisfactory mental attitude."

I have seen railroad shops and railroad terminals littered with everything that

was conducive to ugliness, and I know that the employees in such premises could not have a mental attitude that was susceptible to carefulness.

I have seen other kinds. I have seen railroad shops with their planted gardens of flowers, clean everywhere, whitewashed walls in their roundhouses, everything conducive to a mental attitude that would lead to safety.

Another paragraph: "A man who is a good citizen, who is interested in the solution of the problems of the community in which he lives, the man who tries to raise his family under proper environment, the man who tries to keep up a good order of things about his home, is a man who has developed a proper mental attitude which is conducive to safety."

My friends, there is a very great deal in that last paragraph about the environ-

ment of our employees, whether they are conducive to a bad thinking or a good thinking, when they go about their duties.

Mr. Johnson, we feel very much repaid for asking you to come here. It is peculiar that the chairman of the Program Committee should respond to your paper. I want to assure you that I did not select myself for that purpose because I feel unable to respond as I should to such a paper as you have prepared, but the other members of the committee thought that I should respond to your paper, and hence I am here before you.

We are very happy to have had you here, and we hope that as we meet from year to year you will again come among us.

CHAIRMAN WHITE: I believe we have in this room a gentleman whom I would like to have stand up for a moment, Mr. C. L. Close, Manager of Bureau of Safety and Welfare, United States Steel Corporation, New York.

MR. CLOSE: I appreciate very much the opportunity to observe the intense interest that is being displayed in safety work. I have been deeply interested in it for many years, and some of the statements made this morning indicate how essential

it is that we cultivate the individual. We may issue instructions galore, but from my experience it is absolutely necessary, if we hope to achieve the success that all are so desirous of achieving, that we devote much more time to the individual and I think, as Mr. Johnson stated, to recognize the suggestions made by those in the ranks. It is gratifying to them as it is to any of us I think, when we make a suggestion and see it given favorable consideration; we should not be unmindful of the fact that the man in the ranks gets the same thrill out of that, and if we can cultivate him and assure him of our interest, I think we will be able to attain the ends we are trying to attain.

CHAIRMAN WHITE: Before having a report of the Nominating Committee, I am going to ask Mr. Bailey to come forward, as he has something to tell us.

Mr. Bailey has worked very hard on the Committee of Train Service Accidents, and I am sure he is entitled to all the consideration we can give him.

C. T. BAILEY (O. S. L. Railroad Co., Salt Lake City): I should like to propose for your consideration, or rather suggest to this section, that consideration be given to the appointment of a committee to study non-train accidents. I was very forcibly impressed with the necessity of this when I took up the study of train service accidents, and in going over the statistical data furnished by the Interstate Commerce Commission.

I have found that out of the total number of casualties reported to the Interstate Commerce Commission, 72 per cent, the big majority, are non-train accidents, and the analyses of the causes of these accidents are lacking. I think a committee should be formed in this section to give serious study to non-train accidents particularly and make a report at the next convention.

If it meets with the approval of the chairman I make a motion to the effect that a committee of that kind be constituted.

FRED HARTENSTIEN (Lehigh Valley Railroad, Bethlehem, Pa.): It affords me considerable pleasure to second the motion just made by our friend, Mr. Bailey. I think such a committee is a real necessity to go out and make a study of non-train accidents, the same as Mr. Bailey and myself make of train accidents and service accidents. I believe there is a very large field there and I believe a lot of good can be accomplished by the appointment of such a committee. I hope we shall be able to select that committee before this meeting finally adjourns.

CHAIRMAN WHITE: I think this would be a very good addition to our committees. I am strongly in favor of it.

(The motion was carried.)

CHAIRMAN WHITE: I wish to appoint the following tellers:

Fred Mitchell, N. Y., N. H. & H.

Z. B. Claypool, Frisco.

W. R. Spettigue, L. A. & S. L.

I will now ask Mr. Hill to make the report of the Nominating Committee.

Report of the Nominating Committee

CHARLES E. HILL (New York Central Lines, New York, N. Y.): Your committee met some weeks ago and gave quite a little consideration to the personnel that they expected to submit for your consideration as officers for the ensuing year. In the recommendations we are about to make, it was the judgment of the entire committee that these men are being recommended to you by virtue of their records and their activities in safety work, not only in these gatherings but on their respective railroads. Therefore your committee begs leave to submit the following report:

As chairman, E. R. Cott, supervisor of safety, Hocking Valley Railway Com-

pany; vice-chairman, J. E. Long, superintendent of safety, Delaware & Hudson Railway Company; as secretary, C. F. Larson, superintendent of safety of the Missouri Pacific Railway Company.

We sincerely hope that these recommendations meet with your approval.

ROBERT SCOTT (Atlantic Coast Line, Wilmington, N. C.): I feel I voice the sentiment of this entire section when I say that the committee on nominations has done exceedingly well. Therefore, I move you that the nominations be closed.

(The motion was seconded and carried and a motion was regularly made, seconded and carried that the report of the Nominating Committee be adopted.)

ADJOURNMENT

Wednesday Luncheon, September 28, 1927

**ROBERT SCOTT, Toastmaster,
Director of Safety and Insurance, Atlantic Coast Line Railroad Company.
Wilmington, North Carolina.**

TOASTMASTER SCOTT: It pleases me very much to state to you that we had 400 tickets printed for this luncheon today and every one of them was sold. The largest attendance that the Steam Railroad Section has ever had at a luncheon was 239 last year.

I think that indicates in a most forcible way the interest that our Steam Railroad fellows are taking in this work. I think it goes a little further than that. It indicates that every lady and gentleman in this room is looking forward to receiving a real message at this luncheon. I am satisfied that no one will be disappointed.

Since the sessions opened last Monday morning, I have gained a great deal of information. Some of it will be most valuable to me in my later years. For instance, those of you who attended the session in this room Monday afternoon heard Dr. Haggard, that eminent surgeon, who has charge of surgery at the Vanderbilt University in Nashville, Tennessee, make the statement that cancer is no longer a thing for us to worry about. He told us that if nipped in time a cancer may be plucked out by the roots just like a corn. That, to my mind, was a very important statement.

A little later in the afternoon we heard Dr. Cattell make the statement that although he is three score and ten and then some, he still experiences a thrill at the rustle of calico.

We listened this morning to Mr. Fritch when he told us some of the things that he has observed in connection with safety on the Rock Island, and perhaps most of you observed that he dealt with the practical side of safety. That was one of the most reassuring things to me, that Mr. Fritch believes in practical safety. I want to assure our guests—and by the way you remember that in past years we have only our own family at the speakers' table. Today it is our great pleasure to give the places at this table to presidents, vice-presidents and general managers of our railroads. I am sure that meets with the hearty approval of everyone here.

We heard Mr. White tell us about the "think" unit on our railroads. You know we have so much to do with track, locomotives, cars, machines, and things of that sort, and it does seem to me that the "think" unit is the part that is most important of all. I believe that what Mr. White told us is going to be an encouragement to all of us to go back and devote more time to the "think" unit of our railroads.

Mr. Johnson stressed the importance of appealing to the human side of our men, and going out into the communities and spreading safety. That is something that some of our railroads are a little short on.

I merely touch upon those things because these gentlemen whose names I have mentioned are our guests at the table, and it is a great pleasure for me to bear my testimony and my approval of these things they told us about.

Now we come to the most important part of our luncheon. I am going to experience a real thrill in introducing to you, or introducing you to, a president of a real railroad. It is the first time that I have ever had a privilege of this sort, and I assure you that I am indebted to your Program Committee for giving me this wonderful privilege.

Before I introduce the speaker, I want to tell a story that I heard many years ago about a fellow who was in charge of the side show of a big circus. He found himself up against it in this way. The old fellow with the gray hair and the long whiskers

who was reputed to be about 100 years old, passed away. He set out to find another one. He heard about an old man down in the mountainous part of North Carolina, and he heard that this old gentleman was 104 years old. He traveled by train, by automobile, by horse and buggy, by horseback, and finally on foot. He came to a little two-story house on the side of the hill. He saw an old gentleman sitting out there about five o'clock in the afternoon, basking in the sunshine. He went up to him and said, "Are you Mr. So-and-so?"

"Yes, that's my name?"

"How old are you?"

"I am 104 years old."

"Well, how would you like to join my side show?"

"What do I do?"

"You get \$50 a week and all expenses just to sit on a little platform and let the boys and girls come up and pay ten cents to see you. You let them stroke your whiskers, and that is all."

"I'd like a job like that, but I am not sure that I can accept it."

"Why?" What is interfering?"

"I will have to ask dad first."

"Ask dad? Where is your dad?"

"Dad, oh, he is upstairs putting Grandpa to bed."

We all remember the time when we looked upon railroad presidents as men having gray hair and perhaps a few whiskers, the wise men of the country, but somehow or other the gray hairs have disappeared, and you see young, vigorous fellows managing our big railroads. Today, gentlemen, it is my pleasure to introduce to you a man of that type, a young, vigorous man.

I am going to introduce to you a man who started as a rodman on the Illinois Central Railroad in 1896. In 1898 he became roadmaster of that same road. In 1909 he was promoted to the position of assistant chief engineer. In 1910 he became division superintendent in the transportation department. In 1915 he was made general superintendent, in 1919 assistant general manager, and in 1920 vice-president and general manager, and in 1920 vice-president and general manager of the Central of Georgia Railway; and in 1924 president of that railroad and of the Ocean Steamship Company.

In 1926 he was elected president of the Illinois Central Railroad, one of the finest railroads in the world.

I have great pleasure, ladies and gentlemen, in introducing to you Mr. Larry A. Downs.

Address

L. A. Downs, President, Illinois Central System, Chicago

It is a privilege and an inspiration to address men like you who are making our world a better place in which to live and work. This congress of safety workers gives testimony of the human principles which permeate modern business. It proves that business today, for all its emphasis upon material values, is soundly concerned with the protection and conservation of human life.

I place first emphasis upon the human value of safety work, but I have full regard also for its material value. We railway men have reason to know how payments for accidents and personal injuries cut into the revenues of the railroads. Good safety work tends to reduce this drain upon railway resources. Not only that, however; it also helps to safeguard the utility and productiveness of one of the most valuable assets of the railroads—their trained personnel.

Every railway employee represents an investment of time and money spent

in training him for his work. That investment is lost when the worker is killed; it is idle and unproductive when he is incapacitated by injury, and it has a greatly depreciated value when he returns to work handicapped by injury. Loss of productiveness from this investment may seem a small thing in one individual case out of a large organization, but in the aggregate the loss may be large. The railroad of which I am president, for example, has an annual payroll of around 100 million dollars. That is equivalent to 5 per cent on two billion dollars. It might be said, therefore, that the employees of our railroad represent an investment of two billion dollars. That is almost exactly three times the railroad's property investment. However inadequate this comparison may be, it at least illustrates the point that safety work helps to protect not only lives but also the vast investment that is represented by personnel.

Moreover, safety work contributes toward the fulfillment of an obligation, both legal and moral, which rests upon the railroads. The Transportation Act specifies that the railroads must be operated efficiently and economically, and it is mandatory upon all members of railway organizations to carry out their share of this requirement. Injuries and loss of life in accidents are inefficiency and waste of the most flagrant kind.

Appeal to the Instinct of Self Preservation

It seems to me that the hope of success for safety work among railway employees lies in appealing to the instinct of self-preservation that is inherent in all mankind. The very nature of the railway business is such that the ultimate in safety cannot be achieved by the installation of safety appliances. Neither can employees be warned specifically against all the possible hazards of accident they may encounter. This is true because the contingencies which may present themselves in the course of a day's work on a railroad are almost unlimited. Employees are shown the safe methods of performing their customary duties and are warned against expected unsafe practices, but that still leaves a large field wherein safety is a matter of the individual judgment and initiative of the worker. Covering that field satisfactorily is unquestionably one of the chief problems of our work.

The only practical solution of that problem is to train employees in the habit of making certain of their own safety and of the safety of their fellow workers under all conditions. Safe practices must be made instinctive. When this is accomplished, every member of the railway organization will function as a safety appliance of the most efficient type. The human intelligence can adapt itself to circumstances better than any mechanical appliance that could possibly be devised. Special attention, therefore, must be devoted to the safety training of new employees. Train new employees properly, and it will be only a matter of time until our organizations will consist entirely of men who are habitually safe workers.

When workers automatically and unfailingly observe safety precautions in everything they do, the goal of safety work, which is the prevention of avoidable accidents, will be attained so far as they are concerned. Getting the newcomer to railway service properly trained in safety is the surest and most direct road to that goal. We must make every effort to reach the new employee with our program of training almost as soon as he enters the service. At this stage of his development into a railway worker we have a fertile field in which to work. His mind is more receptive to new ideas, and his responsiveness to suggestions and instructions is greater at this time than at any other. By thoroughly saturating his mind with the idea of safety, we can make him a permanently safe worker, preventing at the outset the formation of unsafe

habits. But if the instruction is delayed, we are likely to find that we have lost our best opportunity and are confronted with a problem of correction instead of a problem of instruction. In that case our problem is complicated, because, as we all know, bad habits once established are hard to overcome.

At the same time, however, it is essential to press safety training vigorously among the older employees, as well. The power of their example to new employees is highly important. Beginners in railway service customarily follow for some time the methods they see used by their co-workers, especially by the veterans. If the older employees are habitually careful, the younger man in nearly all cases will form and keep the safety habit. All that safety workers can say and do to impress new men with the importance of safe methods is likely to be wasted effort if the new men see older workmen, constantly taking needless risks and, as the saying goes, "getting by with it."

I believe most railway employees are sensible of the duty to observe safety precautions which they owe to themselves, to their families, to their fellow employees, and to the public. They may occasionally fall short of 100 per cent compliance with safety standards, but when faults are called to their attention they will honestly try to overcome them in the future. On the other hand, every organization probably contains a few men who do not respond to safety appeals. Either they are temperamentally unable to comprehend the importance of safeguarding themselves and others, or they are careless, reckless and indifferent and will not take the time to do things safely. The influence and example of such men are so harmful that I believe drastic measures are thoroughly justified in their cases.

Violation of Safety Instructions a Serious Matter

I believe it would aid the advancement of safety work as a whole if the administration of discipline were more frequently invoked for violations of safety instructions. Disciplinary penalties for infractions of safety rules are now assessed chiefly in cases where such infractions result in accidents. It seems to me this has the effect of punishing the men concerned for the consequences of their faults instead of for the faults themselves.

Supervising officers should be always on the alert to eliminate any compromise with rules and instructions, and especially with those pertaining to safety. Questionable methods may operate satisfactorily while all conditions are favorable, but that is no reason for tolerating them until they demonstrate their danger by causing accidents. Disciplinary penalties imposed for such practices as soon as they are observed will act as a sharp reminder that they are unsafe and forbidden and ordinarily will serve to put a complete stop to them before any harm is done. Surely both justice and expediency are better served by administering discipline in this manner than by delaying its use until an accident calling for much heavier penalties has resulted.

The same principle which governs safety work among railway employees also holds good to a great extent with respect to safety work directed toward the prevention of accidents to the public incident to railway operation; that is, our best results probably will be obtained by reaching the younger generation with our program of safety training. This does not mean that I lack appreciation for the "Cross Crossings Cautiously" campaigns and other efforts primarily intended to reach adults. On the contrary, I am thoroughly impressed with the value of such work, and I heartily favor continuing to do as much of it as we possibly can. But I place even greater value upon the safety work that is being done in the schools. Here we are reaching in their most impressionable years the boys and girls who will be in a few years the men

and women whose cooperation we need in our safety work. Among them, too, are many future employees of the railroads. By good safety work in the schools we can with relatively little effort and expenditure imbue the minds of thousands of our future citizens with an enduring appreciation of the importance of safeguarding themselves and others at all times.

I look for this work to yield increasingly valuable returns each year. The principal benefit at first is likely to be a reduction in the number of accidents to youthful trespassers upon railway property. As time goes on, I believe, we shall see its beneficial effects not only upon those who enter railway employment but also upon those who drive automobiles, ride trains and otherwise enter into the safety problems of the railroads. Then, too, it is likely that those who have had this safety training in their youth and have seen the value of such training proved in later years will in turn hand it on to their children by both precept and example, thus continuing the chain of benefits indefinitely.

This is looking quite a long way into the future, but the long-run viewpoint is essential in safety work. The best safety program is one which coordinates the day-by-day activities of the present with comprehensive plans for the future safety work not only must be continuous in order to yield results; it also must be progressive in its scope.

Maintaining Interest in Accident Prevention

In addition to enlarging the scope of safety programs, I believe we should see that the methods used in such programs are changed from time to time. People quickly become inured to whatever is offered unchanged to their attention, and they do not long respond to any one stimulus. Continued use of the same material and reiteration of the same statements soon cause loss of attention and, consequently, of effectiveness. That is true even of what at the outset are exceptionally striking posters and most forceful slogans. "Safety First," for example, was a splendid, effective slogan when it was first produced, but constant use has worn it almost threadbare.

Novelty, on the other hand, retains attention and makes new impressions, and these are essential factors in safety work. The value of novelty should be utilized as much as possible in safety work by introducing from time to time either innovations in methods and material or some unique variation of those previously used. The important object is to present something that is new or that seems to be new. It may require considerable thought and some additional expense to have novelty in this work, but I believe the results are more than worth the cost.

Planning safety programs and methods, and supplying the driving force that sets them in operation are only minor details of the weighty responsibility that rests upon safety executives like yourselves. Your most important task, because upon it chiefly depends the success of your work, is far more difficult than any of these. It is the task of imparting to others a share of your own interest and enthusiasm in the advancement of safety work and inspiring them to cooperate heartily in furthering it.

The railroads have won for themselves an enviable reputation for efficiency. On-time trains, comfortable travel and prompt delivery of shipments in good condition are now accepted by the public as a matter of course. Railway employees also hold a high place in public esteem. They are generally regarded as examples of courtesy, sobriety and efficiency. While upholding our prestige in these matters, let us strive to win for the railroads and their employees an equally good reputation for safety. There is a prize well worth our ablest efforts.

Already it is nearly within our grasp, thanks to the good work you men have done.

In the light of your past accomplishments, I look forward with confidence to the time when safety will rank with efficiency among the outstanding attributes of railway service. I know you can be counted upon in the future, as in the past, to do your duty courageously and intelligently, and I can assure you that you will have at all times the wholehearted support and cooperation of every railway executive in your endeavors toward that end.

TOASTMASTER SCOTT: A curate was once leaving his parish and was the recipient of many gifts, from snippers to surplices. One old lady, wishing to be original, sent the retiring curate a bottle of choice cherries preserved in rare old brandy. The curate, acknowledging this gift, wrote this dear old lady something like this: "I appreciate the choice cherries, but even more so the spirit in which they are sent."

Mr. Downs, on behalf on this Section, I thank you for your wonderful message. It will be an inspiration to us, and I will now call upon Mr. Thomas H. Carrow of the Pennsylvania Railroad to make a brief response to your address.

The Railroads Sincerely Behind the Safety Movement

MR. CARROW: Mr. Downs, Officers and Fellow Workers: If I had about a spoonful of that brandy I would be able to deliver a speech that would eclipse anything that I have done, and that is going some. I am up against a very serious proposition, and that is the difficulty of selecting from a multiplicity of impressions what I ought to say within the few minutes I have at my disposal.

I do wish, however, to make a few observations. The first thing I want to say, Mr. Downs, is that I know the hearts and the minds of these men here; and if I could draw a picture of the inspiration and the encouragement that you have given them, I am sure you would feel more than justified in the effort you have put forth.

Some great philosopher has said that the history of the world is written in the biography of its great men. I know that to be a fact from reading many biographies.

At the present time I am in the midst of one on the great Napoleon Bonaparte; and Europe for 20 years was a simple description of the activities of that man's monumental brain. That observation applies to the railroads of the United States. They did not grow out of a mass of money, they were not projected into the wilderness because somebody wanted to make money, but because such men as Harriman and Hill and all the great leaders that have gone before, had the vision to see and the courage to do; and the reason today the railroads are what they are is because of the Atterburys and the Downs and the Markhams and the Crowells and all the rest of the men at the head of these railroads who are leading them on to the greatest success that we have ever known. And the end is not yet. Never in the history of the human race has machinery been gathered together so efficiently, never have men been taught so completely to do the job that they have to do as on the railroads today. Trains are on time, and we are having comparatively few accidents.

When I was asked a little while ago to respond to this eloquent speech of Mr. Downs, a little poem that I learned in childhood came to my mind:

When I was a beggarly boy and lived in a cellar damp;
I had not a friend nor a toy, but I had Aladdin's lamp;
And when I could not sleep for cold, I had heat enough in my brain,
And builded with roofs of gold my beautiful home in Spain.

When you think of the genius on the railroad, when you think of the undeveloped capacity of railroad men in the United States, you can look forward to a consummation which is not only devoutly to be wished but one that will be realized, not only in efficiency but in safety.

I could not help thinking of a quotation that has been a great inspiration to me, as

our distinguished guest unraveled his theme. "The world does not need so much to be taught as it does to be reminded," and if that philosophy applies in any branch of the railroad business it applies in safety. How often do we stray from the paths of rectitude because we are not reminded of the necessity of going the right way; and how often do our men get in the traps and the dangers around the railroad because we do not provide the ways and the means to warn them.

Mr. Downs, it is difficult for me to close. I want to draw one inference, I want to make one impression upon the minds of our fellows here and then I shall have finished; and that is, if there is yet lingering in the cerebellum of any individual here the shadow of a doubt that the railroad executives of this country are not in sympathy with and anxious to promote safety on the American railroads, let him forever hold his peace. So far as I am concerned, such failure as we have made thus far is attributable to us, and not the officers, as some few people have indicated from time to time. It is inconceivable that any man in charge of the safety work on the Illinois Central Railroad, for example, could go with an analysis to Mr. Downs and ask him to put a proposition over without his acceding to it, and the same applies also on the Wabash. The only point that I want to make is to search our own heart; if we are not getting the results that we ought, it is because we have failed to present our case in an intelligent manner.

The Positive Side of Life

I am through, but I want to pay just one moment's tribute to my good friend, Mr. Clarence Howard, and in doing so I will convey a lesson to you and I will emphasize the fundamental principles that our distinguished guest has elucidated.

This is a little poem on the positive side of life, Mr. Howard, and I had not thought of reading it until I looked into your smiling face, and then I heard what the gentleman said and I know it is appropriate and I know you will like it.

"Keep on looking for the bright, bright skies,
Keep on hoping that the sun will rise,
Keep on singing when the whole world sighs,
And you will get there in the morning.

"Keep on sowing when you miss the crops,
Keep on dancing when the fiddle stops,
Keep on faithful till the curtain drops,
And you will get there in the morning.

"Keep on trusting in the cause of right,
Keep on looking to the dawn of light,
Keep on fighting for safety till you've won the fight,
And you will get there in the morning."

TOASTMASTER SCOTT: I don't think this luncheon would be altogether complete without paying just one word of tribute to our worthy chairman, Mr. J. D. White. Mr. White joined this Section as late as the year 1924, and in the brief period of two years became its leader, the largest section in the National Safety Council. Mr. White is a man whom we all respect, he is a man whom we all love. We respect him because of his ability and his devotion to the cause, we love him because he is Jim White.

MR. WHITE: Mr. Toastmaster, Mr. Downs, Ladies and Gentlemen: I just want to say to the members of this Section and to the members of the Safety Section of the American Railway Association, that they all know me well enough to know that

in all our meetings in different parts of the country I have been proud of the fact that I represented the Illinois Central System. When I became chairman of this Section, the first thought I had in mind was to secure a speaker from our railroad at this luncheon, and I had no trouble in getting the President of the Illinois Central System to join in our program here today. I want to tell you, Mr. Downs, that it is a great pleasure to me and my ambition has been realized. Not only that great pleasure has come to me, but I have also bestowed upon my old friend, Bob Scott, the greatest thrill he has ever had in introducing a speaker at our luncheons, by giving him the privilege of introducing a real railroad president from a real railroad.

TOASTMASTER SCOTT: The time has come for this luncheon to close. If you will kindly arise, offering a vote of thanks to Mr. Downs and Mr. White, the luncheon will be over.

(A rising vote of appreciation was extended to Mr. Downs and Mr. White.)

ADJOURNMENT

Wednesday Afternoon, September 28, 1927

E. R. COTT, Chairman
Supervisor of Safety, Hocking Valley Railway Company
Columbus, Ohio.

The meeting convened at two-thirty o'clock, the chairman, Mr. E. R. Cott, supervisor of safety, Hocking Valley Railway Company, Columbus, Ohio, presiding.

CHAIRMAN COTT: Without any preliminaries, I am going to introduce to you a man who is a factor and an important one in the accident program. There are two or three things involved in the successful completion of any program. It reminds me somewhat of the definition that I heard once of the word "pep", an analysis of the three letters that composed the word. The speaker said that the first "p" stood for purpose, the letter "e" in that word for energy, and the other letter "p" for perspiration. Those are three factors in carrying out any program, but before you can have any program you must have knowledge, you must have some basis for your program. It is this gentleman and his organization that furnish the basis upon which we planned the program. I am speaking of Mr. M. O. Lorenz, Director of the Bureau of Statistics of the Interstate Commerce Commission at Washington.

Statistical Work as it Relates to Safety on Steam Railroads

M. O. Lorenz, Director, Bureau of Statistics, Interstate Commerce Commission,
Washington, D. C.

Recently at a safety conference, I heard a gentleman ask whether statistics had ever saved a life; and he suggested that the reduction in accident rates has resulted from the efforts of safety engineers and not from statistics. I submit that this view shows a misconception of the purpose of statistics in relation to safety work. Obviously, statistics do not directly save lives. The most that can be claimed for them is that they are of assistance to those who are engaged in the work of accident prevention. If they are, in fact, of so material use in this way, let us eliminate the expense of compiling them. Although you who are gathered here are in a better position than I to give an authoritative answer to the question whether you need statistics in your work, I will venture to give some of the reasons why I think that they should be of help to you.

I am reminded in this connection of the native official of an oriental city who was asked by the government to fill out a blank form which contained, among others, a question as to the number of deaths in his city during the past year. He replied, "In my city it is the will of Allah that all must die: some die old and some young; it can do us no good to concern ourselves about the number that die each year."

One of the reasons for concerning ourselves about the number of persons that die each year in various classes of railway accidents is that effort may be concentrated on the types of accidents that occasion especially large numbers of deaths. One may discover from casual reading of the newspapers that there are frequent deaths at grade crossings; but it is only after statistics have been compiled that one can make the general statement that of the 7,090 persons killed in connection with the operation of steam railways in

1926, 2,388, or 33.7 per cent, were nontrespassers at grade crossings and 2,623, or 37.0 per cent, were classified as trespassers on the right of way; so that, taking these two groups together we may say that 70.67 per cent of the railroad fatalities occur because people, other than passengers or employees on duty, are on your right of way at the wrong time. Such facts show that for the most part the reduction of the number of accidental deaths in railroad operation is one that requires the cooperation of the public and is not merely a question of care in operating the railways.

The 2,623 trespassers killed in 1926 included 196 children under 14 years of age and 255 young persons from 14 to 21 years. The majority of the trespassers killed are not hoboes. Surely, equipped with such facts, you can make a stronger appeal to the public to cooperate in preventing such accidents, than if you simply read in the newspapers here and there about persons struck by trains.

It is not my province to tell you how to prevent the many accidents to automobilists and trespassers. I realize that this is but one phase of a broader public accident problem, since total motor car fatalities in the United States are probably ten times as great as the fatalities in motor car grade crossing accidents, and fatal accidents from all causes in the United States are about five times as great as those due to motor cars.

Full Understanding of the Public Necessary

Doubtless much more can be done than has been done in the way of education and warning of the persons who have occasion to go across or along your tracks, and doubtless, if the public saw the whole railroad problem in its proper light, it would be willing to contribute more than has been the case in the past toward the expense of extensive and effective crossing elimination. We, as people, have the capacity to produce more food, clothes and other necessities of life than we need and are spending untold billions of dollars a year for luxuries. Such a people can afford to make its highways as safe as engineers think they should be made. The problem is to cause the money to flow in the right direction. This is a State and local problem more than a Federal one. But if the recapture of excess earnings under Section 15a of the Transportation Act should ever yield large sums, it might be well to distribute the money to the railways for crossing protection.

There were, at the close of 1926, 27,847 protected and 206,512 unprotected highway grade crossings with steam railroads. It seems hopeless to make them all fool proof, but doubtless there are thousands of dangerous crossings which would be eliminated or more adequately protected next year if the funds were available. Here is a magnificent enterprise which requires the co-operation of the railroads, the newspapers, the school teacher, the legislator, the inventor, and the rest of the public. When we consider that in 1926 over 1,000 accidents, involving 225 deaths and 1,506 injuries, occurred because automobiles were run into the side of a train, we can appreciate the fact that educating drivers to be careful is one of the most important features of the accident problem.

The first use, then, of the accident statistics is to point out the most important groups of accidents. The statistics should be of use, in the second place, in showing something about the causes of the accidents within any one group. Thus, to take one group at random, the statistics show that in 1926 over a thousand casualties to employees occurred from operating switches; and the analysis of causes shows that in about a third of the cases the switch lever or ball fell or caught on the foot or other part of the operator's body. This would indicate the need of a special campaign on how to operate switch levers,

or some invention to make them safer. In fact, we undertook to publish statistics regarding causes in response to a demand from those in railroad safety work who wish to know just what part of each operation is especially hazardous.

The third way in which I regard accident statistics as distinctly useful is to afford a test of how successful the safety engineer has been. When you work hard to reduce the number of accidents, it will naturally help to keep up your interest and enthusiasm and to get more support for your work, if you can point to some results of your efforts. In this respect the statistics have a remarkable story to tell. Twenty years ago steam railroad operation involved about 10,000 fatal accidents annually. In recent years, notwithstanding an increase in mileage and a great increase in the volume of business, the annual fatal railway accidents have been reduced to about 7,000, a saving of 3,000 lives annually as compared with the conditions 20 years ago. This improvement, too, has been mostly since 1917, that is, during the period when safety work has been emphasized.

This fact should encourage you to renewed efforts to make a still further reduction. The decline in the number of accidental deaths above noted was shared by all three classes, passengers, employees and other persons, but not equally. Taking the three-year period ended June 30, 1907, as a base for comparison, the number of killed was reduced nearly 70 per cent for passengers, nearly 58 per cent for employees, and about 16 per cent for other persons. That the class, "other persons," shows so little improvement is to be explained by the growth in automobile accidents. They nearly neutralize the remarkable progress made in reducing the trespasser fatalities, which are about half as many now as they were 20 years ago. Here, also, the gain is most apparent after 1917. The Railroad Administration seems to have given a great impetus to safety work which the resumed private control has continued.

A Fifty per cent Reduction in Twenty Years

Turning to the record of injuries, we note that the number of railway passengers injured annually is now about one-half of the number reported 20 years ago, but for employees and other persons the total number of injuries reported has increased. Per 1,000 employed, the number of employee injuries for all classes is greater now than 20 years ago, although for trainmen the accident rate has declined. It is in reducing the nontrain injuries, or those resulting from the use of tools and machinery, from falling, and from handling heavy objects, that you are doubtless expected to make a most striking advance in the next few years.

Yet a fourth reason exists why statistics may help to save some lives. There is nothing like competition to stimulate effort. These statistics are being used in comparisons of the records of various steam railways, one with another. Injustice may sometimes be done in the use of the statistics in this way if the reports are incomplete for one company and complete for another. We have found, for example, that some wonderful records in the number of train accidents per million locomotive miles were the result of not including the cost of clearing wrecks in such calculations where this item would have brought the total to the \$150 of expense which makes a train accident reportable. We hope by close study to make the statistics for various roads more nearly comparable.

Thus, in four ways I think accident statistics may be of help: (1) in showing the most serious classes of accidents; (2) the throwing of light on the

causes of accidents; (3) in showing the progress resulting from safety efforts and thereby justifying renewed effort; and (4) in stimulating effort by competitive comparisons.

CHAIRMAN COTT: There are not many men who have the peculiar fitness to take so-called dry figures and analyze them, and from those figures convey a picture to those who have not that ability. Still there are very few people in the country who can enthuse over statistics. There are not very many shoutin' Methodists among the so-called statisticians. I would not attempt to respond to Mr. Lorenz' remarks only as acting chairman of the afternoon, to thank him for his presence and his message. I shall, however, have the privilege of asking a certain gentleman to come to the platform, I almost said introduce him—that, I am sure, is unnecessary—a man who is able to take statistics, and not only likes them but eats them. Mr. Carrow, will you please respond?

Mr. Carrow's Response to Mr. Lorenz's Address

T. H. CARROW: Gentlemen, it may not seem credible, but for some unaccountable reason circumstances have combined to put me in the limelight here more than I had anticipated. I suggested, as the boys will tell you, when I was assigned to discuss Mr. Lorenz's paper, that it might be inappropriate because I was going to make a report as chairman of the Committee on Statistics. But Mr. Larson replied somewhat along the line that Mr. Cott just suggested, something about my appetite for figures, and that is why I am here.

"God moves in a mysterious way his wonders to perform. He plants the footsteps on the sea and rides upon the storm."

This meeting is one of the finest illustrations of the development of a situation which you do not anticipate. I rather indicated something of that in my report yesterday but I could not do so to the extent I should have liked.

I can see very clearly before me the fruition of many, many of the dreams and aspirations that I have had for 10 or 12 years, and this avidity that I have for eating statistics alive and whole is bearing fruit. I don't think, for example, that Bailey would mind my saying that one of the reasons he put that chart up there was because he arranged to get a chart for me somewhat like that in Salt Lake City, and because perhaps it took the American Railway Association about 90 days to pay the bill.

Other things are developing to indicate what we may expect from statistics, but the combination of circumstances, and the element in this combination that impresses me most, is that my good friend, Mr. Lorenz, should be here. Mr. Lorenz succeeded a gentleman by the name of Meyers in the Interstate Commerce Commission, and I had very pleasant relations with him before Mr. Lorenz was appointed. I don't know just what the year was, I didn't have time to check it up, but for a number of years Mr. Lorenz has been in charge of the statistical section. I want at this time sincerely to express my thanks publicly for the many, many courtesies he and his organization have shown to me, and in showing them to me he has shown them to all the railroad men of the country.

You perhaps never knew that I have had a force of men in Washington, on several occasions as long as a month at a time, developing information for special reasons, and in every instance Dr. Lorenz and his amiable staff have rendered full and complete assistance. The latest illustration of their cooperation is a statement that I should have liked to bring here; but I couldn't because it wasn't received in time to summarize it. They have prepared a set of detailed causes of train accidents and train service accidents by individual railroads; and I have no hesitancy in predicting that when the railroads of the country, like the B. & O., the Santa Fe, the Pennsylvania, and the New York Central, see the detailed information opposite each railroad compared with the other railroads with respect to train accidents and also train service accidents, there will be a development of specific interest in certain quarters

where perhaps it isn't developed to the extent it may be. I mean, with respect to specific details, not with respect to the whole proposition of safety.

I went down there to Washington a good many years ago as a sub-committee for the officers' committee of the A. R. A. to formulate this statistical information. I will say to their credit that these causes and the general classification conform to the recommendations that were made by the railroad people. I expect to get still further information from them.

As I grow older, I find out that a great deal of information is developed which is never utilized. I have no doubt in the world that many like my good friend, Isaiah Hale, have spent hours preparing safety bulletins on the railroad trains (when he had a spare hour or so) that he never brought to a conclusion; that Charlie Hill, for example, gathered information about highway crossing accidents that he did not for the moment tabulate and utilize; and that other members of our section have ascertained many important facts that they didn't put in the way of action.

This statistical information prepared by the Interstate Commerce Commission is what I might call, off the bat, pseudo-science. It reduces the occurrence of accidents to a science from one standpoint, namely the science of specific statement, and they say science is anything that is tabulated in systematic manner.

Massed Facts Are Impressive

One of the reasons we have to have statistics is that the human mind is not impressed by isolated cases. You might get a thrill from reading a report on one of the railroads of an accident in which ten people were killed at a highway crossing, but it would soon disappear. There would be nothing in the thing that would indicate to you that you ought to take precautionary measures. But it might appear differently if you had tabulated information showing that in the last ten years there had been 100 cases of trucks colliding with trains, and derailments and collisions that resulted in a great many injuries to passengers. For example, I recall one accident on one railroad where 25 passengers were injured. That would impress you. Then if you have the actuarial mind (a statistician is the man who gets such facts together and an actuary is the man who reads into the figures their proper significance), if you get the figures and have the vision and imagination of the actuary, as Dr. Lorenz has, then the next step is the action that is suggested by the figures. No one with any imagination at all can read these figures and study them long enough to understand their various ramifications without getting some of that pep that we fellows who are statisticians get.

I was much encouraged by the knowledge and facility with which Bailey spoke about statistics. If you think that Bailey did that on a summer evening when he had a spare hour you are mistaken. It took him, I will venture to say, what would be equivalent to a solid week's time to prepare that statement and figure it out and read into it its various significances.

To get down to a practical basis of this discussion and to indicate to Mr. Lorenz what practical use we have made of it, I can say, Mr. Lorenz, that the goal that we established in Salt Lake City in 1924, a 35 per cent reduction in accidents by the end of 1930, was predicated on the most careful analysis and calculation of the statistics that appeared in your several bulletins. If it had not been for those bulletins which you put out from time to time, the 35 per cent goal never would have been established; and it would seem to me that what has been accomplished under the impetus that is given the safety movement through that idea would justify all the effort that has ever been put on accident bulletins.

Then after we established the goal we would have been in a dilemma, a very serious dilemma, if we had not had the information to suggest a program of activities. So the following year we went again to the bulletin, we read all about getting on and, of course, coupling cars, operating switches, working around the

tracks, in the shops, and so forth; and we formulated a program of activities for 12 consecutive months; and under the leadership of our good friend Bentley, who is a student of statistics, we have had every month since 1924 one of the finest programs of safety activity illustrated that any business in the United States has had.

This morning in the wee small hours I thought to myself: if Thomas Edison had fallen into the safety business, instead of having four hours' sleep in twenty-four he wouldn't have had one, because I am growing more convinced that of all the various branches of human activity, there is nothing that will challenge the constructive imagination like safety effort. I don't believe any of you boys who are heartily interested in accident prevention on your several railroads have a single hour in your life that some suggestion, or suggestion of a suggestion, doesn't come to your mind. If you could pause for a moment and close your eyes and get the impressions that you have got since you came to this place, it would all resolve itself into embryonic activities that you have already started on your lines. As I lay in bed this morning thinking about this discussion, I thought of the unlimited possibilities of this work of ours, and I am telling you, friends, that if there is anything in my philosophy, you have the world beat; because there is nothing under the blue canopy of heaven that can afford more interest to you, can satisfy and tickle your mind and vanity more than what you can do for safety.

A New Type of Accident Prevention Code

The reason I made that suggestion was because of the latest advantage that I hope to derive from safety. I spoke of scientific information. We haven't anything that is worthy of the name of science so far as rules and regulations and instructions are concerned along accident prevention lines.

How are we going to get it? By continuous, consistent, systematic study of accident statistics. As a beginning in that direction, I have to offer for your consideration a tentative set of safety rules which I shall not even present to the reporter to go into the minutes, but shall describe them, rather, as to how I think they will ultimately be worked.

Most safety rules that I have ever seen might as well, like most literature that is on the market, be thrown into the waste basket. I venture to say that on many of the railroads of the United States 50 per cent of the employees could not locate their safety rule book if you would ask them to, and then so far as the supervisory forces are concerned, I would wager every cent that I have, including the mortgage on my house, that there is not one of them that could pass an examination on the safety rules; and the simple reason is that they are not scientifically prepared.

Here is what I propose? We do not want any don'ts and we do not want any musts. I think it resolves itself into prohibited and required. A thing is prohibited that ought not to be done, and a thing is required that ought to be done. If you examine all the statistics that Mr. Lorenz has spoken about, you will find out that 50 to 60 per cent of the accidents are attributable to things that people ought to do but do not do. You can't say "must," so we must make it a requirement. I will illustrate what I have in mind.

The first thing we will do is to classify the rules under the character of the work performed, like coupling and uncoupling cars. Let us start off with that.

"Prohibited: Going between or in front of moving cars to couple or uncouple or to connect or disconnect hose." And everyone of them starts with prohibited. There are no dittos.

"Prohibited: Using foot or hand to adjust drawbar, knuckle or lockpin while cars or locomotives are in motion or coming together."

"Prohibited: Riding on leading footboards of engines or end sills of cars when cars are coming together."

Friends, please understand that I don't know how these rules ought to be stated,

I don't know exactly what ought to be covered; I can't talk about them like Bailey can; but men like Bailey and Phillips who know all about the practical thing can put the finishing touches on them. I am merely giving the idea.

The other side of those rules is the requirement side, and this is where you will find the innovation: "Required: Look in both directions to see whether engines or cars are approaching before going between cars."

"Required: Watch out to avoid slipping, tripping, falling or turning ankle on coal, boards, stones, rubbish, tires, frog rails, switches or hose."

"Required: Watch for unexpected movement of cars or locomotives due to slack running out, grade, misunderstanding or not observing signals given."

"Required: Use lift lever to uncouple. When lever is inoperative on one side, use lever on opposite side." I don't know whether that is right or not. That is one that I copied.

"Required: Watch out to prevent being caught between overhanging load in cars."

"Required: Watch out to avoid being caught between cars and platforms or cars on adjacent track."

"Required: Watch out to avoid being burned by steam or hot water when uncoupling hose."

Why are they requirements? Because from those causes we have the bulk of the accidents.

Some Text Book Essential in Teaching Safe Practices

How are you going to impart the rules? Simply like a professor of anatomy or chemistry or any other science gets his students into the classroom and teaches them. The human mind is not capable of carrying all those things for ready reference without some sort of textbook.

How will you enforce them? You may not be able to hold a man to task for violating one of these requirements the first time; but carry with this set of rules a continuous accident record, and if a man is injured from causes from which you can reasonably conclude that he violated one of these rules, if the injuries are sufficient over a period of years, he is not fitted for that class of service.

The rules carry with them the idea of a record.

I don't know to what extent you gentlemen have made analyses of your accident records of your individuals, but if you will examine the record of 25 conductors who have 15 years' service, you will find that the number of injuries range from none at all for the majority of them, or a large proportion of them, to as high as possibly 25. If you have that information in your hands and you have the record of the man showing that he did not fulfill these requirements, then you have the information necessary to take action.

Under operating locomotives, I could give you the rules, operating hand brakes, operating switches. For example, this is a very simple one. You can't imagine what rule would come under operating switches outside of the book of rules, but here it is. There are no prohibitions under that that I have yet found. It is requirement from beginning to end, one requirement:

"Required: Care to avoid injury from: A, lever flying up; B, ball falling on foot or hand; C, slipping, tripping or falling; D, being caught between locomotive or car and switch lever or stand; E, being struck by locomotive or car; F, sprain or strain."

That is a requirement rule that no man can carry in his head unless he studies it, unless he is trained in it.

That goes on all through getting on and off cars. There would be 25 or 30 rules. Then we have station employee accidents, maintenance of way accidents, motor car accidents; and the scheme that I propose is that this classification of work will

make it possible for the safety agent, the yardmaster or the trainmaster to watch a man doing a job and tie him up with the rule that covers the kind of work that he is doing. It has all the possibilities of a literature on safety. We have no safety literature to speak of, it is all written in a hit or miss manner. Take any of the other sciences like the engineering department, the mechanical department, and you can find volumes in any library, but what can you find on safety? A few desultory tracts like I have written, or Isaiah Hale and some of the other fellows; but from the scientific standpoint I ask you what is there in literature on safety today?

With the use of Mr. Lorenz's statistics and the development of the programs that we have and the safety rules, we will find out that in the end, aside from the general matter which is always back of it all, we will have in a few more years a much better safety record on all the railroads.

A Clever Play upon the Word "Analyses"

CHAIRMAN COTT: When I was a boy in school I pronounced the word analyses, "analysis." I see now why they say "ses" instead of "sis." Mr. Carrow has that peculiar happy faculty of analyses, he sees what figures mean.

This section of the National Safety Council owes a debt of gratitude to Mr. Carrow for the assistance that he has been to us.

I want to interject something into this program before I call on the next speaker. It is a personal matter with me. The railroads entering the city of Toledo, Ohio have conducted in the past two years, and will again this year, a series of safety rallies under the auspices of the local Safety Council. For two years we have held 12 rallies at Toledo that have been attended by on an average of 1,100 persons per meeting. Mr. Hill, Mr. Carrow, Mr. Bentley and a number of the gentlemen who are here have come to those meetings and given them a message. In a way, we are faced with the possibility of listening too much to ourselves there, and we have a series of six meetings beginning next month. I am going to ask some of you gentlemen if you will volunteer your services in coming there during some month this winter and speaking to some 1,100 or 1,500 railroad employees from the 14 roads which enter the city of Toledo. I shall write some of you and I hope you will remember what I have said to you this afternoon.

Now the next number on the program brings us to another factor in our accident prevention work.

The rules of the Interstate Commerce Commission are rather peculiar. The records of the railroads are kept on a different basis from those of industry. We only report to the Interstate Commerce Commission those accidents which cause the employee to lose more than three days' time in ten days immediately following the accident.

The purpose of the Interstate Commerce Commission has been to divide hurts from injuries, a phrase, I believe, that it would be well for all of you to remember, to divide hurts from injuries. In this business of railroading we will perhaps always have hurts. Injuries will be avoided.

A number of years ago one or two leading railroads began to make a remarkable safety record and a number of us wondered what it was all about. The only reason that they made it was that they began to divide hurts from injuries and reported to Mr. Lorenz only injuries.

There is only one man who is really a competent judge to determine what is a hurt and what is an injury. That man is your surgeon. If he has the interest of the men with whom he works and the companies by which he is employed, he will attempt in each particular case to determine whether it is a hurt or an injury and do justice to the individual employee and the company by sending the hurts back to the shop and the injuries on to the hospital.

This man is an important factor in our reporting to Washington. So I think it is right that we should hear from a surgeon and secure the benefit of the advice of a man who is favorably known throughout the United States. I take great pleasure in introducing to you Dr. G. G. Dowdall, chief surgeon of the Illinois Central System.

Cooperation Between the Surgical and Accident Prevention Departments of the Railroads

G. G. Dowdall, M. D., Chief Surgeon, Illinois Central System, Chicago, Ill.

I deem it a pleasure, and at the same time a duty, to appear before this group of Safety workers comprising the Steam Railroad Section of the National Safety Council. The surgical department of the railroad is so intimately connected with the safety work that to me it seems necessary to have a close understanding between the company surgeon and the safety worker. Therefore, the subject of "Cooperation Between the Surgical and Accident Prevention Department of the Railroads" is one of considerable importance.

From the standpoint of the surgeon, the excellent results that have been obtained through the efficient organization of the safety department, appeal strongly to him. The surgeon sees the direct results of the safety work as evidenced by the material decrease in the number of personal injury cases, and consequently I feel that I can assure you of the active interest and full cooperation on the part of the individual company surgeon, provided the way is made clear to him as to how he can extend that cooperation from a practical standpoint.

From the standpoint of the safety department, it can be readily appreciated that the railroad surgeon is the man actively in the field in the handling of personal injury cases and that it is, therefore, important to elicit the interest and active cooperation of the surgeon in order to bring about the most effective results along the line of safety.

First, and it seems to me foremost in the prevention of accidents, comes the question of the physical fitness of the individual employee. I believe that we will all readily admit that ill health, or even temporary disability, greatly increases the hazard of accidents, dependent upon man failure. There are large numbers of men who are not giving their best service to the work in which they are employed, not from carelessness, not with willful intention of shirking, but due to the fact that they are ill, and many times not aware of it. Good health in an individual is of inestimable value to himself and his employer. Ill health decreases efficiency, results in nervousness, irritability of mind, often causes one to do something erratic or impulsive with the result of an error or accident. The healthy man is a safe and reliable man.

Therefore it is of the greatest importance that only the physically fit should be selected to make up the group of employees in an industrial organization. A comprehensive plan whereby every applicant for employment is required to undergo a reasonably strict physical examination before being accepted, is necessary to insure physical efficiency on the part of that group of employees.

When the Illinois Compensation Act was put into effect, May, 1912, the Illinois Central Lines deemed that an opportune time to make effective the required physical examination of all applicants for employment in Illinois. It had previously been felt such an examination was desirable, but in order to offset possible objections, this particular time was selected. So apparent were the beneficial results resulting from this examination of applicants, that on

August 1, 1914, the same rule was made effective on the Illinois Central System. It has been my opportunity, therefore, to observe directly the beneficial results resulting from the selection of physically fit employees, and speaking from the standpoint of safety alone, the results, in my opinion, have more than justified the expense, to say nothing of the improved efficiency of the individual in his work. Then, too, the physically fit employee has a greatly increased expectancy, as regards his continuous service, as well as lessened temporary disability because of disabling illness.

The second most important factor in promoting safety by increasing physical efficiency, is the medical re-examination of the old employees, particularly those engaged in the engine, train and signal service. In the past there has been opposition to such general medical re-examination on the theory that it might cause some physically defective employee to lose his job. However, in the past few years there have been a number of serious accidents entailing a considerable loss of life, as well as large property damage. The resulting investigations have shown that these accidents were caused by the failure of man power, and that this failure was due to some pre-existing disability, and further that a previous medical examination would have disclosed the presence of this disease, which constituted a greatly increased hazard. So much publicity has been given this subject that the public generally is becoming awakened to the necessity of the compulsory medical re-examination at stated intervals, of all engine, train and signal service employees on the railroad.

Physical Incompetence Led to the Accident

One of the largest railroads serving the Chicago territory with suburban service somewhat recently had a serious accident, resulting from collision of two suburban trains. Many people were killed and an investigation shows the engineer of one of these trains was responsible for this accident because of physical incompetence. The history showed that this man had been in bad health for years, but that since his examination for promotion from fireman to engineer 11 years previously, he had not been given a physical examination to determine his fitness for his responsibilities as locomotive engineer.

The coroner's jury sitting on this accident brought in findings recommending strongly the necessity of regular medical re-examination of old employees in the engine and train service. Growing out of this accident, that particular railroad has recently completed a general medical re-examination of all of its old employees in the engine, train and signal service. It is not possible to compute the number of accidents prevented by this particular re-examination, but the percentage of physical disabilities disclosed was somewhat high. Many conditions can be corrected with proper medical treatment in the individual case, and also those employees with certain physical disabilities, who now occupy the more responsible positions, can be transferred to positions of lesser responsibility. The results for safety growing out of such an improved condition are great, indeed.

The Interstate Commerce Commission has manifested an active interest in this subject and as some of you may know, the medical and surgical section of the American Railway Association has spent something over two years in a careful survey of the entire field with a view to determining a recommended standard practice covering the regular physical re-examination of old employees in the engine, train and signal service. While constructing the standard for physical re-examination of the old employees, there was also developed a recommended standard for the physical examination of all applicants for employment.

It is felt that the examining surgeon can be made to accomplish a great good from the standpoint of safety. The elimination of the physically unfit is one of the most important factors in this great work composing the safety movement, and it is, therefore, to be strongly recommended that there should be a routine examination of all applicants for employment by a capable examining surgeon, as well as a medical re-examination of old employees also by a competent examining surgeon.

An analysis of a somewhat recent medical re-examination of a comparatively small group of old employees, engineers and conductors, shows some interesting facts. The engineers showed markedly the results of over eating. Of this group 90 per cent of the engineers are over weight; 60 per cent weigh over 200 lbs. Practically all of them were found to eat daily about three times the required amount of food. The percentage suffering from diabetes was found to be unusually high, and all of this group of engineers had blood pressure well above the normal.

The conductors were also over weight but not to the extent of the engineers. This is due, no doubt, to the fact that as locomotive firemen doing hard physical work they develop large appetites and upon being promoted to engineer, they sit down but continue to eat about the same amount.

Both classes were found to have a high percentage of infected teeth; also tobacco was used excessively and positive Wassermann tests of the blood showed an unusually high percentage.

Careless Personal Habits Responsible For Ill Health

We see, therefore, that the principal factors of the diseased conditions present or beginning, were due to over-eating, infected teeth, excessive use of tobacco and over weight. With proper medical supervision and regular re-examination it is felt that these conditions may to a very large extent be prevented entirely, or relieved by proper dietetic or medical treatment. The prevention of human waste offers one of the greatest opportunities to the surgeon and safety worker, and with the promise of immense results to the industrial manager, the individual worker and his dependents, as well as to Society in general.

The surgeon is directly concerned in the matter of reducing temporary disability by getting the injured employee back to work as promptly as possible, proper consideration being given to the disability present. The careful attention of the surgeon in handling each case is of the greatest importance. The first man interested in getting the injured man back to work should be the surgeon. This is not the proper function of the foreman or employing officer. If the doctor in charge of the case can be made to realize the importance of daily suggestion to the patient with reference to his returning to duty, and by that is not meant that the injury should be minimized, but the attitude of the getting back on the job. All of you who are experienced in safety work realize the mental attitude of a certain number of employees when they are injured, and I am speaking now of the serious injuries. The attitude of many of these employees is, first, that they have a claim against the company; and also perhaps some accident insurance coming to them. A third factor, even with an honest employee, and especially in the winter time, is that he does not feel very well and that it is easier to sit beside the fire with the family than it is to make the effort to get back to work. Then, too, there is the question of uncertainty in the mind of the injured man with reference to whether he has a serious or perhaps a permanent disability, added to which is the sympathy of his fellow employees.

All of these things the surgeon must contend with and tactfully bring about

the proper mental attitude on the part of the patient, to the end that his desire to return to work is increased.

The wide-awake surgeon will know something of the various types of railroad work so that he can talk intelligently to the injured man regarding his ability to get back to work within a reasonable length of time. The doctor must analyze the situation both from the standpoint of the injured man as well as the company. He must know there is a place that the injured man fills and that it is expensive to bring in another man and train him for that particular job. The surgeon will honestly consider the interest of his patient in keeping with his professional traditions, but he will always bear in mind the importance of getting the injured man back to work with as little loss of time as is consistent with the condition present. The company must be willing to take back the injured man and put him on the job, even though he is not able to function 100 per cent. There is no cure for an injury better than getting the injured man back to work and keeping him interested in his job.

Getting the Employee Back on the Job

In the case of fractures or dislocations with resulting limitation of motion, the surgeon by encouraging that man to get back on the job persuades the patient to use the injured part to a very much better advantage than any physiotherapy treatment. After the acute inflammation subsides it is the regular continued use of the affected part that to the fullest degree restores the function, and the improved mental attitude of the patient because of his returning to work, is often remarkable.

The surgeon must be the judge, and he should be given full authority to weigh both sides in each case with reference to the work to be performed and nature of the injury, and then decide. It is important that a plan should be in effect whereby the surgeon is furnished close supervision of every case, thereby permitting him to release each man to return to work at the earliest date consistent with the injury.

Therefore, the plan should provide that an order for treatment be issued by the employing officer and accompany the patient coming under the care of the surgeon, and the surgeon should be given full authority to handle each case until the injured man, in the opinion of the surgeon, is able to return to duty and perform at least the major portion of his work, with safety to himself and others. There should be a check by the employing officer so that it will be promptly known and investigated when an injured employee having been discharged by the surgeon, does not promptly return to duty as directed.

It is of distinct advantage to the surgeon in handling these more serious cases if an arrangement is in effect so that at least a limited number of the more difficult cases, as determined by the surgeon, may be assigned to some lighter work than the customary job. In this way the surgeon can release the man for duty at an earlier period, thus improving his mental, as well as physical condition, by getting him back to work and at the same time lessening the time to be computed in considering claim against the company for time lost.

The malingerer is an extremely difficult case to handle. In the case of intentional malingering, especially if the patient has had some previous experience along similar lines, it requires extremely careful examinations to determine the exact extent of the incapacity because the information furnished by the patient cannot be depended upon. The premeditated malingerer is, therefore, a problem by itself and as we all know, has been given thoughtful attention.

There is another class of cases less serious, but still more difficult to handle from the standpoint of the surgeon, that is the neurotic patient. They truly magnify their troubles. Every persuasive power and tact and patience on the part of the surgeon are necessary in the handling of these mentally disturbed patients. They know that they have been seriously injured and develop a mental complex with reference to a

permanent disability. Paralysis is the condition most frequently conjured up in the mind of the patient. The influence of meddling people who surround him is disturbing. They encourage him not to return to work, argue that the company is liable for the injury and the longer he remains away from his work the more will be the claim. It is this class of patients that offer the greatest menace when solicited by the ambulance chaser.

An important factor in prolonged temporary disability is insurance. Accident, Brotherhood, Lodge and Compensation insurance all exercise this tendency. The surgeon can tactfully offset these influences by anticipating the period that the injured man will be able to get back to work, by beginning two or three weeks ahead of that time trying to convince the patient, then as the time approaches it may be extended somewhat, but the surgeon must reach the limit of persuasion and sympathy and then definitely fix the time, making report to the insurance company concerned, as well as furnishing the employee a surgeon's discharge certificate.

Every surgeon appreciates the advantage of getting the injured man back to work in less than the three-day period prescribed by the Interstate Commerce Commission. This cooperation is most important because it reduces the reportable accidents; also encourages the patient in the direction of minimizing the injury. However, care should be taken that too much pressure should not be used on the surgeon or the employing officer in making a drive for safety. It has come to my knowledge that under the stress of the safety campaign with comparative ratings of various divisions, a master mechanic sent an injured employee to an outside private physician, the bills being paid by the master mechanic himself, in order to prevent his records from showing this personal injury. This perhaps somewhat unfairly shows the active interest taken in the safety work on the part of Illinois Central employing officers.

The Physician Is an Important Factor

It can be seen, therefore, that the surgeon is the most important factor in efficiently carrying on this work. There was a time in the development of the American railroads when the company surgeon or the surgical department was looked upon by the average railroad manager as a necessary evil or supernumerary attachment, without importance. The surgeon was grossly underpaid; in many cases receiving only railroad transportation as compensation for his services.

In the last decade or two great progress has been made in the way of education concerning health, preventive medicine, welfare work and social economics. Perhaps even more than the railroad manager has other lines of industry shown a keener appreciation of the large economies that accrue from the physical efficiency to be derived from healthy employees who possess a full time life and working expectancy. Fortunately the progressive railroad manager is coming to also appreciate the many advantages to be derived from the selection of physically fit employees in the first place, and then to depend upon regular medical re-examination of the old employees to keep them fit.

Going a step further some far seeing executives have appreciated the advantage of building up a hospital system, comprising a group of medical and surgical specialists who are made available to their employees for furnishing early treatment in beginning diseases, thereby preventing more serious developments and complications, and also providing the very best of scientific facilities for treatment of the serious or more complicated cases among their employees.

The insurance companies have proven for us the value of careful medical examinations with early preventive treatment. To them there was evident an immense and large apparent returns because of their permanent interest in the policy holder. They could see in dollars and cents the direct saving, if sickness or accident were prevented and also if life were prolonged. Life conservation and prevention of accidents and sickness meant large immediate returns. They went after it and were willing to

spend money for it. One of the larger insurance companies report that as a result of careful systematic medical re-examination and by encouraging their policy holders to obtain early and prompt treatment of beginning disease conditions, they have increased the life expectancy of each policy holder by something over eight years.

Contemplate, then, the similar advantage to any railroad if the physical fitness and efficiency of the employee can be materially increased each day that he works, and if the working expectancy of the old, trained and experienced employee can be increased by anything like eight years. Think of the benefit accruing to that railroad organization.

The safety worker and the surgeon are working to the same end in promoting this greatly to be desired result and it is essential that full cooperation should be extended on the part of each. This to the end that the Safety work be so effective that there will be no injured men, but secondly if there is, that the surgeon will promptly get the employee back on the job unless absolutely prevented, and finally that during the convalescent period the surgeon will diplomatically keep the injured man in good spirits with the frequent reminder that he will be "back to work soon."

CHAIRMAN COTT: Dr. Dowdall, I think I express the appreciation of this section this afternoon when I say to you that I believe yours is one of the most practical papers that has ever been presented to this section.

If the Illinois Central is ever so nearsighted as to let you out of the fold, I think you need only send your application to this group of safety officers and you shall not long be out of a job.

Without taking any cracks at any of our own men, there are perhaps some of us who wish you worked for our road.

I liked your note of warning in which you speak of the possibilities of carrying the accident records from the sublime to the ridiculous. One must be careful that they do no injustice or harm by bringing men back on the job or keeping them on the job when there is possibility of doing injury to the injured man or those with whom he works.

We have a man on the program selected to properly respond to you. This man, it happens, has had most recent and direct contact with railroad and other service. I think it is quite right and proper that a good safety officer who has had four broken ribs in the last few weeks and who knows something about surgeons and their activities should reply to you. Mr. L. G. Bentley of the Chesapeake & Ohio, Richmond, Va.

Mr. Bentley Responds to Dr. Dowdall's Address

MR. BENTLEY: Do I walk like a crippled man? Friends, I am only going to take about three minutes of your time. It is not my purpose to discuss the very able, complete and impressive paper of Dr. Dowdall. He has said, I think, the last word in so far as that is concerned.

I heard one of our one hundred per cent safety men say this morning that any safety worker who expected to get results without working in close contact with this surgical department was doomed to failure, and I think I am justified in assuming, that the splendid record that is being made on the Illinois Central Railroad under the direction of Mr. Downs, and under the immediate supervision of your chairman, Mr. White, is in no small measure due to that spirit of cooperation that has been made evident to you in the address of Dr. Dowdall, whom I have known for some years as an expert along this line.

Mr. Cott sounded a note of warning, that we should not overdo this matter of getting the injured man back to work. It will handle itself, gentlemen, if the proper amount of interest is evinced by the supervising officers, by the foreman and by the surgeons, your accident records will follow that interest and it will not be long until

you find among your men the same disposition that I recently found on the Union Pacific Railroad, where objection had to be made by supervising officers to allowing their men to return to work too early.

I mention the Union Pacific because we all know that the Union Pacific has been foremost in that line of work in recent years. Now, gentlemen, I want to say that Dr. Dowdall has not spoken to you as a theorist or as a visionary; he has spoken to you as a practical railroad surgeon of many years' experience, who knows that these plans that he has recommended to you are workable and have been worked.

I doubt the absolute—I wouldn't say truth, because I question that—but the exactitude of one of Dr. Dowdall's statements. He said that all surgeons know of the requirements of the Interstate Commerce Commission that men must return to duty within three days if they are not going to be reported. I doubt if that is the case on all railroads, and I present to you this thought, that there is a virgin field for you to go back home and work along that line to inform your surgeons as to the part they can take and consistently take; because I have found on some of the railroads that the surgeons did not know that the Interstate Commerce Commission had such a requirement.

Dr. Dowdall, I know that I voice the sentiment of every member of this convention in saying to you that we sincerely appreciate your trouble in coming here, the time and study that you put on your paper, and I foresee that it is going to be of untold value to us when we return to our fields of activity.

ISAIAH HALE (Santa Fe Railroad, Topeka, Kansas): Supplementary to Mr. Bentley's very appropriate response, may I assure Dr. Dowdall, and I believe I speak for a great many more railroad safety officers here when I assure you of my appreciation of an interest in your paper. It is very unique and valuable because it is the first surgeon's report I have heard that was written in English.

CHAIRMAN COTT: I have several notes on the desk here from people who wish that certain safety officers among them might be introduced. Since we must be out of this room in fifteen minutes we cannot take the time to accede to your wishes. I think this is the second time in the history of our safety meetings that we have had the privilege and pleasure of being addressed by a woman. You will recall Mrs. Craig who addressed us a number of years ago. I have the pleasure of introducing to you Mrs. C. F. Longstreth who will now speak to you.

Woman's Place in Safety

Mrs. C. F. Longstreth, St. Louis, Mo.

"They talk about a woman's sphere,
As though it had a limit;
There's not a place in earth or heaven,
There's not a task to mankind given,
There's not a blessing or a woe,
There's not a whispered 'Yes' or 'No,'
There's not a life, or death, or birth,
That has a feather's weight of worth,
Without a woman in it."

Much has been said of late concerning the place of woman in the world today. Time was, and not so far distant, when she was content to dwell within the four walls of her home. Hers to look well to the ways of her own household and when her brief thread of life was woven, it was suffice that her

own children rose up to call her blessed. The American woman is heir to the richest inheritance of the human race. Born of a rugged pioneer stock, a God-fearing nation, she has been led by the visions and ideals of the noblest impulses which ever turned a wilderness of great forests, mighty rivers and boundless prairies into smiling gardens and glistening fountains. Hers has been an inherent desire to go forth and subdue the wilderness.

Life was a joyful adventure and the dangers were no handicap. Life was work and the vast forests were there to be cleared. Life was full of promise; there were the great open lands—theirs for the taking. Life was the gift of God, and never forgetting, she set the stamp of her God-fearing character upon each succeeding family tie—in the home, in the community, and in the nation.

Thus a new people was born, a new and greater civilization came into being. The factories of the far east, the farms of the middle west, the plantations of the sunny south, the trappers of the frozen northland, and the fishermen of the seas have compelled independence to give way to interdependence to such a degree that today the welfare of each individual is woven into the fabric of modern society. Self-isolation and self-preservation are no longer possible. We have, voluntarily or no, become a people of interdependent relationship and we cannot escape its challenge.

The Human Ideal Is a Home of Happiness

Man is born of God and is commanded to "subdue the earth"; to love and to serve his fellows. What a divine privilege! What a human responsibility!

Man must live. He seeks his mate, his woman, and together they build a home, a place of love and service. Children are born; friendships are formed; sickness—health; poverty—wealth; sorrow—happiness; life—death; but always the home.

"Oh little homes, you little homes of love,
Strength of a man; a woman's song, laugh of a child;
Warmth of a fire, glow of a lamp.
Ye narrow, walled-in worlds of joys and fears,
Built of the commonplace of smiles and tears."

An accident happens! Someone was careless, someone forgot to play safe. And what of the home? The strength of the man is broken; the song of the woman is hushed; the laugh of the child is stifled. Never is that home the same again. It lies a broken and a withered thing. Safety is home-making. Carelessness is home-breaking. The National Safety Council sponsors a new crusade—it wages war, not for a sepulcher of the past, but for a shrine of the future—a shrine of better homes, better parents, better children, a better race.

One of your neighbor cities has very fittingly and aptly adopted the slogan, "The Heart of America." I like its sound—but may I tell you just where the real heart of America is? It is in the American home, throbbing with the love of human kindness and pushing out through the veins and arteries of our great commonwealth, carrying with it the love, pity and tender compassion of a humanity intensely interested and vitally concerned with its brother's safety and well being. This and none other is the heart of America and it is for us, here assembled, to pledge ourselves anew to this far-reaching task of talking, breathing, actually living safety, so that this great American heart may beat on. Wrecked lives of little children, broken bodies of men and women, incalculable and unprecedented property losses stab at the heart of the American home and her life blood ebbs.

This great throbbing heart of America, this citadel of society, is being invaded continuously by accidents of a preventable nature, whose toll is many thousands of lives annually and hundreds of thousands of serious injuries. These are conditions which challenge the home makers of America to demonstrate that women can do, by accident prevention methods in the home, what men—you of the National Safety Council—have done to stem this tide of economic loss, personal injury, distress and death. We are fast learning that effective prevention is much more to be desired than effective cure. An accident cannot be cured; therefore it must be prevented.

Prevention Is the Higher Duty

It is one thing to rebuild the health of a disease-ridden body or a socially and economically demoralized home; but an entirely different and more valuable thing to prevent such mal-adjustments. It is one thing to take care of, through our organized efforts, the wreckage and misfortune caused by accident, but a much more constructive and commendable thing to prevent such human wreckage and misery. One of our surgeons of national reputation writes: "If ever our nation is made safe for health, it will be womanhood that will accomplish it." And I believe it equally true if ever our nation is made safe for our manhood and our little children, it is for the American woman to bring about that safety. Down through the ages it has been woman's biggest job to lift up, and to hold to her great beating heart of love—her manhood. She clings to him and like the angel of the psalmist of old, she bears him up lest he dash his foot against a stone; and there is no measuring the depths of a woman's love and devotion and self-sacrifice. And until we can write "Safety" upon our thresholds and carve "Service" upon our hearthstones, the world will echo only cries of pain, the sun will shine only to show us grief; each rustle of a leaf will be a sigh, and the flowers fit only to garland graves.

Never in all history has there been a greater challenge to womanhood. Never did woman have so much to live for, never was her physical environment so ample and adequate; never was there so many to live with, and yet never were the rules of life so complex. Never has there been such privileges of life for patient service and courageous endeavor and never has there been such responsibilities for womanhood. She must know no creed, no social rank, no riches, no fixed standard of education. But hers must be a true and unbiased understanding of human life. Thus may she become an invincible unit for public service and personal inspiration carrying the torch for higher and finer things in civilization. Sympathy for the distressed, protection for the weak and light for them who walk in the darkness of ignorance. Seeing that all the good that has come down from the hardihood of her pioneer mothers shall not be lost in the mad struggle of the present day.

There is one, and one only, way that our manhood, our womanhood and our childhood may be made safe for this and future generations, and that way is through the medium of education, and that education must begin in the home. Education for safety! It is for us to carry the message for safety back to our homes and to our communities. Interest our womanhood in its colossal importance and she will turn all heaven and earth to the end that safety in the home, in the school, in the shop—safety everywhere—may no longer be an idealistic condition to exist in the distant future, but that it may be alive and a growing condition existing now.

Have you ever stopped to consider the far-reaching contact of womanhood? Do you know of her various organizations whose influences are incalculable? Who would dare to estimate the power and the service of the General Federa-

tion of Women's Clubs? What they have done for the causes of American citizenship, legislation, public welfare and international relations they can do for national safety. There are the parent-teacher associations, business and professional women's clubs, mother's clubs, Y. W. C. A. and similar women's organizations which need but to be interested in—educated in, if you please—and the zeal and ardor of their enthusiasm and constructive work would know no bounds. I believe if such groups can be brought to a keener realization of the magnitude of this problem of education in accident prevention, they will, in a surprisingly short time, pass on such knowledge; and there will come that day when all men, in a truer sense than ever before, will possess that inherent right to "Life, liberty and pursuit of happiness."

Have you caught a glimpse of our great America of today? We are stepping forth into a larger and better life; our people have a vision intensified by our task and present achievements. In her youth America was often foolish, frequently ruthless in her daring and accomplishments. She amassed unbelievable wealth, but oftentimes at the expense of life and limb of her manhood. Now, in her sober days of maturity, she is learning how to spend her wealth for the betterment of mankind and she is teaching her children that true service is the supreme commitment of life.

Education of the Individual Is Progressing

By the wisdom of our Constitution we have established the rights of self-preservation and self-determination. Superstition has given way to knowledge. With broader vision, greater opportunities, larger rewards, we have gradually but surely grown into greater appreciation of the value of life. Health is being protected, life prolonged, strength for greater accomplishments assured through strict observation of the rules of sanitation and hygiene. Hospitals and nurseries are built and endowed to insure the health of the mother and her newborn babe. Our public schools are teaching our youth the proper care of the body, the use of soap and the tooth brush; and our great industrial institutions are expending millions of dollars that their manhood may come to a better understanding and appreciation of the worth of human life. Factories are equipped with safety devices; grade crossings are protected; traffic regulations are enforced. All this is being done that man may live, may seek his mate and establish his home that it may hold his children, teach them wholesome habits of living and instill high ideals and the spirit of service.

A little girl ran eagerly into her father's study one morning. Very proudly she displayed the stalk of a flower she had lately pulled from its garden bed—its roots with the damp earth still clinging to them.

"Just look, Daddy," she said, "what I pulled out of the garden just now, all by myself."

But the father was a busy man and waved her aside. Not to be silenced, she insisted he listen to her and again she spoke:

"Daddy, you must look. I pulled it up all by myself," and proudly taking hold of the roots, she added: "And the whole world had hold of the other end."

Ours is a colossal task—this making our homes and our communities safe. And we have to admit that there are times when it seems that the whole world has hold of the other end. But we Americans are a willing and an energetic people, we are possessed of a divine restlessness which will not permit us to accept things as they are; but impels us to crave and to seek something better. Civilization towers in pyramidal grandeur up to the blue of heaven. At its base is the great mass of humanity, constantly growing in numbers. Out

of this common material our nation is busily engaged in building its structure of civilization. Out of the mass we are finding our way to better conditions. We rise from the base of the pyramid, out from our own narrow cells into the azure blue of unselfish service and passionate sympathy born only of love.

It is the presence of the masses which means much; it is necessary for many lives to touch ours; necessary for ours to touch many, if there is to be power and understanding and real worth in what we do and what we are. You who feel alone, misunderstood, unappreciated go out into the crowd. Sense their tragedy; know their joy; ache with their heartbreak; taste the salt-sweat of their labor. Among them, they become a part of you, and you will instinctively take hold again for you will know it is all worth while. It is for this instant that you have cared.

A Tribute to Womanhood

CHAIRMAN COTT: I don't feel capable of responding to such a paper. It touched our hearts, it gave us a new purpose and a new vision.

Mr. Shedd, will you respond for me, please, and for us?

L. F. SHEDD (Superintendent of Safety, Chicago, Rock Island & Pacific Railway, Chicago): Never in my life was I more impressed with a certain thing that I have always thought was right, namely, that brevity is the soul of wisdom.

If all inside information is correct, the speed with which I have to go through with this is almost beyond belief.

Mrs. Longstreth, I am not unmindful, I am fully conscious at this moment, that I am enjoying a special privilege and have been given almost a unique opportunity.

One of the real attributes of the safety man is that he is unselfish, he covets nothing, he wants to do something for the other fellow. Yet I think there are a lot of you in this audience today, probably every one of you, who are having to exert honest resistance to keep the influence of that old green-eyed monster down. I think that every one of you would like to stand in Shedd's place today and attempt to tell Mrs. Longstreth how you and I and the rest of us appreciate her coming, how we appreciate her paper and how we doubly appreciate the able, forceful presentation of it.

I am not going to be here very long, fellows, not in this position at least, I am not going to say God bless the ladies, but I do want to pay just a little tribute to this good woman and her kind. She is a woman, a mother, a safety woman. What greater combination could God Almighty smile on with favor than a woman, a mother, and one who is able and so willing to present this great magnanimous subject to us fellows.

The Spirit of Woman Guides Effort

Woman, what would we do without woman? Mrs. Longstreth, it was a long, long trail, as they used to sing, to Tipperary, but is a longer time from that scene enacted in that beautiful garden located eastward of Eden where God created man and gave him woman as his helpmate. It has been a long, long march from that time until the enactment of the Nineteenth Amendment to the Constitution of the United States gave you women what you were always entitled to. You have come into your own, you have not only taken your place in safety, you have taken your place in the world, and if you fellows all had your hats on right now, I would tell you to get up and take them off to Mrs. Longstreth and her kind.

I don't believe in reading papers, I think it takes the snap out of them, but I know of no more convincing way, my good woman, that I might pay a tribute to womanhood than to read what I copied, I am frank to tell you, from a page in

the Chicago Tribune a few days ago, that page run in connection with the seventy-fifth anniversary of the organization of the Marshall Field & Company industry in this city, the greatest of its kind in the world.

May I read it? I want to read it least I should mix it up.

"The business which is now called Marshall Field & Company celebrates its seventy-fifth year. It began in a little shop in Lake Street conducted by Potter Palmer. In a different sense it began in a New England village with the birth of a girl. Her name was Fidelia Nash. She grew to womanhood and was wooed and married and her name became Fidelia Field. She was the mother of Marshall Field. How unbelievable it would have been to her if someone had said, 'In 1927 your picture will be published and your influence recorded in a city of three million people a thousand miles away.' There was no such city, Chicago was a struggling swampy little town. Yet she in her country village helped to build Chicago. She built a boy, she put into his character some of the staunch unyielding substance of the New England hills, she taught him that what was worth doing at all was worth doing better than it had never been done before. She taught him the principles upon which he later built his belief that no trade is a good trade unless buyer and seller are satisfied, upon which he built his conception of the nobility of service. She taught him his religion, inspired his patriotism and his faith in the goodness of men and women. These were his foundation stones. Having these and health, and the love of work, it was not hard for him to build.

Woman Is an Ally in Accident Prevention

The business which he has thus founded has been made great by millions of other women. Men, to be sure, have managed it, but the influence and confidence of women have been the greatest factors in its success."

Fellows, get that, "but the influence and confidence of women have been the greatest factors in its success."

And in conclusion, "and seventy-five years will be a short period in the life of Marshall Field & Company, and its present achievements will only be a beginning of its future worth, if the character and ideals of Fidelia Field shall continue to find their counterparts in the character and ideals of this institution."

Your paper was beyond question ably prepared, it was beyond question cleverly delivered, showing that you had given this matter considerable thought, as you women usually do.

I know that I voice the sentiment of each and every one of you fellows here today when I thank Mrs. Longstreth for coming here, for adding this beneficial part to our meeting toward making it a success. I hope she will come again, we will always be glad to see her.

We need the women. God taught us that in the beginning, that we need women. They are good safety scouts if you get them coming your way.

We have, Mrs. Longstreth, going all over this country today, a safety special. We are trying to reach a goal of 35 per cent in the reduction of accidents.

The question is asked, are you on board? Let me tell you that you are, and you may take your husband with you for I know he is a safety man. You brought him here. Take him on the safety special.

There is a place for everybody on that safety special.

CHAIRMAN COTT: I appreciated one phrase of Mr. Shedd's response when he spoke of women as an ally. She has been an ally by and for us a long, long time.

All of you safety workers know Mr. Z. B. Claypool, assistant director of accident prevention department of the St. Louis & San Francisco Railway Company. I will ask him to come forward at this time.

Causes of Accidents	Suggested Remedies
1. Not instructed properly.....	{ Give proper instructions. Place with competent man.
2. Inexperience	{ Caution. Personal attention. Place with competent man. Use judgment in assigning jobs.
3. Carelessness	{ Caution—Attend Safety Meeting for instructions.
a. Temporary	{ Lay-off. Reduce rank. Posters.
b. Permanent	{ Change worker to a place where there is not the great element of danger. Discharge.
4. Familiarity with the job.....	{ Surprise tests. Caution. Change of work. Illustrations of what may happen.
5. Over-confidence	{ Same as above.
6. Taking chances	{ Put bulletins in his possession. Eliminating necessity of taking same. Teach a man to anticipate danger.
7. Akwardness	{ Change job. Discharge.
8. Nervousness	{ Medical treatment. Explanation to remove fear. Not too much hurry.
9. Temporary physical disability..	{ Foremen apply first aid. Send to company doctor. Cause man to attend Safety Meeting.
10. Permanent physical disability..	{ Pension if eligible. Discharge.
11. Defective machinery	{ Regular and careful inspection.
12. Personal trouble	{ Consultation. Suggest to man mental concentration. Give him time to settle trouble.
13. Ignorance	{ Same as No. 2 (Inexperience).
14. Excitement	{ Determine speed of workman. Foreman make man feel at ease on the job. Discuss the cause.
15. Too much of a hurry.....	{ Make your hurry safe (Think right). Think faster than you work.
16. Dissipation	{ Warning. Discharge.
17. Afraid of the job.....	{ Same as No. 8 (Nervousness).
18. Shop joker	{ Advice. Lay-off.

19. Bad shop lay-out..... Report to proper officials.

20. Untidy surroundings Systematic inspection.

Foremen must set the example.

Foremen must keep a constant supervision on accidents.

Foremen should carry out safety instructions coming from the company.

Foremen should report back or suggest safety devices.

7. New Business.

Everyone present should be called upon individually and made to feel that he is a part of the meeting in having taken part.

8. Summary of Activities for the current month and cumulative for the period, of unsafe practices and unsafe conditions reported. Corrected, and on hand for handling at the next meeting.

	MONTH			PERIOD TO DATE		
	Reported	Corrected	On Hand	Reported	Corrected	On Hand
January	10	6	4	10	6	4
February	8	5	7	18	11	7

Clean Housekeeping—Education of the Worker—Supervision

a. Clean Housekeeping.

Clean housekeeping not only reduces accidents, but it increases production and raises the quality of production. Cleanliness is next to godliness with all the people, yet with a few people it seems next to impossible. Many a workman who prides himself with being a skilled mechanic would leave his wife if she kept house as slovenly as he keeps shop.

A shop superintendent once resorted to a clever ruse to stimulate interest in clean housekeeping. He had a sign made reading, "THIS IS THE DIRTIEST PLACE IN THE SHOP." Once each week the shop superintendent awarded this sign after a personal inspection at some unannounced time, and said sign had to be kept prominently displayed there until that department was made cleaner than some other one. There was a lot of rivalry among foremen in effort to avoid this sign.

Clean housekeeping will receive *no more* or *no less attention* than the officers in charge demand, yet a shop has to be made clean and sanitary in the first place before you can ask or expect the shopmen to keep it so.

b. Education.

Personal contact with the worker has greater value than any other form of education. Since personal contact is not possible for all of the time, we depend upon illustrated bulletins to some extent for a substitute. Bulletins with greatest appeal are the illustrated ones, wherein the picture tells the story. The illustrations should show the correct way of performing work or else both the right and wrong way. Bulletins should be specific to the work at hand and deal with the essentials. Little value as to the actual prevention of personal injuries comes from the use of what we might term General Bulletins, which might be classed as applicable in any place at any time.

Special noon hour meetings can be used to good advantage in amplifying your accident prevention activities. These meetings should be short and snappy, of not over 20 minutes' duration. The time should be split 10 minutes each on shop operating time and lunch hour. This is an excellent way to reach the entire plant collectively by personal contact once a month.

A great deal more frankness could and should exist between the management and the workmen as to cost and profits in selling the accident prevention

idea. You don't buy or sell anything else without bringing in these factors. You invite skepticism to even imply to workmen, that a corporation, out of the goodness and magnitude of its heart, because of humanitarian interest alone is going to give them something for nothing. Accident prevention has its humanitarian side, but usually that is the only side stressed. It also has its business side, which you realize more fully when asking for authority to spend more money. The man in overalls will appreciate the opportunity of being a business partner with the management in the accident prevention business. Show him how you both make money working together and both lose money if you don't.

c. Supervision.

The type and quality of work performed in addition to the manner in which it is performed will depend upon the foreman's ability to supervise and the minimum they will accept. This brings to us the time-worn slogan, "The foreman is the key man." Just as the sergeant, more than the captain, determines the morale of a company in the army, so does the foreman more than the shop superintendent determine the morale of the shop workmen. Just as the type and efficiency of the sergeant, however, depends upon the type of captain he reports to, so is the foreman influenced by his superior officer in the shop.

If a shop foreman is held as responsible for personal injuries in his department, as he is held for quantity and quality production overtime and operating costs, that foreman will then give personal injuries the same amount of attention, otherwise he will not.

The shop superintendent will demand of his subordinates just what is demanded of him, and the order of importance of such demands will be gauged by the way the shop superintendent has received them. So you want to start from the president down in selling your accident prevention program and not from the common laborer up.

When the foreman's ability to operate a shop free from personal injuries becomes a factor in obtaining promotion, on a par with production and other qualities, then will more attention to safe operation be given by foremen. We frequently hear it said, "A shop plant is just as safe as the shop superintendent makes it." Let us advocates of safety accept our part of the responsibility and say, "A shop plant is just as safe as the accident prevention department helps the shop superintendent to make it. This means keeping the score as previously enumerated under another heading, all of which means finding the weak spots so that the shop superintendent can effectively work out corrective measures. You of the accident prevention departments are the finders, the shop superintendents are the fixers. In this rapid and progressive mechanical age, new and added responsibilities are constantly being added, on to industrial foremen, with little if any preparation being given to the foremen. The need is here and the time has come to hold Industrial Foremen's Conference in your shop plants at least semi-annually, to improve the every day practices of the foremen. An outline of such meeting which the speaker attended in one of our shops is given below. Meetings were held for two hours every morning from 8:30 a. m. to 10:30 p. m. with the ranking foremen of all departments present and the chief mechanical officer of the shop and division.

Foremen's 12 Days' Conference, Two Hours Per Day

OUTLINE OF MEETINGS

First Meeting—The Foreman's Job.

Second Meeting—Interest Factors.

Third Meeting—Leadership.
Fourth Meeting—Orders, Directions and Suggestions.
Fifth Meeting—Orders, Directions and Suggestions.
Sixth Meeting—Orders, Directions and Suggestions.
Seventh Meeting—Safety and Accidents.
Eighth Meeting—Instructional Responsibility of the Foreman.
Ninth Meeting—Instructional Responsibility of the Foreman.
Tenth Meeting—Instructional Responsibility of the Foreman.
Eleventh Meeting—Instructional Responsibility of the Foreman.
Twelfth Meeting—Cooperation.

3. SUGGESTIONS

When an order may be given as a suggestion.

1. With experienced men.
2. When responsibility is to be placed on workmen.
3. To encourage progressiveness.

COSTS OF FAULTY ORDER

1. Ill feeling between the foreman and the workman.
2. Lowers the morale of the individual.
3. Broken machinery.
4. Delays.
5. Accidents.
6. Lowers production.
7. Waste of material.
8. Waste of time.
9. Morale.

In considering the cost of faulty orders, the word morale was deemed so important as to receive separate treatment.

COST OF MORALE

1. Dissatisfaction.
2. Labor turnover.
3. Men lay down on the job.
4. Loss of business.
5. Increased accidents.

Some of the things a foreman may do to increase the Morale of workers:

1. Keep good tools and in repair.
2. Keep good material.
3. Keep a clean shop.
4. Keep an orderly shop.
5. Give a square deal.
6. Promote proper understanding.
7. Maintain good discipline, properly administered.
8. Being honest.
9. Fostering good working habits.
10. Loyalty on the part of the foreman to his men and to the organization.

Seventh Conference—Safety and Accidents

Objectives.

1. To present the probable cost to the men and the company of carelessness in operation of the shop.

2. To enumerate the probable causes of carelessness and to suggest the possible remedies.
3. To promote a greater feeling of responsibility for accidents occurring in their respective departments.
 1. Costs of accidents.
 1. Compensation.
 2. Damage suits and legal action.
 3. Loss of time.
 4. Decreased production caused by effect on rest of men.
 5. Decreased earning of the company and employees.
 6. Human suffering (a) direct, (b) indirect.
 7. Increased insurance rate.
 8. Reduce accidents.
 9. Increase loyalty.
 10. Make instructions easier.

After a discussion of 21 specific cases of handling men, it was agreed that good leadership is productive of both quality and quantity in the shop output and that it is an essential factor in the control of labor costs. From the group was then drawn out a list of 19 essential elements of good and effective leaderships.

The conclusion of the group as developed in these discussions in a final summary were:

1. A foreman can be a good leader and at the same time be sociable.
2. A foreman should be the leader in his department on technical and practical knowledge of the work.
3. Occasionally the foreman does not realize his responsibility as a leader in the broadest sense of the word.
4. A foreman to be a good leader should be open-minded to suggestions from his superiors and should give consideration to suggestions from his men.
5. A foreman to retain his position as a leader should be constantly informed on the new methods of shop production and technical information relative to his department.

Fourth-Fifth-Sixth Conference—Orders

Objectives.

A comparison of a complete and incomplete order.

An Analysis of the causes of faulty orders, and the development of remedial measures.

The effects of the faulty orders.

From the request that orders be given for example, it was developed that orders are of two kinds: 1. Routine Orders; 2. Special Orders.

Routine Orders are not so likely to show fault in the giving as the special order. This is due to practice and standardization of the Routine Order. Thirteen examples of orders were given and from the discussions of them, 25 causes of orders not being carried out, and their remedies were listed by the group. It was further worked out that three types of orders are issued, i. e.:

COMMAND

When issued:

1. In case of an emergency.
2. Fear job may be done differently.

3. When foreman assumes entire responsibility.
4. As a last resort.
5. More frequently with inexperienced.
6. With over-confident men.
7. In case of necessity.
8. To men with low mentality.

DIRECTION

When an order should be issued as a direction.

1. In giving routine orders.
2. When the how is needed.
3. With the green man.
4. When the routine orders are changed.

In the beginning it was pointed out that the conference was not necessarily a foreman's training school; but was set up for the purpose of getting a perspective view of their own job, looking at them from an analytical point of view and for the purpose of pooling the ideas of the foreman based upon their extensive experiences and that from the ideas presented, practices may be better.

Number 1. The Foreman's Job

The various members of conference listed their responsibilities which totalled 25 various duties.

These responsibilities were given a rating based upon their relative importance. The group members were then asked to mark the one which they thought most important, ranking it as number one and so on down the line until ten of the most important responsibilities had been ranked. Points for discussion were given which brought out from the group what is meant by supervisory and managerial responsibilities. These two points were discussed at length with the final conclusion that—

Supervisory Responsibilities are those which a foreman has in observing conditions in his departments.

Managerial Responsibilities are those which a foreman has in handling his work so as to reduce costs.

The discussion also brought out an additional responsibility—Instructional
The discussion also developed the following:

1. That both foreman and the workmen are held responsible by the management for production, but the greater responsibility rests with the foreman.
2. The foreman's responsibilities cover a wider range than those of the workman.
3. The workman's job is primarily that of doing the work.
4. The foreman's job is primarily that of planning, directing, giving instructions where needed and seeing that the work is properly done. It was brought out that there were two ways for a foreman to carry out his responsibilities.
 - a. Do the job.
 - b. Consult his superior when the problem was greater than he could solve.

Second Conference—Interest Factors

Objectives.

- a. To prove that interest on the job will reduce productive costs.
- b. To emphasize the foreman's responsibility of maintaining interest of his

men and of discovering the possible ways of accomplishing this. Cases were cited by those present from which a chart was made listing 12 causes for lack of interest of workmen, and listing suggested remedies. Fifteen interest factors were brought out which may be used to promote interest of the workmen. The conclusions of the group were that:

1. Requires less supervision.
2. Increase production.
3. Give better quality of work.
4. Give better cooperation.
5. Attract better new men.
6. Decrease labor turnover.
7. Make for better plant spirit.
8. Damage to material and equipment.
9. Increase taxes.
10. Increase labor turnover.
11. Bad reputation for company.
12. Reduces morale.

Objectives 2 and 3 previously treated under Item 6 in Order of Business for Accident Prevention Meetings.

Eighth-Ninth-Tenth-Eleventh Conference

Objectives.

1. To bring out the cost of poor instructions to the green workman and partially trained workman.
2. To give practice instructions to the foremen, following accepted standards of good procedure.

One example will give a quick insight into this interesting part of the conference. The leader gave instructions to one of the foremen on how to sharpen a hand cabinet scraper. He used purposely a very poor method in putting over the lesson. The foreman failed to get the instructions. The following analysis of the failure of the instruction was listed by members of the conference:

1. No explanation.
2. Didn't tell the learner the way.
3. Didn't bring out the most important thing.
4. Didn't take ample time with the learner.
5. Didn't have name of the tools.
6. Didn't have patience with the learner.
7. Didn't tell the learner how to do it.
8. Didn't check up during the process of the instruction.
9. Learner didn't know what was coming.
10. Instructor was too "hard-boiled."
11. Killed the morale of the learner.
12. Attempted to teach too much in a short time.
13. Didn't take into consideration the learner's previous experience.

The leader gave another demonstration of teaching on the method of sharpening the same cabinet scraper and to the same man. In this demonstration he attempted to teach a good lesson and not to commit the errors that were committed in the first demonstration. In making an analysis of the second job of teaching the group brought out the following points:

1. The teacher aroused the interest of the learner.
2. Gained his confidence.
3. Showed him how to do the job.

4. He back checked the learner.
 - a. For the benefit of the learner.
 - b. To determine whether the instructor had left out any points in instruction.

To be 100 per cent efficient in instructing his men, he must—

1. Do the job.
2. In the shortest time possible.
3. With the greatest amount of ease to himself and the learner and with due care for the equipment.

Twelfth Conference—"Cooperation"

Objective.

To determine the cause of poor cooperation, the causes of good cooperation, and their effects upon the entire organization.

Fifteen specific cases were recited for discussion and around these cases were built up the causes of poor cooperation listed below:

1. Suspicion.
2. Interference.
3. Grouchiness.
4. Know it all.
5. Failure to take problem to right person.
6. Misrepresentation.
7. Inaccurate information.
8. Dishonesty.
9. Foreman to meet another half way.
10. Selfish motives among departments.

11. Jealousy.
 12. Taking matters over superior's heads.
 13. Giving inadequate information.
 14. Passing the buck.
 15. Not being loyal.
 - a. To superiors.
 - b. To company policies.
 - c. To men.
 16. Fails to confer with superiors.
 - a. Fear of criticism.
 - b. Negligence.
 17. Failure to recognize organization as a whole.
 18. Turning in incomplete reports.
 19. Gossip and tale bearing.
 20. Holding back important information.
 21. Knocking other departments.
 22. Fails to appreciate problems of other departments.
 23. Frame up on other departments.
 24. Where "sit-for-tat" conditions exist.
- The Group listed the following costs of poor cooperation:
1. Increased labor turnover.
 2. Increased delays.
 3. Increased accidents.
 4. Loss of business.
 5. Decrease in production.
 6. Bad reputation.
 7. Increased material costs.
 8. Increased production costs.
 9. Increased personal injuries.
 10. Increased fuel consumption and supplies.
 11. Destroys morals.

After foreman has attended a conference of this nature there is no doubt in his mind but that he is the "Key" man and he has a much better conception of how best to use the key.

Conclusion—"Future Objectives"

Having attained a desirable organization for the Preparation, Presentation and the Application of your accident prevention ideas, what are your ultimate objectives? Here are listed some valuable ones which have been tried and proven by some industries and will eventually be in vogue by all first-class Dividend Paying Railroads:

1. Machinery guarded 100 per cent.
2. Employees furnished individual goggles with lens ground to prescription for those with impaired vision. A record of every workman's eye test. Goggles worn 100 per cent of the time by workmen and their foremen. Visitors and officials required to wear goggles when walking through shops where workmen are required to wear them.
3. Physical examination, photograph and finger print record of each man entering the service. This will work to the benefit of all honest men regardless of creed or color, organized or unorganized labor.
4. A centralized personal record bureau which keeps the positive as well as the negative record, telling the extra service an employee (worker and foreman performer as well as that which he did not do or

- did wrong. Accident Prevention or the lack of it a part of such record.
5. The Accident Prevention Department operating on a Budget System the same as other departments, appropriation based upon results. The Department functioning on its merits as a business unit of the organization and not as a side line or a charity institution.
 6. A Personnel organization, coordinating the various other departments and obliterating the imaginary dead line existing between the management and the workers.

CHAIRMAN COTT: It is unfortunate that Mr. Claypool was put on the tail end of this program. That paper was the result of a real study and honest purpose. I trust that all of you will secure copies of it and study it because it deserves it.

I am sorry we must hurry this on. By the way, I want to call your attention to the fact that Mr. Claypool is with the accident prevention department. I like the name, as I know you must. He has representatives here with him today.

Mr. Hartenstein, who was on the program to respond to Mr. Claypool, will do so, at his own suggestion tomorrow in order to give the hotel an opportunity to go to work in this room.

ADJOURNMENT

Thursday, September 29, 1927

The meeting was called to order at nine o'clock by **Chairman White**.

CHAIRMAN WHITE: The first part of this meeting is devoted to the Safety Agents' and Inspectors' Session. Mr. A. V. Rohweder, Superintendent of Safety, Duluth, Missabe & Northern Railway, Duluth, will preside.

(Mr. Rohweder took the chair.)

CHAIRMAN ROHWEDER: The object of the Safety Agents' and Inspectors' Session is to give you men who are in these capacities an opportunity to discuss anything that you have in mind about your particular job. From now until ten o'clock the meeting is open for a general round table discussion.

D. M. MOORE (Safety Inspector, Kansas City Southern): I would like to know how to get away from injuries from squirt hose. I would like to know if any road is using cold water squirt hose. We are told it is not practicable on account of not being able to clean the deck, but I feel you had better have dirt on deck than blood.

C. D. SHAFF (New York Central, Syracuse): We are using a large number of cold water squirt hose on our modern power, and they have been the means of doing away with a lot of quite serious accidents. Before they were adopted on our railroad, we had about nine squirt hose accidents a month, and they have been very materially reduced. I believe it is largely due to cold water squirt hose.

CHAIRMAN ROHWEDER: I presume Mr. Moore would want to know whether your mechanical department considers the cold water squirt as effective as the steam squirt hose.

MR. SHAFF: Yes.

MR. HARTENSTIEN: I can't tell you much about squirt hose, but I do want to explain fire fighting apparatus on locomotives that are so equipped in terminals. It all depends on our locomotive engineer and the manner in which he applies the injector. He can put on the injector to produce cold water instead of hot, and it makes it perfectly safe to handle. We have brought that about through a study of the conditions and through instructions to our engineers, and it is working out very satisfactorily.

JOSEPH PRATT (Reading Co., Reading Pa.): We have not had any injuries from using that fire protection hose. The hose are tested once a month.

CHARLES A. HAMER (Frisco R. R., Kansas City): How much respect are we entitled to from some of these hard-boiled men when we go around and condemn a tool that is unsafe? I'd like to know how much respect is shown to men like myself on other roads.

CHAIRMAN ROHWEDER: I would say that your safety inspector should be, in my opinion, empowered with sufficient authority to place a B. O. tag on tools that are in his opinion in bad order, and that that authority ought to be respected the same as it would be of any other officer in the respective departments. That is the practice on our properties with our safety inspectors, and I presume it is on a great many other roads.

Mr. Shaff, you do quite a little bit of that. What authority has the safety inspector in connection with B. O. tools and B. O. equipment when he makes such an inspection and finds such a condition?

MR. SHAFF: We are very closely cooperated with by all the men who handle this work. If we find anything in our inspection that needs repair, there is no question about it, it is taken care of, and at once. We have no trouble whatever

in getting any condition or any defective tools that come to our notice taken care of right off the bat.

MR. HART (Michigan Central): By selling safety to the heads of departments we have secured full cooperation in taking out of service any tools or equipment not safe to work with. We have the mechanical departments so arranged that the superintendent or his representative appoints a man as tool inspector who makes a report in some shops twice a month, some only once a month, on all tools, and he has to give the number of tools inspected, the number found defective in the hands of men, and so on, to the end that these men are ashamed to have the inspector find any defective or worn-out tools, and they get them to replace them. Defective or worn-out tools are gradually decreasing on the reports, and very often we will have a shop without any tools condemned.

CHAIRMAN ROHWEDER: Is there any railroad that has a standard set of inspection regulations in connection with tools, ladders, scaffolds, and so forth, so that the inspector is guided by that sort of standard?

MR. HAMER: The Frisco has a standard of safety rules. I didn't ask the question to criticise my road, because I am one inspector who is backed up by the supervision to the last ditch; and when any man tries to go against the standard of safety at Kansas City, he has a pretty hard job.

Discussion of the Standard Hand Brake

A. C. EBRIGHT (St. L. & S. F. Ry. Co., Monette, Mo.): I'd like to know if there is some way we can have a standard hand brake. We are having worlds of employees injured by the operation of hand brakes. We get a cut of cars and start to set a brake, and we find so many different kinds that we don't know which way to operate them. We would like to see some kind of standard brake adopted.

CHAIRMAN ROHWEDER: Mr. Hammond, what have you got to say about a standard brake?

MR. HAMMOND (New York Central): I've got a lot to say about a standard brake. I am afraid we will not get very far with it. The Mechanical Section of the A. R. A. turned us down at one time. A standard hand-brake would be a mighty fine thing, for this reason: The majority of our equipment today has so many different kinds of hand brakes that about every day you find a new type, with the result that many times if men don't first try the brake or test the brake before depending upon its use, they run across a new-fangled hand brake and it takes about five or ten minutes to find out how to operate it.

Not long ago I made an analysis of accidents on our lines due to the operation of hand brakes, and I think that Mr. Bailey has given us a fine contribution when he put before us this wonderful paper. I didn't have a chance to debate the paper. Probably I would have gone into it a little deeper if I had told him what I know about operating hand brakes, but it is a wonderful contribution to this meeting.

As you know, every time anything is said about operating hand brakes, generally Red Hammond has his fingers in it. I have always been and still am in favor of a uniform, standard hand brake, but as I told you in the beginning, I think it is love's labor lost to try to tell the managers of the different railroads what would be the proper hand brake to adopt.

I could talk a great deal on this subject. I have got my views as to what I think ought to be a safe, a standard hand brake, but it doesn't appear to me that we are going to get very far, because we were turned down once before by the Mechanical Section of the A. R. A.

My thought along this line, if it can do you any good, is that a hand brake should be proper to protect the car and it should be provided with a brake pall that is weighted and self-operated; but we find now that approximately 95 per cent of all

hand brakes used on train equipment on Class 1 railroads of the United States are operated from the brake step board. I never did like them, but I guess we have to swallow it. The only thing we can do now is to try and educate and teach our employees the proper manner of setting this brake from the brake step board.

I always hoped that I might live to see the day when there would be adopted a uniform, standard hand brake, but I am afraid that instead of getting better we are getting worse on account of the different varieties of hand brakes that are now being used.

MR. HARTENSTEIN: I want to bring to your attention a report submitted by our friend, Mr. Bailey, in connection with the use of hand brakes. Personal injuries and deaths occurring from that classification are about equally divided as between defective brakes and the carelessness of the man. That indicates quite clearly that there is a general lack of inspection of the hand brakes on freight equipment, and the only reason I particularly mention that is that I believe every representative here should go back home with the full intention of bringing that feature to the attention of his management so that they can tighten up on their inspection of hand brakes.

MR. HAMMOND: We recently had an accident caused by one of our switchmen falling off the top of a metal roof car. You know most of the roofs of cars nowadays are metal. We put a coat of paint over that, and if the roof of the car is a trifle frosty, you realize that it is mighty dangerous to step over the metal roof.

At one time we thought that we would put a little stone dust in the paint as we painted the roof of the car and in that manner we might prevent slipping, but we found that when we made a mixture of this stone dust and paint, the stone dust went to the bottom of the paint and we got no use of it. I want to ask this assembly if they know of any way, after the roof of the car is painted, that they can scatter sand or dust of any kind on top of the paint. It appears that the man who made this report said there were certain railroads that were dusting the top of the paint with stone dust or sand, after the cars were painted.

CHAIRMAN ROHWEDER: We are using sand on the fresh paint. After the coat of paint is applied we are scattering a fine coating of sand over the top. Of course, the difficulty is that the sand does not remain after considerable use. It wears off very rapidly.

The New Train Master Got Results

MR. MOORE: In the hand brake days we had top inspection, and now we haven't it on a great many lines. We haven't it on the Kansas City Southern. I am of the opinion that if we had top inspection at all division points, we would eliminate many of these injuries caused from setting hand brakes. I would like to know the lines that have top inspection at all division points.

(The following roads reported that they had top inspection: Frisco, Baltimore & Ohio, Union Pacific, Lehigh Valley, New York Central, Santa Fe.)

MR. BAILEY: The Interstate Commerce Commission requirements call for top inspection.

MR. HALE: Theoretically the Santa Fe has top inspection, in every-day practice I imagine it is quite as thorough as is yours, but in every case it is not as thorough as it should be.

JOSEPH CLANCY: (N. Y., N. H. & H., Boston): At one of our big yards we used to have damages of about \$1,000 a day. We got a new train master to take care of the yard. Immediately he changed the inspection. Previous to his time when a chain of cars came into the yard, one man started at one end, one man started at the other end, and another man went over the top. When the two men met they changed places or crossed over and went the opposite way. Each man had a hang-out at the different ends of the train, and that was the easiest way for them to do

it. The man that went over the top went over independently. If it pulled up it was all right; the chain might have been wrapped around a wheel, he didn't know anything about that. The new train master had three men go along together; they started at one end of the train and went along the full length of the train. The two men watched and inspected to see that the chain was taken up properly. The damage in thirty days' time was reduced from \$1,000 a day to \$125 a day. Our accidents decreased along the same lines. Any man who had over a \$10 damage had to come and have a personal interview with the train master. If he could possibly help it, he never had another interview. That was one of the reasons the damage cost was cut. Another reason was that the train master insisted that they ride the cut solid into the rest of the train; they couldn't unload and let them come together the way they wanted.

In this yard they humped anywhere from two to three thousand cars a day. They had approximately 1,000 employees, and this proved very effective, so much so that the train master is now the superintendent on one of our divisions, and it is my opinion that his good work in the yard and the inspection were the reasons that put him there.

Adoption of Continuous Cut-Off Lever Advocated

T. B. McCAMPBELL (C. C. C. & St. L., Indianapolis): It has been my pleasure, gentlemen, to serve on Mr. Bailey's committee on Train Service Accidents. I am very happy to say that Chairman Bailey of that committee included practically all my recommendations with the exception of one, and Mr. Bailey doubtless had good reasons for not including that recommendation. That was for the continuous cut-off lever on train equipment. We all know the haste of yardmen in the average large yard of the country. We also know that if there is a defective cut-off lever the man doing the cut-off will not go on the other side to operate that lever, but he will reach in and get it. We are trying to keep our yardmen out from between cars. I know of no better way to do that than to have the continuous cut-off levers on our freight equipment.

I think the Steam Railroad Section should give serious consideration to the adoption of the continuous cut-off lever on freight equipment.

CHAIRMAN ROHWEDER: It seems to me the matter of the continuous cut-off lever is one particularly for the Safety Section of the A. R. A. in conjunction with the Mechanical Division of the A. R. A. We might, a little later, if the regular chairman desires, pass a resolution to the effect that that be given consideration by the Committee on Brakes of the A. R. A. Safety Section.

I would like to hear some discussion on shop accidents or maintenance of way accidents. A great percentage of our injuries, at least from a statistical standpoint, are appearing in the maintenance of way and mechanical departments. Are there any inspectors here from the shop end?

How many railroads are furnishing their shop employees with a proper examination for corrective lenses in shop goggles? What is their system of checking up goggles in service? That is as to whether the goggles are in good service condition, suitable for wear, free from scratches, and so forth, so that they are getting the maximum they can get out of their eye protection furnished through the medium of goggles.

MR. BAILEY: I am not one of the inspectors and I know I should not talk on that subject. I will say, however, that an examination was made by our oculist, requiring all mechanical men to pass that examination to determine whether they needed a correction. Up to a certain time that correction was furnished by the company. Employees entering the service after that time were required to reach a certain standard in vision. If they did not and the employing officer saw fit to employ them, they were required to provide themselves with the proper type of goggles.

D. G. PHILLIPS: We had an odd experience with the use of prescription goggles. We had a man at Toledo and had a hard time getting him to wear goggles. We found that he wore glasses for defective vision, and our goggles, of course, did not fit him. He didn't wear them, and I wouldn't have worn them either if I had been that man. We almost fired him because he didn't, but about six months ago we changed that man to the use of prescription goggles. Any man on the Wabash who needs prescription goggles gets them free of cost to himself, both with respect to the examination and the goggles.

We had a safety meeting in Toledo about two months ago, and we invited this man with whom we had had so much trouble. He came there with the pair of prescription goggles in his hand, and he said, "I am going to make a confession to you fellows. I use these for my reading glasses at home, they are so much better than the ordinary glasses that I wear." The ordinary glasses that he had been wearing had not been the proper glasses for his eyes, and he hadn't known it until he had his eyes fitted for a pair of goggles. If you want to prevent eye injuries, be sure you have eye glasses that fit the eyes of the men.

Goggles for the Employee Where Necessary

MR. BAILEY: There is one question that we were interested in with reference to providing goggles for engine men. On stoker fired engines, locomotive engineers and firemen are inclined to wear goggles to protect their eyes from cinders and dust. We do not prescribe the type of goggles that should be worn. In an efficiency test on our railroad at one time, we found an engineer wearing a goggle that distorted color. That is of such importance that instructions were issued that where enginemen were wearing goggles they must be passed on by the oculist of the company to protect against that contingency.

R. EDLESTON (Michigan Central, Detroit): On the Michigan Central in 1923 we were getting eye injuries extensively. In our steel shop in West Detroit, about three per cent were wearing goggles. There were enough goggles in that shop to supply the whole outfit, but the men would not wear them. We finally had to let them know that they would have to wear their goggles or get out. We put our foot down and demanded that they wear goggles. In 1925, in a steel shop with 135 men, we had only two accidents in the entire year, whereas in 1923 we had six a month; those in 1925 were not eye cases, either.

We have come through this year so far in our mechanical department with one eye case of a severe nature. All of our eye cases now are of minor importance, due to cinders flying and such minor things as that. We have gone very deeply into eye injury prevention. We examine our employees for eye and ear defects. If a man needs glasses, he needs special lens goggles. These goggles are provided for the men at the company's expense. We have quite a number of goggles supplied to the men on our railroad. It is making a wonderful change for the betterment of safety. If a railroad says it is an enormous expense to supply prescription goggles, I would answer that it is the cheapest thing that any railroad can adopt.

We had a man who was a first-class mechanic. He was trying his best to maintain the requirements of the shop from an efficiency standpoint. He was pulling about 65 per cent on a shop checking average. We finally got hold of the man, sent him to the oculist, and found his eyes were defective. He didn't know it. After examining his eyes we got him special lens goggles, coupled with his own glasses. That man is now checking 92 per cent, and runs as high as 150 per cent in his shop checking average, showing that we practically won out with that man, and he has more than 50 times paid for those glasses by having his eyes examined and by having the proper glasses supplied.

We also inspect to see if men's eyes are affected by the glare of furnaces. Thus

have time, go up there and get a lesson in the treatment of highway traffic; it will do you good.

We are building a park system north along the Chicago lake front, and starting at Irving Park Boulevard and going to the city limits, there are two highway traffic lanes 45 feet each, with a service road alongside, of 22 feet, and on those two 45 foot lanes nowhere between Irving Park Boulevard and the city limits will there be a grade crossing, stop and go signal or a policeman with a whistle, the movement of traffic will be without interference.

I spend my spare time trying to do something for the masses of the great metropolitan city of Chicago. Therefore, I am interested in saving lives at highway crossings where they cross steam railroad lines, or where the electric or interurban lines cross. It isn't the fault of the railroads, by any manner of means, that there are so many people killed at railroad crossings; it is more the fault of the man sitting in the automobile driving it. Sixty-five per cent of the accidents on the Lincoln Park System are caused by motorists who won't comply with the rules of the road. That is the trouble at the railroad crossing; they don't stop to think, disregard signals and signs—in other words, they run wild.

A Plan for Distribution of a Safety Booklet

I have a suggestion. It will cost the railroads in money an amount just equal to the cost of mailing it to each individual who receives it, and that is pretty cheap. It may have been tried elsewhere. I have looked into it and I can talk with assurance. In the state of Illinois next year there will be close to something like 2,000,000 automobiles operating on the highways. Thirty-five per cent of the traffic today on the highways of Illinois out in the country is represented by automobiles that are known as foreign automobiles or have come into Illinois from other states. Therefore, you have quite an interstate traffic back and forth.

I propose to you that the proper kind of literature be prepared on this railroad crossing question and the motorist's part in it, and that that such literature be placed in the hands of every motorist with the license plates, not only in this state, but every state in the union. For instance, the proper piece of literature, if handed to Mr. Louis L. Emmerson, Secretary of State of Illinois, who distributes the license plates, will reach the Illinois motorists. Mr. Emmerson has said to me personally that he will cooperate in putting that piece of literature in the envelope that contains the license plates. He said, "I will go further than that, I will put a piece of literature of that kind in every letter that goes out of this office to any motorist." You can do that in Illinois, Indiana, Ohio, New York, Pennsylvania, California, Missouri, Iowa, Kansas, and all the rest of the states, because there is no secretary of state and no man living who is not interested in saving human lives.

It is not the railroad company's fault, as I said before, in the great majority of instances that people are killed at highway crossings. It is the fault of the careless automobile driver. I have had them hit me when I was standing on Lincoln Park Highway, dead still, at five o'clock in the evening. Of course the driver was drunk but he hit me just the same. Probably if he was down in the country, drunk the same way, and driving at break-neck speed, he might have run into the side of some wonderful equipment of the New York Central or the Pennsylvania, and then have a damage suit on his hands to repaint the train.

I have a dummy folder prepared with figures on just what it would cost you to mail it. The various Secretaries of State get out a pamphlet that contains a digest of the automobile laws and regulations. Such data would appear in the folder, together with the state road map. The motorist will keep this in the pocket of his car or in his possession and never let it get away from him.

Can you visualize, for a minute, Mary and John going down the road in an

automobile in a strange country, and Mary having this folder in her possession, with the road map telling what is coming next and with all this propaganda as to caution at railroad crossings? Would John get hit? The folder is to be compiled in a simple, concrete way, viz.:

"Don't cross tracks immediately after train passes.

"When you come to a blind crossing, stop. Get out and look.

"Look out for ruts at bottom of hills approaching railroad crossings.

"There is a sign like this at every railroad crossing. Your life may depend on obeying the warning.

"Always throw your gears into second speed before crossing railroad tracks. If you should become stalled on railroad tracks, don't lose your head. Never under any circumstances speed up to beat a train at crossing.

"Don't attempt to make a high crossing grade without shifting gears; you might become stalled on the tracks at the top. Be extremely careful when driving at dusk and twilight when the vision is poor."

These slogans are illustrated in the proper manner in the folder. I believe if this were put out in Illinois alone, the saving in lives would be tremendous. In Illinois when you kill a man it costs \$10,000 and you have a devil of time proving that it wasn't the railroad's fault. I say again that in 85 per cent of the cases it is the fault of the motorist.

I would like to have this body of men think over the proposition of putting this folder out over the entire country.

The Cost Would Be Merely Nominal

Some fellows say, "How are you going to do that?" I told you when I started that I was a railroad man, so I know a little bit of what I am talking about. You can distribute the cost of this expense the same as you distribute the cost in the A. R. A. You can put it on a mileage basis or handle the expense as a part of the cost of operating traffic bureaus or classification committees. It would make the cost amount to practically cipher when you think of the educational features and the saving of life and prevention of accidents. It has got to be done in such a way that it won't act as a boomerang or some mugwump will get up and say the railroads are trying to get away from providing grade crossing separations. Grade separations will come in due time. They come in all communities when the density of traffic and population require them. To ask the railroads of America to go out and separate every grade crossing would be financial suicide; it couldn't be done. Therefore, the only other way, as I see it, is to take some simple method like this, get the cooperation of the Secretaries of State of the several states, particularly where the motor traffic is heaviest, and put out this folder of propaganda and educate the public mind that when they see a railroad track they must pay attention to it and not run across the roads as though it were not there. Then we will start cutting down in a practical way accidents at road crossings on the highways.

CHAIRMAN WHITE: Mr. Fyfe, I want to thank you for coming down to see us and bringing this wonderful message to us. I am sure that all the members of this Section appreciate what you have said, and to show our appreciation, I am going to ask the members to give you a rising vote of thanks.

(A rising vote of thanks was extended to Mr. Fyfe.)

J. F. GRONZKI (Portland, Oregon): I should like to ask if we can get copies of the bulletins Mr. Fyfe has just explained.

MR. FYFE: I have no duplicates. I just sat down and took the time to paste this together as a sort of dummy. I can have some prepared and turn them over to the proper committee and cooperate with that committee. I should be very glad to do that. It is just as simple as two times two make four. When you distribute the

expense over an entire state or over an entire system, the cost is so small to the individual line that there isn't a road whose cost wouldn't be paid twice over by the elimination of one accident. If you will just be good enough to designate to me to whom you want these delivered, I will get up some photostats and let you have them.

CHAIRMAN WHITE: As I am a member of the Highway Crossing Committee of the A. R. A. and live here in Chicago where I can get in touch with Mr. Fyfe, what do you say to the proposition of my getting hold of these and mailing them out to all those who write about them?

LEW PALMER: Is that the A. R. A. committee or the Steam Railroad Section Committee of the National Safety Council? There is no difference between the two organizations, but I think there is a chance of getting it over to the public in a little different way if you utilize the Steam Railroad Section Grade Crossing Committee, and I think the resolution was very nice, but I believe the gentleman deserves and wants some prompt attention. I can pledge to you, as a member of the Executive Committee of the National Safety Council, that that Executive Committee will support any action taken by the Grade Crossing Committee of the Steam Railroad Section of the National Safety Council. The National Safety Council is pledged to support our different sections, and as this, we are proud to say, is our most important and largest section, I am sure we will be very glad to support this splendid way of putting over one of the best things that I have heard in this conference.

Approval From the Council Committee

C. E. HILL: The suggestions that have been made here by our distinguished guest have, of course, been considered heretofore by many of the railroads, but not in the manner that he has outlined. I think his suggestions are well worthy of our most serious consideration on our own lines. For his benefit, the New York Central Lines put out literature similar to that in the States of New York, Pennsylvania, Indiana, and Mr. Emmerson offered to do it in Illinois, but the question has always arisen as to doing it uniformly and by all of the railroads combined.

I happen to be chairman of the Advisory Committee on Public Safety of the National Safety Council, and this very feature was discussed in a meeting we had Tuesday night. I know that the National Safety Council, if the railroads so desire, would be glad to sponsor it and handle it uniformly. However, if that is not thought advisable, my recommendations are that all of the suggestions that have been made here be referred to the Committees on the Prevention of Highway Crossing Accidents both in the Steam Railroad Section of the National Safety Council and the Safety Section of the American Railway Association, because these two committees coordinate at all times and there will be no duplication.

The Committee on Highway Crossing Accidents of the Safety Section is to have a meeting today. I am making that suggestion now so that Mr. Rowe's committee can consider that feature at this time and then decide upon what further cooperation they may need from the other agencies of the National Safety Council.

CHAIRMAN WHITE: That is perfectly satisfactory to the Chairman.

MR. GRODZKI: I would like to offer one suggestion in addition to what has been said, and that is that the circular be gotten out in the form of Mr. Fyfe's exhibit, which is much preferable, as I see it, to something printed in book form. I would be very much in favor of something on a card that could be displayed more readily.

MR. BAILEY: I make a motion that this be referred to the Highway Grade Crossing Accident Committee of the Steam Railroad Section of the National Safety Council.

MR. BRENNAN: I should like to amend that to the effect that it be referred to the Highway Crossing Committee of the A. R. A. also.

MR. BAILEY: I accept the amendment.

(The motion was seconded and carried.)

MR. FYFE: I don't want any of you to get the impression that this is the way it would be printed. The theory of this is that it will be of the size that will go into the license plate envelope; it is printed on map stock, the same as the Secretary of State prints his highway map. When they get one of these in Illinois, they have an official highway map of Illinois. You know and I know that any motorist who gets an up-to-date highway map of any state will keep it in his car. When he pulls it out to look at it, he gets smashed right between the eyes, as to his responsibility in connection with railroad crossings.

MR. GRODZKI: Does that show the railroad crossings?

MR. FYFE: You can't get an official map to show all the railroad crossings. It shows the major highways on concrete, and that is all.

MR. GRODZKI: Out west where they haven't got the railroads as thick as you have them here, we could show them.

Glad the Prodigal Has Returned

MR. HALE: I want to hark back just a moment to the report of Mr. Mitchell on Monday as chairman of the Committee on Membership. In the 12 or 13 years' history of this Section, we have had our prodigal sons, members who did not put a proper value on home ties and strayed away. Three or four years ago we were all very sorry to know that one of our long-time members and a big railroad had withdrawn. It happens that no longer ago than Saturday of last week or Monday of this week, that prodigal returned, and Mr. Mitchell was not furnished the data. I know that you will all be very happy to know that the Chicago, Burlington & Quincy is again a member of this Section.

CHAIRMAN WHITE: At the conclusion of this round table we are going to have the installation of officers. I am going to ask Mr. Hill to take charge of installing the new officers at the proper time.

I want to take this occasion to say a few words with respect to the wonderful sessions we have had here, and also the wonderful success of our speakers' luncheon yesterday. I am deeply thankful to every member of this session for the assistance and cooperation that have been given me the past year. I want you fellows, all of you, to give my successor the same loyal support that you have given me. I want to call particular attention to our executives' days. I think every executive that we had on our program said just the things that we wanted him to say. I believe every man will go back to his railroad with more pep in him to put this thing over. I know I am going back to the Illinois Central and I am going to talk bigger and better safety than ever before.

I want to call attention to the things said about discipline. You remember, in my opening address, I stressed discipline. I believe in it. I believe that is the only way we are going to put it over, so far as our employees are concerned. I don't mean just to go out and kill a fellow, or that sort of thing, but I have been out on the railroad myself for 18 years in an official capacity and I know just what the official on the Division has to say when some of the higher officers get after him to hurry the trains out of the yard and get off on time, pass up inspection, don't test the air, and all that kind of thing. We want to follow that up and see that they do the thing right. If they don't do it right, there are some men you can pat on the back and get anything you want out of, and others you have to sting. If you can't get it by patting them on the back, then sting them. All of our executives said that. Mr. Fritch of the Rock Island said so, Mr. White of the Missouri Pacific said so, and Mr. Johnson of the D. M. & N. said so. We are all agreed on that. Why should we stand back? Let's go out and talk it up and make the fellows understand that proper discipline is for their benefit and not to hurt them in any way.

I am holding out to you the complete elimination of accidents on our railroads. I believe we can bring that about. We have control of our employees; our men work with us; we have good morale, and we have men whom we want to hold their jobs. All we want to do is help them hold their jobs, not get them killed or get them to lose their jobs. We want to make our discipline count for good and have the men understand it.

I want to thank you all again for the assistance you have given me, and I hope that our next meeting will be just as successful, that we will have as many men present or more.

The next thing on the program is the round table discussion. That was to be conducted by Mr. Isaiah Hale. On account of Mr. Hale's having to leave, we have picked on Mr. C. T. Bailey of the Oregon Short Line. Mr. Bailey has a reputation for ability as a speaker on the safety movement and cannot be excelled when it comes to conducting round table discussions.

MR. BAILEY: When I looked on the program I found our old friend Isaiah Hale was delegated to this important duty. I looked forward with pleasure to being able to sit there and listen to some good discussion. I see they have cut the deck on me and slipped me in here. We are ready for the discussion.

W. R. SPETTIGUE (Los Angeles & Salt Lake R. R., Los Angeles): I would like to ask for an expression from the representatives of the railroads here who have adopted the new whistle signal for highway crossings. I refer to the locomotive whistle signal of two long blasts of the whistle, followed by one short, followed by one long rather than the two long blasts and two short blasts that we used to have. I would like to know what success you have observed in the adoption of that new signal.

The New Whistle for Grade Crossings

ROBERT SCOTT (Atlantic Coast Line): The Atlantic Coast Line Railroad, operating on the South Atlantic Coast, has adopted this new whistle signal of two longs, a short and a long. I regret that this new rule has not been in effect a sufficient length of time for me to testify as to its real value. I can say, however, that the safety department is very much gratified over this change, and all of our operating officers are watching the experiment with a great deal of interest. All of us have every reason to believe that it is going to produce good results.

C. C. MILLS (Frisco, Oklahoma City): The Frisco Lines have neighboring lines that have adopted this system, and we have studied it thoroughly. Within the next few days it will be adopted on the St. Louis & San Francisco Railroad. We feel it is a success.

J. A. CARNEY (C. B. & Q., Chicago): We have been using the new method of whistling for something over a year, and we feel that it has cut down our deaths at crossings by one-half. We have had a number of letters from automobile drivers who have thanked us for that method of whistling, saying if it had not been for that whistle they probably would have been caught.

I recently rode on the end of one of our trains. A Ford automobile stood very close to the train, turned down toward the ditch, and from the look on the man's face it was clear that if we had not whistled up to the crossing as we did, we probably would have gotten that man and his car.

MR. LAW (Illinois Central): I am a locomotive engineer on the Illinois Central pulling the Panama Limited, and I adopted this new whistle some time before my company did. I find that the motorist does not hear or does not heed the first part of the signal, and I do know from personal experience that the last blast of the whistle has saved me from striking many automobiles. I hope that the railroads of the United States will adopt that new signal and the engineers will sound it

according to instructions and let the last blast of the whistle end at the road crossing.

MR. BAILEY: The discussion so far seems to be very much in favor of changing the rule. I believe it was considered by the American Railway Association Safety Section, and I don't know what action was taken.

C. E. HILL: As long as you are talking about the grade crossing situation, I thought a brief statement as to flash signal protection might be of interest to the members of this body. We can make statements as to what we believe results to be by reason of certain things, but we don't always know them to be true. The only definite way of knowing whether or not you are gaining by reason of doing something is by making an analysis and knowing what your results are, both prior and subsequent to making this definite change. So far as the whistling is concerned, I think it has shown an improvement in that respect.

Facts About the Electric Flash Light Signal

I want to speak with reference to electric flash light signals that were adopted by the American Railway Association about three or four years ago, which I presume all of you are familiar with—the alternating flash light signals which operate upon the approach of a train and give the appearance of a horizontal swinging signal. The question has arisen as to whether it is more effective to have these located at the side of the highway or in the center of the highway. Our railroad, in keeping with many other railroads, first started to applying them at the side of the highway because we had no previous experience as to the effectiveness, whether at the side or the center, but since then we have had an opportunity to make an observation. At the close of 1926 we had upon our entire lines 105 crossings where these signals were located in the center of the highway, and 513 where they were located at the side, in the proportion of about one to five. During that period we had a total of 89 accidents where we had this type of protection, only 11 of which occurred where the signal was located in the center of the highway. That was in the proportion of one to eight.

During the first half of this year we had 60 accidents where we had flash light protection, only three of which occurred where the signals were located in the center of the highway, in the proportion of about one to twenty, although the signals were in the proportion of one to five.

An objection sometimes has been raised to placing the signal in the center of the highway because it was a hazard in itself and motorists would run into it. In answer to that, of the 11 accidents that occurred in 1926 where the signals were in the center of the highway, only four of them happened because of running into the signal, resulting in five slight injuries. During this year, not one has been due to running into the signal itself. Furthermore, we do know that motorists run through gates, they run into sides of trains. I don't feel that we can permit that to be any excuse particularly. The center installation tends to check the speedy motorist, divides the traffic and gets them over safely. I mention this as a safety feature solely.

It was my privilege to give this information before the Public Service Commission of the State of Illinois at their request, and they were very much interested. We are continuing that analysis, and as a result of our study installations are being placed in the center of the highway wherever it is physically possible to place them so.

MR. BAILEY: Before attempting to change rules we should have a sufficient analysis upon which to base our argument.

MR. GRODZKI: Does the railroad stand all that expense or is part borne by the county?

MR. HILL: I really believe we should not get into the question of expense, but just the question of safety. The expense in many instances is divided. That feature will take care of itself.

MR. BRENNAN: The Long Island was the initial road to adopt the flash light. We had it in use about a dozen places on the system for two years prior to the adoption by the Signal Section of the A. R. A. We put those lights on the side of the highways first, but found they were not as effective there as in the center of the highway, and, as Mr. Hill pointed out, where it is physically possible to put them in the center we are doing that now.

Recently we have secured the cooperation of the highway departments in the various counties on our lines by having them widen the road at that particular point so as to enable us to have them in the center. We are now lighting the concrete bases. They are about three and a half to four feet high, striped, and illuminated so a man coming along at night can see them. In five or six years we have had only one man injured by running into the light, and that was on a stormy night when his windshield was covered with rain. He admitted that afterward.

We feel that the flash light has been conducive to a greater degree of safety than any other device that has been adopted by the American railways at crossings. We feel that the wigwag, which we adopted in some places and which is the standard on the lines west of the Mississippi, has not reached the minds of the people in the East as it has on the Pacific Coast. For that reason we are going to adhere almost entirely on our lines to the flash light and as far as possible keep it in the center of the road.

We have on Long Island, as most people know, the most condensed form of train operation and vehicular traffic in any part of the world. We have the biggest grade crossing problem in any part of the world. We operate in three of the boroughs of Greater New York and two outlying counties. It is a long piece of line that we can hardly see on the map, but which has 500 miles of coast line, and that induces many people to come from New York over the wonderful highways, and we have to be on the alert eternally. We operate on that track approximately 1,200 trains in 24 hours, and that is some operation.

Some Opposition to the New Whistle

MR. BONE (Missouri Pacific): Some time ago we adopted two longs and a short and a long whistle. I am with the St. Louis Terminals, and our railroads operate through quite large territories of suburban towns. We have found quite an opposition to this class of signal, due to the fact that it annoys the public. I would like to ask whether any of the other railroads have found that opposition to this signal. That is one great problem that railroads have, to keep the public satisfied. Has any other railroad had that objection from the public?

ROBERT SCOTT: There has been some slight opposition. As a matter of fact, there is opposition to any kind of whistle blowing, especially in densely populated sections. However, I believe that after the people become accustomed to this signal and when they realize that we are blowing the whistle for the purpose of saving lives, they will follow our desires and fall in line with us.

MR. BONE: It has been quite a job for our train masters to keep the public satisfied in those suburban towns. We frequently have to go out and call on folks who have sent in complaints with regard to too many blasts of the whistle.

MR. BRENNAN: On the Long Island we have had our men arrested and taken into court a great many times for violation of what is known as the nuisance law. The City of New York insists that the excessive and unnecessary use of engine whistles constitutes, under the statutes of that state, a nuisance, and until advent of the automobile and the importance of blowing whistles became so manifest to all

observers, we had a good deal of that, but not since. They realize now that you can't blow the whistle enough.

MR. SPETTIGUE: In Southern California the municipalities of Riverside, Pasadena, Ontario, and various other places have objected to the old standard whistle. It is not improbable that they would object even more to the new whistle.

MR. CARNEY: We have had a lot of opposition along our suburban territory for some time to the blowing of whistles at all. It seems that our through trains from the west arrive in Chicago between seven and eight in the morning, and we have a lot of suburban trains interspersed with them. The people who have to get to Chicago in the early morning ride those trains and those who come late object to the whistles. We have tried out an air whistle, one with a soft tone which carries very well and which is not disturbing and which we believe will somewhat solve the problem. One of the troubles with the steam whistle on our locomotives is that our mechanical engineer designs a whistle which makes a certain amount of noise. We all know that a whistle is supposed to be a musical instrument and that musical instruments of that kind require a certain amount of pressure in order to make the proper tone. We put the same whistle on our engines whether they carry 250 or 2,500 pounds pressure, usually; the result is that we get all kinds of tones. It seems to me the solution is the adoption of some kind of an air whistle. We have used them for about a year, and they work very successfully. The public likes them, and under certain circumstances we can hear them better than we can a steam whistle.

MR. GRODZKI: We are now experimenting with a whistle something like Mr. Carney has mentioned, a sort of chime whistle that is not shrill and carries just about as far as the loud steam whistle that we used to have.

MR. BAILEY: There seems to be a question involved as to the spacing of the whistle. The time consumed in the entire operation of blowing the whistle for the crossing is the same, but it is differently spaced. I think that was one of the objections, with reference to the density and the loudness of the whistle. There are many communities continually disapproving the loudness of the whistle. We have been experimenting on the Union Pacific System with a similar device, as Mr. Grodzki has stated, but it seems to me that with some statutory requirements where state laws require the whistle to be blown for grade crossings, we have a conflict of city ordinances and state laws. In one of the states on our line we had that matter up and finally it was satisfactorily adjusted. We were requested to blow the whistle according to law.

Trouble With Dies Flying Out of the Hammer

MR. SHANNON (Hocking Valley): I would like to ask what difficulty, if any, the roads have had with regard to dies flying out of air hammers? We had a lost finger and a broken jaw from that?

MR. HAMER: The only reason I can see for that is inability of a man to hold the hammer where it belongs.

MR. CLANCY: I understand there is a new hammer that has a shoulder on it. It prevents the die coming out altogether. We have quite a number of accidents due to that. Of course, we have a clip that is supposed to hold the die in there, but the clips become defective and once in a while there is an accident. We have a boiler maker foreman in Boston who told me that he had some kind of a wire connection that will positively eliminate that source of accidents. I will be glad to send you a sketch of it if it does prove effective, and will find that out immediately upon my return.

GEORGE KELL (Canadian National): We have been experimenting with the steam whistle on the front end of our engines. After a great deal of opposition by certain of our officials, the general manager instructed us to put two whistles on the same

engine. The intention was that the whistle that we had on the front of the engine, being a brass bell whistle, sounded better than the old whistle. We placed two brass whistles on the same engine, one on the back end or original place, and one at the front end. We sent a number of our officials out with that engine and made tests, and even the man who was opposed to the placing of the whistle on the front end had to acknowledge that the signals could be heard clearly and distinctly at least one-half mile farther. We have now obtained 50 new engines with the whistle placed on the front end of the engine. They are in front of the box. On the other engines we carried the steam pipe from the dome to the front end of the engine.

QUESTION: Then you have condensation, don't you?

MR. KELL: To a certain extent. We lowered the pipe in the back end and put a drip in there to carry the condensation away.

MR. BAILEY: There seems to be one railroad that approves our old friend Walsh's original suggestion.

MR. EBRIGHT: That whistle ahead is a great thing for the engineer, the fireman and the head brakeman. A whistle up next to the cab knocks the hat off your head; it is deafening to the employee.

MR. BAILEY: That is one serious objection voiced by locomotive employees with reference to the shrillness of the whistle being located so close to the cab.

Problem of Handling Creosoted Ties

MR. McCAMPBELL: We are having a lot of our track men receiving quite serious burns from handling creosoted ties. I would like some of you men to tell us the methods you are using to prevent that class of accidents.

MR. BAILEY: We have experienced the same trouble on the Union Pacific. Particularly in hot weather when they are perspiring freely, they are liable to rub their heads or faces and cause infection.

MR. PRATT: We are using tongs, as far as I know, and we are not having any reports of men being burned with creosote. The ties are fairly well seasoned before they are sent out to sections to put them in.

W. J. ORR (Toronto, Hamilton & Buffalo): We had a man who lost his eyesight from creosote flying off the tie.

MR. BRENNAN: Will Mr. Orr make clear how it got into the young man's eyes?

MR. ORR: He was driving a spike in the tie and the creosote from the tie flew up into his eye.

W. J. HERROLD (Chicago & Alton): On our western division we experienced some difficulty with a motor car not properly operating the electric blocks. It will not tip the block when it passes over, for some reason or other.

MR. HEAVY (Erie): We have a light type car in operation and we experienced that difficulty where the track has not been used after a shower of rain. I have checked that operation many times and I have found no solution to the problem so far. I find that where the rail is clear that is not true, where there is no rust and the rail is clear it operates the block every time.

MR. HERROLD: That is the trouble we have; after a rain the block will not operate. After some other train has passed through the operation is successful.

MR. BAILEY: It seems to me the subject is well worth further consideration. In view of the fact that it is a matter of new operation, it might be well to refer that to some committee for investigation and report.

MR. HEAVY: We have had innumerable infections from creosote ties. Four years ago at this Section I put forth an honest endeavor to find some preventive for that thing. We find different types of men who are more apt to get that poison in handling

ties on a hot day. I don't know whether or not any of the other railroads have taken into consideration whether those are accidents or just occur as an infection due to the type of man handling the ties. It is very rare to find a Mexican or a colored man who is poisoned with creosote. If anybody has discovered a preventive I would like to hear it.

MR. KELL: We had the same trouble on one of our divisions, just one. Men were complaining of getting their hands poisoned and contended it was from creosoted ties. I inquired and found they were using a very cheap class of glove. When they took off the gloves their hands were perfectly yellow. I asked them to stop using the gloves for a little while. They did stop and we had no more poisoning.

MR. HEAVY: We have made all of those experiments with canvas gloves, leather gloves, gauntlets, and we find no difference. After the leather glove becomes saturated with the creosote fluid, the poison is more dangerous; the glove is not a preventive.

MR. BONE: We adopted the plan of furnishing vaseline for the men who unload ties. We ask them to use it. The supply department furnishes them vaseline in small cans. Whenever a man uses vaseline and thoroughly rubs it into his hands and face and skin, we do not have any accidents of that type. We don't require them to wear gloves unless they want to. That is up to them. I think this cheap glove that they wear can become saturated with creosote and be really worse on their hands than if they didn't use it. We have not had any trouble with anyone when we could get them to use vaseline on their face and hands before handling creosote timber.

MR. BAILEY: I am sorry that the time has come when we must close this discussion. You no doubt recall that yesterday afternoon, due to the time that was consumed and the necessity for providing a room for the banquet, the reply to Mr. Claypool's paper was omitted. I think this would be an opportune time to ask Mr. Hartenstein to make the reply to Mr. Claypool's paper that was postponed.

I want to thank you gentlemen for your consideration of the chairman. I hope you have all benefitted by the discussion we have had.

Response to Mr. Claypool's Paper

F. Hartenstein, Assistant to General Manager, Lehigh Valley Railroad Company, Bethlehem, Pa.

Mr. Claypool has apparently given considerable of his valuable time and attention to the subject of "Maintaining Safe Working Conditions in the Plant." He not only deals with accident prevention, but gives us an outline of meetings held in shops where the general duties of foremen and other supervisory forces were discussed for the purpose, as I understand it, of increasing efficiency and thereby increasing production, as well as other matters worthy of consideration and adoption.

In checking his suggested plan of safety organization, I do not find that it differs materially in operation from the one on the road that I represent, and the order of business is practically the same. I fully agree that safety organizations are necessary to assist in obtaining the results that are so essential in accident prevention work. Officers of such an organization should be the leaders in the safety movement and should have a full measure of assistance from everyone connected with the property from the president down.

The big job of the official of any property, in my opinion, is to be able to select an accident prevention organization, including safety supervisors, inspectors and committeemen, that are sufficiently interested in the movement to give their time and attention to increasing efficiency and effecting an im-

provement whenever and wherever it appears to be possible. Like the activities in other operations on the properties we are connected with, if we lag in this work it is reflected in our accident records and increased expenses, both to the victims and the company.

The principal problem of any safety organization is to create an interest in the work that will not vanish, but will remain seated in the minds of employees so firmly that self-preservation will always be their first consideration.

The third essential of Mr. Claypool's splendid presentation includes good housekeeping, education and supervision. The responsibility for applying and enforcing these essentials rests upon the shop superintendent, the master mechanic, the general foreman and foreman, and any laxity on their part will be

noticeable by the attitude of the men working under them toward the safety movement.

I want to refer briefly to his remarks on education: Before we can educate efficiently any man on any subject, we first must inspire his interest. If this cannot be successfully done, then the effort becomes a loss of time and labor, but if the employee can be inspired with the required interest, education then becomes an easy problem and we can expect results for the efforts.

I am in hearty accord with issuing and posting safety bulletins and displaying moving pictures showing the proper way to perform work to avoid injury and the results obtained by employees who do their work in a careless manner, but it is my opinion that the best results can be obtained by personal contact with the men on the job. The safety organization must sell accident prevention to the supervisory forces, and they to the men working directly under them, and when this is accomplished an improvement will be noticeable in our accident record.

On September 5 of this year the American Engineering Council made public

a report which should be of vital interest to all captains of industry, and the report refers so closely to the shop conditions on the railroads that I am going to take the liberty to quote it, believing that the investigation and report made by the Council will be of special benefit to the railroads, particularly in the shop plants:

"The American Engineering Council made public yesterday a report on its national safety and production survey which has been in progress for more than a year, declaring that industry must free itself from unnecessary waste by using modern safety methods to decrease accidents.

"A. W. Berresford, of Detroit, past president of the American Institute of Electrical Engineers, is chairman of the Investigating Committee.

The Meat of the Accident Prevention Problem

"When these losses and costs have been eliminated or brought down to the irreducible minimum,' the report says, 'then, and then only, will the highest production be secured, the most efficient operation realized. The dynamic force which can attain this highly desired objective has but one source; it resides in the management. Therefore, a responsibility, which cannot be evaded, rests upon the managers and executives of industry to make safety a major interest and a controlling care.'

"After a study of the 'accident and production performance of twenty industries and sixty product groups based upon an exposure of over fifty billion man-hours,' in which forty-six local committees comprising 230 engineers in all parts of the country participated, the investigators asserted that the truth of the thesis, 'The safe factory is the efficient factory, and the efficient factory is the safe factory,' has been established.

"The evidence also proves,' the report continues, 'that the accident situation in any factory can be controlled and that the accident hazard can be steadily decreased.

"The evidence further proves that that quality and thoroughness of management which secures consistently high efficiency of production as a major objective, will also attain a high safety record as an accompanying major objective.'

"The report contains 13 detailed findings built up from data covering 13,898 companies, 122,028 company-years, 2,454,413 employees, 13,143,569 man-years and 54,430,707,000 man-hours. These findings follow:

"Maximum productivity is dependent upon the reduction of accidents to an irreducible minimum. There is such a close relationship between safety and production that it is impossible for a plant to have continued increases in productivity unless it reduces at the same time, its accident rates.

"The experience of individual companies unquestionably shows that material reductions in accident rates can be simultaneously obtained with increases in production rates.

"The rate of production per man-hour, for the industrial groups studied, was 14.4 per cent higher in 1925 than in 1922.

"The rate of accident frequency per man-hour was 10.4 per cent lower in 1925 than in 1922.

"The rate of accident severity per man-hour was 2.5 per cent higher in 1925 than in 1922.'

"The report makes the following six general recommendations:

"That the same executive direction and control be given to decreasing industrial accidents as is given to increasing productivity.

"That those agencies which collect and disseminate accident statistics adopt uniform terminology and standardize their records so that they may be compiled on a comparable national basis.

"That the executives of those plants having high accident frequency and accident severity rates initiate, direct and control ways and means of lowering such rates to at least the low rates obtained by other plants in their industry.

"That industrial trade associations, engineering societies and other agencies, concerned with the improvement of industrial operation, bring to the attention of their members the necessity of improvement in safety performance as a vital step in the strengthening of their industrial position.

"That industrial trade associations endeavor to secure such action on the part of executives of their industries as will result in each plant having the lowest accident rates obtainable."

My friends, there is food for thought in the Engineering Council's report. Their recommendations can be adopted on shop and other properties operated by the railroads to good advantage, and I suggest their serious consideration. I agree with them that the same executive direction and control should be given to decreasing industrial accidents as is given to increasing productivity.

While the number of accidents resulting in death and personal injury on the railroads are decreasing, the cost of settling claims made in connection with them is increasing, and the reason for the increase in the cost of settlement is quite clearly understood. Our problem then becomes one of "how we shall further decrease accidents and the suffering and expense that follows?" We agree that over ninety per cent of them are caused by unsafe practices. Shall we continue as we have in the past, or shall discipline be used to a greater extent in further efforts to obtain the desired results?

Symbolic Emblem Presented to the Section

(Mr. White resumed the Chair.)

BEN ROBINSON (Pullman Porter, Portland, Oregon): Mr. Chairman, Delegates to this Convention: Beginning with the message of safety as given by our president on the first day of this Sixteenth Annual Safety Congress until this hour, the Pullman porters' safety representative and ourselves have summed up the whole matter today as follows: Up-to-date equipment, up-to-date safety operation, and up-to-date safety service. We realize that the Pullman car, after all, is operated on the great steam railway systems and trunks which serve as a field of our operations in which we strive to make safety converts who will continue to spread the message of safety.

In adding our bit we present this emblem known as the Steam Railway Medley designed on an old Pullman hat-bag by a Pullman porter representative to the Sixteenth Annual Congress.

We wish to present this to the Sixteenth Annual Congress as expressive of our appreciation to this occasion.

CHAIRMAN WHITE: Gentlemen, we now come to the installation of new officers. I have asked Mr. Charles E. Hill to do this for us, but he cannot remain, so I am going to ask none other than Robert Scott of the Atlantic Coasts Line, our good friend who reminds me of the slogan of the Illinois Central, courtesy and efficiency always, to officiate.

MR. SCOTT: We have now come to the last minutes of our session. It goes without saying that it has been a profitable and pleasant session. There is only one feature about this installation of officers that does not appeal to me, and that is that our good friend Jim White is going to step down and out.

MR. BRENNAN: I think before Mr. White steps out, it is entirely appropriate that the Steam Railroad Section of the National Safety Council should take cognizance of the fact that we have had during the 1927 period a most efficient, courteous and capable chairman. That is no reflection on what I may think of Bob Scott, Tom

Carrow, Charlie Hill and the other distinguished members who have served in a like capacity on previous occasions. Notwithstanding that the Illinois Central has had a lot of good advertising out of putting J. D. White here, the steam railroads of the United States members of this section have had advertising also, and advertising of a kind that we are going to carry back with us to our respective properties.

Most of us know that Mr. White suffered a serious illness during the period of incumbency as chairman. He was obliged to go fishing up in the North Woods. I am sorry he didn't come to Long Island. He went to the next best place, and he is back here in perfect health.

I think his ability as a chairman has not been questioned at any moment during the sessions which we have attended here. His courtesy has been uniform and the quality of kindness always in his voice and manner are things that we will carry back with us as pleasant memories. Let me say, without burdening further a busy convention that is about ready to adjourn, Mr. White, that I know I echo the sentiment in the heart of every man in the Steam Railroad Section when I say to you that we trust you will carry with you all the time a feeling that you brought to us many kind thoughts, many good words of advice, and that God will bless you, give you full strength and health, and that you may always know that we love you and hope to meet you many times.

CHAIRMAN WHITE: I just want to say, Mr. Brennen and friends, that I appreciate what Mr. Brennan has said. I thank you all.

A Valuable Opportunity for Forming Friendships

MR. McCAMPBELL: I wish to make just a little correction in your remarks, Mr. Scott. You said Mr. White would step down and out. We all agree to his stepping down, but not out.

MR. SCOTT: Your amendment is accepted.

I wonder if every member of this Section appreciates one phase of our activities here, and that is the opportunity for forming friendships. I can say from the bottom of my heart that the men who are in the Steam Railroad Section of the National Safety Council are the men who are very close to my heart. I regard them as friends, and I wish to hold that out to you gentlemen as an opportunity for making friends among those who are engaged in safety work in a national way. I speak from the viewpoint of one who is a grandfather, and when you get to that point, gentlemen, it is not so easy to make friends. I urge you young fellows to make all the friends you can, because you can't have too many in this life.

We now come to that part of our program where we install our officers.

I will call on Mr. C. F. Larson of the Missouri Pacific, who has been elected your secretary for the ensuing year, and present him to you.

MR. LARSON: Gentlemen, the honor that has been placed upon me, one of the newer members of the Section, is one that I very deeply appreciate. I know that the position carries with a very large amount of hard labor, but it cannot be any harder than the labor of the past year in getting up the program which I understand has not been condemned, at least, at this meeting. It is with great appreciation that I enter upon these new duties, and I hope I shall be able to carry them on with the same singular ability of my predecessor in the office. I thank you for the honor you have bestowed upon me.

MR. SCOTT: I am sure we are going to have an efficient secretary during the year. He has demonstrated his ability already.

I will now call upon a young man who has served this Section well and is going to serve as vice-chairman for the coming year. Mr. John E. Long, of the Delaware & Hudson.

MR. LONG: Friends, I wish I had the eloquence of a Scott or a Hale or a Carrow or a Hill or of my good friend, Mr. Brennan, so I could express to you my appreciation. However, I do appreciate it very, very much. If I get half the kick (and I understand kick is the proper word, because it was used by a college president at the banquet last night) out of being vice-chairman as I have secretary, it is going to be very much worth while. I have enjoyed working with you, and I want again to express my appreciation of the opportunity of working with you during the last year and the hope of working with you during this year as your vice-chairman.

MR. SCOTT: Now we come to the presentation of our chairman for the ensuing year, the man who is going to lead this Section, the man who will hold the destiny of this Section in his hands, to a large extent. His ability has already been demonstrated as a leader.

I have great pleasure in presenting to you Mr. Emerson Cott.

A Reminiscence of the Milwaukee Convention

MR. COTT: Gentlemen, in 1920 in Milwaukee I attended my first meeting of the Steam Railroad Section of the National Safety Council. I boarded a train out of Chicago. My wife was with me. We were not acquainted with anybody else on the train. I noticed, a seat or two away from me, a dapper looking young gentleman with gray hair, whose feet hardly touched the floor, and he called for the porter and asked him put a little foot cushion under his feet. My wife was rather attracted, as other women have been, to this gentleman, and later during the journey I made his acquaintance. His name was Robert Scott, of the Atlantic Coast Line Railroad. I don't know whether he recalls that, but he was the first person who told me anything about the Steam Railroad Section of the National Safety Council. I had merely been ordered by my general manager to be there.

It struck me as rather significant that this morning he should be the one to present me as your new chairman. I owe a debt of gratitude to Mr. Scott. Through the years he has given me many a word of advice and counsel.

He perhaps knows of my impulsive and erratic sort of nature, and now and then he has served to put on the brakes to keep me from skidding. I am really grateful that I was privileged to be introduced to you as your new chairman by this gentleman on my right.

A word or two, brief as I can make it, about our plans for the coming year. They of necessity are in embryo. I pledge you, however, a democratic organization for the year. I pledge you my best efforts regardless of how valuable they are. I will give you what I am able to give you.

I hope to surround myself with men who are capable of giving me advice and counsel. Any success that is made during the next year will be largely due to the kind of workers that I may be able to secure to surround me and to help me during the year. I am in search of those men now. I called together a few men a little while ago upstairs to advise and counsel with me about our program and plans for the future year. I am not making any promises; performances will answer, for if you make promises and break them, then, of course, you are in bad. I think I can safely pledge the united, whole-hearted effort of Mr. Long and Mr. Larson in trying to make the coming year a success.

We do pledge you that we will have an executive committee this year of workers, because no man is going to stay on that committee who does not work. We hope to be able to evolve a program for you. Yesterday or the day before, a resolution was passed by this Section instructing the incoming chairman to appoint a committee to make a study of non-train accidents. We also have a standing committee headed by Mr. Bailey on the subject of train service accidents. It is thought that these two committees should be transferred to the Safety Section of the American Railway

Association. It is our thought that in the future the Steam Railroad Section of the National Safety Council should confine itself to the public side of our problem. Here is the place for inspiration, some education and contact. Here is the place to air our public problems. The other section is the place, we believe, where the details of operating safety problems should be handled and aired.

I talked this matter over with Mr. Shedd before coming on the platform, and he has agreed to accept these committees so far as he as chairman can do, and I understand their Committee of Direction will take the matter under consideration at an early date.

Your bulletin service of the Steam Railroad Section will not duplicate that of the work of Mr. Bentley. It is our thought that the National Safety Council should and will produce for you during the coming year posters that are aimed at the public hazard and that you can secure your public safety posters through your membership in the National Safety Council, thus not duplicating Mr. Bentley's splendid endeavor in that direction.

This is a short outline of what we have in mind. Some of you are going to be called and asked to give of your time and of your service. During the coming year you may answer that you are busy men. The Executive Committee of the Steam Railroad Section wouldn't be worth a continental, gentlemen, unless there were busy men on it. We have no place for other than busy men upon that committee, and I hope you will realize that you as individual members owe some obligation to the railroad and the people as a whole by giving of your time, giving of your mind and giving of your heart in this work.

I feel that I have an obligation and responsibility, but I trust and hope and pray that I will be at least somewhat equal to it and will be able to follow in the footsteps of those who have gone before, to make the year a successful year, to give you a program which you can be proud of as you should.

I want to thank you for the favors that you have given me since 1920. I have only tried to be helpful, not hurtful. Any mistakes that I have made have been of the mind, not of the heart. I want you and hope to keep you all as my friends, and I hope to make you and keep you as my friends by being a friend to you.

MR. SCOTT: Before I present you this gavel, Mr. Chairman, I wish to assure you of the whole-hearted support of this entire Section. Gentlemen, let's give him our full support and let's go back home and do the job right.

ADJOURNMENT

**SIXTEENTH ANNUAL SAFETY CONGRESS
NATIONAL SAFETY COUNCIL**

Taxicab and Fleet Owners Section

New Section Officers

Chairman, J. ROBERT CLAIR, Liberty Mutual Insurance Company, Boston, Mass.
Vice-Chairman, HARVEY D. WOOD, Yellow Cab Company, Chicago, Ill.
Secretary, J. E. DOBBS, Detroit City Service Company, Detroit, Mich.
Poster and Slide Committee Chairman, F. T. COLEMAN, Continental Bakeries, New York City.
Membership Committee Chairman, J. G. WILLIAMS, National Association of Taxicab Owners, Chicago, Ill.
Publicity Committee Chairman, S. J. STEINMANN, Indemnity Insurance Company of North America, Philadelphia, Pa.
Statistics Committee Chairman, A. E. LUNDSTEADT, Bowman Dairy Company, Chicago, Ill.

Tuesday, September 27, 1927

J. T. SMITH, Chairman
Assistant General Manager, Yellow Cab Company,
Philadelphia, Pa.

The first session of the Taxicab and Fleet Owners Section of the National Safety Council, was called to order at nine-thirty o'clock by the vice-chairman, J. Robert Clair, Liberty Mutual Insurance Company, Boston, Mass.

VICE-CHAIRMAN CLAIR: I wish to welcome all those present to the Sixteenth Annual Congress of the National Safety Council and to the meetings of this Section. I hope you will all fill in the registration cards and turn them in, so we will know who is here.

I might say about our program that this should be a very busy and, I trust, profitable day for us. The first business on the program is the appointment of a Nominating Committee, and I will appoint Mr. Dale Harman, Mr. J. E. Dobbs and Mr. Harvey Wood.

I think we can immediately proceed to introduce our first speaker. The subject is "Safe Operation of Motor Driven and Horse Drawn Vehicles in Congested Districts." This paper will be read by Mr. M. T. Hanrahan, Superintendent of Vehicle Service, American Railway Express Company, Chicago, Ill.

MR. HANRAHAN: I have a little apology to make about the briefness of this paper. In the first place, for 60 days I have been organizing and perfecting the Trans-continental Express Air Service, which has kept me quite busy. However, I am glad to be here to contribute what I know about the handling of vehicles in congested districts. I was a close observer the other evening of the handling of the traffic down at the Soldiers' Stadium, and I am going to pay the Chicago Traffic Division and the South Park police organizations as fine a compliment as I can for the orderly handling of that great body of pedestrian and motor traffic without an accident. I haven't heard of one accident that occurred there, and I think the police department deserves a great deal of credit for the organization they perfected to handle that traffic.

To begin with, there were 705 people killed in Chicago during the first nine months of this year, and I think the larger percentage of those accidents were children in outlying districts. The larger percentage of these accidents didn't happen in congested districts. They occurred through careless drivers and half-wits who were driving cars and motor vehicles around the outlying districts.

Safe Operation of Motor Driven and Horse Drawn Vehicles in Congested Districts

**M. T. Hanrahan, Superintendent of Vehicle Service, American Railway Express
Company, Chicago.**

It is a difficult proposition for all large organizations operating vehicles in large cities to prevent accidents involving their equipment. While the humane feature is the most important, the economic waste is a serious factor, even though there may be no loss of life or serious injury to the public in the majority of cases. The problem of the safe operation of all classes of vehicles in congested districts is becoming increasingly difficult because of the traffic outgrowing our present street facilities, and there is a question in my mind whether we can go any further in the direction of additional safeguards until some action is taken

~~we~~ improve the roadways, either by double decking or whatever plan suggests itself as being the best for the needs of the situation.

However, as there does not appear to be any hope of immediate relief in street conditions, we shall have to devote ourselves to the best means at hand for controlling the situation; and speaking for the American Railway Express Company, which I have the honor of representing, we are doing everything possible to eliminate accidents.

Our company undoubtedly ranks as one of the leading vehicle operators in the United States, and we have an added responsibility, in that we are, perhaps, more intimately connected with the public than a great many other large organizations; and for this reason every man in our organization is impressed with the necessity of safeguarding our operations so as to avoid accidents.

It was a comparatively easy task just a few years ago to handle our business with a low ratio of accidents, but with the ever-increasing flood of motor vehicles, together with the increase in population in large cities such as Chicago, it has become a big proposition to devise ways and means for the prevention of accidents.

Careful Selection of Men to Operate Vehicles

Long before the motor car came on the scene we began our safety campaign by careful selection of men to operate our vehicles, as we realized that the ground work of accident prevention depended almost wholly on the human element, and no amount of planning could offset weaknesses in that respect. It has been a rule of many years standing with our company that only men of good habits and character could secure positions with us, and more especially in the vehicle service. The additional requirements are first-class physical condition, coupled with experience as a driver. We consider that it requires as much skill to drive a team of horses in congested districts as it does to operate a motor vehicle.

A motor car is wholly under the control of the chauffeur, and, if in good mechanical condition and operated carefully, should not become involved in any accidents. Horse-drawn vehicles cannot be brought to a stop as quickly as motor vehicles, and there is always the uncertainty as to what a team of horses will do under certain conditions. It is in these situations that the driver's skill comes into play, and our long experience confirms the theory that we have always held, that safety work is valueless if the selection of competent drivers is neglected.

It is our policy never to buy any but the best horses available. They must be sound, and, above all things, have a good disposition. Any that we discover in our service inclined to viciousness are immediately disposed of, as we consider that no matter how good a workman a driver may be, he must have proper tools to work with.

All of our heavier types of wagons are equipped with brakes, and they are kept in first-class condition. I doubt if any operator in the country pays as much attention to repairs as we do; for that reason the possibility of accidents due to defects in equipment is very remote. It is also our policy never to load a wagon beyond what we consider the ability of the wagon and the team to handle safely. Because of the street congestion confronting us daily, it is impossible for a team to control a heavily loaded vehicle properly in an emergency.

As regards our chauffeurs, we pursue the same careful program in their selection. They must be morally and physically fit. We consider our vehicles no place for half-wits. Too many chauffeurs today are only a lap ahead of their keepers. We consider our first and most important step, the careful selection

of candidates for chauffeur positions. Having done this, we put our applicant drivers on probation for a period of from three to six months before they are eligible for a permanent position. At the beginning of the probationary period, a corps of instructors take the candidates through a rigid course of instructions, covering the mechanical features of a truck, traffic regulations, etc., after which, the candidates are given a driving test under the observation of the instructors, through traffic conditions which our regular chauffeurs meet daily. During this test, each candidate is carefully watched to determine if he has the proper mental balance to operate successfully one of our trucks. A man may pass the mechanical tests and still not be a safe man to operate so dangerous a vehicle as a motor truck. The instructor, at the conclusion of the test, makes a report to his superintendent showing how the candidate reacted to the various conditions met in the test.

The superintendent determines from this report if the candidate is desirable. A further requirement is the test by city authorities, unless he has passed this before applying to us. Thus in the case of every chauffeur there are two checks on his competency. No chauffeur should be allowed to work out his own salvation. Rather should a carefully worked out set of principles or rules be laid down and the man held strictly accountable for their observance.

The Driver Should Be Able to Move Instinctively

Instructions to the chauffeur, which should be such that in case of emergency he will act instinctively, must be followed by ample supervision. Our company feels that the time spent in educating chauffeurs would be wasted if this were not carefully followed up with proper supervision. We maintain a corps of inspectors, all selected for their executive ability, experience and long service. A great many of these men, in fact, are seasoned veterans of from 25 to 30 years' service and they are all wedded to the idea of safety first. These men devote their entire time to vehicle control. Furthermore, to keep safety principles fresh in the minds of our vehicle forces, articles are published in the company's magazine, *The Express Messenger*, and meetings are held in our stables and garages for the discussion of accident prevention. Record is kept of all accidents in which our men are involved, and they are called in on every accident regardless of the extent of injury or damage, and the case is carefully gone over to show them how it was possible to have avoided the accident, provided, of course, our man was at fault. Unless an accident is of such consequence to warrant his dismissal, he is given another chance, with the understanding that a demerit will be filed against his record, and informed that three demerits mean dismissal.

This plan has enabled us to keep our accident record where it compares favorably with that of any similar organization in the United States. We operate approximately 8,200 horse-drawn vehicles and 3,670 motor vehicles, a total of 11,870 units.

The mechanical condition of motor trucks plays a large part in accident prevention, and I think every one will agree that so far as the commercial vehicle is concerned, good business judgment dictates that it must be kept in good operating condition. The braking power of a motor vehicle is of prime importance, and in my opinion, all motor vehicles should be capable of stopping from a speed of 20 miles per hour on a dry, smooth, hard surfaced road by means of foot brakes alone, in a distance of not more than 50 feet. Of course, it is understood that a careful and properly trained chauffeur will not attempt to drive in congested districts at a speed of 20 miles per hour and it follows that if the brakes are in a condition to function properly at a high speed, they are doubly

efficient. We have found from long experience that the safest speed limit for our motor trucks is 12 miles per hour, and to insure that that speed will always be maintained, we have placed on all our motor trucks, a sealed governor, which prevents a greater speed unless the seal is broken and the governor adjusted. Frequent inspection of the seals is made to prevent any tampering by the chauffeur. We take pride in the fact that we have never had a report nor an arrest of one of our men for speeding. Of course, this is expensive, because greater speed means greater operating efficiency, but we are willing to sacrifice all this in the interest of public safety.

We feel, naturally, that we must anticipate daily what the average pedestrian will do in congested districts, and we have impressed on all of our drivers and chauffeurs the importance of not having their attention distracted from the road in front.

All accident prevention work must start and finish with the man in charge of the operation of the vehicle, and if his education has been properly attended to, there can be no question but accidents will be kept to a minimum, provided, of course, that there is adequate traffic control, by means of lights or other devices, and more important perhaps than anything else is traffic officers in sufficient numbers to regulate the traffic properly. Mechanical traffic control, by means of the numerous devices now in use, is very helpful, but the presence of numerous traffic officers in congested districts is not only important, but absolutely necessary.

Discussion of the Use of Governors

VICE-CHAIRMAN CLAIR: It is highly desirable, gentlemen, that we conduct some discussion. I know we all have our problems concerning the particular job on which we are working. I hope no one will leave this morning without giving us an idea or two or perhaps asking a question concerning some point in which he is interested.

I am sure we are all very much obliged to Mr. Hanrahan for his paper.

WILLIAM HINCKLEY (People's Gas, Light & Coke Co., Chicago, Ill.): I would like to ask what kind of governors you use?

MR. HANRAHAN: Our Motor Vehicle Department has two or three different kinds of governors. I will get the information and give it to you.

MR. HINCKLEY: I wonder if Mr. Hanrahan knows what success they have, how long these last on various types of equipment.

MR. HANRAHAN: I think they are lasting all right. I don't remember, but I think we had only one case in five years when a governor has been tampered with by the chauffeur and he was promptly discharged.

I learned something new the other day. We have governors on our tractors and demand so much mileage and so many moves per tractor, and the operator's performance sheet has to show just how many moves he made in eight hours, how much mileage he covered. I understand one chauffeur jacked up his front wheels, where the governor was, and spun the front wheel, but it didn't register any distance. He was taken off the job.

J. A. HEINZ (Swift & Co., Chicago, Ill.): Do you have the same mileage on all sized trucks, regardless of the truck? I mean the governor.

MR. HANRAHAN: Yes, on the motor trucks we do, except a few trucks which we operate in outlying districts. We put on a truck last week for the air service alone, which is geared for 45 miles and in case the operator has to come in from the Municipal Field, which is about 12 miles out, we give him the benefit on the highways where there is little danger of accident.

Most of our trucks are operated in bus districts, and we have practically four

or five cities within the corporate limits of Chicago. You find one at 63rd Street; at Crawford is another one; at Wilson Avenue another. They are very congested too, with a lot of business.

P. J. HEBRON (American Railway Express Co., St. Louis, Mo.): Are the trucks governed at 12 miles which operate between those outer towns?

MR. HANRAHAN: Yes, they are all governed at 12 miles an hour. I am wondering what effect, if any, you have noticed on the length of the drives, where they have hard pulling.

It may be possible that the American Express has pretty good roads where they go. We take a truck of our own every once in a while and govern it down to 12 miles an hour. That is for heavy duty equipment. For light stuff I get 16 or 18 miles an hour. When we get into the heavy duty, we get the complaint that the truck won't pull out the governor, and is stuck there. It runs us into considerable expense. I don't know how it affects the American Railway Express Company. Some of our mechanics can remedy it, but our chauffeurs have a time doing it.

Speed Regulated to 12 Miles an Hour

MR. HANRAHAN: Your tonnage is about double ours. The average load of express on the three and one-half or five ton trucks wouldn't average 5,000 pounds. The tonnage with your equipment of all kinds is heavier and I don't know whether a governor at 12 miles an hour ought to be put on your trucks, because they probably don't travel over 12 miles an hour with the loads they carry.

C. S. GOLDSMITH (The Brooklyn Union Gas Co., Brooklyn, N. Y.): Are most of your trucks electric trucks?

MR. HANRAHAN: No, we have about 200 gas trucks and 175 electric trucks. All our equipment is heavy equipment. We have no small equipment at all in Chicago.

MR. GOLDSMITH: The American Railway Express in Brooklyn has practically all electric trucks and they are limited, of course, in speed.

MR. HANRAHAN: We operate only horse-drawn equipment for all Loop business. All our terminals are within a mile and a half or two miles of that congested district and we use horse-drawn vehicles exclusively on that. We find that we can sometimes use a horse for 20 years and keep building him up all the time, because the work is just a little exercise for him. We go four miles outside the Loop with horse-drawn vehicles. After the four miles we use the electric. Beyond that four miles is gas. We get along very nicely.

VICE-CHAIRMAN CLAIR: Mr. Hanrahan, as I understand it, you require each of your men to undergo a physical examination?

MR. HANRAHAN: Yes, we have an insurance company in our express service, and we ask them to join this insurance company. Of course, in joining the insurance, they have to stand a physical test, and if there is anything wrong with them—sometimes we find a minor defect—we just send the man to a doctor and fix him up and bring him back.

VICE-CHAIRMAN CLAIR: Does the examination include a color vision test?

MR. HANRAHAN: I am quite sure it doesn't.

VICE-CHAIRMAN CLAIR: The subject of giving drivers color tests in order to be sure they are able to recognize traffic signals is something about which there has been quite a little talk, and I believe serious consideration has been given to making it a requirement for taking out a license in Connecticut.

D. J. THELAND (Northland Transportation Co., Minneapolis, Minn.): I would like to ask Mr. Hanrahan's opinion in regard to the speed of the governors as it affects safety. Do you consider it safe to have vehicles governed down to a certain speed which might make it impossible for a vehicle to pass another, and in attempting to pass a vehicle, not be able to drop into the line of traffic again, and in that way cause an accident?

MR. HANRAHAN: I can't quite agree with you that he would have an accident if he got out of the line of traffic and wasn't able to make the hill as he thought he would. He would have to wait; that is all.

We instruct our drivers not to take any chances. It might lower his efficiency as far as the load is concerned, but I don't believe it would add to the hazard to take the driver outside the string.

MR. THELAND: You don't think there would be any danger of the governor shutting off while he was passing and making it necessary for him to drop back?

MR. HANRAHAN: No.

P. J. HEBRON (American Railway Express Co., St. Louis, Mo.): Mr. Hanrahan has told you practically everything concerning our company. His work is in Chicago; mine is in St. Louis. The town is a little different down there. We have a great number of hills. We also have our trucks governed to 12 miles. As Mr. Hanrahan stated, the chauffers are delayed if they have a load. That has been our experience in St. Louis. We have several chauffers who go a distance of six or seven miles, and we raise the governor to 14. Those men have three and one-half ton trucks and bring in their tonnage every night.

VICE-CHAIRMAN CLAIR: We will immediately proceed with the next paper, which will be given by Mr. William Hinckley, Superintendent, Automotive Transportation, Peoples Gas, Light and Coke Company, Chicago, Ill.

Introducing the New Driver to His Job

William Hinckley, Superintendent, Automotive Transportation, Peoples Gas Light & Coke Company, Chicago, Ill.

Do you realize the importance of starting the driver on the right road to his job?

Fatal automobile accidents, estimated figures, in the United States in the year of 1920 amounted to 9,106, and in 1926 to 23,000, a vast increase of fatalities which human intelligence cannot replace, not to mention money spent on autos or accident repairs.

At this point we have a little road book. I haven't it with me, but if you will write to us, I will send you one. This book embodies traffic rules, not in detail, but generalities, with a few designs of intersections, which show the driver how we want him to handle his car. We also include about 30 or 40 don'ts and try to impress the driver with all the points in this book before he starts out with his car which is, of course, after his credentials have proven satisfactory.

Our first move is to ascertain from the applicant just what he knows relative to traffic rules and regulations. We do this to determine just what he knows about his job. When we find him lacking we attempt to educate him on the essentials of traffic regulations. We then take him into the office and introduce him to the office force and do the same in the shop in order to make him feel at home. He is questioned as to what he knows about the mechanical end and asked to demonstrate his ability by performing the work which is generally supervised by the shop foreman. In many respects this brings out the question of truthfulness which we deem necessary. If he is inclined to make false statements to obtain a position he might do a lot worse after he gets the job.

If the applicant has spoken the truth he is ready for the wheel under the supervision of the foreman, assistant foreman or an A-No. 1 mechanic. These men know their game and are of good standing in our organization. They carry but two ideas in their minds, "Safety First" and "operation of the car." They are also good judges of human nature and make allowances for nervousness and excitement when noted on a man taking over a new job. The applicant is

allowed to pursue his own course until such time as our man thinks he is able to handle the car properly. Here we change the course and he is taken over a prescribed route through heavy traffic conditions.

Deviating for the moment to put my point of view over, I would like to ask the following question: Why does an automobile make a hog of human nature? The term hog might be changed to suit one's ideas but the term is proper, as I see it. This demonstration drive with the mechanic brings out this point strongly and we base our opinion on the candidate's ability to fit our organization, which we try to keep within the safety zone. For instance, we pull a man to the curb and note what movements he makes in pulling out into the traffic lanes. He either shows respect for the other fellow in the lane of traffic or the hog comes out and he busts into traffic. The same course is pursued along these lines at intersections, lanes of traffic, etc. If the man shows respect for the other fellow he is considered desirable but if he shows no respect at all he is cautioned about the hog element and given an opportunity to change his ways.

Heavy Traffic Brings Out a Man's Characteristics

After the elimination of the hog we endeavor to determine just how his mind functions relative to carelessness. In other words, keeping our idea of safety in mind, the man in charge will guide him into places of traffic to determine his thoughts as to how much he relies on what the other driver will do. He is also checked on traffic signals and lights and we explain the dangers of running through lights and also that a stop light means just what it says irrespective of what traffic conditions are.

Assuming that the routine proves satisfactory we endeavor to explain a few of our ideas on driving. A black-board with a street layout with intersections showing proper and improper methods of driving is used. The black-board is cleared and he is asked to answer questions by making a sketch on the board.

When we are sure he understands our ideas the man is ready for the job. Our efforts do not stop here, as he has to satisfy the man he is to drive for and ourselves on the operation of the car. The probation period is six months and if he survives we term him a permanent employee, provided he takes care of his job and decides to stay.

In conclusion, safety meetings are held once a month and the men are represented at these meetings. Bulletins are posted on the procedure and the attention of the men is called to them.

Last year we ran into 89 accidents on a fleet of 230 pieces of equipment. In each instance the committee, consisting of our staff engineer, the superintendent of transportation and the superintendent the man was working for, sat in on the case. One thing we are handicapped by in the Peoples Gas, Light and Coke Company, is that the superintendent of transportation has charge of very few chauffeurs. The bulk of them are distributed to other superintendents, and we cannot bring the powers that be to believe that we ought to have jurisdiction in sizing up the men as they should be sized up.

In other words, if a man is a good gas fitter, we have an awful time dragging him off a truck, and we have to pound it into his head to go along with our ideas. It is about the same in other lines of our work. Cooperation is getting better along these lines every day. The continual pounding is making them see the light of day, but I don't believe it will work as efficiently as if the man having direct charge could lay out the work as he sees fit.

Out of those 89 accidents, 14 per cent were at fault. We felt that our drivers were careless. There were 15 per cent that were possibly avoidable, and the

rest were accidents where our men were absolutely not to blame, where they stopped at traffic signals or stopped at stop streets or were stopped in traffic and somebody backed into them from behind or the side, and there was absolutely no chance of the party causing the accident collecting any damages from the Peoples Gas, Light and Coke Company.

We are striving to improve that record by the use of a bulletin board, and three colors of stars. We use a red star for an "at fault" accident; a blue star for an "avoidable" accident; and a yellow star for an accident "not at fault." When a man gets three red stars within a year he is dismissed from the service, irrespective of what his record has been. If he gets five blue stars, he is dismissed from the service. We are now at the point where we think we will have to lower these stars. In other words, the supervisor or vice-president of operation, who has charge of the transportation department, is contemplating cutting that to one red star or three blue stars for immediate dismissal.

MR. JONES (Indiana Indemnity Co.): There are a few things I would like to ask. Pertaining to drivers who have formed the habit of pulling in on the left-hand side of the street, if reports are sent to your company, what action is taken?

MR. HINCKLEY: In the first case, a reprimand; in the second, a lay-off; in the third, dismissal.

MR. JONES: Pertaining to the number of accidents—blue stars, yellow stars and red stars—if a man should be in an accident that would cause him to receive a red star, how long a period do you allow him to go without taking that mark away from him?

Three Accidents in a Year Bring Dismissal

MR. HINCKLEY: We allow him to go one year from the date of the first accident. If he has two more, he is dismissed at the end of the year, but we give him a year from that date, which is ample time, I believe.

As a matter of fact, the supervision of our company, as I said, is right now contemplating bringing that down, due to the fact that we haven't made the big drop in the percentage of accidents we should in 1927 to date, as we did in 1926 over 1925.

MR. JONES: Supposing a man should violate some traffic rules and a pedestrian should write in to the company and tell of his violation, is that information of value, or do you request this man who makes the complaint to give further information, and to appear at the trial against the driver?

MR. HINCKLEY: We do not. In a case of that kind we would summon the driver to the front. We would ask him the question. You can pretty nearly tell whether the man is lying or not. The average pedestrian will not write a letter unless there is some cause for it. That is the way we feel.

In the public utility business we believe in service first, and the consumer or pedestrian on the street is always right.

MR. JONES: My opinion differs somewhat from yours, because I drive a car every day of the week, and you will often see that the truck driver isn't at fault. You must appreciate that a truck will only travel at a certain rate of speed. Many of us fellows who are driving what we call high-speed cars push in and push out the truck driver. The truck driver isn't always given the break.

Understand I want to put this to you as an individual who is not interested in defending either party. Every man driving a truck isn't what he is represented to be. I think the truck drivers feel that they want to give the passenger cars the benefit of the road, but you always find that if the car is scraped as you say, the man with the passenger car wants to put it on the driver of the truck.

MR. HINCKLEY: That is an accident there. Now you are bringing up two versions, as I see it. You are talking about pedestrians reporting violations in the first place, and then you cite what is really termed an accident. If one of our trucks scrapes an automobile, that is an accident. Where the man makes a complaint against us in the case of an accident, our claim department goes out. He gets this man's side of the story. We get our driver's written report and compare notes.

We also go to the witnesses when there are witnesses obtainable. We have very few accident cases where witnesses are not obtainable. When they are not obtainable, the man gets the "break" provided he has proper length of service and the reputation. We are humane, or try to be.

On the other hand, if it is a fellow we have had a lot of trouble with and we know he is a little bit haphazard, he gets no "break" from the committee. But anything that comes in as an accident—if one of our cars touches another car—the instruction is: "Bring in that number if it is possible to get it." We go out and consult the witnesses, and ordinarily your witnesses will give you a "break" on it and the man is worked on accordingly.

In the last twelve years of operation, we haven't had three letters from the pedestrians come into the office, drawing to our attention the fact that our drivers are not obeying traffic laws and regulations or are abusive in giving the pedestrian the right of way.

Age May Disqualify the Applicant

C. C. BENEDICT (Standard Oil Co. of New York, New York City): I would like to ask what regulations you have, if any, regarding the age of a chauffeur. Do you have an age limit and what has been your experience?

MR. HINCKLEY: Ordinarily we have set no age limit. In other words, if a man is capable to do the work on a truck or car, provided he isn't too old to be active, he is eligible for the job. If a man is 45 years old at the time of hiring, we do not allow him to participate in what we call our pension.

Every employee of the Peoples Gas, Light & Coke Company is allowed a pension. That pension is added on at two per cent each year of service. When a man is 65 he is asked to take the pension, and in the automobile end of it unless a man at 65 is very active and has the ability to go along, he is dropped.

The element of youth is left to our own judgment, and it is our aim when we are hiring drivers for the transportation department not to go under the 23 year mark, if we go that far. Most of our men today run between the ages of 27 and 30.

MR. BENEDICT: It has been our experience that the driver 21 years old is inclined to have more accidents than the one 26 or 27.

You spoke about instructing your new driver in the mechanics of the car—teaching him about the mechanical part of the truck. Is that done just so he will have a little more intelligent knowledge of what he is handling, or so he can make minor repairs?

MR. HINCKLEY: It is done so he will have more intelligence. We ask our men not to touch the cars. We find the average chauffeur "gums up" the job more than it is worth, provided we let him go ahead on that basis. We have one set of trucks making a 50-mile zone from State and Madison Street, on which we allow the driver to change spark plugs and make other minor adjustments.

JUDSON C. DAVIS (Hartford Accident & Indemnity Co., Chicago, Ill.): Are the safety meetings held on company time or on the time of the employee?

MR. HINCKLEY: They are held on company time, and if the meetings extend over time, the men's time goes on on the same basis. They are called in at 3:30 in the afternoon. Their quitting hour is 4:30.

W. F. COULTER (Hartford Insurance Co., Hartford, Conn.): What percentage of

the men are turned down in the test when you run them through a mechanical test, when they are applying for a position and you are not sure they are telling you the truth?

MR. HINCKLEY: We lose about three out of five on the truthful statements. The average man will tell you he knows more than he really can put over in the shop, when you send him out to do it, not realizing he will be called.

P. J. HEBRON (American Railway Express Co., St. Louis, Mo.): Is the man's previous record investigated before he comes in?

MR. HINCKLEY: Absolutely. We are assuming now his credentials are O. K. and the man has passed what we call his application test. That is where my talk started. We look into that thoroughly before we take a man on, and if there is any doubt at all we make a very thorough investigation by sending a man out to look up his record.

G. O. GILBERT (Illinois Bell Telephone Co., Chicago, Ill.): Do you use the policy of bringing men from the shops to promote to chauffeurs or do you hire them outright?

MR. HINCKLEY: Both ways.

MR. GILBERT: What percentage?

MR. HINCKLEY: In regard to bringing them from the shop into the chauffeur jobs, there aren't very many men who go into the shops lazy enough to want the chauffeur's job. If they get into the shop, they stay there and don't want to get out. When our lay-off periods come, it is hard to get the mechanics to go driving. That percentage is small, and I wouldn't say it would be one-half of one per cent of the total men on our turnover.

The Problem of Who Should Employ the Driver

MR. GILBERT: Do you expect the drivers to do other work than chauffeuring?

MR. HINCKLEY: We expect our men to do as they are told, whether it is chauffeuring or something else. In the public utility game, such as we are in, there are instances when the chauffeur can be used nicely, and if he has to use a pick or shovel or anything else, he does it.

T. B. HOWE (Aetna Life Insurance Co., Cleveland, O.): I gathered from Mr. Hinckley's paper that he believed the men in charge should hire the employees, but I gathered from the trend of his paper that his concern really does not do that. It sounds as if there were another employment manager. Do you believe the man in charge should do the hiring?

MR. HINCKLEY: I think he should, but we are handicapped in that respect. Our officers have come to believe, in the last two years, that it should be done; but on the other hand, the superintendent who hires this man hires him from his point of view. It may be a laborer or it may be a delivery man or a truck driver or maybe a gas fitter. Gas is the essential thing and that is where we lose out. We have pretty good control over our delivery men and personal car chauffeurs, but the minute you get into the gas fitting subject, you are touching something you can't handle.

J. A. HEINZ (Swift & Co., Chicago, Ill.): Are your chauffeurs organized?

MR. HINCKLEY: They are in this respect: Some years ago Tim Murphy, known to many of you from the vicinity of Chicago, organized what he termed the Gas Workers' Union. That took in everybody—our laborers, our men operating engines, the gas fitters, and the chauffeurs. In other words, they were all Tim Murphy's union men, up until last year when the stationary operating engineers took them over and they are all Tim Murphy's Union.

MR. HOWE: I would like to have the question I asked previously referred back to Mr. Hanrahan.

MR. HANRAHAN: You mean about the employment of chauffeurs? We have, as

I say, six stables. We have three garages and three stables, and each stable has an assistant superintendent. One man has charge of all the horse-drawn stables and one has charge of all the garages. All of the help is hired by the superintendent, who has charge of the garages, and as a man goes along his demerits are charged up to the superintendent. So if he gets a "dead one" in the service, we say to him, "What did you do that for?" We charge him up with the caliber of man he gets in. If he gets a burglar, we call him in as well as the burglar. It makes him doubly careful when we go after him as well as anybody else.

VICE CHAIRMAN CLAIR: I think this has been a fine discussion, Mr. Hinckley.

I might say that we have some well defined ideas as to what the activities and functions of this section should be. We feel we should be one of the leading sections in the Council. After all we are the men who are going out, literally rolling up our sleeves, and tackling this problem of educating the men behind the wheel. We are not talking theory. We are practical fellows. We are the men in touch with the drivers. As I say, it is our work to get to the man behind the wheel, and that human factor is surely the big problem.

The last paper will be presented by Mr. Harvey D. Wood, Safety director, the Yellow Cab Company, Chicago, Ill.

Some of the Real Problems of Taxicab and Fleet Control

Harvey D. Wood, Safety Director, Yellow Cab Company, Chicago, Ill.

I am very keenly interested in this section, primarily of course because I need help. But other than that I have been identified in various sectional meetings with the National Safety Council for some time, and it is only in the last year and a half that I have come over with the Yellow Cab Company and have become interested in this section. Previous to my connection with the Yellow Cab Company I was in the public utility business, and the Public Utility Section, as you know, is a real section. They are very active, and they have some wonderful sessions. I hope some day to see this section grow and expand to that size so that we will have bigger and better meetings and more interesting discussions brought out.

Along that line, I am going to apologize, Mr. Chairman, for not having a paper. I didn't come up here to give you any information. I came up to give you some more fuel to "chew the rag" about, something which we can all talk about at the luncheon, to add to the questions Mr. Dobbs submitted in the mail some weeks ago.

There are three important things in connection with the driver that some of us automatically and others systematically consider in employing a man or in putting a man to work. They are, of course, selection, training and supervision. Those three subjects cover the whole field, as I see it. They can be subdivided and resubdivided, and on the selection phase of the thing you enter into your psychological test or you enter into the personality or qualities of your employment manager, whichever method you may employ. Then you have various ways of measuring your candidate, whether he would fit this kind of job, whether he should be a ribbon clerk or a taxicab driver.

That is something that is more or less undeveloped as to the finer points, anyway. I hope some day in the immediate future we will get something started on the selection of drivers. Why is a man picked for this particular job? Now I often ask the drivers that. They come in, and I talk to all the new classes. I sometimes single a fellow out and say, "Why did you come to work here? Were you out of a job, and did you see an "ad" in the paper and come over here, or did you come because you were attracted to the organization because of its reputation on the streets, or because of the possibilities you have here of making a success of yourself or something like that? What was it?" You know as well as I do what the answer

is. I know before I ask him. It is usually that he was out of a job and needed money to buy some bread and beans and so he came here to work.

Is that the way it should be? I don't know whether it can be changed or not. Maybe it can. But I have in mind, in the selection of a man, to get the thing down to at least a point where we can pick a fellow because he is adapted to that kind of job. Now I don't believe there is an organization in the world where there is a bigger clearing house than in our organization for that proposition, because we have every nationality, every religion and creed and everything else mixed up in our staff of 6,000 drivers.

We have to have that sort of conglomeration, you might call it, because we cover the city of Chicago. We have garages over here on the West Side in the Italian section, and we have them over a little farther on the South Side in the Bohemian section; and those lines are very definitely drawn here in Chicago, as you Chicago fellows know and as most of you on the outside know. Those communities are very typical of their nationalities. They are not mixed up. They are real Bohemian or real Italian or Jewish or Hebrew, whatever it may be. Then you have your section in Evanston where we have some fellows driving our taxicabs who are college students, very bright fellows.

Careful Training Is Important

You see, it makes it necessary for us to draw from the various communities the class of individuals who live in that community. So there is your selection problem.

Now we come to training. That is a big problem, training a man in our business. I have to stick to our business. I don't want to pass up the fleet owners, but the taxicab business is my business.

We have school cars and school car instructors; and I am not altogether sold on the class of fellows that we now have on those school cars, because some of them are capable of being instructors and others are not. Others have just gotten in there because they have had long years of service and it is a sort of fatherly job and so the job is passed along to them. That isn't, of course, as desirable as it should be, but probably in the industrial makeup of things it is efficient to a certain extent.

Training the new man is a problem, because he doesn't get any money while he is being trained. He is out there on his own hook and usually when they come they haven't a great deal of money saved up, and we spend a great deal of time running that fellow around the streets, finding out how well he can drive an automobile. Some day he will be missing unless his money starts to come in.

In the taxicab business there is your problem. You work on a commission basis, and how are you going to hold the new man while you are training him? Is it practical to pay him so much a day? If you started to pay the fellow for the period of his training, would you get a lot of fellows in there for that period and when you got ready to have them go to work would they disappear? Is there some way that can be worked out so once you get a new man you can keep him on the school car or embryo stage of development until he is absolutely trained, without getting him discouraged so that he will leave you before he gets into the cab? I can't cover the truck because you have a salary problem there and it is entirely different from the taxicab where you have a straight commission job.

I think a lot can be said on the training of a man. There isn't enough of it done. There isn't a day that I don't have a driver—of course, this is reflecting on our efficiency—who has had an accident the day before, and I ask him how the accident happened, to describe it. For instance we will take an accident where he was caught on a wet creosote block street.

Incidentally I think there should be a law against having these streets, but I guess there never will be. But supposing the driver got caught on a wet creosote block street and skidded into the car ahead of him. That man had probably only worked

two weeks. I ask him, "When you were instructed, weren't you told about the hazards and dangers of this creosote block street when it is wet. It is almost impossible to stop a car on a street of that kind."

Well, he didn't remember whether he had been told about it or not. In other words, we crammed so much stuff into him that he couldn't remember. I know positively that he had been instructed in that, because in the course of his training he goes to the garage from which he is going to work and goes in a "meter" cab with a member of our No Accident Club (which I am not going into today), who is an old-time driver and very efficient in driving an automobile. He goes out "on the meter" with this fellow for one day while the man is picking up business. In the morning he is given a card, telling about the man he is going to "ride the meter" with, and on the back of the card are 12 questions I have prepared for the new man to ask the No Accident member. Those questions relate only to safety, and three of those questions are given over to the problem of creosote blocks, or, as I call them, wood block paving.

Questions That Emphasize Unsafe Conditions

Question No. 4 is, "What is wood block paving?", and the other fellow is supposed to explain to him that it is wood blocks soaked in creosote.

Question No. 5 is, "When is wood block paving the most dangerous?" The answer is—When it is wet, or something like that, or when it is sprinkling.

Question No. 6 is, "How can I stop my car most effectively on a wet creosote street?"

I know those fellows ask the questions and are answered. Still in two weeks the fellow has forgotten the things he has been told. Whether the method is thorough or not, I don't know. Maybe we try to cram too much into his head. But we find the man having accidents, because he has not profited by the experience of the fellows who have gone before him.

So the training is a big problem. I think sometimes we rush over things too fast. But as I said a while ago, the problem presents itself that if we don't rush over these things the man is liable to become discouraged and leave you before he goes to work.

Supervision is a big problem in our business. Probably there is no other industry that is equal to it, because once a man gets on a cab he is virtually out from under supervision. Don't misunderstand me. Of course we have supervision, but it is not like it is in the factory, where you have your foreman walking around supervising the actions of the employees. Supervision, I think, is something that can be minimized considerably if you will develop a higher type of driver; in other words, if you will get a man on whom you can rely on your cab and one who takes a lot of individual responsibility and does not have to be closely supervised. I think supervision there would probably be reduced to a minimum if that condition could be reached.

Now we come on down here to labor turnover. Of course, that is all related to the other things, but labor turnover embodies a great many things. Labor turnover is caused a lot of times by insufficient salary. It is caused by working conditions not being desirable. It is caused by an overbearing immediate superior or something like that. Labor turnover, as we all know, is a big, expensive item, and I would like to have some discussion on that subject, of how you can make the job more attractive.

I don't want this to be taken as a criticism, but I have heard considerable in the papers this morning about discharging men. I am not a molly-coddle or anything like that, and I am not very easy with a fellow when he has an accident, but there is danger in being too liberal with your discharges, I think.

For instance, you might have a man working for you for six months or a year,

and he might have had during that period a number of accidents, and when you go over those accidents with him it may appear they are careless accidents to a certain extent. In other words, they are largely avoidable on his part. We are trying to develop a method now where we can take that man back on the school car or into the school instruction and salvage him, rather than discharge him.

We are trying to do this for several reasons. One reason is that you can't learn the taxicab business over night. When you have an investment of six months or a year in a driver he is a valuable man to you. If the fellow has been earning his living and making some money for you during that time, he is a valuable man to you and should not be promiscuously discharged if there is any hope for him. We are going strongly after that thing. We are not babying him, but trying to analyze and find where the faults are and attempt to correct them. I think more should be done along that line, rather than so much discharging, because every man wants to work, and if the job is not attractive to him, it is probably as much your fault as his. I think something should be done to encourage and show him his mistakes, or you should be broad-minded enough to make any corrections where it is your mistake.

All Drivers Employed at a Central Point

M. T. HANRAHAN (American Railway Express Co., Chicago, Ill.): I have a question I want to ask Mr. Wood. Do the men in charge of these various garages around the city employ the chauffeurs who work out of that garage?

MR. WOOD: No, but that is taken care of pretty nicely in this way: We have an employment department and an employment manager here. It is up to him to get drivers. This new man will be sent out to the garage, and he can be discharged by his garage manager on his first offense. He can be given a yellow ticket and discharged. The garage manager has that authority.

MR. HANRAHAN: Is there any one man who employs all the chauffeurs?

MR. WOOD: Yes, one man.

MR. HANRAHAN: I don't see how he can do it intelligently.

MR. WOOD: He has help; he has a staff.

MR. HANRAHAN: It is under his supervision and he has assistants? If one of his assistants got a bad actor into the service he would charge it to the assistant?

MR. WOOD: Yes.

MR. HANRAHAN: Have you any way of distributing the capabilities of the employment officers?

MR. WOOD: No. That thing struck me pretty nicely a while ago, about giving the employment manager a demerit when he picks the wrong fellow.

MR. HANRAHAN: I think that is one of the ways our company keeps away from bad fellows, because each garage man, superintendent of the garage or assistant superintendent, is charged with employing men who work out of his garage.

He has some trucks and is authorized to employ men. When he employs a man, he is given an application which is filled out by the application clerk, and before the man is passed on, his ability and recommendations are gone over, but if the man proves a bad product, he is charged to the assistant superintendent, and if he gets too many bad actors into the service he is called in and they tell him, "You are all wrong." That is the way we keep him on his toes.

MR. WOOD: Of course, that thing is done here, but it isn't done that accurately. Of course, this is true in any organization. The labor turnover in any department will sooner or later get to the head or the foreman of that department. That is true of course. But it isn't checked that closely.

MR. HANRAHAN: You need a good judge of mental equilibrium. Some people can analyze a man as soon as he comes into the room. If he sits down and talks for five minutes, they know whether he has the mental balance to be one of their men or not.

A. C. WARFEL (Hartford Accident & Indemnity Co., St. Louis, Mo.): I would like to ask if in the taxicab company they have any bonuses or rewards for safe driving?

MR. WOOD: Yes, the Yellow Cab Company has a semi-annual bonus, and the amount of money the man gets is determined by his "booking," that is, the money he brings in, his seniority and his accident record. We have a demerit system, and if a man has an accident, he is given so many demerits. If he doesn't have an accident and has a good record, he gets 52 merits a year, a merit a week, and that advances his commission. He gets 30 per cent when he starts, and if he gets enough merits he can go up to 32 and with more merits up to 35 on his commission; and later on we have a degree which we call a gold star, which is only conferred on a few men and they get 37½ per cent. Of course, their bonus is determined by their seniority and their accident record, because they are given a demerit when they have an accident. The garage member gives them a demerit. Their bonus is determined along that line.

DALE HARMAN (Yellow Cab Co., Kansas City, Mo.): I would like to answer for Kansas City. We don't operate in Chicago. Our bonus is given monthly, the same merit system being in use as in Chicago, except that the volume of the accidents is taken into consideration as the number of demerits. One demerit is any accident. If it is a big accident he gets two to five.

In connection with that, we have a safety club where the drivers participate in the money that goes into the fund. They divide themselves into teams. There are eleven in our organization, a captain and ten men. The drivers put in a nickel a day for every day they work. For every nickel they put in, the company puts in a nickel. That seems small, but it amounts to quite a little. The organization has about 275 men, which amounts to over \$600 a month. For every day they don't have an accident the company puts in a \$5 bill. The more money we can spend in that way, the more we keep down our accidents.

Most Drivers Have a Keen Sense of Pride

MR. WOOD: I believe the majority of drivers have a very keen sense of pride. Maybe it is hidden away, but you can bring that out; you can appeal to their sense of pride.

Here in the Yellow Cab Company we have just organized in the last month an organization which is known as the No Accident Club, and a nucleus of that organization was formed at a banquet in a hotel here, which the Chief of Police attended, and 67 drivers were presented with diplomas and gold badges. They are the gold badge members of the No Accident Club. The diploma is made of parchment paper and framed and it is a beautiful thing. The text of it is that he has been driving for so many years for the Yellow Cab Company and it is a recommendation of his service. From that nucleus has grown a club of something over 500 members.

The other grade of membership is what we call the white badge members. Those men must have a year's seniority and to have driven a year without a chargeable accident. Those fellows are just as proud as they can be of that membership. You hear it every day down there. If they have an accident, they will come right back to Mr. Prince's office (he is secretary of the club), and say, "I just had an accident. I was standing down on so-and-so and an automobile ran into my rear end. I had a personal injury." It was absolutely the other fellow's fault, as our driver was standing still. He comes back and says, "Do you think I will be suspended for that accident?"

That isn't an exception. It takes place every day. The thing is too young yet to tell how much good it will do, but I believe that we are going to get somewhere with it, because these fellows are out working among other fellows all the time, spreading that proposition to all the stands and garages and talking safety, thinking

about accident prevention. When you get them to thinking about accident prevention, you have them started on the right road.

S. R. MILLMAN (Aetna Life Insurance Co., Hartford, Conn.): We had a statement from people who drive trucks that the curtailing of their speed to 12 miles an hour helped them greatly in the elimination of accidents. Now we have a cab company here which is operating cabs as fast as they can safely be operated. I wonder if they find that the slow traffic cut to 12 miles an hour with these trucks causes accidents to the fast moving traffic like the taxicab.

MR. WOOD: Yes. Over here on Canal street these big trucks poke around here and the driver figures they are going faster than they are and starts to swing around and tries to swing too late. Yes, there is no question about it. We have more accidents where there is slow-moving traffic than we have on Lake Shore Drive where we'll go 40 or 45 miles an hour.

H. L. MUNGER (Erie Taxicab Co., Erie, Pa.): Do you find the driver who has an accident now and then improves any? If you hold him in service, does he get away from accidents?

MR. WOOD: Generally, yes. We always call them "neutrals." Of course, I rather give the "neutral" a quota. He doesn't know it, but I give him a quota. I know that in the first two months is going to have a few accidents. They are not going to be serious, because he is trying his best not to have accidents. He is trying harder than he will at any future date. They are not going to be serious, but he will have a few accidents and take them seriously and will improve with age as he goes along.

MR. MUNGER: I may have some problems that none of you have. I have two drivers who have both had fatal accidents, one in 1912 and the other in 1917. Neither ever passes a traffic signal.

MR. WOOD: I don't condemn a driver for a fatal accident. Circumstances always have to be considered. We have a number like that.

We had one of the worst accidents I ever heard of recently. Of course, it is human failure. This happened at 4:20 in the morning on the South Side on a street with traffic lights. One of our old-time drivers, 42 years old, was responsible. He was going on his last run and was taking a woman passenger south and he crossed the Midway out there. It is wide open. There is nothing to obstruct the view on either side. You can see for blocks both ways. In addition there is a traffic department. A DeLux was going east with the green light, and they were both going 35 or 40 miles and collided. The driver of the Yellow cab, as I say, was an old man. He had 24 stitches taken in his head and two or three ribs broken. He ran through a red light and never saw the other cab.

MR. MUNGER: Some of them discharge a man.

MR. WOOD: In this particular case, I am afraid the fellow will not only be discharged but will go to the penitentiary, because it was a bad accident and purely and simply his fault, and I guess he can't get out from under it. The police saw the accident.

MR. MUNGER: I have come to the conclusion that an accident man is oftentimes the best man you can hire.

A Fatal Accident on Jackson Boulevard

MR. WOOD: That is sometimes the case. We had a fatal accident down on Jackson Boulevard. One of our good drivers was driving down Jackson Boulevard at a fair rate of speed and a man ran out and ran right into the rear of the cab, fell on the pavement and fractured his skull. The driver never knew the fellow hit his cab. There is a fatal accident.

We had another case on the boulevard not so long ago. It is a pretty fast boulevard and the fellow was going across a street where there was a safety zone. There was a fellow standing on the safety zone, and just as our cab got within three feet of him the man stepped in front of the cab. The cab was going 25 or 30 miles an hour and the fellow stepped right in front of it and was killed.

VICE-CHAIRMAN CLAIR: Gentlemen, I think an important point has come up, as to a man having an accident and what his future experience will be. I can tell you from my experience, in working with 500 taxicab drivers for years, that I agree with you, and would much prefer to take a chance, if necessary, with a driver who has had a good, hard jam, because he has learned his lesson.

On the other hand, you don't want to place your confidence with the fellow who comes in and says, "I haven't had an accident for 15 years." I always laugh at those fellows, because I say that doesn't mean a thing, and I will tell you why. Those are fellows who are over confident. They pat themselves on the back and say, "I am a good driver. I have done it for 15 years, and I am going to do it for 15 more. Nothing can happen to me."

MR. HINCKLEY: I would like to know what Mr. Wood's experience has been with the men of whom he speaks, the men who have been dismissed from the organization, when he tries to bring them back. I have had some sad experiences along those lines I would like to know how long you have been doing it.

MR. WOOD: I will tell you what I know. I started keeping records of drivers last year, 1926.

When we have a driver who comes back now, he is sent up to my office. He has to get an O. K. from the assistant general manager. He sends him to my office to get his accident record and sends out to find what his earnings were for the period, and the reports against him, etc. He weighs the man's sincerity in coming back. In other words, there is where your judging the man comes in. He also figures out whether or not he is capable of improving. Nobody wants to do wrong, but maybe he can't keep from doing wrong. There is no use in worrying along if he hasn't the capacity to improve. He uses his judgment and talks it over with me. He asks

me to look up his accident record and give my opinion as to what I think of the type of accidents he had, whether they were careless accidents, or accidents that would have happened to most anyone. We weigh the man like that and give him to understand we are going to watch the record closely and see if he is improving, and with that little psychology he is put to work.

MR. WARFEL: I would like to ask if anybody here is familiar with the court plan set forth in a magazine with which I am not familiar, called *Maintenance and Operation*, issued several years ago. I happened to see part of the page and wanted to get more of it. I thought some of you might be familiar with that method.

MR. HINCKLEY: I might give you a synopsis as to what they do on that, and accept corrections if I am not right on it.

As I understand it, every Tuesday evening there is a safety meeting, and the

meetings are held after hours. The men having accidents in the Standard Oil Company are brought into these meetings. They have their judge and their jury and it consists of five or six drivers along with the supervising force.

The man is brought in and gives the judge and jury his testimony. If I remember rightly, it is handled that way, and the course of procedure depends on what the jury's verdict is. Sometimes the man is given another chance. Sometimes he is discharged. It is based on that as nearly as I can get to it.

MR. WOOD: I don't see how it would work out in our organization. I have thought it considerably. As I see it, the important thing is to talk to the driver at once. There is no use in the driver coming with his own statement unless you get a witness his statement at the same time and weigh his case from two or three sides. You don't get a witness' statement, sometimes, for two or three weeks or a month. There is no use in bringing a man up after the accident is three or four months old and talking to him.

SECRETARY DOBBS: Along this line, I would like to offer for your approval a little form I got up. I have to contend with all the different things—accidents, methods of prevention, and everything else, and I have constantly thought how I could reduce the work or improve it.

Along the line of investigating an accident, I have had a lot of difficulty in questioning a man and deciding as a judge would in a justice court, and then rendering a decision. The man goes away very much dissatisfied, and he probably talks to his superintendent and goes to the assistant general manager and says he doesn't think he was to blame for the accident.

So I got up a little form, which I think works out well. I find it very helpful in establishing a permanent record. I call it the "driver's liability test," and on it I have about 36 questions. To run this liability test all these questions have to be answered in the negative to relieve the man of any and all responsibility in the accident.

It starts off like this:

Questions That Place the Responsibility

"Was he intoxicated or had he been drinking?" If the answer is "No," that is good, and if it is "Yes," it involves the man immediately.

"Was he speeding at the time of the accident?" We will say the answer is "No" as we go along.

"Was he going too fast for the conditions?"

"Was the intersection a blind corner?"

"Did he fail to stop if he could have done so?"

"Did he turn improperly?"

You will notice that if the answer is "No" it is continually relieving the driver, and if it is "Yes," that is where your fault is.

"Did he fail to give proper signals?"

"Did he fail to look in the proper direction?"

I have covered pretty nearly every angle a man can slip up on in getting himself involved in an accident.

Then, too, I have also some general questions which defeat him if you have left out any technicalities, such as, "Was our driver entirely to blame?" Sometimes he is.

"Was he negligent?" There is an answer that is general. If you find he is liable to be just slightly negligent, you could put the answer "Yes" and fight it out with him along that line.

"Was he careless?" This is reducing the word "negligent." Maybe he wasn't negligent but was reckless. Maybe he wasn't reckless, but was careless.

Then we have a few others, such as:

"Is his attitude or character unfavorable?"

"Did he fail to tell all the facts and truth?"

"Was it possible for him to avoid the accident?"

"Did he act outside the scope of his duties?"

These questions and a lot of others which I haven't mentioned go to relieve the man of any responsibility which involves him, and if the answer should be "Yes," that he was careless, if you can see that the man was careless, you are the judge, of course, and you must decide how he was careless.

Down below I have a few lines for notes. If you put a "yes" after any one of the questions, explain the question in the notes. If he was careless, you might explain that he failed to do some little thing which contributed to the accident.

If a man can pass the drivers' liability sheet test and get a complete record of "no's" he is absolutely not at fault. Sometimes a man parks at the curb and is struck by a passing vehicle and he passes this test, and we find he was parked

properly at a place where he should park, and had his vehicle lined up properly along the curb. He will pass a good test. But if you find some little fault with him, you can charge him with it and get a permanent record with an explanation here.

VICE-CHAIRMAN CLAIR: I am sure all of us should be interested in getting a copy of this questionnaire of Mr. Dobb's.

MR. WARFEL: How do you find the accident record of the courteous driver, Mr. Wood?

MR. WOOD: To me courtesy in public relations is only, in other words, safety first. I don't preach safety first. That is all bunk. I want to make a man observe the golden rule. I want to let him interpret it in his own language and apply it in his own way; so long as he observes the golden rule he won't have traffic accidents. I don't care anything about the slippery street or the intersection or anything else, if he is a man out on the street who regards the other man's rights and appreciates the value of public relations which are good, in other words, if he knows any act of his may put a blemish on his company's name. If he has that confidence and responsibility, he won't have accidents.

VICE-CHAIRMAN CLAIR: I think we all agree that "courtesy" is very nearly synonymous for "safety." It is invariably so in safe driving, and if a man has a sense of decency to give the other fellow the necessary amount of consideration, he invariably will be the safe driver.

D. A. HALEY (Illinois Roadway Lines, Chicago Heights, Ill.): I was going to ask if any gentleman in the room can see any excuse for a rear-end collision.

MR. WOOD: No, sir. There are three kinds of accidents I won't excuse a driver for—rear-end collisions, turning around in the middle of the block, or striking someone when he pulls away from the curb.

A Certain Kind of Concentration

MR. HALEY: Suppose a driver with a previous good record has a collision of that kind, and he could have avoided the seriousness of the accident by using his head, which he didn't do. He did the wrong thing. Is the driver after that any good? Wouldn't he do the same thing again?

MR. WOOD: I heard Mr. Ross talking the other day about concentration and he said some girl came out of a meeting where the professor was giving a talk on the subject of concentration. She was quite enthused about it, and when she met the professor some time later she said, "Your talk was just wonderful! It helped me so much! I have been able to concentrate so much better since attending your lecture."

The professor was pleased and said, "Just what are you concentrating on now?"

She said, "Oh, just lots and lots and lots of things."

That is the way some people concentrate—on just lots and lots of things. If a driver has a diverted mind, he is going to have an accident. If he is not concentrating his mind on driving an automobile on the streets of Chicago, he is in a bad way.

I never pass up the opportunity with a bunch of new men to impress upon them that they must know the city. It is inherent in all of us to have a certain amount of pride, and a taxicab driver naturally takes the attitude he is supposed to know everything.

I have been studying this city for years, and there are many streets I don't know. You might expect the new taxicab drivers to be less informed than I am.

Someone stops the driver and says, "Will you drive out to 12325 Windemac?"

The driver says, "Yes (that is out on the North Side I guess.)" He starts out at random along Michigan Boulevard. He is trying to figure out where it is in the meantime. All at once somebody in front stops and he slams on his brakes too late and hits him. It is caused by a diverted mind.

I want to talk on that a minute. It is a poor thing. Right over here the other day I had a driver in my office. He had been having quite a number of accidents. I asked him, "Well, Cox, what do you find to be the most confusing thing you have to contend with?"

He said, "I think probably no left hand turns in the Loop."

"Have you any specific case?"

He said, "The other day I picked up a passenger at LaSalle Street station, and I wanted to go to a number on LaSalle Street, so I started down LaSalle Street."

As you fellows might know, LaSalle Stops at Jackson Boulevard and you have to turn left to go over to LaSalle, but you can't turn left. There is no left hand turn. So you have to turn right. In order to get onto LaSalle you have to go to

Sherman and make a right hand turn on Jackson, and you can make a turn on LaSalle.

He came down LaSalle. He didn't know about this no left hand turn on Jackson. He got up to the light. It was red against him. He was waiting to make the left hand turn and one of the older drivers came near him and said, "You can't make a left hand turn." So he had to make a right hand turn. Then he couldn't make a left hand turn on Clark and was getting further from his destination all the time. He then turned right and went down Clark Street.

When he got to Van Buren and Clark and he knew there was a street over there where he could make a right hand turn. So the only thing for him to do was to get back to that street. He turned west on Van Buren and headed past the LaSalle Street Depot again.

He was telling me all about the trip. I said, "That was rather confusing, wasn't it? You know, you left something out in telling me that."

He said, "I don't know what it was."

I said, "what were you thinking about when you were going west on Van Buren, approaching the LaSalle Street station?"

He said, "I was trying to figure what that street was that I could go through on."

I said, "While you were driving weren't you also thinking about this man back of you. If a pedestrian had stepped off the curb in front of your car, you would have run over him and never known you hit anything, wouldn't you?"

He agreed that that was true. That shows the value of knowing where you are going before you start. Most of those fellows do, of course. I try to preach that to them.

ADJOURNMENT.

Tuesday Luncheon, September 27, 1927

The luncheon meeting convened at one-fifteen o'clock, Vice-Chairman Clair presiding.

VICE-CHAIRMAN CLAIR: We haven't a principal speaker here. If our present plans go through, I hope we will all be the principal speakers this afternoon.

I feel there is almost an apology due to many of you men, for the reason that you didn't hear from us more often during the last year. The situation was out of our personal control. Through the enthusiasm of Mr. Dobbs we were able to get out this questionnaire, which at least has accomplished something.

We have big visions, gentlemen, and one of the reasons we called you here this afternoon was that we knew that whoever came to this luncheon meeting, could be depended upon for enthusiasm. We feel that anyone who is here today has the progress of this section at heart and will be with us in the future. I want to thank you all personally for coming, because I consider it a tribute to this section and to its future.

I am going to suggest that we run this meeting this way: There are two questions which I wish everybody here would answer.

First, we want to know what the best stunt is that you have used in your accident prevention activities with your drivers. Secondly, we want to know what you recommend as a topic to be later investigated by means of questionnaires sent to all members of the section and which subsequently will be returned to you in the form of a monthly letter.

Mr. Dobbs has some things he has found as a result of this questionnaire which he sent out, and I am going to ask him to start the ball rolling and give you some of the high spots of the replies he received from his questionnaire.

SECRETARY DOBBS: As I see our objective, it is specifically, accident prevention methods, and I decided—and nobody held me back except the Section Chairman on several points—to launch a questionnaire to find out what is being done, as we are all doing something. Every safety engineer with every organization has worked out his own idea and his own scheme in producing some kind of stunt or method of preventing accidents.

My questionnaire got to pretty nearly everybody on the list. I got them back and checked the questions that were the highest. This is the way it read:

"In an endeavor to determine the relative weight and best preventive methods for vehicle accidents, would it be possible for you to contribute to this questionnaire in answering the questions listed below?

"Have you used any of the following preventive methods? Will you check the ones you have used?

- "1. Psychological tests.
- "2. Other methods of selecting new drivers.
- "3. Supervision by foremen or superintendents.
- "4. Drivers' schools.
- "5. Book of rules with literature.
- "6. Making drivers pay for damages when they are found negligent.
- "7. Discharging drivers, for poor record.
- "8. Trial by jury of drivers or superintendents.
- "9. Educating the driver by direct mail.
- "10. Contests with cash or prizes.
- "11. Weekly or bi-monthly meetings.
- "12. Are there any other methods which you know of or which you have used?

If so, will you kindly explain these in detail?"

Taking the questions as they rank, No. 10 was used the most—contests with cash or other prizes. That seems to be the leading item in preventing accidents. You gentlemen all know yourselves how that works, because you have probably used it. It has a very good effect in keeping the men interested and reducing accidents.

The second in rank was No. 6—making drivers pay for damages when they are found negligent. I am glad of that, because I had the courage to install it in our company against a lot of protesting, even from the general manager. He didn't think it was right, but I was thoroughly sold on it, and I got it by. He was afraid it wouldn't work, but he left it to me, and I had the courage to try it, and it is working with us. It seems to be the second leading stunt here on this questionnaire. Many others are using it.

The third is discharging drivers for poor record.

The fourth is supervision by foremen or superintendents.

The fifth is a book of rules with literature.

Those are the questions which we would like to have discussed. I would like to launch this question more thoroughly with more companies, to get a more accurate reading, but this tells the story that most of the companies are using contests with prizes and finding the best results. Those are the peak preventive methods and that is what we have been driving at here for a long time. If most of them are using it and most of them claim to get the best results, that must be the answer to our difficulty.

More Accurate Information Is the Object

M. T. HANRAHAN (American Railway Express Co., Chicago, Ill.): Mr. Chairman, let me ask you something. You say most of them use it. Suppose one man drills a fleet of ten vehicles, would you give his version the same identical rate that you would the man who drills a thousand? That is the question. If a man drills 500 or 600 or 1,000 vehicles his opinion ought to weigh a good deal more than a man who has ten. That is what I would like to know.

MR. DOBBS: I haven't gone into it deep enough to classify that. However, we have some pretty big companies reporting, and that is the leading point. I would like to launch this on a bigger scale and get more accurate information.

MR. HANRAHAN: What proportion of the members present are in favor of that, and of those who are in favor, are they representatives of the taxicab companies or fleet owners?

SECRETARY DOBBS: That is the thing on which I would like to get further information. We will be drifting toward the objective when we get some information along that line. That is exactly our purpose.

VICE-CHAIRMAN CLAIR: This, you see, gentlemen, is a beginning. Right away we have started with the why and wherefore and I am sure if we follow the procedure as we have lined it up, we will accomplish something.

For instance, if each of us gets a statement from our secretary and he asks us specifically what has been our experience in running contents, with bonus awards or other prizes, among our groups of drivers, we will have an opportunity of a clearing house for our respective idea and results. We plan to issue a compiled general statement to everybody. This will not only apply to a group of ten vehicles, but it will also apply to a group of 1,000.

That is the thing, gentlemen, we are going to try to give you. That is the thing we want to discuss and that is what will start us in the right direction.

SECRETARY DOBBS: Along this line, I would like to call on Mr. Coleman if he is here. I have a very interesting letter from him which answers every item in detail, and he includes that item.

VICE-CHAIRMAN CLAIR: Mr. Coleman is not here. I happen to know him and to

have been working closely with him. Mr. Coleman is with the Continental Baking Company and they operate 105 fleets from coast to coast. That is an example of a big company operating both trucks and teams which is running bonus contests very successfully. I am sure that is the gist of what Mr. Coleman reports. He finds, both for teams and trucks, that the contest with a cash bonus is probably the most effective thing that he has tried.

SECRETARY DOBBS: I will explain one experience I had with making the drivers pay. In connection with that I got up a sort of an agreement. It is an application for employment, with an agreement. The driver signs an agreement to pay for any damages when he is found negligent.

I want to picture to you the condition we had before this system was placed in use. The driver would come in and say, "I don't want to pay for it. Why should I pay for it? You ought to have insurance." He used to get hard-boiled and want to throw the secretary out of the office and everything else. Then we put this application in use, and every man had to sign it before he came to work for us. It established one thing in his mind, and every time the man came to the office after an accident he was absolutely expecting to pay for it. He admitted that he had agreed to pay for it, and you could see that the man's attitude was entirely changed. He drove as if he thought if he ran into a fender he would run into his pay check, where previously some of them claimed a right to two or three accidents at least. Some would say they worked for such-and-such a company and busted up two or three trucks and never had to pay for them. We found very few cases where the men refused to sign the agreement.

It is for the moral effect. The man knows what is coming to him if he scratches anybody's fender, and he is going to be careful.

A Signed Agreement Is Effective

MR. HANRAHAN: Are you connected with any labor union?

SECRETARY DOBBS: No.

MR. HANRAHAN: Can you legally demand of that man to pay that? Can he not make a memorandum of that and any such time as he leaves your service, demand full payment?

SECRETARY DOBBS: There is a legal technicality involved, but to answer your question quickly, I will say we have defeated many drivers in court. The judge would often ask, "Have you an agreement or contract?" and we would present it to him, and he would rule in our favor if he found the man was negligent. If the man is negligent he acts out of the scope of his duty, and according to the interpretation of the law, the employer has a right against him.

MR. HANRAHAN: Do they take it out of his salary?

SECRETARY DOBBS: We do. We have done it many times.

P. J. HEBRON (American Railway Express Co., St. Louis, Mo.): You could never do that in Missouri.

VICE-CHAIRMAN CLAIR: Here is another point. If a general questionnaire went out, we would be able to get, from all states, the general reaction to this sort of thing with a consensus of opinion on what different people in different parts of the country thought about it. Of course, in some states, in some locations and under certain circumstances, this may be impossible. We know that in all safety activities certain things are good under certain conditions, certain situations and certain locations. In other places they may not be as effective.

I think each of us should get up and say what has been our most effective means of preventing accidents, with a few reasons. There may not be two that agree, but we want to find what each one of you think, so we can investigate and get the details.

C. S. GOLDSMITH (The Brooklyn Union Gas Co., Brooklyn, N. Y.): We have no

safety engineer in our company. We have a general safety committee and each department has a subcommittee, which is, of course, the general safety committee. As far as drivers are concerned, we have tried no stunts and had no campaigns for safety.

We do this, however, if a driver has three accidents in a year and he is to blame and we feel he is to blame, we let him go. We caution him and call him in a couple of times a year, and have some police officers who are traffic men give him traffic rules. In that way we bring the matter of safety before him. But aside from that, we have tried no stunt.

VICE-CHAIRMAN CLAIR: About the subject you think most beneficial?

MR. GOLDSMITH: I would be most interested in finding the best means of promoting safety, whether contests with cash awards or discharging the man, whatever it is.

Personal Pride Makes the Average Man Reliable

W. O. HINCKLEY (The Peoples Gas, Light & Coke Co., Chicago, Ill.): It has been our experience in handling men that the touch of personal pride will do more than anything else. I don't care how tough a fellow is, how hard-boiled he seems to be, there is a certain amount of personal pride in him.

Since the installation of our accident board with his name stuck up there with a red star or a blue or yellow one beside it, he feels a certain amount of regret if his name gets on there, and consequently we have cut down our accidents pretty nearly 65 per cent. That has been our experience.

Now as to what would be the most essential thing to use, I am in favor of the same idea that is carried out in a great many organizations: that is, the standardization of traffic signals. The railroads throughout the country have their standard track and their standard signal. An engineer on one road can take his train across another and get by. To me that is a vital point, to bring safety not locally but nationally, all over the country, and have everybody understand it.

I realize that is a big problem, but unless we do that, I don't believe we are going to accomplish our end.

A. E. LUNDSTEADT (Bowman Dairy Co., Chicago, Ill.): We have featured the National Safety Council posters. We have had contests for safety slogans and tried to get men to write safety slogans. That fell flat.

I would like to see this division of the National Safety Council conducted along the same lines it has been conducted.

MR. HOWELL (Federal Insurance Co., Hartford, Conn.): I would say that the questions you have asked are primarily for fleet owners and taxicab owners, and are questions which the insurance man can't possibly answer.

From our viewpoint we think the general giving of safety talks to the drivers is inclined to show them how by their record they can eliminate further accidents, and by distributing safety literature, slogans and things of that sort, we can eliminate a good many of the careless accidents.

We have thought a great deal of the matter of discharging drivers or making them pay for accidents, but I am open to conviction and would like to hear some more along that line.

I think we should do further research work in this section.

A. C. WARFEL (Hartford Accident & Indemnity Co., St. Louis, Mo.): The only thing I had in mind was where there are fleets of interstate or intercity passenger buses or in some cases taxicabs or trucks, in view of the accidents which do occur, some provision should be made for the installation of a first aid kit, the same as you find in the passenger car of the train; not necessarily as big, but a small, compact kit, and some little first aid instructions could be given the driver, so in emergency he would be able to save a life.

P. A. WEINMAN (Lumberman's Mutual Gas Company, Chicago, Ill.): I have been driving for a good many years. It seems to me that the fleet-owners with slow moving vehicles should instruct their drivers who are moving at a snail's pace to keep on the right hand side of the road. I believe they would avoid a good many accidents. I think the greatest nuisance in the world is to run into a fleet of milk wagons, and that is the thought I would like to see gotten over to a lot of fellows.

H. L. CUMMINGS (Yellow Cab Co. of Virginia, Richmond, Va.): I think the thing that will help us all, taxicab or fleet operators, is to get busy on character building among our men—sell to them the principle of applying the golden rule, in public relations, with the passenger, the pedestrian and with the driver of the other car. When you have done that, you can successfully conduct contests in your organization which will materially decrease accidents. Those are the lines on which I have been working.

I have been running a little contest this year, with the drivers themselves conducting it. I operate 55 cabs and have 70 drivers. They originated the contest themselves. Each morning when they go to work they pay a nickel for their manifest or trip sheet, which goes into a general fund. The organization is divided up with ten men to a team. At the end of the month the team with the best record divides that money. For five months during this year the fund was carried forward. It could not be divided, because there were no accidents. We have been operating 55 cabs and 70 drivers since the first of January, with this contest in effect, and we have had five accidents, which have cost less than \$600. One was a personal injury which cost me over \$400.

Necessary to Build Up Morale Again

MR. HANRAHAN: Prior to 1915, while I was with the American Railway Express Company, we had about 500 wagons in Chicago and we had nobody to tell us how to run the wagons; but after the unified companies got together, Mr. McAdoo put them all in one and he let the labor union walk in and tell us we must do business with them.

After 1918 I found that the morale of the man had lowered a little bit. He did things and he thought he could get away with them. So we made out a set of rules and we submitted the rules to the labor union and asked if they would approve the rules. Then we said, "We are going to apply those rules. There is to be no drinking, no speeding, no misconduct or misapplication of any rule." Of course, you can see that in applying those rules it made one of our supervisors or employment officers a little hard-boiled. He was going to apply the rules because they applied them to us.

Of course, in many cases that were brought to my attention I took into consideration the length of service of a man. Maybe I knew him personally, because I was in contact with a lot of those men at that time and knew them well. I overlooked a lot of things which the rules said I shouldn't overlook. But I did it just the same.

It has reached the point now where they want us to apply the rules in their favor sometimes, and, of course, we just reciprocate and say, "All right, we will do that." So now it has developed to where if a man commits an offense once or twice or three times, it is left to my judgment as to whether this man should be forgiven or whether he should be dismissed, and usually the man is brought to me for trial. He has a hearing in my office with the union officials and with the supervisor under whom he works, and he is given a fair trial.

I think myself it has reached the point where an employment officer has to be a little hard-boiled in order to maintain discipline. I notice since I have applied these hard-boiled methods that our morale is better. I don't have as many drivers committing offenses as I used to, because I say, "You are through now. You have committed this same offense before, and I told you the last time you were up here that if you

came up again, no excuse would be taken." The result is I don't have one-third of the accidents I used to have, and I am getting a better caliber of men, because they know they can't get back into the service.

I disagree with Mr. Wood of the Yellow Cab when he said he got better work out of a man after he had been dismissed. I try them before they are dismissed. I give them all the "breaks" before they are dismissed. If a man gets three trials and is cautioned and is under the supervision of a high-class inspector and still goes out and breaks one of our rules, I say he is not fit for the service.

So you might class me as "hard-boiled," so far as employing men is concerned, I don't re-employ them. If they are out, they are out. They know they can't get back. I think our fleet will compare favorably with any other.

Difficulty in Setting Up Standard Contest Schedules

W. W. CLOUD (President, National Association of Taxicab Owners, and President of the Yellow Cab Company, Baltimore, Md.): We are very sympathetic with the activities of the cab companies and fleet owners with the national association. I think it is important that we get back to fundamentals where we can agree and work along with the truck owner.

I think it would be impossible, and I am sure my friends, the cab operators, will bear me out, to set up rules for safety contest schedules that would be applicable to both fleet owners and cab operators. The business is entirely different. One handles merchandise and the other handles humans. I speak from actual experience. I have been in close contact with the industry for the past 18 years, and have been in close contact with the accident side.

For the benefit of our good friends in the insurance business, we carried insurance up to the time it reached \$210 a cab and then stopped short, because we couldn't afford it. Now the rate in Baltimore is \$450 a cab and \$550 property damage, which, of course, is out of the picture. But I do think we can get together on a basis, and I think questionnaires as to a subject could be distributed and answered and I think we would get some practical suggestions. But I believe positively, based on experience, that we would be unable to set up a safety plan of contest and awards that would be applicable to both taxicab and fleet owners.

J. G. WILLIAMS (Secretary, National Association of Taxicab Owners, Chicago, Ill.): We have about 150 or 160 companies operating taxicabs, running from three or four cabs to 3,000.

There isn't any one best stunt that we have found that everybody can do, but we do find this: that the best thing that can be done is for the owner of the enterprise to get dead in earnest, just head over heels in earnest, so earnest that he doesn't intend to have any accidents. And when he gets in that frame of mind he doesn't save them, because he finds a way to meet every man that is going out of the garage and says to him, "Now, nothing like that today." And they understand that kind of talk.

We have a man in Nashville, Tennessee, who operates between 30 and 40 cars. He requires every one of his drivers to deposit \$50 in cash before he goes to work, and if for any reason he leaves that service, on account of accidents or something of that sort and he takes him back, he puts up \$100. The universal experience with those men is, that when they are \$100 men—have put in \$100 (and he has a number of them)—there is never a peep, never a come-back. It is all over. They have their money in there and they pinch the nickel and drive carefully.

Everybody in the world knows that you can drive carefully, and that is that, and if you want to make them drive carefully, you can do it.

We have a man in Des Moines whose insurance ran so high he couldn't pay the premiums. He had to carry his own insurance, and he was frightened to death.

He operates 100 cars. He took off his coat and stood with those men. He told them from now on they weren't going to have any accidents. He said, "Now that applies to the best men I have." All right. The next day his best man came in: there was something the matter, and he was gone. That happened to three of them, and then it stopped, because they found that the whole business was going. He told them he was going to fire the whole business, and that stopped it.

We have a man in Fitchburg, Massachusetts, and some of you gentlemen know how crooked and hilly those streets are. He operates 20 cars. He has been operating for seven years and his total cost has been \$100. He operated 20 cars last year and didn't pay \$1, not a cent. How does he do it? He doesn't have any stunts. He sits up with those drivers and they know that they can't have accidents.

That is the whole thing about these accidents. It isn't some trick you can do. That isn't it. Doggone it, you can do a thousand tricks, and start early in the morning and keep it up until late at night and impress on their minds you aren't going to have this, and it will keep you busy, but you won't stop them then.

We have various illustrations. A man from Providence operates 40 cars. He operated them last year and his whole accident cost was \$400, \$10 a car. Think of that! How wonderful that is! He has 27 men who have been with him for over 10 years. And he has one man who has been with him 19 years, and so on. If you ask me how he does it, I don't know and he doesn't know, except that he just isn't going to have any accidents. He has made up his mind.

Safe Driving Is Merely An Attitude of Mind

Now as to topics we can get interested in, there is a mob psychology about this whole thing of driving and any man can drive safely who wants to, who tries to, who gets into the habit of doing it. Now can't we inculcate in the minds of these men the habit of driving safely. You can break the habit of reckless driving and form habits of driving safely, and every day you drive safely, your habit is stronger. If we start with that idea, we can form a safe driving habit.

I think that is a lot better than depending on periodic or spasmodic stunts. Not that they are not good, for I believe everything in the world you can do in this safety business does some good, but there is a way to form a safe habit of driving. We will find that out.

R. E. PLIMPTON (Associate Editor, Bus Transportation, Chicago, Ill.): This is my first visit to the Congress. I wrote down in answer to the first question:

1. Competent management.
2. Operating practices.

I am not deprecating the work of the specialists at all, when I say that I think a good many people are tired of safety specialists and take refuge from them. I hope their work will be a substitute for the failings or inefficiency of the management.

Operating practices follows No. 1, I believe, because if we go to the root of this thing we have to have some information about sound operating practices, to find out what accident prevention matters have done.

SECRETARY DOBBS: I want to remind you that, while Mr. Williams' talk was most excellent, don't you think that some of the methods explained come under the heading here of supervision by foremen and superintendents, and another one applies quite strongly to this one of discharging drivers for poor records? It comes under that heading, so the questionnaire also covers that. He told how one man got up and said he was going to fire them, and did. So it comes under that heading and the other comes under supervision. Possibly supervision is one of the best stunts.

N. M. MARSHMAN (New Haven Chamber of Commerce, New Haven, Conn.): I am not interested primarily in the operation of any particular fleet. I am interested

in the operation of all commercial vehicles on the highways of the city of New Haven, and it is on account of that interest that I am here and am trying to absorb some information from this meeting.

There are two or three reactions that just hit me between the eyes. Do you men, who are firing these men for poor records, realize that you are firing them to be picked up by someone else and their poor records continued? While I realize you are interested in the individual record, the time is not far distant when we will be interested in the safety operation on the highways; and that factor has to be considered, whether you have a right to fire a man and send him out to be hired by someone else, and let that poor record be continued on the highways.

A factor which was held in New Haven has been a contest of fleet owners on the basis of accidents per 1,000 vehicle miles operated. We grant you can pick all

ports of holes on that basis, but it is a basis to start on, and we find the retail merchants are interested in knowing whether this or that company's record compares with the other fellow's.

If your men are interested in having the drivers know the results of accidents, teach them first aid. I know of no better way than giving them first aid work and letting them realize the accidents that might happen, and teach them how to try to save the patient. The first aid lessons bring before them the results of accidents, and when a man properly knows the results, he becomes interested in it.

Mr. Williams hit the entire problem of safety operation between the eyes and it went down at the count of ten, when he said that the entire thing depends on the executives. There isn't an industrial plant which is safe, unless the executives of that plant demand that it be safe. That applies also in your business.

I would be interested in hearing from the National Safety Council, through the Taxicab and Fleet Owners Section, regular information as to what has been carried on. It don't want that for myself, but want to pass it to the smaller cities in

Connecticut and the city of New Haven. I would like to pass these ideas on, because many of these people are not now in a position to become members of the National Safety Council. It would be impossible to sell them. That is a suggestion of what I think can be worked out with better service to this section. It is nothing more than up-to-date methods.

VICE-CHAIRMAN CLAIR: I feel that every person here is one of our real standbys. I think we are getting along very well. We would like to hear from those who haven't talked, but it is now time for the Public Safety session.

ADJOURNMENT

Wednesday, September 28, 1927

The meeting convened at ten-five o'clock, Vice Chairman Clair, presiding.

VICE-CHAIRMAN CLAIR: I know you will pardon us for calling the meeting together so late, but we wanted to wait for as many late-comers as possible, and the nominating Committee has been having a session outside. I do want to say a few words about the general scope of this section, looking ahead to our future activities. We have a section here which should be of substantial benefit to every fleet-owner in the country, regardless of whether the vehicles which he operates are taxicabs, delivery, laundry, milk or bread wagons or trucks.

Look ahead to the day when we will have papers read during the meetings of this session on air hazards. It is the thing that is not far away, gentlemen. Already, Mr. Hanrahan told you yesterday, the first express plane has taken off. It is something we want to look forward to. It is something we want to begin to study, because it won't be a great many years before we will become interested in hazards of the air, and we soon will have fleets of airplanes not only doing commercial but passenger work.

We want to say something about the small fleet manager. We welcome the small fleet manager. We want him to come here and participate and give this section the benefit of his experiences. I know, in servicing fleets from five cars to 3,000. But I am most interested to get to the small man, because I find he is fighting his problems, and in his small way, if you will, is working ideas out which with a little adaptation and revamping can easily be used on larger groups. The small fleet manager is as welcome here as the large operator.

We are now ready for the report of the Nominating Committee, submitting their action of officers for the next term.

DALE HARMAN (Yellow Taxicab Co., Kansas City, Mo.): We have selected Robert Clair as chairman; Harvey D. Wood, as vice-chairman; J. E. Dobbs, secretary.

If the chairman will accept those three as nominated and leave it to these three men to appoint the rest of the committees, that would be the recommendation of the committee which you appointed yesterday.

VICE-CHAIRMAN CLAIR: You have all heard the report of the Nominating Committee. Unless there are further remarks, I would like to ask for a motion that the report as submitted by the Nominating Committee be accepted and this order of officers be elected for the coming year.

P. J. HEBRON (American Railway Express, St. Louis, Mo.): I move the report of the Nominating Committee be accepted as read and these men be elected for the coming year.

(The motion was seconded and carried.)

CHAIRMAN CLAIR: I am not going to take up any valuable time, gentlemen, giving you an elaborate speech. I have tried sincerely in the last two days to give you the idea that I am really heart and soul behind the future of this section. I want to say this: that you may depend upon me absolutely to work with anyone and everyone who has a problem of any kind in which this section can be of assistance.

Leaving the matter that way, gentlemen, I hope that the things we try to do will speak for themselves, and I trust that we may have everybody's sincere cooperation.

DALE HARMAN (Yellow Taxicab Co., Kansas City, Mo.): Mr. Chairman, will you have an opportunity to talk on this compulsory insurance law later?

CHAIRMAN CLAIR: I don't know of any provision that has been made to talk on this compulsory insurance at a later time.

MR. HARMAN: Is any action going to be taken at the present time?

CHAIRMAN CLAIR: In what respect?

MR. HARMAN: Is a committee to be appointed to investigate the experience or get the benefit of the experience of Massachusetts or any other state that has recently adopted compulsory insurance and inquire into the rate and into the extent of the insurance, as to volume, etc., or the amount, whether it has been found that it is too high or that they could get along with a lesser insurance and thus lessen the rates, and whether the experience has been such that it would bring a reduction in the rates?

I know of a number of cab operators—possibly the same thing is true with the fleet operators, I am not familiar with them—who have been able to show by handling their own insurance that there should be a much lower rate inaugurated by the substantial companies or the conference companies as they are called, and I think that is a subject that this section of the Safety Council could well give a half day's discussion to.

A Committee to Study the Effects of Compulsory Insurance

CHAIRMAN CLAIR: I think Mr. Harman's point is very well taken. I don't know of anything that is being done at the present time that has more of a general interest than this Massachusetts compulsory insurance law and how it will work out.

Would your idea be to hold this meeting some time this week or appoint the committee and let them work separately?

MR. HARMAN: That would be immaterial. I would like to have the committee appointed to go into it.

Mr. Cloud will bear me out that we appointed a committee a few years ago in our Taxicab Association and they went as far as they could. That was about three years ago. We went to Baltimore, Hartford, and had conferences with all the large insurance companies. But there have been a lot of new things and ideas put into it, and there have been different things found out that would possibly revamp the thing.

It might be a little selfish on the part of some of us cab operators in wanting the experience of this section, but it would be beneficial to the cab operators because I know our taxicab section is going to open the matter up again.

CHAIRMAN CLAIR: I think the whole subject has a general appeal. Not only the taxicab man is interested, but the motor truck fleet operators generally are interested, because it is going to come home to him just as closely.

I would like to put that motion of Mr. Harman's before the members.

HARVEY WOOD (Yellow Cab Company, Chicago, Ill.): I will second the motion.

CHAIRMAN CLAIR: It is moved and seconded that a special committee be appointed to take immediate steps to investigate the latest developments of the Massachusetts compulsory insurance law.

(The motion was carried.)

I will take the members of that committee under advisement. Perhaps Mr. Harman or Mr. Cloud could suggest someone.

W. W. CLOUD (Yellow Taxicab Co., Baltimore, Md.): I would be glad to serve, but I would be put in a rather embarrassing position, because I have recently been appointed by the Governor of Maryland to investigate and report to the next legislature on this subject, and that would really keep me out of any active participation. I would be very glad though to give the benefit of my experience.

CHAIRMAN CLAIR: I think perhaps the investigation of the Massachusetts compulsory law will be one of the main things this section can do within the next few

months, and I am sure there isn't anyone here from any state but who wants to know the developments in this connection.

F. T. COLEMAN (Continental Bakeries): I have been trying to divide allegiance between the Food Section down stairs and the Taxicab and Fleet-Owner's Section. I don't want to have a conflict, and I would like to get a motion before this meeting to see if we can get the program committee to meet with the Food section program committee so we won't have a conflict.

I have between 3,000 and 4,000 vehicles on the road every day. I have about 5,000 employees on the Food Section. So I have been trying to get the Food Section together so we can get some interest stirred up. They have appointed a committee to meet with the Taxicab and Fleet-Owner's Section. I thought you possibly would appoint a committee so we wouldn't have a conflict.

CHAIRMAN CLAIR: When may we meet your committee?

MR. COLEMAN: Any time.

CHAIRMAN CLAIR: I am sure we would all be glad to cooperate with your group and we will instruct our program committee to get in touch with you before the next year's program is lined up so that we can get together. Will that be satisfactory?

MR. COLEMAN: Yes, thanks.

CHAIRMAN CLAIR: Our first paper this morning will be given by J. C. Williams, secretary, National Association of Taxicab Owners, Chicago, Illinois.

The Soul of Safety

**J. C. Williams, Secretary, National Association of Taxicab Owners,
Chicago, Illinois**

Robert Burns wrote an epistle to a young friend in his early days, and he started it by saying:

"How my subject seems, me gang.
Let time and chance determine,
Perhaps it may turn out a sang,
Or perhaps turn out a sermon."

I don't see how anybody can talk a whole lot about safety without finally preaching a sermon about it. It is in that class with eternal things, especially if you are going to talk about the spirit.

We have here "The Soul of Safety." If you are going to talk about the spirit of safety, that is a tremendous thing and a very vital sort of thing. There are all sorts of spirits in the world and some are for safety and some are against it. The spirit means this—it means essence. It means heart, the pervading influence, the peculiar characteristic or quality. It is the animating principle.

Spiritual things are spiritually discerned. The spirit of safety is a spiritual matter. It isn't a matter of facts or figures about how many people are killed, because now we know a whole lot more about the number of people who are killed than we did last year or the year before. Figures come in right along. Knowledge of figures doesn't make any of these things less. Of course, if we use them properly, they are an advantage, but the spirit of safety isn't that knowledge of facts and figures.

The spirit of safety is not in the mechanics of the car. That helps tremendously, but it doesn't supply a spirit of safety. It isn't in brakes. It isn't in good roads. Because the more roads we build, the more cars we get to fill them. And if we have a little boulevard in this part of town so as to make the congestion less, the day it is opened everybody who has been driving over on the narrow street comes out and drives on that boulevard. Spirit isn't there.

The spirit of safety isn't in parking regulations. Yet it is a wise and necessary thing to have parking regulations, else we would never be able to move the traffic, to get by or get anywhere. Well now, it isn't in restriction of vehicles, because in this Loop down here the vehicles are not restricted and they move and move and move. Of course, the movement is much slower, but you get where you are going by and by and you move on and on, but the spirit of safety is not in those things.

The spirit of safety is not in laws, because there can't be enough police officers to enforce the laws to save all life, and if a motorist doesn't intend to obey the laws, who is to blame him? You can't have enough officers. There is no possible way. The spirit of safety is not in laws. It is not in regulations.

The spirit of safety is not in bonuses you pay your drivers. We try that. We give them more. We give them all the rewards we can to get them to drive safely.

The spirit of safety is a spiritual thing. Nobody in the world ever entered the Kingdom of Heaven who didn't intend to go there. The scripture says, the Kingdom of Heaven suffers violence and the violence takes it by storm. That means this: That you will never get in there unless you make up your mind to go, and furthermore, unless you walk the straight and narrow road; and it is thorny and it is rocky and everything else. You can't get there unless you try. Neither will you get the spirit of safety without all the effort you have in it. It isn't the broad road. The broad and winding road is the other one where the people are killed and where you have your accidents and where you don't care, the road which everybody is using. But this safety road is the narrow one.

The Soul of Safety Is the Desire For Safety

The spirit of safety arises from this thing—the wish to do. If you want to get into the Kingdom of Heaven, you must have the wish to go in, and then you must follow it with the intention. Now that we want to do this safety work, we have the wish to do it. We have the want to do. We have to do it day and night, and then when we want to do a thing—here is where that part comes in—the ways and means will multiply. We will find thousands of ways to do it and ways to tell other people and ways to try to get other people to do this thing. If we are after it ourselves.

Don't employ experts, if you are an executive, and turn over to them the operation of this safety and forget about it yourself, or at the end of the month check them up and say, "This thing isn't worth a damn. It isn't worth a cent. You aren't getting anywhere," and then get another safety expert. There is nothing to all that. Get in behind this thing yourself, with your heart and soul, and wish to do it. You can find ways. You will accomplish what you want to. That is the spirit of safety. That is the soul of this thing, and that is the thing we have got to get.

The means will be just as varied as there are individuals, and you will get new ideas and you will get those people with you interested and determined to do the thing safer themselves. That to my mind is what we are talking about, and a person who sincerely and earnestly and with determination follows out this whole safety idea and program will find ways, he will find means, and he will ultimately be successful.

CHAIRMAN CLAIR: Thank you very much, Mr. Williams. That was a very fine talk. Are there any remarks or discussions?

I was one of the people who recommended that we devote at least one paper to the discussion of horse-drawn vehicles during this session. I did that with the thought in mind of which I have spoken so many times, of trying to increase the scope and usefulness of this section, and so, as always when a subject is suggested,

they came back and said, "It is your job." That is what happened to me, and the title of this paper is, "The Safe Operation of Teams and Wagons."

The Safe Operation of Teams and Wagons

**J. Robert Clair, Safety Engineer, Liberty Mutual Insurance Company,
Boston, Mass.**

As compared with the scope and general appeal of our automobile accident problem, we are not faced with a national issue regarding the safe operation of horse-drawn teams and wagons. There is a practical need, however, for definite research and preventive work in the field, which is the subject of this paper.

The peak of general usefulness of the horse, as a pleasure or commercial unit of transportation, is slowly declining. And yet there are, in the United States today, literally thousands of commercial fleet operators who are directing groups of horse-drawn vehicles as the most efficient and economical method of distributing their products. The bulk of these fleets will probably be found in the laundry, the bakery and the farm products industries. To the managers of these fleets, our subject is an all-important one. They are as anxious to work out the details of their accident prevention campaigns as the fleet operator who is directing groups of taxi cabs or Mack trucks. It is within the scope of this Section to interest the operators of team and wagon fleets as well as to make positive efforts to offer them some constructive remedies.

I believe that it is something unique to have papers read on the subject of horse-drawn vehicles before the members of this Section. We trust that our efforts this year to include the subject will increase our usefulness to members and perhaps interest a number of fleet operators in our activities who have previously not been attracted by our motor vehicle discussions.

For those of us who have had considerable accident prevention experience in both the automobile and horse-drawn vehicle fields, many interesting comparisons between the two unavoidably present themselves. The two problems are practically specialized and distinct from each other and yet, paradoxically, they have much in common.

National statistics regarding accidents involving horse-drawn vehicles are meager to say the least. Separate classifications of this type of accident rarely appear on the reports from state or federal authorities who would otherwise be expected to tabulate such things. Where such figures do appear they are usually approximated with no attempt made to analyze causes.

Some Interesting Groups of Statistics

The statistics which I have used for the purposes of this paper represent figures which I have personally collected from sources to which I have had access. In most cases they are from commercial fleets which have been or are being serviced by our engineers. For comparative purposes we have figured an accident frequency rate which has been obtained by tabulating the number of accidents reported during a given period from an equal number of commercial motor vehicles and wagons. The resulting accident frequency rate per motor vehicle was .98, while the rate for wagons was .51. This means that a motor vehicle is twice as liable to become involved in accidents as a wagon. A further analysis of causes among nearly 3,000 team and wagon accidents reveals a number of interesting facts.

Among 53 causes of accidents to horse-drawn vehicles, the following 23 causes

lead in the order of importance. In each instance the comparative frequency rate is shown.

1. Horse shied, 12.5.
2. Runaway, 9.5.
3. Horse walking off, 8.4.
4. Other vehicles struck in passing, 7.7.
5. Our vehicle damaged when parked, 7.3.
6. Damage to our property at intersections, 5.7.
7. Our vehicle cut off, 5.0.
8. Caught in car track or rut causing collision, 3.9.
9. Other vehicle skidding into us, 3.0.
10. Other vehicle struck our vehicle in passing, 2.9.
11. Other vehicle side swiped, 2.6.
12. Side swiped by other vehicle while moving, 2.3.
13. Other vehicle damaged at intersections, 2.3.
13. Damage to property by horse chewing same, 2.1.
15. Striking parked vehicle when pulling out from curb, 2.0.
16. Backed into by other vehicles, 2.0.
17. Skidding into other vehicles, 1.9.
18. Hit in rear by other vehicle, 1.9.
19. Backed into other vehicle, 1.7.
20. Personal injuries caused by running or walking into our vehicle, 1.4.
21. Failure of equipment, 1.3.
22. Turning in street, struck by other vehicle, 1.1.
23. Miscellaneous, 11.1.

Injuries to Drivers of Teams and Wagons

A study of injuries to drivers of teams and wagons, which cases fall under Workmen's Compensation, shows the following list of causes:

1. Getting on or off wagon, 27.0.
2. Vehicle hit, throwing driver, 16.3.
3. Runaway, 7.9.
4. Falling while making deliveries, 5.1.
5. Loading or unloading, 5.1.
6. Sudden movement of horse, throwing driver, 4.2.
7. Strain, lifting supplies, 3.3.
8. Wheel passing over foot, 2.3.
9. Hit by other vehicles, 2.3.
10. Kicked by horse, 2.3.
11. Struck by falling box, 1.9.
12. Struck by falling wagon shaft, 1.9.
13. Bit by dog, 1.9.
14. Wheel struck car switch, driver thrown, 1.9.
15. Falling off vehicles, 1.4.

Accidents which are peculiar to horse-drawn vehicles and which do not appear under Workmen's Compensation cases concerning drivers of motor vehicles are as follows: These causes are listed in the order of their frequency:

1. Runaway.
2. Sudden movement of horse throwing driver into or off wagon.
3. Kicked by horse.
4. Struck by falling wagon shaft.
5. Bit by horse.
6. Stepped on by horse while unhitching or harnessing.

The following causes for horse and team collision accidents which are not found among causes for automobile accidents are as follows. These are also listed in the order in which they are most frequent:

1. Horse shied.
2. Runaway.
3. Horse walked off, damaged property.
4. Property damaged while making delivery.
5. Twisted reins.
6. Horse's hoof caught in rut or car track.
7. Personal injury to children playing about team.
8. Property damage resulting from child striking or annoying horse.
9. Personal injury caused by being frightened by horse.
10. Personal injury to others while getting on or off wagon.

So much for statistics. Without devoting any further time to comment upon their features, I shall proceed to consider the commercial horse-drawn vehicle itself.

The Old Team and Wagon Have Been Little Improved

The mechanical development of the motor car has been of a surprisingly mushroom nature. Comparatively speaking, the automobile is yet a youngster. Many of us remember those good old peaceful days before its arrival. And yet, in shortly over a quarter of a century, we have witnessed the development of a sturdy, fast, self-propelling machine which has brought with it many commercial advancements and blessings and yet, we regret to say much tragedy and unhappiness.

During the years of the remarkable progress made in the mechanical construction of our motor vehicle, our team or wagon has remained quietly in the background, practically neglected, unnoticed and unimproved. I think it is fair to say that at the present time, considering the modern team or wagon as we meet it in its common form, it is, mechanically at least, 25 years behind the times.

I feel very privileged to be able to inform you that we have had the pleasure of being able to assist, in a number of small ways, in what I consider to be one of the most radical and revolutionary attempts for the construction of a mechanically safe wagon. In this regard, I wish to pay special tribute to Mr. A. A. Clarke, treasurer of the General Baking Company, for the unique contribution he is about to make in the field of safe wagon construction.

I had the pleasure of viewing this new safety wagon as it has been developed by the General Baking Company in New York on September 26.

The type of wagon, to which the new mechanical safeguards have been added, is of the standard enclosed body, box type, with the driver operating from the front.

I am sure that a brief summary of the specifications of the mechanical safety features of this new wagon will prove most interesting.

1. From the front and left side of the old regulation toe board, has been built up permanent partitions to a height of about 18 inches from the toe board level. This gives a cab effect. From both front corners of this partition, wooden corner posts have been erected which meet the visor, or projected roof, of the wagon. This new cab construction protects the driver from being thrown headlong from his seat; effectively prevents him from making an improper and unsafe left hand exit from his seat, and the front right supporting column offers him much needed protective assistance in getting on and off the wagon.

2. A canvas weather-boot, or curtain, may be adjusted so as to extend

around the front and left sides of the cab enclosure to a height of about 12 inches. Above the permanent partitions a rein slot, with flap protection, is cut through the front section of this curtain. The lower ends of the curtain hang on the outside for the proper shedding of rain. This curtain makes for new protection against the elements for the driver and adds substantially to his comfort. When not in use this weather curtain is rolled tightly to the pro-

ecting top of the wagon and secured at the top of the two supporting columns by means of straps.

3. The right-hand side of the driving seat has been cut out and entirely eliminated, necessitating the driver to operate from the left-hand side of the driving seat. More will be said concerning the advantages of the operation of wagons from the left-hand side of the seat in a later paragraph. There is an

auxiliary, hinged, right side seat which may be dropped into place for the use of a route foreman or supervisor when it is necessary for them to ride with a salesman.

4. A rear vision mirror is attached about midway on the left-hand side of the extended roof of the cab. This is a new and most necessary addition for the safe operation of a wagon.

5. The wagon is equipped with the patented "Ferrel" type brake. The "Ferrel" brake, without doubt, is the most effective wagon brake yet constructed. This brake is applied by means of a foot pedal which extends up through the toe board in the front left-hand corner of the driving cab. This brake pedal is equipped with a regular self-locking Reo motor truck ratchet.

6. A chain for locking the right front wheel is affixed handily below the toe board.

7. There are two steps for entrance to, or exit from, the driving cab. The first, or lowest one, is so hung that its permanent position is directly in front of, and about one inch away from the tire of the right front wheel. The face of this step is about six inches square. It is made of corrugated non-slip metal with upturned flanges front and rear. The nearness of this step to the wheel protects the driver's foot from becoming caught between the step and wheel. The second step is located on the frame work at the base of the shafts and takes the form of a circular piece of corrugated non-slip metal about three inches in diameter. The safest means of exit from the seat is backwards.

Tail Lamps With Candle Are Preferred

8. Tail lamps of the candle-burning type are favored in preference to electric or oil burning styles. These are affixed to the rear left-hand side of the wagon. They extend out beyond the wagon body so that the driver, by glancing back from his left-hand operating position, may always be sure that they are alight.

9. The rein hook is attached to the projecting roof of the cab on the front right-hand corner. This is to avoid striking the driver's head should he be thrown forward.

10. The toe board has a semi-circular section cut out of its right side which exposes the top step to the view of the driver and gives his foot safe and easy access to it.

These are the outstanding mechanical safety refinements which have been built into what may be a history making horse drawn vehicle. Up to the present, horse drawn vehicles have been sadly neglected in respect to development and improvement along lines of safer operation and protection to the driver.

Without going into further detailed explanation, it will be most interesting for you to note how the improvements on the General Baking wagon have been planned to meet the driving hazards as I have tabulated them in the above statistics.

I regret that time will not permit a study of that form of wagon, frequently called the retail type, in which the driver sits or stands in a cab located in the center of the body. Comparatively, this is a highly hazardous vehicle. At some future date, it is hoped that we may be able to make a study of this.

I believe that our engineers were among the first to recommend, for greater safety in driving, that the drivers of teams and wagons be required to operate from the left-hand side of the driving seat. The hoary custom of the right-hand side for horse driving is a thing of the past—at least for commercial purposes. The old order is changing. Reasons for this are plentiful.

We recognize the fact that a left turn is one of the most hazardous ma-

neuers a vehicle can perform on a highway. At intersections controlled by automatic traffic signals, the left turn is invariably eliminated. This is done not only for greater safety but for the more expeditious movement of the traffic flow. A left turn necessitates the cutting of the line of vehicles progressing in the opposite direction which slows down the movement of both lines.

The left turn is highly hazardous for the motor vehicle. How much more dangerous is the same left-hand turn for our comparatively slow moving horse-drawn vehicles! The left-hand drive is more efficient and the safest operation point for motor vehicles. No one has thought of paying much attention to our horse-drawn teams and trucks up to now.

Hazards of the Horse Driven Vehicle

From the right, a driver cannot give hand signals to the man following to signify his intention to stop, turn, or back, except by a mechanical arrangement which is clumsy. In making a left turn, this right-hand driver, especially if his wagon has an enclosed body or a high load, is at an extreme disadvantage. Should he wish to take the ordinary and desirable precaution of looking back, before turning left, he must extend his body far to the left, lean out, and look back. In the meantime, the forward movement of the vehicle usually continues unattended and with all manner of potential accidents. If the load has an ordinary overhang, even this bad attempt at safety is not possible. Again, should the vehicle of this driver who is leaning far over to his left, be hit in the rear, the driver is at once in danger of being thrown from his seat and severely injured.

Commercial fleet owners who realize the hazard of the right-hand drive have shown themselves willing to stand the expense of a few radical mechanical changes in their equipment for the sake of greater protection to the public and to their operators.

A few final words about the horse: Special care must be exercised in seasoning and breaking in each animal properly. It is oftentimes necessary to put two drivers on a wagon, for the first day or two, in cases where the horse is green. Feeding must be carefully supervised to fit the individual peculiarities of the stable inmates. Periodic weight checkups are often made to secure indications of poor treatment or the health of each animal. Records should be carefully kept of the accident experience of each horse. Continually bad offenders should be replaced.

A List of Essential Precautions

"Unattended horses walking away and damaging property" and "runaways" are the leading causes of wagon accidents. The necessary precautions to be taken against these types of accidents are as follows:

1. Let each driver study and know, to the best of his ability, the peculiarities of the horse which he drives.
2. Stand wagons in front of parked cars instead of behind them. This is very important.
3. Never leave a rig standing without locking wagon brakes or chaining the right front wheel.
4. Tie ropes should be used on horses when it is necessary to feed them on the street, away from the stable.
5. We have found the old bit weight to be perhaps the most inefficient method of securing a standing horse.

We realize that when a horse becomes frightened, or otherwise takes it into his head to run away, that he will haul the wagon in spite of brakes, chains or

bit weights. We do feel that the above five precautions are worth while, at least to retard the speed or to keep the runaway in nearer the right-hand curb.

Constructive progress is being made to assist the operators of horse-drawn vehicle fleets in solving their accident problems. We trust that these remarks may serve the purpose of bringing to the attention of those interested a few of the most recent preventive ideas.

P. H. HEBRON (American Railway Express Co., St. Louis, Mo.): Why do you use a candle-burning tail light?

CHAIRMAN CLAIR: One outstanding thing, especially with people who distribute food products, is that kerosene is smelly and the driver is apt to get it on his product. Cleanliness is the leading reason.

A Candle Burning Tail Light That Is Snuff Proof

The reason the electric type isn't favored is because it usually necessitates the carrying of a storage battery or dry cells, which is quite an expensive investment to a fleet-operator who has many vehicles. Then there is the maintenance expense.

We have a candle-burning tail light that is practically snuff proof. It will burn brightly without being blown out. Each wagon has to carry a spare candle, and in placing the lamps as they are placed, he has a check on them all the time.

MR. HEBRON: Could you give me the name of that type?

CHAIRMAN CLAIR: I don't believe I have it here. But I will make a note of it and see that you get it.

MR. O'NEIL (Travelers Insurance Co.): Could you tell us why you park in the rear?

CHAIRMAN CLAIR: Our recommendation is that you park wagons in front of other parked vehicles in preference to behind them. We find in the analysis of accidents which we have made that "horses walking away from the curb and damaging property" is the third leading cause for team accidents. We find that a horse, if he sees something in front of him, has an instinctive tendency to walk to it. He wants to go up and nose it. Invariably if a horse does that, he will chew off pieces of the top or of the upholstery. Also he may walk too close and the shaft of the wagon damages the back of that vehicle. That is the first thing.

In the second place, if the horse walks away, and he is behind a parked vehicle, he will knock off a bumper or a fender, because a horse can't judge clearance distance. I have a bulletin which I would be glad to give you, showing pictures of these hazards and why we recommend these precautions.

Dairy Wagons Sometimes Double Park

SECRETARY DOBBS: I would like to ask a question, on chaining the right front wheel. It seems to me that would bring a lot of accidents in the case they are double parked. We find our teams are constantly double-parking, and we adopted the chain but had to use it on the back wheel, because if we put it on the front wheel we would be pulling the horse into the car a number of times.

CHAIRMAN CLAIR: I think it is an unusual thing that you are allowed to double park.

SECRETARY DOBBS: We are compelled to.

CHAIRMAN CLAIR: That is an unusual condition. As I said before, we have tried to recommend a safe practice which will fit the majority of cases. I would say that double parking was something beyond the ordinary. For that particular condition, it might be that it wouldn't be best to chain the right front wheel.

The next paper will be given by Mr. C. C. MacMahon, superintendent of transportation, Commonwealth Edison Co., Chicago, Illinois.

Safety and Its Application to Electric Trucks

C. C. MacMahon, Superintendent of Transportation, Commonwealth Edison Company, Chicago, Ill.

After what has gone before, Mr. William's talk and the chairman's, what I have to say may seem rather insignificant in a way. Rather than speak on generalities, I am going to confine myself to their application—safety application to our particular department. At the time I was asked to give a talk before this body, I was asked to explain the practices and policies that we have set up and adopted in our particular department of the Commonwealth Edison Company. So that is what I am going to do, and I am going to give you workable ideas of what we are doing and how we are doing it.

We have been in the safety movement probably 13 or 14 years, and I will be frank in admitting that when the safety movement was first established in our company, I was very skeptical. It seemed rather unusual that a company of our size would employ a lot of safety engineers, because I felt that we were normal, doing things by safe methods, and wouldn't have any reason to do anything that was unsafe. I thought there would be a particularly hard row to hoe in order to sell the idea of safety.

That was my personal attitude. We were at that time—I am speaking of the company, not the department I am in—killing on an average six employees a year. We were electrocuting some; some were falling off poles; some were slipping off ladders; some were being killed this way and that. After the first year of operation, I think the total fatalities dropped to about four, which indicated that safety work was having a good effect. We went along for about three or four years and finally got to the point where we didn't kill one employee during the entire year. Then I began to take a very great interest in the safety movement.

Where you have a fleet of trucks similar to the ones we have—we have practically 300 electric vehicles and 200 small gas cars (we have no commercial gas cars) covering an area like Chicago—safety is a great thing. So we established a safety division in our particular department. We hold safety meetings every two months. Where possible, we have a speaker from the Chicago Safety Council. Then the supervisory members of the department also talk on their particular activities and the activity of the department, and one of the things we find very essential is to get the employee, speaking particularly of the driver, to make suggestions or talk about the safety meeting. Some of them are rather reluctant to talk, but we bring out ideas and we ask questions, and we finally get them to talking. Our meetings always start at six o'clock and some of them last until eleven o'clock, which indicates the interest the men have.

We bring out every phase of safety we can possibly think of. We instruct the men on safety methods of operation, the mechanical end, all tools are very carefully inspected, and the handling of the cars while employees are working on them. As to the chauffers, the new man is given a very careful test before he is allowed to take a car out on the streets of the city. He is given a three days' trial and then we explain all the rules of safety to him. He is instructed just what to do in the event an accident should occur, and we impress on the minds of our men that accidents do not happen but actually are caused. We try to make that clear, to bring that out so it will be uppermost in the man's mind.

We find that the safety suggestions we encourage in our departmental

meetings have great value. If a man begins to thing safety, talk safety, and discuss measures of doing things in a safer manner than perhaps he is doing them at the present time, he will be more careful. We encourage suggestions and any man who offers a suggestion which is accepted is rewarded for it. We find we have gotten some valuable suggestions on safety from our employees.

But we find also that eternal vigilance is very necessary. We have our meetings, as I said, every two months. We spend a lot of time and energy in serious talks to the men, trying to encourage safety ideas; but occasionally we will find one who has disregarded all the rules of safety, and as a result, we have had an accident.

We have only had one fatal accident in our department since the department was organized, and this department was organized about 22 or 23 years ago. This accident occurred in June, 1926. One of our mechanics had to do a job on the front end of one of our trucks and in order perhaps to give him more freedom of movement, he moved the truck out into the aisle, and this happened to be a very large garage. There is a 60-foot aisle in the garage.

Details of a Fatal Accident

That was at six o'clock in the morning. One of the drivers of one of the departments came in for his truck, and it so happened that he was a little bit late. He found his truck parked in the stall, but the truck this man was working on was in such a position that he couldn't get his truck out without moving the truck from the aisle. The man had a safeguard. He had a light underneath, but due to the fact that it was comparatively late, the man didn't see the light. He walked around the back end of the truck, stepped up into it, and before the man could make a noise to indicate that he was under there or to get out, the other fellow had moved the truck the full length and the man under the truck was crushed under the battery department and died before we could get him into a car to take him to the hospital.

You can imagine the feeling of the man, who through perhaps being just a little late, had caused a death. You who are executives and who have to do with a large number of men and who have had a death in the family, you might say, can appreciate the feeling I had. I don't know that I have ever had anything that affected me like that particular case. It was the first and only one we have had, and I hope it is the last. The man who was killed attended all our meetings and the man who moved the rig, while not one of our men, was a company man and attended all the safety meetings of his department. It was one of those items of haste which enter into things and cause trouble.

Just recently we had the first accident we had had for some time. We had two last week—one week before last and one last week. In spite of anything we can do to emphasize the necessity of eternal vigilance, one of our men rode on the fender of a car at midnight to go to lunch. A taxicab, presumably, so the report goes, cut him off on the boulevard, and the driver says, in order to keep from killing the man on the fender, he had to swing across the parkway and he hit a tree and knocked off the fender on which the man was riding and wrecked the car, and the man is in the hospital.

Sometimes you wonder what you can do to instill safety ideas into some of the men. The only thing we do is keep everlastingly at them.

Another thing in connection with electrical vehicles is the necessity, the absolute necessity and importance of withdrawing or removing the running key so that when the driver is absent the car will be absolutely harmless.

Only last week out on the South Side, the driver claims he had the key in

his pocket. There were some children of a curious nature who got onto the car, one of our large panel rigs. If the man had his key in his pocket, they must have found something to operate the switch, and it is rather doubtful to me, considering the age of the children, that they would know enough about it. They started the car, it shot across the street and they jumped off. The car ran across the sidewalk, ran over a little fellow and broke his leg.

I presume in handling fleets a lot of you gentlemen here are in the same position I am. We found in the past three years that our accidents were gradually increasing, that is, the property damage accidents. The surprising thing was that we found the accidents were being caused by our older drivers; so we discussed it, and conceived the idea—I don't know whether we originated it or not, but we conceived the idea, I will say—of developing what we call a trial board. It is composed of three supervisory members, two employee members, and one member of the safety bureau, and the chairman. We hold meetings every week, and every man who becomes involved in an accident must appear before this trial board and stand trial, and prove that he was blameless, or else take the responsibilities for the accident.

A Bulletin Board That Is Essential

In addition to this trial board, we have what we call the bulletin board. It is a board about 42 inches long and 30 inches wide. It is a board like you see in the hotels, where you can insert numbers and names and symbols. This is arranged with the first column on the left being used for the name. On the margin at the top is, "The Transportation Department Accident Board," and on the right hand margin is the year. It is divided into two columns, January and December inclusive. On the first right-hand column is the name of the man who may have occasion to appear on this board. The findings of the committee or the trial board are posted, the name of the driver or the mechanic or whoever it may be that is involved. His name appears on the board, and three at fault accidents during the entire year indicate to us that the man is unsafe, either in that particular position, or else is an unsafe employee for the company.

So we have set up a number of accidents—three is the number—which are sufficient cause either to dismiss or remove the man from that particular job. We have had only one occasion to remove a man since this trial board has been in effect.

It is rather surprising what lengths the men go to not have their names placed on the board. We also have provisions in our rules and regulations governing this trial board that any case may be reopened if the man can produce sufficient evidence to warrant it. You gentlemen have perhaps some similar methods in your own particular departments, but if you have not, we would recommend it. It is a great help.

I have heard quite a number of safety men talk, and I think one the greatest things we have to stress is the mental attitude of all of us who are in this movement. We cannot, in my opinion, over-estimate the importance of obtaining and maintaining the proper mental attitude. I have heard safety men emphasize that if such-and-such a thing isn't done, we are going to have an accident, or that this place will burn up if we don't do this and that. I think we have to know in our own minds absolutely (not only believe but know), that accidents will not happen, instead of leaving a loop-hole and saying they may happen. We have to emphasize it in our own mentality and minds and know that accidents will not happen. We have to sell ourselves and the

individual on that particular phase. That is my idea of it, and that is what I try to do.

In closing, I am going to recite a little excerpt from Mr. P. Y. Young, one of our Edison men, whose paper on safety impressed me as being a very fine thing. He stated: "And the end is that the workman shall live to enjoy the fruits of his labor, that his mother may have the support of his arm in her age, that his wife may not be untimely a widow, that his children may have a father, and that cripples and hopeless wrecks who were once strong men shall no longer be the by-product of industry."

Gentlemen, I think that covers the safety situation almost completely. I think it is well worth thinking over.

CHAIRMAN CLAIR: I wish to thank Mr. MacMahon for his very interesting talk. Are there any questions or other discussion on Mr. MacMahon's remarks?

The point brought out by him in regard to removing the starting key or plug from the electric truck is perhaps the greatest precaution that can be taken, as far as my experience has gone; and I couldn't help thinking when he was reviewing the fatal accident which occurred to his mechanic, that it would be a good rule that all starting keys should be removed from all electric trucks while in the process of repair.

Efficiency the Outcome of an Accident

MR. MACMAHON: I intended to speak on that. I would like to take just a moment.

We learned quite a lesson from that accident. It is very unfortunate though that we have to have accidents to teach us things. The rule has been ever since the safety movement started that running keys must be removed from the rigs when they are being worked on in the garage. Running keys must be removed from the rigs when the driver absents himself from the rig. He must get into the habit of removing that key. He must put it in his pocket. One of our strictest rules today is that if a rig is found on the street with a running key in position the driver is immediately removed from the service of the company, regardless of what department he may be in.

In our department, after this fatal accident, we got chains that would reach from handle to handle at the cab entrance. We have firmly fixed to that chain a card that is almost indestructible, made of oilcloth or canvass. It is very substantial and there is written or printed on this card, "Hold, Man Working on Car." In addition we have a flag at the rear end of the car. Any man who works on a car, regardless of whether he is underneath the car or on the side of the car, who doesn't take these precautions which we have set up, we figure is an unsafe employee for our department and take the necessary steps to remove him.

But the running key rule has for years been in effect, and once in a great while we find somebody violating it. But since we had this last accident, this fatal accident, we have never found a man who has been guilty of negligence to the extent of leaving the running key in position. We make it so the man can't get into the car without seeing the chain barring his entrance and a large card warning him that there is a man working underneath the car.

CHAIRMAN CLAIR: We are very fortunate, gentlemen, in having with us today the next speaker on our program. Mr. Marcus A. Dow, of Vander Poel, Pausner and Jefferson, Inc., New York City, a past president of the National Safety Council. He is also a past chairman of the Steam Railroad Section of the National Safety Council and for many years was general safety agent of the New York Central Lines.

Telling the Driver How Accidents Happen

Marcus A. Dow, Vander Poel, Pausner and Jefferson, Inc., New York City

I have been asked to discuss for a few moments this subject of "Telling the Driver How Accidents Happen," and I think it is a very important thing in connection with motor vehicle or commercial vehicle safety movements.

There are, of course, two very important elements in safety. One of these is the mechanical element, and as far as the operation of a vehicle is concerned, the mechanical element includes the proper application to the vehicle itself of every known safety device or method of construction that will help to prevent accidents.

The other element, however, and I think really it is the all-important element, is the human element. It has been variously estimated by men who have spent years in safety work that from 80 to 90 per cent of the accidents that occur on the streets and highways or in industry are accidents which mechanical safety devices in themselves alone will not prevent. They can only be prevented by the exercise of proper care and caution on the part of the individual. In other words, safety is an individual responsibility.

I have had the experience during the past year of carrying on a safety service for a number of large fleets of motor vehicles, and I find that the majority of the drivers of commercial vehicles or any type of automobile for that matter, are not sufficiently educated as to the predominating or outstanding causes of accidents. The great trouble with the average mind of the motor vehicle operator is that when he thinks about an accident at all he thinks of the accident caused by major violations; and that is due to the fact that such education as he has received as to accident causes has been, for instance, by reading stories of accidents in newspapers. He will pick up a newspaper and he will read where in the dead of night an automobile running at a speed of 60 miles an hour crashed into a tree and the driver and occupants were instantly killed. Or he will read where a bottle of gin found about the wreckage told the story, and the accident was due to the intoxication of the driver operating that machine. Temporarily at least his mind will become impressed with the fact, as he sees it, that the majority of the highway accidents are due to the untold number of drunken drivers careening about. Or again he gets the impression that the traffic magistrate, doing what he humanly can to increase safety on the public highways, adopts a very laudable policy of inflicting severe punishment upon the so-called speed maniac brought into his court. Columns of publicity then give the public the impression that the majority of accidents are due to reckless speed on the highways.

I don't want for a minute to give you the idea that I offer any excuses for the drunken driver or the so-called speed maniac, because we all know that every automobile with an intoxicated driver behind the wheel is a potential death car, and every motor vehicle operated by a reckless speed maniac is a deadly weapon. We can't be too severe in our dealings with that class of offenders against safety.

However, I had occasion to analyze the accident experiences of a commercial fleet of about 2,000 motor vehicles. Neither speeding nor intoxication was a factor of any consequence in the accident experience of this particular fleet, although they were not having an enviable experience, by any means.

We found the majority of their accidents were due to seemingly inconsequential acts of inattention, thoughtlessness, and negligence on the part of the drivers. Therefore, it seems to me the educational feature of this work is the

all-important feature and that an educational campaign, to be effective, must be conducted along such intelligent lines that you will convey to the drivers of the automobiles not only the fact that you want them to be careful, but you must tell them how to do it.

The average motor vehicle operator, commercial or otherwise, desires to be a careful driver. But it doesn't get you anywhere to simply put up a few posters which say, "Drive Carefully" or "The Best Safety Device is a Careful Man" and let it go at that. You have to be more specific and get down to brass tacks before the best results are to be obtained.

In the lines of my experience with the motor vehicles we are serving, in the company I represent, I get around about every four or five or six weeks and by personal contact with the drivers convey to them specific information as to how accidents happen. To give you some idea of how this work is conducted in my particular instance, I am going to ask you to assume for a moment, or put yourselves in a frame of mind where you can consider yourselves, a group of motor vehicle drivers to whom I am carrying a safety message based on actual experience.

Many Backing Up Accidents Are Serious

Now we have found, during the past few weeks in this particular concern in which you men are operating motor vehicles that there was an unprecedented number of accidents, due to backing up, backing up carelessly, backing up quickly and suddenly, backing up without looking behind to see what the conditions were before backing.

Perhaps you will think a backing up accident is only an inconsequential thing, causing a slight damage to someone else's property or a bent-in bumper or something of that kind. I had occasion the other day to read a story, tucked away in an obscure column of a New York newspaper, which told of a man killed while cranking his car, because the driver of a truck parked a few feet in front of him backed up without looking behind and crushed this man between the rear end of the truck and the car he was cranking, killing him instantly.

We have another case of an employee who was injured by a fellow employee only three weeks ago. He got up on the seat of his car and without looking back to see what the conditions were before backing, without finding he had only three feet to back up, backed up suddenly without warning, and caught the fellow employee who was putting water in the radiator of his car and crushed his thigh bone so badly that this man today lies in the hospital with his injured body from his arm pits to his knees incased in a plaster cast, perhaps hopelessly paralyzed for life; and all because of a single moment of carelessness and thoughtlessness on the part of a fellow employee.

Tell your drivers how the accidents happen and tell them in such a way they will be forcefully impressed, and remember the lesson you convey to them.

We had an experience with one of our fleets. (I am talking to you as safety representatives here for the moment). An employee of a large baking concern we serve was struck on a railroad bridge crossing, and the accident report indicated that this man approached the crossing at a speed of 45 miles an hour. His view was obstructed by a building on the corner. When he got to the first rail he discovered a freight car bearing down upon him. He was obliged to turn to the left and go down the track in the hope that he might be able to escape the accident. The vehicle was struck by the train, completely demolished, and the man is in the hospital in a serious condition.

I had occasion only yesterday, in talking to a group of drivers of commer-

cial cars, on the South Side of Chicago, employed by this particular concern in which the accident occurred, to tell them about this accident, and here is what I said to them—'You are now again a group of Commercial drivers and one of your fellow employees was badly injured at a grade crossing accident out here a few days ago.'

"Some years ago, when I was a young fellow, living in Michigan, I went to a county fair and there witnessed a balloon ascension, one of those old-fashioned affairs where the gas bag is inflated with hot air. As we stood there watching that man performing on the trapeze, 2,000 feet in the air, we were horrified to see him slip from the trapeze and fall headlong to the earth 2,000 feet below. He landed on a brand-new plank sidewalk, and every bone in his body was broken into a thousand pieces.

AVOID LEFT SIDE EXITS

"Several days later I was riding on a railroad train, speeding at about 60 miles an hour. Suddenly the train came to a grinding stop. With hearts palpitating we got out to see what had happened. A completely demolished vehicle on a grade crossing told us the story. Over in the field where it had been tossed by the train lay a shapeless, lifeless thing, which a moment before had been a human being, and it looked like the remains of the unlucky balloonist on the splattered sidewalk up in Michigan a few days before.

"One of the passengers pointed to a sign located on the crossing the train had just passed. It was one of these triangular signs upon which were three, short, stuck-full-of-meaning words—'Stop, Look, and Listen!' Now 'Stop, Look, and Listen,' boys, is only a simple rule. It is easy to learn, easy to master. Its observance takes but a minute's time. It is a simple thing, yet failure to observe it becomes a colossal act of negligence.

"The thing I want to impress on your minds, boys, is this: If you come into contact with a railroad train at a crossing, the result, as far as its effect on you is concerned will be just as serious as though you had fallen 2,000 feet out of a balloon."

Tell' your drivers how the accidents happen, and impress on their minds in such a way that it will stick and they will remember it for a long time after you have given them the lesson.

Now then, there is only one good thing about any accident. (That is rather a strong statement to make perhaps, that there is something good about any accident). But the only good thing about any accident that I can see is that it might serve as a lesson, a warning that will help to prevent the occurrence of similar accidents in the future.

Something was said by the previous speaker about the accidents in the operation of electrics, due to the leaving of a switch or starting key in the vehicles. In a large baking concern for which I handle the accident work, we have had accidents due to that character, and they have a rigid rule requiring the operator to remove the switch key when he goes into the store to make delivery, put it in his pocket and have it here. But we had a serious accident where a boy was run over and probably crippled for life.

An Accident Because a Rule Was Violated

Once again you are motor vehicle drivers and I am bringing the lesson home to you.

"Here we have the report of a child, a boy about seven years of age, who was run over by one of these little electrics that can only attain a speed of ten miles an hour. Yet the boy is in the hospital and probably crippled for life, due to the fact that the operator of that car violated one of the most important rules this company has promulgated, requiring the operator to remove the switch key and put it in his pocket and take it into the store with him. It is the only evidence he would have of his freedom from fault, in case of an accident—to be able to produce that switch key from his pocket.

"But one of our men violated this rule. He probably violated it 100 times before and nothing happened, and he considered nothing ever would happen. But here is what did happen: The man parked the car in front of the store, went inside and left the switch key in the car. A boy of about 12 years of age started the car. It collided with an ice wagon in front of it, started the ice wagon down grade, and the ice wagon ran into a seven year old boy who was picking a ball from the curb stone at the gutter. His thigh bones were so badly crushed and his spinal column so badly twisted that the doctors say that boy will never again be able to walk on the streets or play ball like a healthy boy ought to do, all because one of our salesmen did a rotten, careless thing, which he knew he should not do, in leaving that switch key in the car, in violation of rules, because he did not think, did not take the time to remove it."

Analyze your accidents. Carry the lesson of how accidents happen home to your drivers, in a way that they will stop and think about accidents.

"Here is another case. A short time ago one of our men had an accident, due to a car starting up that was parked along the curb. Here is the reason for it, boys, here is a report that shows a car that started up while parked and struck a sedan and turned the sedan over and seriously injured a woman occupant. The report came over the desk reading like this: "I was inside the store making a delivery and my car started up and injured this woman."

"Now just stop and think about that: 'I was inside the store making a delivery and my car started up,' just as though there were something uncanny or supernatural about that. As a matter of fact, you are all motor vehicle operators, and you know and I know that that car did not start of itself, voluntarily and willfully, and take advantage of his absence in that store to injure this woman. That car was not endowed with ghostly power to enable it to do that thing.

"The fact of the matter is that the driver left that car parked on the hill. He failed to cut the wheels into the curb to prevent the car rolling, and he left the engine running. The vibration of the car and the force of gravity started the car down the hill where it struck the sedan, and an injury to an innocent person was the result.

"The car wasn't to blame. The brakes weren't to blame. The hill wasn't to blame. The responsibility rested entirely and solely upon the shoulders of a driver who was careless and did not park his car in a proper way on the street when he went into the store and left it here."

Tell your drivers how the accidents happen. Tell them repeatedly and list our accidents. Classify them as to causes and carry the message home to them so they will understand and realize that the things they are doing are the things that cause accidents, that the things they neglect to do are the things that cause accidents.

Many Accidents Are Caused by Little Things

It is a good thing also to impress upon their minds that the majority of accidents are caused by the so-called little things.

I have a story I like to tell the boys, which was told to me when I was a youngster. There was a young lad over in Holland, that country which is covered with canals so that they require the building of dikes to keep the country from floods. This boy was walking on the top of the dike and observed a thin stream of water trickling down the dike. He went to see what was causing the leak. He found a small hole in the side of the dike through which the water was coming.

The thought came to him that the hole might become enlarged and the greater the stream of water rushing through the opening, the greater the opening would become and possibly the dike would give way and the surrounding country become flooded and people lose their lives.

So he stuck his finger into the opening and held it there through the long, dreary night and into the next day, and finally help came, and he was able to remove his finger from the opening and the repairs to the dike were made.

That was only a little thing—that thin stream of water trickling down that dike—but in the mind of the boy it foretold the possibility of impending disaster. To my mind, that boy had the instinct and the courage and the wisdom of a real safety man. And that is what we want you drivers to be—real safety men, by remembering the little things that cause accidents and guard yourself against them.

"Oh, the pity of it," we say when a careless or drunken man backs up and rushes the life of an innocent child. The pity of what? The pity the child was killed. But do we mean beyond that, the pity that the driver was careless? You know, nine times out of ten the pity is that the concern which employed him had not pounded into his head a few of the fundamental little things about safe driving which he ought to have known but of which he seemed to be ignorant.

The reason for it was that even though he did not intend to be ~~careless~~, even though, as the average driver, he desired to be free from accidents, ~~his~~ mind had not been sufficiently trained along the lines of elimination of the common practices which cause accidents; that requires development of the mind and mental training.

During my experience in the police department (here is a little story I tell to illustrate my point) I had occasion as an official of the New York Police Department some years ago, to meet a great many strange and interesting people. One day they were having one of the annual police field day games for the benefit of the widows and orphans whose husbands or fathers had been killed in the line of duty. It was just after the Dempsey-Firpo fight.

Someone conceived the idea of getting Dempsey to the field as a drawing card. The police asked me to take care of him and see that he was properly cared for. So with a couple of policemen we got him into a private dining room and were serving lunch.

A Celebrity Who Is Always in Training

I sat next to him. The waiter leaned over my shoulder, and wanting to do the proper thing for the world's champion, said, "Shall I get a high ball for Mr. Dempsey?"

I turned and said, "How about it, Jack? Do you want a drink?"

He said, "No, thanks, I don't want any."

I said, "Speak up, if you do. You are not in training now."

His answer has stuck in my mind. Dempsey turned to me and said, "I am always in training."

This is a story I have told to our truck drivers with a good deal of result. If you are going to be successful in cutting out accidents, in being free from accidents, you have to do just as Dempsey says, keep in constant training. You have to be always in training. I don't mean necessarily in physical training alone but in mental training. What is training? If you are a prize fighter, constantly to be in training is to be constantly in trim to meet an adversary in the ring.

You must keep your muscles active that you are going to use in the performance of your driving, you men who are driving automobiles. If you are going to protect yourselves from an adversary and an incompetent, irresponsible driver, who will attack you from the left or the rear, you have to be in constant mental training. As Dempsey said, you have to be always in training. It is up to the men who are in charge of these motor vehicles to help the men along these lines and keep them in constant mental training, and I believe the way to do that most successfully is to tell them forcefully and effectively and repeatedly how the accidents happen. That, I think, is the most important thing in commercial fleet safety.

CHAIRMAN CLAIR: I want to thank Mr. Dow, on behalf of the Section, for his very worth while and interesting talk.

There has been a question asked as follows: "Which method of paying a bonus should prove the most effective—paying annually, semi-annually, or quarterly?"

Perhaps some of you who have had experience in awarding bonus money will be able to answer that question?

I might say, personally, that I have had a lot of experience in operating driver's contests, and I feel that the best thing is to make the contest short; if possible, not to exceed three months. In cases of taxicabs or fleets, it is

oftentimes more effective to pay them monthly. I believe the general theory is to make your contests short, give them awards often, and the effectiveness will be improved.

Are there any further remarks or any further questions, gentlemen? If not, I wish to thank you all for coming here and showing your interest, and I want to ask you this: Will you please, if we find it necessary to call upon you for cooperation during the year, through correspondence or otherwise, please do your best to help us along? We need everybody's help. We are going to work hard and we just want you to work with us.

ADJOURNMENT

**SIXTEENTH ANNUAL SAFETY CONGRESS
NATIONAL SAFETY COUNCIL**

Textile Section

New Section Officers

Chairman, H. C. WASHBURN, The Fisk Rubber Company, New Bedford, Mass.
Vice-Chairman, DR. R. P. KNAPP, Cheney Brothers, South Manchester, Conn.
Secretary, D. FRANK LORD, M. J. Whittall Associates, Worcester, Mass.
Poster and Slide Committee Chairman, LEONARD HOWARD, Dunean Mills, Greenville, S. C.
Membership Committee Chairman, H. W. DONALD, American Mutual Liability Insurance Company, Boston, Mass.
Publicity Committee Chairman, ARTHUR BARLOW, Linoleum Division, Armstrong Cork Company, Lancaster, Pa.
Engineering Committee Chairman, G. W. COOK, The Travelers Insurance Company, Hartford, Conn.
Statistics Committee Chairman, HARVEY SAUL, The United States Finishing Company, Providence, R. I.
Program Committee Chairman, ARTHUR S. JOHNSON, American Mutual Liability Insurance Company of Boston, Boston, Mass.

Retiring Officers

Chairman, G. W. COOK, Travelers Ins. Co., Springfield, Mass.; *Vice-Chairman*, R. B. SHERMAN, United States Finishing Co., Norwich, Conn.; *Secretary*, HARRY C. WASHBURN, Fisk Rubber Co., New Bedford, Mass. *Committee Chairmen: Membership*, H. W. DONALD, American Mutual Liability Ins. Co., Boston, Mass.; *Statistical*, HARVEY SAUL, The United States Finishing Co., Providence, R. I.; *Poster*, IGNATIUS MACNULTY, American Woolen Co., Andover, Mass.; *Program*, DR. GEORGE VAN EMBURGH, JR., The Clark Thread Co., Newark, N. J.; *Publicity*, DR. R. P. KNAPP, Cheney Brothers, South Manchester, Conn.; *Engineering Representative*, W. H. HEINRICH, The Travelers Ins. Co., Hartford, Conn.; *Executive Committee*, The OFFICERS and BENJAMIN F. GRIFFITH, J. & P. Coats (R. I.), Inc., Pawtucket, R. I.

Tuesday, September 27, 1927

G. W. COOK, Chairman

Supervising Engineer, Travelers Insurance Company, Springfield, Mass.

The first session of the Textile Section of the National Safety Council was called to order at nine-fifty o'clock by the chairman, G. W. Cook, Supervising Engineer, Travelers Insurance Company, Hartford, Conn.

CHAIRMAN COOK: We will start the program gentlemen, with a report of the secretary on the meetings of the executive committees during the year.

Regarding the Membership Committee, Mr. H. W. Donald of Boston is chairman, but he is not here.

I won't report on Mr. Donald's work, but he has a very clever scheme which he has developed for getting new members into the Textile Section. He has listed about all the textile plants in the country and has divided them into zones and has endeavored to get one man in each zone to personally solicit the plants in his zone and explain to them the benefits they can derive from membership in the National Safety Council and also from association with the Textile Section. He has had this under way for quite a while and it is a matter of slow development, but I think something good is coming out of it.

Mr. Washburn, you were out when I started off. Suppose you give us a little report on the activities of the secretary during the year.

Activities of the Secretary During the Year

HARRY C. WASHBURN (Fisk Rubber Co., New Bedford, Mass.): The Textile Section held two meetings during the year, the first one through the courtesy of Mr. Finley of the Providence Safety Council, at the rooms of the Providence Safety Council in Providence. At this time the matter of organization mainly was taken up and such offices as remained vacant were filled on suggestions given at that time.

Mr. Sauls stated that in the near future, possibly about January or February, the Providence Safety Council had under contemplation a joint meeting of the Southern New England industrial representatives and thought that at the same time it would be well if the second meeting of the Textile Section was held with them. But for some reason it fell through and that meeting was not held.

The second meeting was held March 23 in the city of Boston in the offices of the American Mutual Liability Insurance Company. Six of the officers who were present at the first meeting were for some reason or other unable to be present at this meeting. We had as guests at that time:

W. Dean Keefer, Chief Engineer of the Industrial Division, of the National Safety Council.

D. Frank Lord, Works Engineer, M. J. Whittall Associates, Worcester, Mass.

A. S. Johnson, American Mutual Liability Insurance Co., Boston, Mass.

We attempted to draw up a program for the meeting being held here today and had considerable discussion on certain topics. As the meeting proceeds today the members will notice just what is going to be done and will learn about some of the things that were brought up for discussion.

It was suggested at that time that the chairman appoint a Nominating Committee to suggest names to fill the offices for the succeeding year. That committee met twice and has brought in a slate which is to be presented later.

CHAIRMAN COOK: We managed to hold both these executive meetings at the same time as the Textile Code Committee meetings so that most of the members of the Executive Committee meetings could attend both meetings; and we have tied the work of the two together pretty well in the last year.

One of the innovations we started, as Mr. Washburn stated, is also being followed out by all the section now, or will be; appointing a Nominating Committee along in the spring and having them arrange to prepare their nominations and bring them in at the annual meeting rather than appoint a Nominating Committee at the meeting to try to get together while the meeting is under way.

Dr. Knapp, we have been asking for reports from different members of the Executive Committee and I am wondering if you will say a word about the Publicity Committee's work for the year.

DR. ROBERT KNAPP (Cheney Bros., South Manchester, Hartford, Conn.): Pub-

licity for the year has not been what it should have been because it is difficult to get from the members contributions which should be made public in the letters. It seems to me that even if something small in the way of suggestions was contributed by every source, it would not be a difficult thing to get up a news letter at least six times a year. But I must confess that the amount of material which I have received is not at all adequate to get out that number of letters; in fact, there has been quite a dearth of it.

I would suggest that a very strong appeal be made to the members to send in material. I don't think it is a matter of not knowing where to send the contributions, but is a matter of being lax in sending it. Perhaps, some are in doubt as to whether it is valuable, but they could at least send it in and I am sure most of it could be used to the benefit of all the members in the section. Their laxity in sending in the material is the keynote for the failure in the number of news-letters that have been sent out. There isn't enough material for it.

CHAIRMAN COOK: I think this news letter is the best thing we have to tie the Section together. It is a fact that some of the smaller sections have the best news letters. I think the Marine Section has a news letter that comes out every month, and is almost a book. It is a wonderful thing, but I think it is purely the work of the man who gets it out who is very much wrapped up in that one thing. He gets all kinds of information from various sources other than the Marine industry. I think he gathers up clippings and puts them in the letter.

I am sure if we would cooperate we could get out at least six news letters a year, and I would suggest you keep in contact with the next man who gets the job and help him push this thing along and make it better than it has been in the past.

CHAIRMAN COOK: Mr. Washburn, did Mr. Donald ask you to report for him on the Membership Committee?

Growth of the Membership During the Year

HARRY C. WASHBURN (Fisk Rubber Co., New Bedford, Mass.): I haven't a report but I might give a few figures which I have obtained from time to time from the National Safety Council in regard to membership.

November 1, 1926 the total membership was 117 for the Textile Section. Since that time six have cancelled their membership and fifteen new ones have been accepted, which makes the present membership to date, as far as I have received the figures, 126, or a gain of nine members.

The membership is divided as follows, throughout the country:

New York	21	New Hampshire	2
Massachusetts	17	Alabama	2
Pennsylvania	16	South Carolina	2
New Jersey	12	Maine	2
Illinois	6	North Carolina	2
Rhode Island	5	Tennessee	2
Missouri	5	Texas	2
Georgia	5	Delaware	1
Indiana	4	Michigan	1
Wisconsin	3	Kansas	1
Ohio	3	Kentucky	1
Connecticut	3	Oregon	1
Maryland	3	Virginia	1

Three foreign members raised the total to 126 in all.

CHAIRMAN COOK: We will start our program with a paper by Mr. Arthur Barlow, Armstrong Cork Co., Linoleum Division, Lancaster, Pa., the subject of which is: "First Aid and Accident Prevention."

Mr. Barlow is a very old timer in accident prevention service and I was much gratified to have him agree to read a paper for us at this meeting.

First Aid and Accident Prevention

**Arthur Barlow, Chairman, Executive Safety Committee, Armstrong Cork Co.,
Linoleum Division, Lancaster, Pa.**

The text book on First Aid, Industrial Edition, issued by the American Red Cross, in the opening chapter defines first aid as, "A bridge that takes the injured safely over the danger of an exhausting or fatal hemorrhage or an infected or blood poisoned wound, a crooked leg or a stiff joint, and puts into the hands of the hospital or surgeon a man who has lost less blood, has a cleaner wound, a straighter leg, who suffers less pain, less shock and is in every way stronger and in better condition for the hospital and the surgeon's further professional care." And as prevention is now recognized as far better than cure in injury as well as in disease, modern first aid instruction also teaches how to prevent accidents.

The relation of first aid to accident prevention is obvious for as the burnt child dreads the fire, so does the man who is brought into contact with those who suffer, and hates to see any one get hurt. He naturally exercises not only common sense in trying to keep himself and those associated with him from getting injured, but his training makes him also an observant and devoted disciple of "Safety First," and he invariably constitutes himself, as it were, his brother's keeper. It is not a difficult subject to study, nor one hard to teach to those interested, and any effort put into trying to make one's self proficient is more than repaid by the knowledge acquired and the possibilities presented for rendering service that may mean saving the lives or limbs of our fellow beings.

For many years we have recognized the educational value of teaching our workers first aid as a mean to arouse an interest in their own selfpreservation and enlisting their active cooperation in the factory policy of accident prevention and comfortable working conditions with highly encouraging results.

We organized classes for the winter months every year, commencing in November, and bring them to a close in March of the following year. These are held under the auspices of the American Red Cross Association, and their Industrial Edition Text Book of First Aid, is used for the course of instruction. The classes meet one night each week, for one hour period. Our works doctor is the class instructor, and advanced students act as demonstrators and assistants in practical exercises. The classes are brought to conclusion by an examination for certificates of proficiency, medals or bars awarded by the American Red Cross.

Our custom is to present the awards earned, at a complimentary dinner to the successful graduates. This is arranged by the officers of our First Aid Association which is composed of certificated first aid graduates, with a present membership of 84, all of whom received their training in our factory classes and are still with the Armstrong Cork Co.

The factory executives make it a point to attend and the interest they have taken and continue to take in our first aid work has contributed immensely to the success we are enjoying in making the course of instruction popular.

In forming our class we try to confine it to about 50 members, and as far as possible endeavor to have each department represented. From 20 to 30 members is a big enough class under ordinary conditions, but we are able to double up on this by always having advanced students who help in training first course students. The Red Cross has arranged for a four-course series of classes and offers to students successfully passing examination tests, certificate for the first course, medal and bar for the advanced second course and bars for third and fourth advanced courses.

We started our last class November, 1926, with 60 registered, and finished March, 1927, with 40 taking the examination test. Nineteen of these were first course for certificates; 12 second advanced course, medals with bar; three, third advanced bars; five, fourth advanced bars; all of whom passed the examination tests creditably.

Our First Aid Association arranges an outing in the fall of each year, for members only, and provides a good old fashion picnic and playtime. A report of this is given prominent publicity in our plant publication and helps to boost interest in our classes.

All qualified first aid men in the factory are given keys to the departmental emergency first aid equipment. During daytime working hours, however, all cases requiring attention must report at the works hospital. Provision is made for care of the injured in every department during night working hours, by trained first aid men, and if a serious accident happens the first aid men make all arrangements for proper attention being given to the injured, takes care of his property and notifies his relatives.

Efficient Service of the First Aid Organization

A feeling of trust and dependance has been created by the efficient service our first aid organization is giving in our factory and we regard it as a compelling influence in winning the good will of our workers and their active cooperation in helping to reduce accidents. I unhesitatingly place teaching first aid to the injured as the very best way I know of to get workers to become interested in their own and their neighbor's safety and well being. And incidentally I might mention here that many who have been through the course of training in our classes have shown such commendable progress in the development of their personal character and ideals of loyalty and service, that they have been singled out for promotion, and in every case are proving worthy of the trust and responsibilities placed upon them.

Their advice and example in guarding their fellows and themselves from the common dangers surrounding them constitute the highest form of safety propaganda. We have experienced many tangible proofs of this in our system of accident prevention and welfare work in the Armstrong linoleum factory and we attribute a lot of the credit for any success we are meeting with in accident prevention to the wholesome influence of the trained first aid men amongst us; and not only in the workshop but in their homes and the community at large they are proving to be a valuable asset. One of our trained men is credited with saving the life of a companion recently by applying a tourniquet to stop bleeding from a severed artery, the result of an injury in an automobile accident.

We frequently read in the daily papers news of some one trained to render first aid saving the lives of others, by artificial respiration, by skillful handling of seriously injured, arresting bleeding, etc. But the thousands upon thousands of minor cases are rarely mentioned; yet were it not for the service rendered by first aid men, much unnecessary suffering and many lives lost from infection would result through ignorance or careless indifference in leaving minor wounds uncared for.

If first aid accomplishes nothing more than is represented by its value in minimizing the dangers of infection, it would more than repay all the expense and effort put into making the study of it universal.

We recognize that the problem of accident prevention is education, and that just so far as we can get the workers themselves interested in their own safety and well being, so will the accidents become proportionately reduced in frequency and severity.

So there has gradually evolved the policy of persuasive propaganda, of appealing to the common sense and self interest of the workers by inviting them to become

active agents in securing for themselves the full measure of safety and comfort our employers desire.

To this end and acting with a common purpose we have a Foreman's Association meeting twice monthly, and a shop committee meeting also twice each month. These meetings are attended by the factory executive, open and freely expressed opinion is invited and encouraged on all subjects relating to safety and industrial relations.

We post the National Safety Council posters and other safety cartoons and literature. We conduct a safety and efficiency competition with cash prizes as incentives. We have a departmental safety competition which is proving to be a dandy method of getting team work with the foremen and workers, who pull together to make good records in accident prevention.

We have a safety engineer devoting all of his time to safety supervision. An emergency hospital with nurse in attendance and doctor attending two hours daily. A welfare nurse who makes daily visitations to sick or injured, giving them help when needed in the homes of our workers.

An Employees' Benefit Association also provides sick and funeral benefits on a most generous scale.

A Building & Loan Association encourages thrift. A system of service bonus rises yearly to a 10 per cent rate at the end of 15 years of service. A vacation with pay is given after two years of service, and above all there is a very earnest and sincere desire animating our executives to give a square deal to all in their service. All this has made for us most enviable working conditions and created a feeling of good will and happy relationship.

But accidents do occur occasionally. I don't mean by this that we have not made satisfactory progress in accident reduction; our records will bear favorable comparison with any similar industry anywhere.

One thing we are proud of, however, is that accidents attributable to unguarded machinery or foreseen hazards have been practically eliminated. Analysis of the causes of such accidents as we have to contend with usually show that they resulted from carelessness, either of the injured persons or of those working with them.

The Company Has a Generous Policy

MR. BARLOW: We pay compensation according to the laws of Pennsylvania and we pay compensation for six days' disability from the time of the accident. Our company is most generous. We do not visit penalty on those who have been injured by making them suffer the financial loss, and we point out to them that we are sorry for the pain and discomfort and sorrow it brings to their own. We don't victimize them in any way by making them assume full responsibility as the law would allow us, even though their own negligence and carelessness may be the cause.

So you see, it happens this way in spite of anything that can be done, and we have, as good an organization, I think, as it is possible to have, and still we are trying to make it better.

Just another word. I believe the giving of rewards is an inducement to the class of men you want to interest and here is something we use for that purpose. (Displays medal.)

CHAIRMAN COOK: I know some of you will want to ask Mr. Barlow something about the details of his plan, and if you have any questions, please ask them at this time.

W. N. CLINTON (Metropolitan Life Insurance Co., New York, N. Y.): I should be very interested in learning a little more of his competitions and the way they are conducted, and what is done to form a basis of comparison between depart-

ments. I would be very interested in having you go into that to some extent, if you will, Mr. Barlow.

MR. BARLOW: Well, we have got to that point now, where the first aid classes have become so popular we have to use some sort of discretion in making up a class for the year, so that we shall not have too many from one department thus interfering with operations.

In making up a class we first get the foreman's association interested and we tell them we would like to have someone sent from each department to attend this class. We give them some names and let each foreman pick out the man he would like to have attend.

Among those we particularly want to see are those whom we regard as night workers. Our operations go on continuously during the night, so it is mighty fine to have someone there on the spot to render not only skilled service, but get the injured man to the hospital; and also to be a representative of the company and see that the injured man gets everything that is worth while. He must also attend to the domestic problems. After the injured man is taken to the hospital and it is found necessary to detain him there, the first-aid man has to go to the home of the injured man and break the news as kindly and gently as possible, and see to it that it does not come to the family or the injured through second-hand means. The first-aid man must do all he can to help them; get them to the hospital, if it is necessary, so they may see their loved one. He must also take care of the man's property which he has left in the locker, so no one will pilfer anything which belongs to him. In short we try to make him feel, through out representative, that he is one of us.

Careful Instruction Necessary in First Aid Work

HARRY D. IMMEL (Department of Labor and Industry, Harrisburg, Pa.): I saw Mr. Barlow's name on the paper here this morning and I couldn't resist coming into the meeting just because I happen to know Mr. Barlow and for nearly five years was supervising inspector of his company. I know what the Armstrong Linoleum Corporation is doing to advance safety in their plant and I want to add a word to what he has said from my own personal knowledge of it. It is representative of the best of what we are accomplishing in Pennsylvania for accident prevention and the advancement of the welfare of industrial workers. I feel that if it could be better known it would be a splendid inspiration to other industries.

DR. ROBERT KNAPP (Cheney Bros., Hartford, Conn.): I certainly agree on one thing Mr. Barlow brought out. First aid should be taught preferably from that book which he mentions—"First Aid, Industrial Edition," which is issued by the American Red Cross. The Prudential Insurance Company has published a small pamphlet on first aid, about half the size of our program here, and apparently has written to all the first aid men in the National Safety Council stating they would send a supply of the pamphlets wherever they could be used.

The only danger about this is the fact that these pamphlets fall into the hands of people who, without instruction, practice first aid in factories and which practice may lead to a great deal of bad results.

I think instructing classes from that "First Aid, Industrial Edition," is something that should always be borne in mind. The Prudential offered, I believe, to send enough of the little booklets to provide everyone in our plant; and supplying them like that would be dangerous because in this booklet it shows how to take foreign bodies out of eyes, which is something an inexperienced person ought never do. It seems to me the importance of that point cannot be emphasized too strongly. These books should be placed in the hands of persons who are qualified to instruct.

LEONARD HOWARD (Duncan Mills, Greenville, S. C.): I would like to ask you, Mr. Barlow, what time you hold your meetings.

MR. BARLOW: We hold them in the evenings, at which time we think we get the better class of men. Our day work comes to a close at five-thirty. We start the class at five o'clock and close it at six. In that way we pay them for a half hour and they give a half hour. You know, gentlemen, when you begin to give things away they don't appreciate it. When they get the right sort of inspiration they put in the spirit you want them to and they are willing to make some sort of sacrifice, especially when they see that you are also making a sacrifice, from which they are receiving benefits.

CHAIRMAN COOK: The second speaker on our program today is Mr. G. S. Bohlin of Cheney Brothers, South Manchester, Conn., who will talk to us on a subject which we have never before had covered in any way by a safety man in the Textile Section.

Safe Practices in a Silk Mill

G. S. Bohlin, Service Department. Cheney Brothers, South Manchester, Conn.

The subject of "Safe Practices in a Silk Mill" covers in a general way much the same ground as in almost any other industry, and can be divided into the customary general headings, of (1) Mechanical Guarding, and (2) Safety Education. There are, however, certain machines and certain hazards peculiar to the silk industry, and these specific conditions will be dealt with in more detail in this paper.

My observations are based on the experience of only one silk manufacturing establishment, namely that of Cheney Brothers, of South Manchester, Conn. Cheney Brothers, however, carry on every operation from the raw material to the finished product, and is the only silk industry which has all these operations, most of the others specializing in some one or more branches, such as throwing, weaving, dyeing or finishing.

Mechanical Guarding

Mechanical exposure is a very real problem in silk manufacturing, due to the fact that the proportion of mechanical machinery to employees is large, several frames or machines being attended by each employee. This condition exists in almost any textile industry.

Mechanical guarding therefore has been a very important item in our accident prevention campaign and a great deal of effort and money have been spent in this direction. In the past a fairly large proportion of the accidents were caused by mechanical hazards, but by consistent and earnest effort to safeguard these conditions this proportion has been reduced very materially. During the ten year period 1915-1924, inclusive, lost time accidents on moving machinery formed 21.4 per cent of all lost time accidents, while during 1926 only 6.5 per cent could be assigned to this cause.

Throwing Machinery. Under this heading is included a variety of machines such as winding, reeling, doubling, twisting, coning, tubing, and transferring frames. The drive belts and pulleys on practically all these machines should be guarded to a height of 6 feet from the floor. Most of these frames also have several set of gears which are exposed and should be properly covered.

Warping Frames. Warping frames of the ferris wheel type have presented a hazard which might be of interest, as this problem includes not only guarding against a real hazard but also the elimination of unnecessary noise. A gear is mounted on the end of each beam meshing with a pinion on the driving end of the frame on which the beam is mounted. Formerly this set of gears was left exposed and in addition a dog was employed to mesh into the teeth

of the large gear whenever the warping frame was stopped so as to maintain the tension in the warp. This dog was allowed to ride on the circumference of this gear continually, making a good deal of noise. A simple guard can be devised to cover these gears with the dog built into the guard and interlocked with the belt shifter in such a manner that the dog is raised while the machine is running and meshes with the teeth of the gear only where the belt is shifted to the loose pulley, thus guarding the gears, eliminating unnecessary noise and still maintaining the tension in the warp.

Looms. The outstanding hazard on looms, is the flying shuttle. Experience has proven that the most effective safeguard against the flying shuttle is proper adjustment of the loom. If the loom is kept in proper adjustment there is small likelihood of the shuttle flying out. However it often happens that

Figure 1. Two sets of gear guards have been installed on twisting frames of this type.

the weaver does not realize that the loom is out of adjustment until a shuttle flies out, making it necessary to provide shuttle guards. We are using a screen type of guard set in sockets on the floor, at the sides of the looms.

Practically all of our looms are individual motor driven, with the driving gears enclosed, thus eliminating the usual long series of drive belts and pulleys which have to be guarded. There are usually one or two sets of gears operating the head motions of the looms, varying with the type of loom employed, which should be guarded.

Spun Silk Machinery. Under this heading are included a variety of machines, such as a picker, dressing frames, drawing frames, spinning frames, etc.

Of these the most hazardous are the pickers. These machines comb out the silk fiber and remove some of the residue of the silk worm, and consist of a drum, revolving rapidly, on which are mounted two or more rows of pins forming a sort of comb. A guard has been devised over these drums, inter-

locking in such a manner that the machine is started in motion by turning the guard or cover down over the drum, and the cover cannot be opened until the drum stops revolving, which it does automatically as soon as the required amount of silk has been transferred to the drum. There is also a set of gears on this picker which should be guarded.

The other machines in this group, although not so dangerous have gears, drive belts and pulleys, and combs which should be protected. Some of these, particularly the drawing frames, also have horizontal shaft under the frame, which we have found it necessary to guard. Occasionally a sliver of silk would drop and become wound on this shaft, in which case the operator, in her

Figure 2. Typical installation of guards for drive belts and pulleys on doubling and twisting frames.

eagerness to save material, would attempt to remove it while the machine was still in motion, and an injury, sometimes quite serious, would result.

Dyeing and Finishing. These operations include a large variety of machines, each one with its own hazard, for the most part consisting of drive belts, gears, and in some cases rollers or drums.

Individual motor drives, with enclosed gears, and easily accessible stop buttons have helped to eliminate most of these hazards.

Dry cans should be equipped with the necessary guards and in addition, a steam gauge reducing valve and check valve.

Stairways, Aisles, etc. Stairways should be maintained in a good condition and provided with the necessary hand rails. On several stairways, which are used by a great many employees at quitting time, and which are four feet or more wide we have installed a hand rail on each side as well as a dividing rail in the center. This is a very effective means of preventing falls in case the employees crowd or push each other.

Aisles should be marked off and kept clean of all obstructions. This also applies to corridors, stairways etc.

Dust, Fume and Steam Removal. In some operations it is advisable to provide systems of ventilation for removing dust, fumes and vapor. This is especially true in shearing operations, dressing and combing rooms, and boiling and dyeing operations. In Cheney Brothers dressing mill we have a dust removal, air washing, system, which is very effective and which maintains an almost constant condition of temperature and humidity throughout all seasons of the year, providing very satisfactory working conditions, in what would otherwise be a very dusty operation. Rooms in which boiling or dyeing is done should be equipped with blowers for removing the steam and fumes.

Figure 3. Coning frames have a series of small belts and pulleys on rear of frames which should be guarded. In this illustration the guard has been removed from the left hand machine to show the belts and pulleys.

Illumination. Proper illumination is very important. Although we have no figures to indicate the amount of accident reduction brought about by improved illumination we feel it must have a very marked result, and in addition provides better working conditions with improved quality of work.

Cheney Brothers have had one problem in illumination which might be of particular interest, as it illustrates an outstanding case of decreasing the possibility of accidents, as well as improving the working conditions and the quality of work to a marked degree. In our dressing mill we have a room for inspecting silk fiber which has been combed, preparatory to drawing and spinning it into spun silk. The main object in this inspection is to remove any foreign material which might still be contained in the fiber. This inspection is accomplished by laying out the fiber in thin layers on a glass with light transmitted through it from underneath. The original benches were made in such a way that daylight was admitted through a skylight in the roof or windows in the walls and

reflected from the inside of the bench through the glass. The reflecting surface, however, was horizontal and not directly under the glass, so that only a small portion of the light was reflected up through the silk fiber. The amount of daylight also varied considerably according to the weather.

In order to increase the light on cloudy days an incandescent lamp was installed under each glass, but this was found unsatisfactory as no provision was made for eliminating the glare of the filament. We are now using benches which employ only artificial light, thus giving a constant intensity of illumination, the lamps being placed out of sight in such a position that there is no glare, the light being reflected from a reflecting surface consisting of a combination of two parabolic curves. In these benches only one lamp is required for two operators, who sit opposite each other and a very soft, pleasant working light is furnished which is amply intense for the work. With the original

Figure 4. Showing screen shuttle guard and gear guards on looms.

benches practically all daylight was excluded from the room proper, while with the new benches it has been found possible to admit a great deal more daylight, thus furnishing a much pleasanter and safer room in which to work. Ventilation and supervision have also been improved, as there are now no shafts extending up to the roof to subdivide the room into sections, decreasing the efficiency of ventilation and making supervision of the room difficult.

In addition to the hazards mentioned which are more or less peculiar to the silk industry, there are a great many other hazards common to all industries. The maintenance departments are the source of a large number of our injuries. These operations have the usual problems of protection and education of the employees and a great deal of attention has been paid to the reduction of accidents in these departments. This phase of the problem, however, is not dealt with in detail in this paper as it is covered in the various other sections.

Skin Infections. Occasionally there are cases of dermatitis, or skin infections of the hands, among employees using dyes and printing inks and also on

Figure 5. Picker machine with cover for drum in running position.

certain silk winding operations. Most of the employees hired for dyeing and printing operations are not affected in this manner, but occasionally we find an employee who is peculiarly susceptible to this form of infection and another from of employment has to be secured for him. In the case of the winding operation there are some individuals who are more susceptible to skin infections than others, and experiments have indicated that these individuals seem peculiarly susceptible to protein infection. Our experiments, however, are not completed, but we hope to find some method of overcoming this difficulty in the near future.

Safety Education. There are so many accidents of a non-mechanical nature, usually less serious but in many cases resulting in lost time, which apparently could have been prevented by the injured employee himself, that a campaign of educating the employees to realize and anticipate hazards has been found necessary in the silk industry as well as in every other industry.

Bulletins and Posters. Bulletins and posters, both those issued by the National Safety Council and home made ones, have proven of value in bringing to the attention of the employees the right as contrasted with the wrong way of performing certain operations. The amount of reduction effected by the use of bulletins is difficult to determine, but no doubt some reduction will result from their use.

Figure 6. Picker machine with cover open when not running.

Training New Employees. The best possible time to impress an employee with his own responsibility in preventing accidents is when he is new and under training. If properly instructed from the beginning he will form a habit of performing his work in the safest manner. Cheney Brothers have instituted a training department which takes charge of all new employees for a certain length of time under the supervision of a trained instructor, who trains the new employees in the best and safest manner in which to perform their particular jobs; he also impresses them with the importance of reporting an accident immediately and receiving first aid treatment promptly, etc.

Group meetings are held of the new employees after they have been employed a short time, at which pamphlets on various subjects are given out and thoroughly explained. These pamphlets include, a Book of Information, the Pension Plan, the Thrift Plan, the Benefit Association, etc.

Figure 7. Properly guarded drawing frame, showing guard over combs.

Foreman's Meetings. It has often been stated that the foreman is the key-man in industry. There is no doubt that the foreman holds a very important position and a great deal can be accomplished along accident prevention lines as well as production lines, by training the foreman in his responsibilities. We have held group meetings of foremen, at which many subjects including accidents have been discussed, and we feel that these meetings have been very much worth while. They have impressed upon the foreman the fact that they have a very important and serious responsibility toward their employees as well as to their employer, resulting in the foreman warning the operators against unsafe practices, more prompt reporting of injuries, and more prompt first aid treatment.

We have also started a Foreman's Manual, a loose leaf book in which are issued printed summaries of the various subjects as soon as the discussions on these subjects have been completed. These books are kept accessible by the foreman and can be referred to when occasion arises. Following are two pages referring to the foreman's responsibility in regard to accidents.

The Foreman and Accident Prevention

Your duty and responsibility in this connection is to:

1. Recommend improvements to make working conditions safer.
2. See that your equipment is properly guarded.
3. See that safeguards, goggles, etc. are properly used.
4. Instruct your employees relative to safety regulations.
5. Correct the unsafe practices of your employees.
6. Enforce safety rules and regulations.

Figure 8. Finishing machine with individual motor drive, driving gears enclosed, and easily accessible stop button control.

General Safety Regulations

In order to make the plant safer and to prevent accidents, you are instructed by the Management to see that the following regulations are observed and to report any infringements.

1. Do not run or push other employees in corridors or stairways.
2. Do not leave trucks, boxes, etc. in aisles or corridors, except in places designated.
3. Do not leave quills, spools, spare machine parts, etc. on the floors.
4. Do not run with trucks or ride on them in the aisles and corridors.
5. Do not throw anything out of the windows.
6. Use guards, goggles, etc. as provided.
7. Do not ride on elevators unless authorized to do so.
8. Do not fool with anyone while at work.

9. Do not wear ragged or loose sleeves, flowing ties, or loose waists and jumpers when working around machinery.
10. Women should not wear their hair loosely, around moving machinery.
11. Report all injuries to your Foreman immediately and follow his instructions relative thereto.
12. Report all defects in machinery and equipment to your Foreman.

Works Council. Cheney Brothers have a form of employee representation called the Works Council. This consists of employee representatives elected by the employees in the various departments. Meetings of these representatives are held regularly. This has been a means of bringing to the attention of the employees the fact that Cheney Brothers are making every possible effort to

Figure 9. Dyeing machine with individual motor drive, enclosed driving gears, and stop button.

reduce accidents, and of impressing on them their own responsibility in this connection.

Safety Committee. The only form of safety committee which Cheney Brothers have employed is a committee consisting of members of the Works Council. This committee makes inspections of all departments of the mills at intervals, and has brought out many conditions which should be corrected, which might otherwise have been overlooked. Through this committee also Cheney Brothers have succeeded in impressing the employees with their own responsibility in preventing accidents to themselves. The members of this committee are appointed by the chairman of the Works Council representatives, the members being changed at intervals, thus making it possible to give this training to a number of employees in various departments.

Suggestion System. A suggestion system has been in operation for some time, which grants employees awards for useful suggestions, the award varying with the value of the suggestion. Although instituted primarily for the purpose of receiving suggestions which will tend to decrease the cost of production, a good many have been received which related to accident prevention, indicating that some of the employees had benefited by our campaign, and were on the lookout for dangerous conditions.

Safety Rules and Regulations. Copies of the Safety Rules and Regulations which have been adopted are posted on the bulletin boards and in addition a copy is included in each of the foremen's Manuals previously mentioned, with instructions issued to each foreman to make it his business to see that these regulations are lived up to.

Figure 10. Dust removal system for battery of velvet shearing machines.

Accident Statistics. Detailed accident information has proven a great aid in determining along which lines our efforts should be concentrated. Investigating thoroughly every accident which has been reported, whether it involved lost time or not is good practice. This involves considerable time, but it is time well spent, as it brings to our attention conditions and unsafe practices which although the accident involved in many cases may be slight might result in more serious lost time cases. This investigation has also brought to our attention quite a number of cases which were not compensable at all, but which might have been so considered unless a thorough investigation had been made.

Cheney Brothers do not carry compensation insurance, but pay compensation from their own funds, according to a special compensation plan which nets the injured employees more than is required by the Connecticut Compensation Act. However, in order to receive this additional compensation

it is necessary that the injured employee report the accident within 24 hours after its occurrence. This has resulted in prompt reporting and prompt treatment of all injuries, resulting in less lost time and less infections.

CHAIRMAN COOK: I know you all appreciate the paper Mr. Bohlin has just given us; I know I did. He has carried out ideas which, we have been told by silk mills, could not be done.

With regard to the shuttle guard, Mr. Bohlin, there is going to be a shuttle guard perfected soon to be used in cotton which I would be glad to have you criticize from the viewpoint of silk mill process. There is one which has been in use for some time and is 100 per cent successful. I would like to get your opinion on it and see if it can be used in the silk mill.

HARRY D. IMMEL (Dept. of Labor and Industry, Bureau of Inspection, Harrisburg, Pa.): I would like to ask what experience you have had, Mr. Bohlin, with accidents resulting from flying shuttles, and if you have analyzed those accidents?

Figure 11. New type of inspection benches using only artificial light.

MR. BOHLIN: We have had very few of them, and fortunately they have not been serious. I remember but one this year. Do you, Dr. Knapp?

DR. KNAPP: Had one who was hit a half inch below the eye.

MR. BOHLIN: By using the screen type of guard it protects the operator from the next loom and she is not so liable to get in contact with the shuttle.

MR. IMMEL: In Pennsylvania we don't accept the target guard as being sufficient, and we have to use the bar guard over in Louisiana. I think in Pennsylvania they have these guards and they are very satisfactory.

MR. BOHLIN: I don't doubt but that they can be used, but we have never been able to get the employees to accept them as yet. We would rather have the screen type and have it as fool proof as we can, but we don't feel that this entirely covers the situation at all.

MR. IMMEL: We have had numerous accidents with the target guard, but in Pennsylvania we have had a full year's experience with the guard they are requiring, and it has done very well.

CHAIRMAN COOK: I would like to have you hear about, and see from slides, the shuttle guard we are going to show you tomorrow. I am sure you will be interested to know about it.

H. C. WASHBURN: Last year I brought up the question of those bar guards and tried to get an opinion from the party who made the address as to whether the guard, as suggested by the commissioner of Pennsylvania, was fool proof, and I succeeded in pinning him down to a statement that they were not fool proof. I was very interested in that guarding question and the question of flying shuttles last year, and I made it a point to ask as many questions as was possible. The main thing I wanted to find out was whether they were fool proof and if they really did guard against those flying shuttles 100 per cent. The gentleman stated at the time that he could not guarantee them as being fool proof.

Now this other guard Mr. Cook speaks of is, he says, 100 per cent fool proof, but I do not know whether it will work on silk.

W. DEAN KEEFER (Industrial Division, National Safety Council, Chicago, Ill.): Is it necessary, in the opinion of the people attending this section, to put in both the

Figure 12. Showing room with new type of inspection benches. Note increased amount of general illumination possible in room.

bar guard and the target guard? That question has come up with reference to the code. I don't know whether it has been definitely decided, or not.

MR. BOHLIN: I don't know as I can answer that definitely. We have not used other types of guards sufficiently to know whether they would be fool proof, that is, to know whether we could get along without the target guard. I don't know if anyone has had experience with that or not.

MR. IMMEL: The time when the bar guard has a weakness is when it is not properly adjusted, or if it is bent intentionally or by accident. If so, it may not confine the target guard and will stop the shuttle. We don't want to cut off any more light or build up any more fixtures around the machine than are necessary, and the target guard does cut off some light. Using both the target guard and the bar guard you would have a higher percentage of shuttles stopped if they are not properly adjusted.

CHAIRMAN COOK: I told you a little while ago that if we could get Mr. Keefer to come in we would get him to give us a little talk or report on the textile code. He is here now, so we will give him the chance to speak.

MR. KEEFER: I have spoken on the same subject several times before so this may be old to some of you.

The textile code, as you know, is being written and prepared under the sponsorship of the National Safety Council and the general American Engineering Standards Committee.

The textile code, as well as any other code, is gotten out for two reasons: to promote uniformity between states and insurance companies, and to save limbs and lives of men. I don't believe I need to elaborate on the subject of saving limbs and lives of men. I will talk about that which is a little more obscure.

The number of companies doing good safety work in the country is comparatively small with regard to the great number of companies operating, and the Code Committee has tried to study safety in textile plants, that is, the safety work being done in some companies, so that it can be made available to, or brought to the attention of, those who, apparently, are not interested enough in safety work; and we think the code will, through those means, help to save limbs and lives.

Several Sections of the Code Are Almost Finished

This committee is composed of 25 experts who have been working for two or three years on this work. When we first started the job we realized we could not get up one code to cover the entire industry. We had to subdivide it into three or four and perhaps more groups. In the first place, there had to be a separate code for the cotton mills; another for bleaching, mercerizing, dying and finishing, all in one; another for woolen mills; another for silk, and so on down the line. We have gotten a start on two out of the whole bunch. The cotton code is pretty well along and I believe if we would submit it to the committee they would O. K. it as it now stands. This is to be done shortly. Bleaching, mercerizing, dying and finishing is 85 per cent complete.

We are now waiting for the subcommittee on this Section of the code to give us some additional data on principles of printing, and as soon as we get that we will be able to submit that code to the committee for final approval.

There are other subcommittees that have been appointed; one on woolen mills and one on worsted mills. We understand they are working now and will come through with their first draft in a comparatively short time. We thought we had a fourth subcommittee organized under the leadership of Mr. Leveridge for the state of New Jersey. Unfortunately, Mr. Leveridge's death interfered and we are now re-organizing that subcommittee.

We hope Mr. Bohlin has enough fundamental data to make it the basis for this section on silk mills. I assure you it is a slow job. Men on the committee are scattered throughout the different parts of the country and we seldom get together. The majority of our work is done through correspondence and we think we are making some progress and that progress will eventually bring the uniformity we want and actually save limbs and lives.

MR. BOHLIN: Before any compensation act was passed in the state of Connecticut, Cheney Brothers formed a benefit association and the employees pay a certain amount of their wages as a contribution to take care of sickness and death benefits. Cheney Brothers pay 25 per cent of what the employees pay and put that into the fund, and in addition to that they have incorporated the scheme, put through by the supervision of the insurance commissioner, of paying compensation insurance for compensable accidents, and we are still operating under the same plan. We operate under the insurance commissioner's plan and not under the compensation commissioner's plan.

The employees are entitled to a pension and also entitled to extra compensation, so instead of receiving one-half of their pay, which is the amount specified by the Connecticut Act, they can receive as high as 75 per cent. It depends on length of service and the number of children they have.

Now the whole scheme of paying compensation or deciding whether it is a compensable case rests with the operating committee and the trustees of the benefit association. In order to properly take up these cases, we have a meeting with the benefit association and the operating committee every Wednesday morning and go into detail and discuss every accident which has occurred during the week previous.

We found that for some years the operating committee was not operating, with the result that we were accepting quite a few cases which were not really compensable injuries at all, and paying compensation for them. By investigating every single one that is reported for first aid treatment, and talking it up with the operating committee, we have been able to eliminate those which have not been compensable. That has helped a lot and has brought up a lot of conditions we did not get in touch with in any other way.

W. N. CLINTON (Metropolitan Life Insurance Co., New York, N. Y.): About what percentage does the company pay into the benefit association, and what percentage does the employee pay?

MR. BOHLIN: Twenty-five per cent is paid by Cheney Brothers and 75 per cent by the employees. In addition to that the company takes care of all administrative expenses, stationery, ink, et cetera. None of that comes out of the fund. The salaries of the superintendent of the association and his assistants, and all of the operating expenses, are paid by Cheney Brothers. There are 90 per cent of our employees belonging to this association.

E. F. CARTER (State Child Welfare Commission, Raleigh, N. C.): Is it optional with the insurance commissioner or board to set up council or prove cases in compensation machines?

MR. BOHLIN: We have been allowed to continue under this jurisdiction in lieu of taking out insurance with the company, or in lieu of taking out compensation insurance. We have made use of him only as an arbitrator and his decision is absolutely final and, therefore, no appeal can be made to a higher court.

W. C. WROE (American Mutual Liability Insurance Co., Atlanta, Ga.): Isn't it true that your agreement of payment is in excess of the compensation law?

MR. BOHLIN: It is, if they belong to this benefit association, they get more. We have to pay at least what the law provides, but we do pay more, sometimes as high as 75 per cent. That does not come out of the benefit association's funds; that is entirely separate from that.

CHAIRMAN COOK: I am afraid we are liable to get into a discussion on compensation laws, if we keep on, and that is a rather complicated subject. Unless someone wishes to ask a question aside from compensation laws or tuberculosis, I think we will now continue with our program.

Unfortunately, gentlemen, Dr. Sawyer was unable to be with us, and Mr. MacNulty, who is on the program for tomorrow, kindly agreed to be the third speaker on our program today.

Safe Practices in a Woolen Mill

Ignatius MacNulty, Chairman, Department of Labor, American Woolen Company, Boston, Mass.

Accidents, as distinguished from occupational dangers, are things that theoretically need never occur and in practice need only occur to the degree in which they are due to unforeseen or unpreventable causes.

The agent should feel it his personal responsibility to decrease avoidable accidents to a minimum through the influence of good preventive measures, such as the setting up of a permanent safety organization in his mill.

If we are to get any of the benefits expected of safety work in woolen

mills, we are of the opinion that those benefits can be obtained best by the organization of a safety committee set up in each mill and functioning as a permanent organization. It is therefore suggested that you appoint such a committee.

The Overseer's Responsibility

By his attitude the overseer should show to the help that he, himself, should obey the rules he is trying to enforce. Let his example be correct. There will be no trouble in his department. Men will follow correctly.

The workman's attitude toward safety depends absolutely on the attitude of the foreman. If he is indifferent the workman will be indifferent. But if he believes in safety, if by what he says and does each day he convinces his men that he is in earnest and is doing everything in his power to protect them, the foreman will get his men with him. Just as the corporal, more than the captain, determines the morale of a military company, so the foreman and subforeman determine the spirit of safety in a plant.

The workman should see to it that he observes all safety rules and regulations set up by the management. That he should cooperate and help his overseer and also by his individual attitude show to other workmen that disorderly conduct, carelessness, indifference, neglecting his small cuts and minor accidents all tend generally to making his job just so much more hazardous and unsafe for them all. He should be instructed that to a very great extent he himself is the hazard and not the machine and very often he contributes with others in creating new hazards.

It is well known that accidents represent a monetary loss as well as human suffering, and a well set up and organized safety committee in a mill should in a short time be able to show its value, by reducing the number of accidents which will be reflected in the reduction of the insurance premiums and lessening human suffering.

The general subject of accident prevention is gradually assuming greater prominence in industrial and public life. Both employers and employees are becoming more receptive to the idea that accident prevention has a moral and human significance and we have no doubt when you adopt the safety committee idea in your mill that safety will have the same local significance among your operatives that it has in its more general and social aspect outside of the mill.

An accurate knowledge of the frequency, severity rates and the causes of accidents is the foundation of all safety work. Therefore each overseer should report every accident in his room to the committee in writing. The committee should try and establish responsibility fairly and justly. This would have a tendency to draw their attention to the fact that all accidents would be checked. A notice should be placed in a prominent position notifying all the employees that a safety committee is working in the mill for the best interests of everyone and ask for the cooperation and help of all operatives to make the safety work a success in the mill.

In many cases the overseer tries to enforce rules with the men which he, himself, does not obey. It is impossible to enforce rules in this fashion, for it is up to the overseer to set the example. The general attitude of the workman is, "what is right for the overseer to do is right for me." This, of course, makes it necessary for the overseer always to think and do the right thing if he wishes to have his men do it.

Causes of Accidents

Ignorance and curiosity of green and ignorant workers.

Fatigue: Statistics show that this is cause of a number of accidents during the closing hours of the day.

Inappropriate and unfit clothing: Loose and flowing clothing should never be worn by anyone working near moving machinery. Reasonably proper clothing and shoes should be insisted upon.

Improper ventilation and poor air: Mental and physical alertness and activity are impossible in a foul atmosphere. This has a considerable bearing on fatigue. This condition has also an effect on the personal health of the average worker and is a cause of sick absenteeism.

Absence of safeguards. As all machinery is more or less dangerous, local management should carefully look into this matter and decide what is safe or unsafe under proper efficient working conditions. Where there is reasonable doubt give the benefit to some form of guard.

Carelessness: This is a characteristic which can never be wholly eliminated

in human nature. It is perhaps the cause of more accidents than any other one characteristic. Not only does it threaten the safety of the worker himself, but also endangers his fellow workmen. A strict observance of rules and a warning against continued carelessness should be insisted upon. By the most stringent methods only can injuries resulting from carelessness be reduced to a minimum.

Disorderly arrangement and unclean conditions: Things lying around in a disorderly fashion, and waste material left lying, furnish a very good possibility for the workman tripping over something. When tools and other equipment are not in use they should always be put in their proper place. Materials placed in passage ways and near moving machinery are the cause of many injuries. Greasy and slippery floors sometimes cause accidents, and some means, such as sand or some other material furnishing a firm footing, should be secured and applied to avoid this condition.

Lack of organization and cooperation: One foreman doing his safety work in one way, another in a different manner, and some discrediting the safety

work in general, have often reduced the value of safety work to a low level; and this results in a condition worse than as if there were no safety practices at all. Local management should try to avoid this condition and set up an example through the medium of his overseers' group meetings that a uniform system of safe practices should be carried out in his mill, each working with the other for the elimination of this form of waste called accidents.

Lack of discipline: This causes a number of accidents, through crowding in passages at stopping time and rushing out of doorways. Discipline has an important part to play in safety work.

The effectiveness of the first aid department in caring for the man and preventing infection depends largely on the cooperation of the foreman in instructing and disciplining his men. He must make his men understand that minor injuries must receive prompt attention, and must show them why a slight break of the skin, if neglected, may cause infection and possibly result in death.

Departmental meetings of workmen conducted by the overseer once a month have proved most valuable in keeping up interest and enthusiasm in safety. These meetings give the overseer an opportunity to place himself on record as to what he is willing to do to protect his men and what they should do. The workmen should also be encouraged to talk and a friendly get-together spirit should be fostered.

General Sanitation Should Be Strictly Enforced

Sanitation in toilet rooms: This should be a very important part in safety and health practices in any mill. Management and overseers should see that this very important and necessary duty is carried out in a very efficient manner. The operatives will appreciate any effort in this direction and should be encouraged to cooperate in this valuable work. Should this be neglected there is danger that the safety effort will be measured by the effort put into sanitation.

Accidents and their painful and costly results are not the problem of an insurance company, but are the problem of good management (outside of the legal and humane aspects of it), as the costs of accidents enter into the price of the cloth and very largely affect its selling qualities. Accidents also affect good production as they affect the productive efficiency of the operatives.

Fewer accidents mean better production and cheaper cloth. Lower costs mean more orders—more work for everybody. Good safety practice is, therefore, good scientific management. And it is here that men will judge you by what you create, and not what you correct.

CHAIRMAN COOK: Mr. MacNulty has given us a lot of good ideas and I am sure there are some of you who will want to ask him some questions. We haven't a lot of time, however, as I notice several of the sections have already adjourned, so, perhaps, your questions can hold over until tomorrow when I am sure Mr. MacNulty will be glad to answer them. At the end of our session tomorrow, I believe there will be a little time for a round table discussion and if you have anything you wish to discuss thoroughly, it can be done at that time.

DR. KNAPP (Cheney Bros., Hartford, Conn.): I don't like to pick on the women, but where do you get the idea they don't have accidents.

MR. MACNULTY: I didn't say they don't have accidents; I said women had fewer accidents than men. Where woman controls her destiny she has less accidents than man, and I have found that to be a fact in every mill I have analyzed. In some mills the average is twenty to one, generally it is five to one. I have found in industries where women have to face the same physical conditions, working in the same at-

nosphere, on the same process, getting the same wages, there will be less women injured than men.

DR. KNAPP: Are the proportions the same? That would make a difference?

DR. MACNULTY: If there are 50 men and 50 women there will be four or five men injured to one woman, working in the same room, doing the same type of work under the same compulsory effort.

R. P. BLAKE (Independence Bureau, Philadelphia, Pa.): I have studied that question and all the statistics I have been able to get ahold of indicate the fact that the frequency of accidents on the part of women is much less than with the men even when, as Mr. MacNulty has stated, the conditions are identical. Women are safer, but why it is so is impossible to understand. Perhaps the answer is that we have a tendency of putting the heavier work onto the man rather than onto the woman.

MR. MACNULTY: That isn't always so. In the modern worsted weaving room the woman is working under exactly the same conditions. There are the same number of looms and under modern production methods she will be working the same number of hours producing the same grade and quantity of work. I have seen the tables and the law of average is equal, and yet they will not be susceptible to the same number of accidents. And why that is so is something I should like to get out of this meeting before I go back East, and I don't care if it comes from a round table or square table as long as I get the information.

ADJOURNMENT

Wednesday, September 28, 1927

The second session was called to order at nine-fifty o'clock by the chairman, G. W. Cook.

CHAIRMAN COOK: We will start our meeting today with nomination and election of officers for the coming year.

A new system which we have adopted, and which has been adopted by all sections, is to appoint a nominating committee at the last executive meeting (in our case it was held in April) and the Nominating Committee we try to appoint is one made up of old officers who know whom they can bring in on a slate at the end of the year, and in that way we avoid some of the mistakes and confusion which arise by appointing a committee in the last minute who brings in a slate of officers whom we are not sure will serve. Heretofore, we have elected officers only to find out a month or two later that they could not serve and then it was necessary to get out and straighten the whole section again. The other sections are doing this same thing now.

In April I appointed a Nominating Committee consisting of the following members:

Mr. Harvey Saul, Past Chairman.

Mr. B. F. Griffith, Former Secretary and Vice-Chairman.

Mr. H. C. Washburn, Present Secretary.

Mr. Saul is not here, but Mr. Sherman, I believe, has brought in with him the decision of the Nominating Committee. Mr. Sherman, will you report?

Report of the Nominating Committee

R. B. SHERMAN (U. S. Finishing Co., Norwich, Conn.) The nominations, as agreed upon by the Nominating Committee, are as follows:

Chairman, H. C. Washburn, Fisk Rubber Company, New Bedford, Mass.

Vice-Chairman, R. P. Knapp, M. D., Cheney Brothers, South Manchester, Conn.

Secretary, D. Frank Lord, M. J. Whittall Associates, Worcester, Mass.

Chairman Membership Committee, Harry W. Donald, American Mutual Liability Insurance Co., Boston, Mass.

Chairman Statistics Committee, Harvey Saul, The United States Finishing Company, Providence, R. I.

Chairman Bulletin Committee, Leonard Howard, Duncan Cotton Mills, Greenville, S. C.

Chairman Publicity Committee, Arthur Barlow, Armstrong Cork Company, Lancaster, Pa.

Engineering Representative, G. W. Cook, Travelers Insurance Company, Hartford, Conn.

CHAIRMAN COOK: You have heard the nominations as presented by the Nominating Committee. Have you any other nominations you would like to put before the Section. If not, will someone move that the secretary cast one ballot for the slate as proposed?

(Mr. Arthur S. Johnson, American Mutual Liability Insurance Co., Boston, Mass., moved that the secretary be instructed to cast one ballot for a unanimous vote. The motion was seconded and carried, and Mr. Washburn, the secretary, cast the ballot.)

CHAIRMAN COOK: We will now open our program with a paper from a division of the textile industry which we have never had represented in the Section—the

carpet industry. Mr. Lord will read a paper on the organization and functions of a safety committee in a carpet mill.

The Organization and Functioning of a Safety Committee in a Carpet Mill

D. Frank Lord, Safety Engineer, M. J. Whittall Associates, Worcester, Mass.

I have been asked to talk to you today on a subject that is very near to my heart and one that I hope will be of some interest and benefit to you. There seems no good reason why this organization should be restricted to a carpet mill, so any of you who are not connected with such a mill need not feel that my thought I may be able to give to you is applicable only to a carpet mill, but may be applied to any industrial plant.

Not very many years ago, such an organization was not known to be as essential to the successful operation of an industrial plant as it is today. Men had their part to perform and they did it to the best of their ability. As they did not have the modern machinery to aid them in their tasks, they were not exposed to as many hazards as they are through the hustle-bustle methods of the present time.

Neither were "Compensation and Liability Acts" in force and a working man was more or less responsible for his own actions in regard to accidents, but today the operators, through the aid of numerous organizations and the cooperation of their employers, are being given the consideration that humanity and good business methods demand.

That there is an interest now being taken by the wage-earner himself in accident prevention puts me in mind of a little story regarding a negro on a piece of construction work. This negro applied in the usual manner for employment, was accepted by the foreman and told to go to the timekeeper for registration and his number check. Among the questions that were asked each new employee was, "Who shall we notify in case of accident?" The negro, much alarmed and with fear expressed in every feature, nervously replied, "Well, massa, if dere is goin' to be an accident round here, why just you notify me."

There is all around us a growing interest and practical effort on the part of wage-earners themselves in accident prevention. Plant safety organization is the manifestation of this employee interest in safety. The fact that the employee's interest in safety may have been inspired by educational efforts and examples of others should not obscure the fact that a growing interest has come about and is one of the notable manifestations in the accident prevention movement. It is common knowledge that compulsory compensation for accident injury growing out of employment has been a great stimulus to that which is better than accident compensation, namely, accident prevention.

In the substitution of compensation for the old employers liability principle, there is seen the displacement of a conflict idea by the cooperative idea as the basically just and sound principle upon which to deal with the whole matter of industrial accidents.

The liability according to negligence plan was one of leaving employer and employee to themselves, each standing on his individual rights as to accidents. The compensation plan, on the contrary, is that of treating industrial accidents as a common liability of modern industrial life to be cooperatively dealt with by society as a whole. It is a combination of all concerned to share the burden imposed by accidents, and it is because this burden is now so widely understood that it has stimulated the work of complete prevention.

And so in this country it has become the pride of many well conducted busi-

nesses to take care of their problems of safety; and why? My answer is, "Because it pays." It pays in money and pays in terms of satisfaction. It pays in money because the operator can be found at his accustomed place, producing goods that the employer supposedly sells at a profit, and in satisfaction because the employer likes to see his workers on their job, hale, hearty and able to fill their accustomed places in the economic fabric in this great industrial world of ours.

I cannot refrain from quoting the managing director of the National Safety Council, W. H. Cameron, in a statement made by him as follows:

Typical safety committee of employees. M. J. Whittall Associates, Worcester, Mass.

"The benefits accruing from accident prevention work among employees are manifold. To the companies involved, the movement has meant a saving of millions of dollars and thousands of lives. To the workman, it has meant the prevention of a tragedy and the possibility of pursuing his work with the knowledge that he is safe from injury and in pleasant surroundings!"

Insurance companies which have taken over the burden of assuming payment of compensation, have made definite allowances on the premiums for certain conditions as outlined by them, provided the insured will adopt their recommendations, and one of these is an organized safety committee for the plant. So you see that there is a direct money saving here. Also direct saving in money is made to the insured for having had good accident experience, and this reflects on the amount of premium paid.

I feel that it is a very commendable idea that a general safety meeting should be held at which the plant manager or someone to speak for him should address his employees and tell them in unmistakeable language what he intends to do

in respect to accident prevention and what he expects them to do. Many times meetings for the executive and supervising staff of large plants are held where the manager has explained exactly where he stood and what he expected; yet at a meeting held perhaps a year later, it developed that many of the same men had entirely forgotten his earlier statements, were uncertain of his attitude towards safety, and as a result were themselves blundering hopelessly. This discovery gives manager no little surprise as he has assumed that one public explanation of his personal attitude would last indefinitely. On the contrary, a continual follow-up is as necessary in accident prevention work as in any other phase of industrial management. Of course, we all know that the managers of our large industrial plants have many and various duties to perform and that their time is pretty well consumed; but I do not recall a single instance where I have suggested that the manager of our plant send some word either of encouragement or criticism to our safety organization, that it has not been done and it is an absolute fact that whenever such communications are received, encouragement is spread throughout the entire organization and a great feeling of satisfaction is felt.

Assuming, then, that the management of your plant has been sold on the safety movement, it is up to you to carry out their desires.

Qualifications of the Safety Engineer

In the first place, it is necessary to select a man as a safety engineer who can cooperate with other safety engineers from the various organizations who have laid down certain essentials. These may or may not be applicable to the conditions in your individual plant, but with the aid of a good safety engineer many thoughts may be brought out modifying and improving the requirements. The following qualifications I consider essential in a successful safety engineer.

1. Knowledge of safe practice. A general knowledge of what constitutes a safe machine or a safe condition is essential, but with all the diversified industries it is impossible for any one to be sufficiently acquainted with all the manufacturing processes to immediately pass on the safety of them. However, there are certain basic principles in safety engineering, the same as in other engineering, and if he knows these basic principles he can shortly get the details required.

2. Knowledge of human nature. Human nature being so different every person cannot be handled the same. One man may be driven, another may be led. Therefore, to get men to play safe, a successful safety engineer must know which method is most effective. Whether it is better to appeal to a man's reason or to threaten him with discharge, or to picture misery and suffering in order to get him to follow safe practices, the safety engineer should be able to decide. In this he must use what is commonly known as tact, for the wrong approach will often lose a man to the safety cause. The safety engineer must have the right approach, just as much as the salesman.

3. Personal characteristics of a safety engineer. He must also be sympathetic. It is sometimes unpleasant to have to listen to the troubles of a workman when you have plenty of your own but it is often worth a lot in future safety dividends. The successful engineer must have a likeable personality and quality of leadership, for men will follow those in whom they believe and trust, and a pleasant personality combined with a sensible mind will make for this leadership.

He must not be afraid of getting his hands dirty. Many a would-be safety engineer has been a failure because he felt his position to be very important instead of letting others feel its importance. It has been said that you can't

teach safety from behind a desk and I know of no truer maxim. The office of a safety engineer should be the whole plant and he should spend most of his time there. Neither can you teach safety by writing letters. Personal salesmanship is the most successful method.

4. The right mind for a safety engineer. Three of the attributes necessary to successful safety engineering are judgment, initiative and vision. To these I would also add a fourth—an analytical mind.

The question of judgment often enters into safety work especially in mechanical safeguarding, for in many suggestions put up to the safety engineer he must be able to recognize the good points and cull out the bad ones. At the same time in discarding the bad or impractical suggestions the question of fact must enter and the suggestor be left without offense.

Initiative is a very important quality in any job but in safety work it is all important for many of the old ideas in educational safety work are "done to death" and the successful safety engineer is the one who thinks up some new way of teaching safety and puts it across.

One of the most important qualifications for a good safety engineer is to be able to get things done. I have seen more embryo safety boosters lost to the cause by the fact that their suggestions for safety were not promptly carried out, than for any other reason. This is partly a management proposition, but the safety engineer should fight for the carrying out of good ideas and not let them die an early death or lose a good booster by not carrying them out promptly. If the idea is not good, let the suggester see why, but don't simply put it aside to be forgotten, for the author will not forget.

Finally the safety engineer must have an analytical mind and be able to take the accident report and diagnose the plant's trouble from this report, and act on the results. In fact, on starting safety engineering that should be his first task. The analysis of these accidents, together with a close inspection of the plant should at least do away with the accidents due to lack of mechanical safeguards, provided, of course, action follows by furnishing these safeguards.

The Ideal Safety Engineer a Wonderful Man

As safety engineers you should visit other plants and see what is being done, in fact, the broad-minded safety engineer would invite a brother safety engineer to visit his plant and criticise or offer suggestions. I always like to have them come around because they give me suggestions and see things which, because I was used to seeing them, had gotten by me.

Summing up, I find the ideal safety engineer is a rather wonderful man for he must be:

1. A mechanical engineer.
2. A civil engineer.
3. An electrical engineer.
4. A diplomat.
5. An orator.
6. An educator.
7. An executive.
8. A public health expert.
9. A sanitary engineer and
10. Finally a good mixer.

A good parliamentarian is a necessity to preside over the committee meeting. This will tend to keep up interest and will certainly demand respect for the meetings, which should never be allowed to move along in a loose, slipshod manner.

I feel that the safety engineer usually makes a good secretary, as he is at all times informed regarding the requirements, and usually has a discrimination due to his training and therefore is able to help greatly in keeping suggestions and reports in a direct line with safety measures exclusively. A safety committee meeting is the place for the discussion of safety measures only.

My experience has brought me to feel that the best persons for this committee are found in the heads of departments, overseers and foremen. I believe it wise to teach the leaders and they in turn pass their knowledge on to the worker. I feel very strongly in regard to this point and I would suggest to any of you who may feel that this safety committee is not functioning as he might wish, to scrutinize the membership closely and see if there are any members who do not appear to be leaders in the plant among their fellow workers. Let me emphasize the word *leaders*. Never allow any of your so-called "drivers" to dominate in your committee, as there can never be true cooperation with your workers if they feel that they are being driven instead of being led.

Details of the Safety Meeting

Now as to the meeting, place and time. This should be arranged to be held at a time to interfere as little as possible with the duties of the members. I find that a meeting held on the first and third Wednesdays at 2:00 p. m. seems to be the most advantageous in the plant with which I am connected. I feel very strongly that two meetings a month are none too many and that the time allotted, namely one hour, allows a sufficient time in which the member may properly bring to a close his day's work. And as to the opening time, I find that this also allows the member to get his work started before coming to the meeting. As to the place of meeting, I cannot too strongly recommend having a room especially prepared for this meeting. I do not feel that the proper amount of respect can be demanded if your meeting is held in the corner of a shop amid boxes and bales which may form the seats for members and officers. Every plant has some room that can be made available for this purpose and the members are not liable to have their minds distracted by the operations going on about them. Have a desk for the chairman and the secretary. Have safety pictures, posters, diplomas and other ornaments on the wall; and above all, provide comfortable seating accommodations for all members. This may seem to be a little thing but you know how true it is "that the little niceties in life attract many."

Now as to the meeting itself, I am going to give you a description of one of the meetings as it is held in my own committee, and you may be able to gather some material for your own use.

The meeting is called to order promptly at 2:00 p. m. by the chairman and if the chairman is unable to be present, the vice-chairman occupies the chairman's seat. Then a roll call of the members is taken, and right here, let me say that there are many times when it is not possible to attend, and so the member sends a substitute. Should the member be unable to attend regularly, his substitute may become a regular member. As the time allotted to this meeting is during regular working hours, absentees are rare and when they continually occur, their names should be dropped and other appointments made.

Next, the minutes of the preceding meeting are read. Then come the reports. First, the report of the nurse at the first aid room is read and acted on. Then the detailed report of any accidents that have occurred since the last meeting are read. These are thoroughly discussed and causes of accidents analyzed and measures to prevent repetition recommended and referred to the safety engineer for action.

At the meeting held on the third Wednesday of each month, the report of the Workmen's Inspection Committee is read and as this is a very important part of the safety organization, I will go into this phase of the work more at length later. Any communications received are next read and referred to proper persons for further action. Unfinished business comes next and I am going to be perfectly frank with you, that this phase is one that reflects the most credit on your committee by keeping the volume down to a minimum and should only be tolerated when there may be absolute necessity.

Then comes new business at which time an open discussion of all safety measures applicable to your plant should be had. It is here that the greatest good can accrue to your work.

At the meeting held on the first Wednesday of each month and under the heading "For the Good of the Safety Movement," it is our intention to always have a speaker or some type of entertainment for approximately 30 minutes. These speakers usually are available from many sources and if your secretary watches out carefully, he will be able to secure many good speakers from the National and State Councils and also local Councils; leading engineers, men from insurance companies, doctors, nurses and many others.

Adding Interest to the Safety Meeting

Recently I have tried to have an occasional meeting, where after the routine work has been disposed of, someone entertains us with something that does not bear directly upon safety. You know that diversion, if not carried too far, proves very beneficial. A short time ago, the Silver Masked Tenor, whom you have all heard over the radio, was at one of our meetings and sang for us several selections and the members all voted that we had had a good meeting and the time was well spent. A real, live secretary can arrange for an occasional meeting of this kind without prejudicing the value of the meeting a particle.

The records of the meeting are now written up by the secretary and copies of same sent to each member of the committee as well as the administrative officers of the plant. This gives a close touch with the committee and the management, and an occasional letter from the main office lends encouragement if a good period without accidents has been enjoyed and also gives us a decided impetus to do better if we have fallen down on anything. I cannot be too strong in my recommendation to keep this close touch.

Now, just a word concerning the Workmen's Inspection Committee. It is the duty of this committee to make a monthly inspection of the entire plant with a view to finding any items which may be the cause of an accident. These items are all too familiar to any of you for me to take the time to enumerate. This inspection is in addition to the weekly inspection made by the safety engineer and you can readily see that the chance of missing any of the dangerous points in connection with the buildings or the machinery is reduced to a minimum.

This committee consists of three men first appointed to serve 4, 8 and 12 months respectively. As each term expired they (or their successors) were appointed for a period of one year so that the committee is never without the membership of someone experienced. The report from this committee is due at the second meeting of each month. Just prior to this meeting the safety engineer calls the Workmen's Inspection Committee together in his office and goes over their report before it is submitted to the safety committee as a whole, for the purpose of segregating any items which do not necessarily come under the safety committee's jurisdiction. This is also an opportune time for the safety engineer to check up with the inspection committee any items which

have been previously reported, acted upon and recommended for correction. It is also a good time for the safety engineer to impress upon the minds of the members many fine points that might escape their notice, and I feel very sure that the intelligent and comprehensive work performed by this committee has brought about many changes in our plant that have been very beneficial.

You may feel that this preliminary meeting may have the effect of the so-called "parlor caucus," but I sincerely believe that this little get-together before the report is turned in not only strengthens the report but keeps the committee alive to their duty. The report is then submitted on standard forms to the secretary of the safety committee by whom it is read at the next meeting under the heading of "Reports," is then laid on the table and taken up for consideration, under the heading of "New Business." At this time the members of the safety committee discuss the questions openly and such items as are questionable are referred to the safety engineer for his consideration and report at the following meeting. The real, live safety engineer will not allow any of these suggestions to pass without giving them his very best consideration.

Accurate Knowledge of Accident Experience Necessary

James J. Hill, of Railroad fame, once wrote, "Ample and accurate information is the best step toward success for everyone." Accident prevention cannot be intelligently and effectually applied to the conditions of work obtaining in any industrial establishment except on the basis of knowledge of accident experience.

To some extent, this experience may be that of others; in other words, such information on accident cost and occurrences as can be gathered from known experiences of similar establishments. However, valuable this may be to the industrial institution or safety engineer, it is manifestly of much less importance to him than the experience of his own establishment. Lessons from the latter are learned in two ways. By study of mass experience and by scrutiny of individual accidents.

The most valuable knowledge we possess is that which comes to us through making a mistake, through experience. Accidents are mistakes as well as experience. To realize on an accident is collecting revenue from the refuse.

We cannot get the full value out of the accident experience unless we are able to interpret the meaning of individual accidents and in particular uncover their true causes.

I believe a permanent record of individual injury cases and of the plant's accident experience as a whole is essential to good industrial management. Even the small industrial concern which employs but a few men having infrequent accidents cannot afford to be without an insurance record.

Instead of relying upon snap judgment and upon mere recollection of where accidents have previously occurred or upon fancied ability to predict where they will happen in the future, each industrial concern should be engaged in building up an accurate comprehensive record of its own experiences which in the end will prove to be its most reliable guide to effective preventive work. The fact that no serious injuries have ever occurred in a plant and that any sort of injury is so rare, should not deter the safety organization from collecting full information on even minor injuries and near accidents. For it is often such plants that operate with a false sense of security brought about by ignorance of their own operating hazards. It may also be said that such plants are apt to suffer severely from lowered morale, uncovered losses and increased insurance rates when the unexpected accidents arrive.

If a plant has over two or three losses from injuries a year, or is large enough to maintain its own hospital, part or full time physician, or even a

first aid room, it is desirable that injury records be kept on forms or cards with which the physical examination record of the injured and the record of any other injuries or sickness may be conveniently filed. The whole constitutes a complete physical history of the individual during his employment. Whether the records are kept in a ledger of the loose-leaf form, on cards, or upon forms in a letter file, every injury requiring first aid attention and every case of sickness developed at the plant or coming under the care of its foreman, nurses, first aid men or doctors should be made a matter of record. Copies of reports to State Labor Departments, insurance companies and others should also be preserved as well as all other data, pertaining to the accident or health history of the individual employee. Such records should be filed in convenient form and always be readily accessible. These records also form the basis of reports to the safety organizations and also form the basis of reports of competitive departments in the same plant.

We have already noted the value of leadership. Each industrial establishment must have leadership in its accident prevention work and above all intelligent and far-sighted leadership.

A leader of recognized standing is essential and he might well be an operating official or at least one of the manager's immediate assistants. An operating official is desirable for this post in order that the effort may be recognized as a distinct part of operating procedure and not as merely subsidiary to it. The selection of an official of relatively high rank not only gives the work dignity at the outset but makes possible prompt decisions on important matters.

It is obvious furthermore that work which is later to become a beneficial part of the operator's duties should be supervised by one of the operating officials. This same official should also have general supervision over first aid and medical work, compensation and relief and fire prevention since these subjects are closely related to accident prevention. By such an arrangement any possible conflict with these subjects is avoided.

Getting Highest Value Out of the Bulletin Board

There is no doubt of the value of safety bulletin boards as a medium for disseminating general and special information on accident prevention, for maintaining interest and for strengthening the conviction among the employees at large that accident prevention is not merely the hobby of the manager or the safety committee but is an integral part of the great industrial movement.

The form and type of bulletin boards, of course, can vary with the size of the plant and this matter can well be left to your safety engineer. They must be so placed and maintained that they may be examined by the men without personal inconvenience during moments when they are not otherwise employed. I find that the posters issued by the National Safety Council serve the purpose very nicely. The material presented by these posters is fresh, interesting, appropriate and true.

One unsound or amateurish poster that provokes ridicule may queer a board for weeks to come. The board itself must be neat, well-painted and suitable for the purpose. A shabby and unkempt board repels attention and labels the safety movement unimportant. Safety bulletin boards do not alone prevent accidents and the mere posting of safety posters, no matter how strong and compelling their message, will not of itself engender a spirit of safety in the plant.

No poster should be allowed to remain in place any great length of time as the material on them will become stale and unprofitable. I also find that if an operator continually persists in doing something about his machine that appears to be dangerous, such as grinding without goggles or running a saw

table without the guard in place, it works to great advantage to find a poster that is suited to his actions and fasten this poster directly in front of the place where the man is working. I have known instances where the worst offenders have become converted. Too much emphasis cannot be placed upon proper selection, placing and handling of the poster phase of accident prevention. There are so many sources from which appropriate safety posters can be obtained that there seems to be no excuse for the smallest plant not being adequately supplied with them.

Even in old age men retain their interest in sports and contests, but in youth they demand to be something more than mere spectators. They desire active participation. It is quite apparent that the games which endure are those which present opportunity for exercise of personal strength, endurance, foresight or skill and in which there is at the same time an element of chance.

Accident Prevention is a Good Game

Another element, however, is required, a similitude to the experiences of life itself. The game of accident prevention meets all requirements and if safety is staged as a contest, men who might otherwise give it but passing notice will enter into it and soon become absorbed; but, like any other game, the objective must be clearly defined. The manner of playing and scoring must be readily understood and the score itself must be made known. Furthermore, this is a game in which men are not opposed to each other but are as a team pitted against obstacles and hazard. To win, the entire team (the plant personnel) must play the game; otherwise the goal line of effective accident prevention will never be crossed. For this purpose, records must be kept of the accidents happening in each department. Careful scrutiny must be made so that every department will be as nearly as possible on the same footing. You can all see how unfair it would be to put a machine shop in competition with a weave room, and so in order that all departments may be on a fair basis, a system of scoring by percentage is necessary.

In order to maintain the utmost interest in safety work, it seems necessary to give as much publicity as possible to the work of the safety committee and they must be supplied with information that will be both helpful and inspirational.

The Workmen's Inspection Committee in particular should have ready access to all safety standards and to the report of regulations of the State Department of Labor, as well as such publications as deal with accident prevention. I find that the NATIONAL SAFETY NEWS, *Safety Engineering*, and "The National Safety Council Transactions" serve this purpose admirably and it is the custom in the plant with which I am associated to have sufficient copies of each one of these publications to pass around among the members and they are continually being encouraged to peruse them at their leisure.

Another feature which can be brought into play in the accident prevention game is the maintaining of suggestion boxes, placed so that any workman in the plant can put his suggestion in the box unsigned if necessary but to bear some identifying number. In arranging these boxes, it is also a very important thing to place at the side of each box, a supply of properly printed and methodically arranged blanks, together with a lead pencil fastened by a string to the box itself. You have got to make it easy for the workmen to put in these suggestions, and if he is required to hunt up a piece of paper and a pencil, he is very apt to have his mind diverted from what might be a good suggestion.

Some plant managements feel that the promiscuous talk that can be made about accident prevention is a detriment to the cause but I feel personally

that the more talk you can create about the plant, the more interest you can build up.

I am not entirely in favor of a long list of safety rules, regulations and instructions. I am more convinced that good leadership which must be maintained throughout the safety organization is far better and will give greater results than to place in the hands of the new workman too many rules and regulations for him to follow.

The chances are that he will spend so much time trying to evade the rules and regulations that his production is liable to suffer. This belief on my part may be due to the very small turnover of labor which is in our plant and I feel that every man knows what to do and how to do it.

If you have boys employed in your plant, don't forget that you were once a boy yourself, and try to impress on the boy's mind that skylarking and horse play are no part of his daily work. And if you are able to show him the error of his ways and appeal to his sense of decency you will always get good results. Don't drive the boy! Lead him along in the way he should go.

Boys Will Take Advantage When the Whistle Blows

There is one thing that has always amused me, when the whistle blows at our plant at quitting time; and that is the sight of perhaps 25 or 30 boys running from the door of the mill toward the gate. There seems to be a little rivalry as to who will get home first to get the big potato. Of course, where these boys run out into the driveway, which by this time has become pretty well congested with the older operators, there is a danger of their bumping against them or tripping them up. So I had occasion to talk to these boys and told them that I didn't want them to do it any more; but just as soon as my back was turned, the running became more violent than ever, in fact two of the boys collided and fell, one skinning his shin pretty badly and the other his arm. I tried to make an example of these two boys, which succeeded very well, and now, much to my surprise and pleasure, the boys leave the mill in a perfectly orderly and sane manner. Running has been discontinued and I think it perfectly proper to say it was a result, not of driving but of trying to show where it was wrong.

The first impressions of the new employee are vivid and apt to be retained. He is probably more influenced by what he sees than by what he is told. If he sees safety signs, safety bulletin boards and various safety devices, he will probably be somewhat impressed. If he is talked to on the subject of safety, he will undoubtedly listen but for final confirmation of what he has seen and been told, he will look to the action of the men around him.

In conclusion I want to say that there is overwhelming evidence of the success of accident prevention efforts in hundreds of scattered and diverse industrial establishments. Their experience has proved beyond question that in both large and small plants, safety work can be made to pay for itself in actual savings. As industrial accident prevention spreads, as it passes out of the experimental stage and becomes an admitted requisite of efficient industrial management, its true value will be indicated by consistent reductions in the statistics of the larger groups, industrial as well as others. That such reductions have not yet manifested themselves to a larger extent clearly is no discredit to a movement, the success of which depends so largely on educational effort.

No industrial executive, however, has justification for delaying the adoption of an accident prevention policy pending a more universal demonstration of the success of the safety movement. Sufficient evidence of its success is already

at hand. Further delay in organizing and prosecuting the work will only lead to additional accident expense and the loss of many indirect advantages that accrue from safety work. Furthermore, an executive who fails to take his proper place in a movement that has been generally accepted and bids fair to become universal, retards industrial progress and permits the continuance of an inconceivable amount of human suffering that he might be instrumental in obviating.

CHAIRMAN COOK: I know Mr. Lord has said a lot of things to which we all agree.

I hope someone here has something on which they can disagree with him, because I am sure he is going to defend his ideas before us today.

We will then proceed to the next feature, which means we have to use the stereopticon machine. Mr. Washburn.

H. C. WASHBURN (Wingret Division, Fisk Rubber Co., New Bedford, Mass.): I thoroughly agree with one little portion of Mr. Lord's paper, because of the fact that most of these little suggestions which you will see displayed on the screen are the result of suggestions made by employees in the plants over which I have supervision. Too much stress cannot be placed on the advisability or the advantages to be gained by suggestions coming from employees, either with regard to guards or safety suggestions.

The most important thing is to give the employee the impression that his suggestion has merit. In almost every case where the suggestion is not feasible or, in some cases even foolish, he believes himself that he has a wonderful invention or suggestion, and you have to encourage him and not tell him that it doesn't amount to anything, or can't be worked out. You have to give him to understand that it has possibilities, that you will consider it and take it up with the management, and after it has been given due consideration a report will be made to him as to whether it is advisable at the time to follow it out, or whether because of a financial standpoint it is better to postpone it to another time.

In every case it is important to bring back a report to the man who makes the suggestion. If you don't, he not only gets the impression that the management does not care anything about his suggestions, but that they are not sincere when they say they want suggestions; and, as I say, if the report does not come back to him or her, nine times out of ten that employee is going to tell some other employee and our aim for more and better inventions or suggestions will not be forthcoming.

New Developments in Safeguards for Textile Machinery

H. C. Washburn, The Fisk Rubber Company, New Bedford, Mass.

In this paper no mention will be made of such general guarding as can be found in plants making sincere efforts to reduce its accident experience. In safety work, as in all lines of endeavor, it is the little things that count, and I will mention some of the simple developments in new safeguards which have recently been devised and which have given such favorable results in our plants.

Although many of the newer types of textile machinery are equipped with slipper locks when delivered from the manufacturers there still remains grave danger of accidents from machines now in use and without such attachments. Regardless of all rules and regulations governing the cleaning of machines while they are in motion, employees are prone to take a chance of injury, especially if the size of their pay envelope is rated on a piece work basis. Such work should never be attempted until the machine has entirely stopped. However, after this precaution has been taken an occasional accident will occur due to a belt creeping from the loose to the tight pulley or in consequence of another employee starting the machine without first ascertaining the reason for its remaining idle.

Such danger is particularly present on speeders and slubbers. On these frames the shipper rod usually extends across the entire length of the machine. Interlocking devices are not feasible from a production standpoint as it would become necessary for an employee who is piecing up ends at the further end of the frame to return to the head end in order to detach the locking device.

One of our second hands devised a simple latch or locking device which effectually prevents the possibility of an accident arising from the causes previously mentioned. Made of one-eighth-inch angle iron and two inches in length, with a square hole at each end, one end is loosely attached to the set screw nearest the shipper rod on the creel stand at the head end of the frame. When the machine is in motion the latch hangs suspended from this set screw. Twisted at the center the halves are at right angles, and after the machine has been stopped the operator slips the free end over the head of a set screw on the shipper rod. Slipping of the drive belt is thus prevented and repairs or cleaning may be done in safety. As an additional precaution the device is painted red and a letter "S" in red is painted on the creel stand rod immediately above it.

On another type of speeder the attachment is constructed of heavier material and in two parts. One part is securely bolted to the curved top surface of the frame head just above the shipper rod guide. The other part is fastened to the first by a bolt on which it may be turned. When the speeder is running this second part rests on the frame head surface. In the locked position it is thrown over and down, the end resting in the opening where the shipper passes through the guide.

Almost a Fatal Accident and Its Result

On a third type of speeder having a shipper rod at the rear and penetrating the frame head, the attachment is similar to the preceding, but fastened to the frame head below the shipper rod. To lock this frame the latch is thrown up and over with end resting on the rod between the head and shipper rod collar.

This locking device, differing only in its adaptability to the machine on which it is to be used, has been attached to slubbers, drawing frames and combers. On slubbers one-half is bolted to the back surface of the frame head. The other half has a slot in one edge which slips over a set screw in the shipper rod collar effectually preventing moving of the rod.

For drawing frames the device is much like the first-mentioned speeder latch, differing only in that this latch is flat instead of twisted. The locking system, however, is the same.

Since the installation of these inexpensive devices we have had no accident on any of the frames due to the causes which the attachment is designed to prevent.

The feasibility and application of a safety lock for starting switches in our plants is the result of an incident which most fortunately did not result in an accident. An overseer, noticing that one of his twisters was not in operation, inquired of an employee as to the reason. The employee replied that a fixer had been making repairs at the opposite end of the frame, but had completed the work and probably had neglected to start up the frame again. The overseer therefore threw on the switch, but observing that the rolls were not turning, immediately threw it off again and rushed to the further end expecting to find a fixer with mangled hands or arms. Fortunately the fixer had gone to the shop after additional equipment without notifying anybody that the machine should not be started pending his return. The incident so affected the overseer that he resolved a repetition of the possible accident should never occur again, at least in his department. Locking the switch in the off position

on each machine appeared to be the logical solution of the matter and steps to this end were immediately taken.

The result is an iron casting consisting of a grooved base, curved on the inner service to fit the front contour of the switch box, the upper portion a four-inch disk with "Safety First—Do Not Start" in raised letters on one surface. The attachment is black, the disk face is red with letters gilded. When in locked position the groove fits over the switch handle securely wedging the device to the top and front of the switch box and effectively preventing the switch from being thrown or frame started. When the switch is off the attachment hangs suspended below the box by a short chain. When in use full protection from the inadvertence of employees is accorded anybody working on or about the frame. As in the preceding cases, the device is easily adaptable with slight changes in design to other types of switch boxes.

One of the Great Hazards in the Mill

One of our greatest hazards coincident in all of our plants presented itself in the compressor warpers. Admitted a dangerous machine at four different points, namely, the compressor roll, compressor chain weight, compressor gear and drive belt assembly, the safety department decided to devise a suitable method of preventing an accident at each of the points involved, notwithstanding the fact that the experience at each plant had failed to show an accident ever having occurred on any of its machines. Information was available, however, that serious accidents resulting in crushed and broken arms and legs had occurred in other plants. In one case a fatality resulted. As far as we were able to learn no method of guarding had previously been attempted. Considerable time was devoted to devising a feasible guard for the greater hazard, that is, the liability of an employee becoming caught between the beam and the compressor roll carrying a pressure of some 2,500 pounds. The other three hazards presented little difficulty and were rectified by recognized standard guarding. Not only should the guard serve as a prevention of accidents, but production must not be retarded. After considerable experimenting, a guard was made and installed at one of the plants and later at the other two. They have been very satisfactory, do not in any way interfere with production, the operator appreciates its value as a means to his protection and the cost of manufacture is nominal.

In detail the guard consists of a wooden frame sixty-six inches in length, nineteen inches in width, made of one-half-inch by two-inch pine stock covered with one-half-inch mesh galvanized iron wire. It is attached by three collar hinges to a one-inch cold rolled steel rod fastened to the sides of the frame on which it may be thrown back at any time should the beam need attention or is removed. The base of the guard is faced on the under side with five-eighth-inch half round cold rolled steel and rests on the yarn as the beam revolves.

Almost every experienced weaver realizes the seriousness of accidents arising from flying shuttles. Consult any one of our weavers and they will invariably tell you that a flying shuttle is one thing connected with the operation of a loom with which they hope they will never come in contact. A flying shuttle may be due to any one of a number of mechanical causes—a loose or broken picker stick, a loose rocker shaft, a loose picker stick bolt, etc. Various guards have been devised to overcome this hazard of the textile industry and although today most looms are equipped with some type of shuttle guard, in many cases they serve only to divert the course of the shuttle in its flight to a direction where the danger of injury to an employee is the least.

Our plants were no exception to this rule. The larger looms were equipped with guards of heavy wire in two halves screwed to the top of the reed cap.

Investigation of the many and continued accidents to our employees showed the guards to be unsubstantial and easily bent or moved out of shape and position when struck by the shuttle. Our line of work demands a shuttle weighing about a pound and a half and nineteen inches in length. The severity of an injury resulting from the blow of a shuttle of this size may readily be envisioned. We also found that although the shuttle occasionally left the loom before striking the yarn, as well as at any place through the yarn, it usually left on the magazine end. We needed a guard that would remain stationary at all times and after some experimenting we have devised one that not only meets this requirement, but has solved the flying hazard. Our present guards are made of three-quarter inch by one-eighth-inch steel, twelve in number, machine screwed to either the top or front side of the reed cap, about seven and one-half inches apart with the exception of the first three.

The first prong, so called, is fastened to the reed cap just above the mouth piece of the box on the magazine end; the second just inside the filler motion about two inches to two and one-half inches distant from the first, while the third prong is far enough away from the second to allow sufficient room for the temple and filler cutter. This arrangement makes it impossible for the shuttle to leave the shed when in motion. To insert or withdraw a shuttle but one way is possible, namely, to slide the same under the second prong and withdraw between the second and third.

"D" Stands Both for "Danger" and for "Don't"

If it is necessary at any time to change the width of the fabric our filler motion remains stationary and the change is made on the off side of the loom. The temple is moved to position between the next two prongs.

Although designed primarily for coarse work we believe that this type of guard should be adaptable for finer work on any loom having a reed cap, the number of prongs and their distance apart depending of course on the length of the shuttle. No better proof of its effectiveness can be asked for than our frequency reduction in accidents from flying shuttles since its inception. We have never had a shuttle leave the loom since the installation of this type of guard and we are fully convinced that it never can.

In conclusion I will mention one other development adopted as a further safeguard against accidents in our plants. It is not a guard in the strict sense of the word, yet it might be considered as a prevention against carelessness or inattention. Occasionally an operator will remove a guard while the machine is in motion, regardless of all rules or instructions to the contrary. On many of these guards we have painted a letter "D" in red as a cautionary measure. Should an operator attempt to lift or remove a guard or cover, the letter appears prominently before him as a warning that danger is hidden beneath; that the frame should be stopped before he proceeds. Posted on the bulletin boards and about the room were different bulletins, some illustrated, advising the employees that the "D" stands for danger. These were removed as soon as it was believed all were familiar with the meaning and object of the letters. Possible results of the application of this idea may be realized by anybody interested in safety work. In the application, however, care has been used lest the "Ds" appear too frequently and the employee gain the impression that nothing about him is safe. In this case the lettering defeats the purpose for which it is applied.

All the safety devices which have been mentioned were devised to rectify hazards pertinent to the textile industry; hazards which have or might arise in our plants. Some of them might be used with slight changes in design in other lines of industry. Their strongest points are that they are simple and

inexpensive, two things which appeal to both manufacturer and official alike, and they can and have prevented accidents.

CHAIRMAN COOK: Several years ago I believe it was Harry Donald of the American Mutual who called my attention to the hazards connected with beam warpers, and discussions with several people revealed the fact that none had heard of accidents on beam warpers. There had been some fatalities and since then we have uncovered, for example, an accident to an employee going to work or coming from work, I don't know which, who was passing one of these beams in motion and his overcoat caught in the beam and he was drawn in and seriously injured. If they had not been able to stop the machine he would have been killed. In Saugatuck Valley we had a case where a beam warper in operation caught up one of the oper-

ators and wound him up in the beam with six inches of warp on top of him. After they cut the thread and got him out there wasn't much left of him.

I am glad to know that the Ningret Division of the Fisk Company have solved that guard problem. I was fortunate in seeing this shuttle guard demonstrated at New Bedford and it is uncanny the way the shuttle will jump back into the shed again. It jumps out and almost turns head down and goes right in again.

I am interested in getting expressions from Mr. Bohlin and Mr. MacNulty on how that type looks to them from the silk and woolen and worsted end. Do you think it feasible?

MR. BOHLIN: As far as I can see off hand, it does seem feasible. I wouldn't say definitely, of course, until we have had a chance to experiment and try it out. But I am tempted to try an installation of that sort.

CHAIRMAN COOK: I would like very much to see it tried and would also like to learn what results you obtain.

What is your slant from the woolen loom, Mr. MacNulty?

MR. MACNULTY: I disagreed yesterday, and I still do. I can see, looking at his machine, that there is no comparison. When I said the weaver would not be

blamable for a shuttle flying out, it was correct. He also is correct, but we are speaking of two different methods. In this case the operators fill in the shuttle themselves, but on up-to-date automatic machines they are filled automatically by mechanism.

Just what it will do on a modern worsted loom I can't tell, because that automatic filler is there.

MR. WASHBURN: We do have some looms of the magazine type, and, of course, the guard has been put on each type of loom just the same.

MR. MACNULTY: I mean the putting in of the shuttle. The weaver has nothing to do with putting it in.

Flying Shuttles Are Almost a Thing of the Past

MR. WASHBURN: Yesterday I heard mentioned the question of target guard. We had that in mind at one time but we came to the conclusion that that side of the shuttle with the sharp metal point would do more damage to the target and to the shuttle itself than some other type of guard, and we felt that the target guard would be of very short duration and, therefore, discarded the target guard and went to work on the shuttle guard.

MR. MACNULTY: I would say in fairness to modern mills that flying shuttles are almost a thing of the past. They are now very, very rare. I don't think it is a very serious problem in the textile industry, and I still come back to the thought and will say that it is not so much mechanical as it is a human problem.

CHAIRMAN COOK: Now, gentlemen, are there any questions you would like to ask Mr. Washburn?

W. C. WROE (American Mutual Liability Insurance Co., Atlanta, Ga.): I would like to ask Mr. Washburn if he has ever tried the reversing of those beam warpers? We experimented with some after we had been told that it absolutely could not be done. There are a good many mills doing it today in the South and apparently it eliminates the point of hazard where the iron wraps around the beam.

MR. WASHBURN: It isn't as satisfactory as the original method for the reason that you don't get the compression from the compressor roll, as you do in the original way. For that reason we roll ours in the direct way. You don't need the guard when you wind your roll in the other direction. However, you have got a hazard when you wind it in the other direction which lies in the fact that an operator may, for some reason or other, slip or fall and get the yarn in between the beam and arm. When revolving toward the back he is going to have his arm carried around to where he gets that pressure with the yarn, and he gets an awful jam, especially with the tie yarn. Although that method of building a beam is all right for some concerns, we feel that we get more satisfactory results having them rolled directly. In fact, we know we have a better pressure and the yarn lies smoother and more compact.

CHAIRMAN COOK: Since we have no more speakers on the program, we can throw the meeting open to discussion and any one who wishes to bring up any subject and wishes a discussion can start something, and I am sure every one will be glad to enter into a discussion on some topic.

F. A. FREDRICKSON (Industrial Commissioner of Wisconsin, Madison, Wis.): We have had considerable difficulty with a great many of the machines in the mills in the textile industry in Wisconsin, primarily in our carding machines and on some of the looms, spinning jacks and so forth. That is due not so much to the point of operation as it is due to the gears, belts, pulleys, sprockets, chains, compressors, etc.

I was just wondering what you gentlemen are doing in the line of protection on carding machines, belts, pulleys, and so forth.

I recently went into one of our mills and succeeded in getting them to protect

the carding machine belt and pulley hazards and also the gear hazards on that machine. We had had a few accidents which were quite serious, and I got them busy on a protector for those belts, pulleys and gears. After they had succeeded in guarding up a number of their carding machines I took a photograph of them and sent it to the National Safety Council. I am sorry it is not here so you could see just what they are doing on that subject.

I think there is a big hazard on those machines. In one of our plants this was particularly so because the machines are so close together, due to inadequate space. It gave them very little room when getting in between the cards, and they were constantly subjected to danger because they came in such close contact with those belts and pulleys. In another mill the condition was somewhat better, but still the hazard was there. Those belts run from the ceiling down to the pulleys that drive the cards. They were easy to safeguard and they put in a belt and pulley guard that closes them up completely. They can readily move in and around the cards now and safeguard themselves from those former hazards.

I am seeking additional information and if any of you gentlemen have anything to say along that line, I should be glad to hear from you.

CHAIRMAN COOK: It is true that you can go into a mill, even in our more modern mills, and see a whole room full of cards and find no belts or gears guarded on those cards. I imagine if one were to go through the mills in New England he might go through 100 mills and not find more than one where gears and pulleys are guarded. There are now improved layouts and there is distinctive progress being made in improvements in textile machinery. On the other hand, if you examine the statistics on textile mill accidents it is pretty hard to develop a very large percentage of accidents due to the belt hazard and gear hazards on cards. In fact, the card bugaboo has been the old English style card hazard due to leaving the door open after stripping.

I would like to see the textile mills with their cards guarded and a lot of them ought to have their belts and pulleys guarded right now.

MR. WROE: The only solution to that is the individual motor driven card. I am not going to enter into any sales talk on that equipment, but down in the South several mills have such equipment and they have experimented with guards on belts and pulleys and they always run into a jam. We also tried reversing but did not have good success. We have had absolutely no success with guards around belts, gears and pulleys and, as I say, the only solution is the motor driven card, but that is a very expensive proposition.

MR. FREDRICKSON: I realize your position, gentlemen, but restriction on accident work in the state of Wisconsin is such that when an accident does occur on such a machine it is a direct violation of the order of the state and naturally the increased compensation applies. When our comeback is this: they don't have them guarded in the South or in the East, they say, "We can't help what they do down there."

CHAIRMAN COOK: I know the Wisconsin situation very well, and if we had the same incentive to guard belts and pulleys we would get a lot more guarded.

I think if the problem were attacked, we could have it done, too. It is probably due to the large number of machines in proportion to the number of employees. If we had a man on every card, we would have a lot more of the men hurt. It not only applies to your cards, but to the entire mill.

ADJOURNMENT

The Accident Experience of the Industry

E. Ross Farra, Manager, Grand Rapids Safety Council Grand Rapids Michigan

We have come to the Sixteenth Annual Congress of the National Safety Council, and it gives me great pleasure to again greet many of you whom I have greeted nearly every year for the last seven years. The present chairman first became connected with the Woodworking Section at the Congress in Milwaukee in 1920. Since that time many safety men have come into the work and a number have gone out of the work for reasons best known to themselves; but I am glad that I see before me today some faces that were present in that meeting in Milwaukee even years ago. As many of you know this is my second experience as chairman of this section.

It is well that we take account of stock once in a while to find out just where we are going and whether we are making any progress along our way. Therefore, the program committee saw fit to annex the topic on which I plan to speak at this time, viz.: The Accident Experience of the Industry, including a resume of outstanding safety measures discussed at past Congresses.

I have always been taught that in the last analysis results are the thing for which we should work. If we look at the statistics for the Woodworking Section for the last seven years, 1920 to 1926 inclusive, we will not show as great an advance as we would have liked. The frequency and severity accident rates for the various years and the plants reporting are as follows:

Year	Plants Reporting	Frequency	Severity
1920	19	43.00	4.46
1921	42	54.74	1.47
1922	69	63.84	2.71
1923	79	42.26	3.36
1924	72	49.56	3.08
1925	100	44.20	2.75
1926	136	62.05	4.51
Seven Years	517	53.81	3.16

If you look at it from that point of view, each year individually, it isn't very illuminating, but if you take the seven years you get a better idea.

I sat in a conference on Saturday morning where at least 30 men who are interested in statistical work were discussing whether we ought to figure our accidents on frequency or severity or both. I have been informed for years, that if you talk about frequency of accidents alone you don't get the picture, and I am also pretty clearly sold upon the idea that if you talk about severity alone you don't quite get the picture. However, if you just think of the severity here, we have made quite a decrease; if we take into consideration the severity and frequency both we haven't made so good a showing.

I think one reason particularly why the Woodworking industries have not made the decrease, as a whole, that the other industries have, has been due to the fact that the woodworking in many industries, especially in the remanufacturing industry, is only an incident.

For instance, Mr. Orth of the American Car & Foundry Company has very large plants; many of them have really big metal fabricating departments. They have very large woodworking departments, too, but those fellows are interested in both, not as though it were a purely metals proposition, where they are interested in just one thing.

Many of the larger companies which are having accidents in their woodworking departments are taking very little interest.

1. In a recent analysis of 1,725 plants which reported to the National Safety Council their accident frequency and severity for 1926, we find that the frequency rate of all plants has been reduced almost 20 per cent and that the severity rate has been reduced more than four per cent. We will notice from the above figures of the woodworking section that, with the exception of 1926, the severity of accidents has made quite a considerable decrease, although the frequency has not changed much. While we were very sorry that accidents have not been reduced more in the companies reporting in the Woodworking Section, yet there are many factors to be taken into account and we believe that real progress has been made which will demonstrate itself in the next few years. While only 19 plants reported their accident frequency and severity to the National Safety Council in 1920, this year 136 reported their last year's experience. This shows a healthy interest in safety because these folks would not have reported their experience unless they were interested.

2. Another favorable condition is the changed attitude of a very large group of manufacturers toward accident prevention. I can very clearly recall some companies that are now doing a real big safety job in their plants who a few years ago thought that safety was all bunk.

3. A number of industrial plants, both large and small, have recognized in the last year or two that while safety is a humanitarian principle it is at the same time a money-saver to any industry that goes into it in a wholehearted way, determined to stop accidents.

"Old Timers" Maintain Passive Resistance

I want to read here a letter that I received from an officer of the Woodworking Section who isn't present this morning. He is the representative of a large insurance company, operating out of New York City, a man who has very wide experience in accident causes, and this is what he says:

"The industry as a whole, especially the remanufacturing end, has been afflicted with a condition which has not been peculiar to other industries. I am speaking now of the smaller size concerns engaged in cabinet making, furniture manufacturing stair building, etc., which comprise the greater part of the remanufacturing industry and are scattered throughout the country. These concerns, at least the majority of them in this section with which I am familiar, have been worked largely with "old timers" in the business, mostly Germans who learned their trade on the other side, and while not entirely antagonistic to the safety program were absolutely disinterested. The majority of these men were of the type who did not openly oppose the measures taken for their welfare, but simply maintained a passive resistance to all such overtures.

"There is no other industry that I know of, outside of the chemical which has had to endure this condition. We have many cabinet plants in this section which we have been working on for years and have failed to make any indentation until, as in some cases, the 'old timers' died off and new blood introduced into the plant became receptive to our arguments. This is the only reason that the woodworking industry as a whole, is not so far advanced as some of the other industries, not because of poor leadership of the section, but because of the greater majority of the employers made it their business to employ full-fledged journeymen even if they had to import them rather than make an effort to teach apprentices. In some cases that have come to my attention even the few apprentices in the shop were friends or relatives of the journeymen who had brought them over from Germany or Austria to finish their trade. This condition, of course, has been aided to some extent by the reluctance of the American-born boy to learn a trade.

of Vancouver, British Columbia, and to the best of my recollection it is the first time in the eight years I have been connected with the section that we have had representation from that part of the country. When we get a man who is so interested in safety that because of the conditions he sees he goes and sells himself to a large organization like the British Columbia Loggers' Association, then goes into that organization and puts over safety in such a real way as I know our speaker has done, we surely want to get some of the good things that he wants to offer.

It gives me great pleasure to introduce to you now Major Henry Steere-Clark, safety director, British Columbia Loggers' Association, Vancouver, B. C.

Safety in the British Columbia Logging Industry

Major H. Steere-Clark, Safety Director, British Columbia Loggers' Association, Vancouver, B. C.

In discussing safety in the British Columbia logging industry, I will confine myself entirely to logging operations as carried out west of the Cascades in British Columbia apart from the mountain section, owing to the logging systems employed being somewhat different, there being two distinct associations.

I am aware that all here are assembled with one aim in view and that is the elimination of preventable types of accidents in industry. What a wide field of endeavor safety really presents to enthusiasts (and I look upon you all as enthusiasts) with unlimited scope for those who are really sincere in their endeavors to carry on humanitarian work as well as the elimination of one of the largest economical wastes in our industries, particularly so of the logging industry.

From records that are available and from observations made in your own logging operations, under modern conditions, it must be conceded that the necessity for thoroughly organized safety work is apparent and should be considered a very important factor in modern business, not by any means merely tolerated as a side issue, as often is the case.

The increasing rates of assessment levied by the Workmen's Compensation Board upon the logging industry in British Columbia (which at present is 4½ per cent of an operator's pay roll) made it imperative that something be done to offset this economic waste. The severity of accidents is reflected in their cost, and as the cost of accidents during the five years, ending 1925, in our industry alone had increased out of all proportion to the increased labor employed, and the increased compensation paid to injured workmen, some steps had to be taken to effect a remedy.

It must also be realized that with few exceptions the methods of modern logging, with the high lead, skidder, sky line, etc., were in use in 1921 as they are today; and yet, the average length of disability (in days lost) for "temporary total disabilities" increased each year from 37 days in 1921 to 42 days in 1925. But in 1926 this was reduced to 40 days, demonstrating that safety work was having its effect throughout the entire industry. The accident cost being \$50,000 less in 1926 than in 1925.

In May, 1925, the B. C. Loggers' Association, comprising forty-one operators, employing approximately 6,000 men in their 67 camps and accounting for 85 per cent of the production on the coast, realized that sound safety work should be introduced, and I was asked to organize a department of safety within the association and carry out a plan of safety education that would be practicable and acceptable to all operations. This presented a prob-

em, for it is readily understood that what may be favorably considered by one operator would probably not suit another.

A glance at the map of British Columbia with its many inlets and a coastline of approximately 3,000 miles, upon the greater part of which logging operations are scattered, will give you some idea of the large territory that had to be covered; and it was soon realized that camps could not be visited at frequent intervals without a numerous staff in the field entailing a large financial outlay. Therefore a good deal of the preliminary work was commenced through the mails, until a personal visit was made when the organization of a camp in regard to safety was thoroughly gone into.

All camps were furnished with a standard, well-built bulletin board installed in a prominent place and furnished with a quantity of suitable posters, obtained from the National Safety Council, supplemented with special posters each month, gotten out by the association safety department specializing our own particular logging hazards.

Quite a number of our operators took out memberships in the National Safety Council through the association, the service rendered by the Council being invaluable in assisting operators who were somewhat apathetic to take an active interest in safety and look upon it as important.

The only safety supervision (and that from a mechanical standpoint only) at the industry received to this date was the periodical inspection of camps by Government boiler and railroad inspectors. Their inspection called for a compliance with the existing safeguards as required by law. That the work of these inspectors is of a high standard and productive of good results is amply demonstrated when the records show that less than one per cent of our injuries had been caused through faulty equipment coming under their jurisdiction.

Yet the number and severity of our accidents during five years ending 1925 increased to a large degree, showing that efforts must be concentrated on an educational program, of which more will be said later.

Re-education a Difficult Task

It was at once realized that we had embarked upon a difficult job and, to quote other authorities, "one of the hardest tasks in the world is to re-educate habit workers and lead them to form entirely new habits at their work, namely use of 'safe thinking' and 'acting' and to exercise constant caution which is often forgotten on the many hazardous jobs found in the woods." It was found difficult too, to make men realize the large margin existing between fear and action, particularly among the "chance-taking" and "bravado types" of men which abound in our industry.

All camps are visited as often as possible, when safety committees are interviewed and a general safety meeting of all employees with the management is held. These safety meetings, supplemented by interesting motion pictures, and held in the evenings, are invariably responsible for a 100 per cent attendance, which is voluntary, and really forms an entertainment that logging crews are looking forward to.

In passing, it may be stated that lectures are sometimes difficult to render, owing to the large number of employees who have but a very poor knowledge of our language. It has been found that those who do understand, however, are it along to their fellow workers.

Each camp, no matter what its size, has its own safety committee, upon the efficiency of which, I am convinced, depends in a large degree the success of accident prevention work.

I think I am correct in saying that there is no more transient population than found in the Pacific logging industry, many men being veritable nomads. No less than 18,000 men were shipped from our own employment office to our camps, which employ normally 6,000 men, making a complete labor turnover three times a year; and yet, while these men are at camp, they are in the main good workers, using the experience gained in many camps, and to use a phrase, "spreading the tricks of the trade" including safety.

Therefore it was found necessary to form a committee in two parts, namely a "permanent one" composed of part management and part reliable old timers, say to the number of four, to which is added a "floating committee" of six, making a total committee of 10 or 12. To avoid favoritism, the floating committee is changed each month and fresh men invited so that safety thought and active interest will spread as quickly as possible and thus all men may have a chance to take an active part. This method prevents the committee from becoming stale and uninterested (their own ideas becoming exhausted if kept on too long); having a permanent nucleus, the committee is prevented from being broken up through men quitting their jobs, and at the same time fresh blood is introduced with new ideas serving to maintain interest.

Free Discussion at Committee Meeting Encouraged

Many good suggestions, not only from a safety standpoint, but from one of efficiency, have been lost to the industry owing to the prevailing idea among many men, (and I've no doubt there was some truth in the statement) that if they made any suggestions they would be considered as "wise guys" and marked men, in line for being fired off the job.

We encourage our camp foreman to be present at all committee meetings, which are held at least once a month. All formality is completely done away with. The discussions then practically become round table talks. Any suggestions brought forward are thoroughly discussed and recommendations made for their adoption or rejection. Each "accident" or "near accident" that may have occurred since the previous meeting is carefully gone over and the committee's opinions quoted on their report. These reports are made in duplicate, one copy sent to the association safety department, the other displayed on the camp bulletin board and kept for record. This enables the whole crew to see how their committee functions, how their interests are studied, and keeps my office in constant touch with safety work in camps. Many sound and constructive criticisms are made on these reports, which are disseminated by circular from our department. Such items as "carelessness," "should have known better," "it was his own fault," etc., are often quoted by the committees and are having their effect on the camp crews, who realize that they are being criticized and helped by their fellow men.

To further encourage the safety spirit, a number of operators put up cash prizes and prizes in kind, to be drawn for at the end of each month, during which the crew should be free from a compensable claim.

A modern Pacific logging operation using a railroad (and they are very much in the majority) calls for many varied types of labor with their own particular hazards. I will dwell briefly on them in the order of operating a claim of timber.

When the claim has been cruised and surveyed, the grading gang clears the right of way to grade the proposed road to the timber. This work calls for the felling and sawing into suitable lengths of heavy timber with the hazards of fallers and buckers referred to later. The blasting of stumps and rock cuts entails many dangers in handling and using powder, many men being injured through not taking safe cover, sufficient time not being given to a delay fuse,

crimping detonators on a fuse with their teeth instead of using crimping pliers and using any old gritty stick to tamp charges with. Many grading gangs work by contract, furnishing their own equipment, which we lead them to keep in shape.

Construction work in building bridges and wharves calls for skilled labor and many hazards are met with, those of falling and hand-tool injuries predominating.

The construction of a camp, which is more or less temporary, carries with it all the hazards met with in building operations, the hazards being increased owing to the rough nature of the ground. Floating camps on rafts have the extra hazard of men drowning, although hand rails and board walks are frequently used, more so since safety work had its inception.

Next in order are the "steel crews" who lay the track. Track-laying machines are sometimes employed but more often manual labor is used, steel and ties being brought forward on flat cars and then manhandled. It is here we find the hazard of crushed feet and strained backs through the improper handling of heavy weights.

The log sawyers, better known as "fallers and buckers," then start felling the timber and cutting it into suitable lengths. In our woods this work is generally done by contract, the men being paid by the 1,000 feet board measure cut, often taking unnecessary risks in their endeavors to make large wages.

Only the merchantable timber is felled, leaving snags and small timber standing, excepting those that may reach the crew near spar trees, should they fall or be pulled down. These snags constitute a serious hazard when yarding commences, but it is too costly to have everything standing cut down, therefore extreme care in their vicinity is the only remedy.

Natural Hazards of Tree Felling Serious

It is in this difficult class of work that most of our serious hazards are met. I refer to natural hazards that often cannot be foreseen. Many men have been killed and injured through falling limbs alone. The upper limbs in some green trees cannot be seen, and if rotten even the blow of an axe or sledge hammer or a slight gust of wind in the tree top may cause it to fall unexpectedly. The fallers, having selected the direction the tree is to be felled, make a notch in the butt, known as the undercut. This notch faces the direction the tree is to fall, the tree being sawn from the opposite side, just below the undercut.

The enormous weight of the tree, or a tree that may be "timber-bound" (unless leaning in the direction of fall) has a tendency to bind the saw, therefore steel wedges are inserted in the saw cut in rear of the saw, which are driven with a sledge hammer. The cutting proceeds until but a few inches are left, leaving part of the tree uncut for the full width of the butt. The wedges are now further driven, supplemented by more wedges if necessary until the tree falls. The uncut portion of wood is not completely broken through until the falling tree is nearing a horizontal position. This prevents a kick back and controls a tree in the direction of its fall.

The hazards met with are numerous; burrs from wedges or badly tempered hammer-heads, "side-winders" (in close timber) caused by the falling tree striking and putting other trees down, and limbs that may be thrown some distance by trees that whip back and forth when grazed by falling trees. Much of our standing timber is from 150 to 200 feet high, the velocity of a falling limb (often less than three inches in diameter) at that height strikes with sufficient force to inflict fatal injuries.

The buckers (who work alone, apart from the fallers) cut the fallen trees

into suitable lengths and they are exposed to similar dangers, particularly if working too close to fallers (a practice that is much discouraged) where they may be caught by the tree that is being felled. The call "timber," which is issued as a warning, is sometimes forgotten, very faintly called, or given too late to allow a man to get into the clear, with disastrous results for anyone within reach. Bucking a tree on the down-hill side accounts for many accidents, this being overcome by careful workers propping the logs ere they are cut through. Slipping, tripping over brush, and falling injuries are numerous, particularly in hilly country, when the timber is down, an extra hazard being added when carrying sharp tools.

How It Is Done

A spar tree is now rigged to which all the logs in a setting are hauled. This tree is carefully selected as to size and soundness and if a suitable one is not at hand where required, one has to be raised. The head-rigger, who is generally in charge of all rigging, climbs the tree with belt, rope and spurs, to free the trunk from limbs and cut off the top to the desired height which may be anywhere from 150 to 220 feet. This is a dangerous undertaking unless extreme care is exercised. A number of cases are on record of men accidentally cutting through their belt-ropes and falling. Wire-cored ropes are now used. Topping a tree is a safety measure, to prevent it breaking off when the spar is jarred in yarding (and falling on the crew working below it) and to prevent the wind from blowing it down before it is guyed, after the surrounding protective timber is cut. The spar is rigged with guy wires, as many as 20 being employed where powerful machines are used; then the various blocks are secured, some weighing 2,000 pounds, through which the moving cables pass, all lines being off the ground. Owing to the enormous sudden strains which this spar has to bear, the rigging of a spar calls for a high order of skill and sound equipment. A number of spars have been pulled down or have broken under the strain, either through some invisible defect in the tree, or because poorly guyed. Large margins of safety are employed in the diameter of guys and the wire cable straps used to carry the blocks. The large hauling block which is subject to heavy and quickly varying strains, sometimes 180 feet from the ground, is further secured by a short safety-strap attached by a shackle to a guy wire.

This causes the block to slide down the guy, in case the strap breaks, and prevents it from striking the machine or crews working below. The spar is barked where guys and blocks are secured, to prevent loose bark falling when yarding begins. The "High Lead" system of yarding commences (is most frequently used) and has many hazards, which cannot be remedied except by exercising constant caution and safe thinking.

The main hauling cable, with a diameter of $1\frac{3}{4}$ inches, and a breaking strain of 83 tons, leads from the drum of a powerfully-gearred machine, passing through the main block in the spar, to the full length of a setting over the felled timber. To the end of the main cable short pieces of line with hooks known as "chokers" are attached, as well as a line of less diameter known as the "haul-back." The "haul-back" passes through two or more blocks, secured to stumps or trees near the ground, and leads to the spar tree through another block to a separate drum.

The hook-tender with his crew of choker-men secure the chokers to logs. Upon a signal being given, which consists of a series of blasts of a steam whistle, controlled by a whistle man near the hookers, the logs are then hauled at great speed towards the spar tree, where they are dropped.

It can be readily understood that countless changing hazards are ever present.

The logs crash through and over anything in their path, bringing down snags and small trees that were left standing, and throwing anything that may be in their way to some distance. The various obstructions met with bring an extra sudden strain on the line, causing it to "whip" a considerable distance laterally, thereby inflicting serious injuries, often fatal, to those men not in the clear. The haul-back line carries the empty chokers and main cable back to the hookers. The empty chokers are fairly safe until they reach the ground and wrap around any obstacle, such as a root or sapling, which they either throw aside or glance away from, causing the chokers to fly about with great velocity over a wide area.

In "skyline" and "skidder" operations, the choker hazards are somewhat reduced, as the chokers are kept suspended near a traveling carriage, which runs upon a fixed skyline. The skyline is some distance above the ground and is stretched between the main spar and a back spar over the logs to be yarded. The injuries met with are wire strand punctures, blows from chokers or cables, being struck by snags or brush, foreign matter in the eyes and tripping and falling.

Loading the Logs

Logs are now loaded on skeleton or flat cars, which have two steel bunks, or beds, for the lower logs to lie upon. These logs are kept in place by steel "cheese blocks" (about one foot high) attached to adjustable chains.

Great care has to be exercised by the head loader in building his loads so that they are evenly balanced and not top-heavy. In spite of this care, the varying size and shape of logs, together with a temporary constructed track, cause many logs to fall off in transit, endangering both the train crews or anyone near the track.

The lifting of logs onto cars is carried out in many different ways, some employing separate loading engines, others have yarding machines with a loading unit, but the method is practically the same. The loaders secure the loading tongs or slings around a log, which is then picked up by the machine and swung over the car and lowered in position. Frequently tongs are pulled from a log when suspended, caused by trying to grasp too large a log for the size of the tongs, instead of using slings, or by soft spots in the wood, or by the bad placing of tongs. Logs falling from tongs, particularly when one end has been lifted higher than the other (as in duplex loading) are a great danger to all within reach. Sound judgment and constant vigilance in handling these heavy weights of various shapes are paramount.

The transportation of logs is practically a railroad operation with its accompanying hazards. Most of our locomotives are geared and move slowly compared to rod engines. All trains are thoroughly equipped with air brakes and are kept in good shape. This is very necessary owing to the very hilly nature of our Coastal logging operation, grades as high as 8 per cent are constantly met with.

Temporary tracks are used until the timber along them has been gotten out, the steel is then taken up and laid into uncut timber.

The prevailing hazards are caused by logs falling off loads when in motion (and I venture to say that all logging railroads in the North-West Coast regions have their quota of fallen logs along their tracks).

The loaded cars are taken to tidewater and dumped. The logs are then sorted and built into booms or rafts by the booming crews and towed to the mill or market. Not many accidents occur among boom men: ax cuts and pike pole injuries prevail, of course, falling into the water is frequent when riding logs, cases of drowning are on record, although rare.

I may mention that in interviewing 75 hand loggers on one lake operation alone, whose work is in a class by itself, and who constantly work on steep ground over deep water, only 21 could swim. All boom crews are lectured in regard to swimming and resuscitation.

Our larger operators have well equipped machine shops employing skilled mechanics where all locomotives and yarding engines are kept in constant repair. The usual hazards found in all machine shops are present, such as belt, spoke, lifting jack, overhead crane, emery wheel, shipping, electric and oxyacetylene and battered percussion tools. These are kept in shape and mechanical guards applied as far as possible. We have found some trouble through men not wearing their goggles when using a torch or emery wheel; this is gradually being overcome.

First Aid Practice Becoming General

Far more attention and interest have been given first aid since the inception of safety work. All camps are required by law to have a qualified first aid attendant, together with an equipped first aid room. This is very necessary, for it takes many hours to reach a doctor or hospital from some operations. Locomotives and yarding machines are also furnished with a certain amount of first aid equipment. Men are using first aid kits more often, causing a considerable reduction in former neglected injuries.

In some camps fallers and buckers, who sometimes are long distances in the woods, also have a first aid kit enclosed in a tin container which is stuck on a stick and placed near the grade they are working by.

The so-called "tough guys" are gradually getting won over to safety after posters and talks on serious infections are presented to them.

Infections from neglected minor injuries, as reported in 1925, amounted to 112 cases, the year 1926 having but 20. Truly a remarkable decrease.

Each camp also has a blacksmith shop where shackles, pins, clevises and tongs are made and kept in repair, in addition to the general blacksmith work necessary for camp equipment upkeep. The saying, "A skilled craftsman is known by the way he keeps his tools in shape" is never better demonstrated than when visiting the camp smith's shops. Some of our operators seem to be proud of a blacksmith who has lots of spare time on his hands during working hours. Recently when in company with an operator, I visited his camp. As we were getting from the launch, I noticed a man fishing on the wharf during working hours. The operator pointed him out to me as his blacksmith. At my expression of surprise, he said, "That's a skilled man at his job and I am willing to pay him good money while he's amusing himself, for I know that the rigging, etc., that he makes is standing up and in good shape, and that's what he's here for. I would fire a smith if he had to pound on an anvil all day and every day, it is a sure sign that his work isn't as good as it should be." On inspecting that shop which is but a temporary shack, similar to many others in the woods, it was a model of order and efficiency.

In conclusion I think you will agree by the foregoing that the constantly changing hazards met with in our industry, where few mechanical safeguards can be adopted, together with a constant changing of labor, present a problem which can only be overcome by intensive safety education, thoroughly backed by the operators in making men realize a sense of responsibility for their own personal safety as well as the safety of their fellow workers.

Our association feels that it is doing its best for the industry and its employees by making sincere endeavors to put a stop to a large economic waste.

It has seemed regrettable to me that the word "accident" is so commonly used as it now is when in reality we mean thereby an injury or bodily hurt. Being a good Democrat, however, I bow to the seeming wisdom of the majority and in the remarks to follow do adopt the commonly accepted meaning of the word. But still I feel a more fortunate selection of a speaker could have been made—one more familiar with the lumber industry, a practiced mill man who from training and experience better knows its peculiar hazards and is more qualified to speak of them and to offer more intelligent suggestions as to how to meet and overcome them; for what I may have learned is rather that character of knowledge acquired by one who watches the game from the bleachers or side lines.

Fatal Accident Makes a Deep Impression

It is true that for a short period in my life I was a participant in the industry and it was during this time that I first saw an accident resulting in the loss of a life. Two cousins of mine, just out of college, had built a mill in Southwestern Georgia which we thought admirably adapted to its purposes, but with no single thought of the safety of those to be employed in its operation. Neither one of us, I think, was indifferent to human suffering and I believe either one of us would have gone to any extent to alleviate pain or prevent an injury to any man, woman or child, but in the erection of this plant no intelligent effort—indeed, no effort at all—had been given to this end, because we had adopted as true the then prevalent idea that sawmilling was a dangerous business and to those who engaged in it accidents and injuries were a necessary consequence and a part of the price to be paid. And, as a result of our ignorance, but not indifference, I witnessed my first sacrifice of a human life on the altar of industry, one which could have been prevented had we possessed the foresight to cover a conveyor chain over which men had to pass.

I do not believe that any normal person is careless or heedless of the sufferings or misfortunes of his fellows. One of the finest traits in the character of the average American citizen is his quick and sympathetic generosity—the readiness with which he springs forward to relieve suffering when it is brought to his attention. As evidence of this witness, the far flung and magnificent activities of the American Red Cross and the response of the nation to appeals of the Florida and Mississippi Valley storm and flood victims. I profess some love and much confidence in my fellow countrymen and venture to say that when it is brought to the knowledge of the nation that the so-called industrial accident is unnecessary—a useless cause of suffering and waste of life and limb—the nation will respond as a unit and join hand and heart with this Council in its endeavors, but the nation, as the individual, must be first made to see and understand, and then it will assume its responsibility, and here lies the greatest opportunity of the National Safety Council.

Twenty years ago the state of mind of the country was the same as ours when we built our little Georgia sawmill, but due to the efforts of this body and the far-seeing men who were its founders a change has come and a still greater one will follow. Sensible men no longer accept as a fact that in industrial and manufacturing enterprises accidents and injuries must occur.

The manufacture of lumber—sawmilling—is reckoned as one of the most dangerous of industries, particularly when the logging side is considered, as it needs must be, as the mill cannot run without timber. The hazards start in the woods and do not end until the finished product has been loaded on vessel or car. Few industries combine more diversified dangers. Component parts are the felling, loading and hauling of the timber before it reaches the mill, and in

all parts of the operation will be found the manifold hazards of steam, electricity and the machine shop, as well as those peculiar to the industry itself. It would be impossible in the time allotted to point out even the most dangerous of these hazards, beginning with the unloading of the logs at the mill. I can remember when I thought that this was one of the most hazardous operations possible—certainly that I ever saw—but I now recall with what amazement I heard an eminent gentleman in addressing this body less than five years ago suggesting, if not advocating, unloading logs by first partially chopping the car stakes on the side next the pond and then shoving the logs off with what he called a “poke.” I am unfamiliar with the operations of the far West, but an injury in unloading logs can be made impossible (excepting always those caused by rank human carelessness), in the Southern Pine mills by using trip stake pockets and shoving the logs into the pond from behind with a crane or specially designed machine which has recently been built for this purpose. The records of our own mills for the past five years will verify the truth of this assertion.

About two years ago I was invited to address the Southern Pine Association at its annual meeting in New Orleans on the Fundamentals of Accident Prevention. In that address I said in effect that no efforts toward accident prevention could be entirely successful without a recognition on the part of the employer of labor, be it in the sawmill or elsewhere, of his duty and moral obligation from a human and not a pecuniary standpoint, to protect to the fullest extent the health, life and limb of his employees. This necessarily to be accompanied by a willingness to meet the obligation, having in mind always the real object to be attained is the conservation of human life and happiness and the mitigation of human suffering. I would, if possible, emphasize that statement here and add the further assertion that safety, or the prevention of accident, must be recognized and treated as a major part of the fixed policy of the industry seeking to secure it. In one sufficiently large to justify it, employing any considerable number of men, it is essential that there be a department of safety with a recognized head—a fixed department of the business itself and of equal dignity with each and every other department of the organization. It can't function otherwise. If the safety engineer is made to feel that his efforts are subservient to this, that or the other department, his heart withers as do the tendrils of a vine upon which hot water is poured, and his future efforts are as barren of results as is that vine of bloom or blossom.

Your Presence Indicates Interest

Your presence at this council is sufficient testimony that the owners of the operations represented by you recognize and have accepted this moral responsibility and the fact that the safety of their employees is a major problem of industry, worthy of and demanding the attention of its chief executives.

I believe that each of you who has had experience will agree that every step toward accident prevention must be based upon a foundation of education. Man lives and everything he does in his every day life is according to habit, and a habit once fixed becomes a part of a man's life. It follows, then, that the thing most to be desired in accident prevention is the education of man to think “Safety” and sanely, and it further follows that he will live it in his daily work. Continuous and persistent effort, and not spasmodic campaigns or drives, can secure this state of mind.

The fundamentals in accident prevention are the same in the sawmill as in all other branches of industry. Into its operation there exist the same elements of machine power, material and man power. All three first enter into the erection of the plant itself, which should be constructed with the maximum of light.

foreman is responsible for the safety of his own men. The individual man should not be lost sight of. Leadership in the men, I think, should be developed. Let the men themselves feel that they have a place in the safety organization and a responsibility for the safety of themselves and their fellows. Appeal to their common sense to counterbalance the influence of the scoffers who are found in all organizations. Get the confidence of the rank and file and you can build up a morale, it means as much in industry as in the Army. A man's pride will carry him as far as will his nerve.

Let me give you our experience. We have operations typical of those in the Southern pine belt. The usual conditions of floating labor and labor turnover, the large percentage of negro labor and illiteracy exist, and the usual number of obstructionists common to all similar operations are to be found. For some years our people have been convinced safety was to be desired and was possible to be attained, and it fell to me, as one of my manifold duties to try to put it across. We made some progress it is true, but the results were most unsatisfactory to myself because I knew we could do better, and I have no reason to believe were they more so to the property owners. I had long been convinced no satisfactory results could hope to be secured until someone was put in charge of the safety organization, charged with the duty, and that duty alone, of teaching and preaching safety from early morn to dewy eve. Just when our owners reached the same conclusion I don't know, but about a year and a half ago they employed our present safety engineer. Now I know that I knew more about logging, saw milling and labor and social conditions in our operations than he did, and he had to spend at least six months in acquiring a knowledge and information I already had, though I must in all honesty admit he knew lots of things I did not and don't know yet.

Figures That Show Safety Improvement

It would hardly be fair to refer to the accomplishments of our engineer during the first six months of his employment, and as reluctant as I am to cite figures and statistics in a talk of this kind, my central idea could not be impressed without giving you a statement of what has been done during the first eight months of this year as compared with the same months for 1926, and in order that full credit may be given I make these comparisons throughout the entire operations.

	Lost Time Accidents			Total Accidents		
	1926	1927	Percent Decrease	1926	1927	Percent Decrease
Lumberton Mill	242	83	65.7	367	224	39.5
Kiln Mill	57	39	31.5	192	79	58.9
Total Mills	299	122	59.2	559	303	45.8
Logging Department	181	136	24.8	215	200	7.0
Turpentine Department	31	16	48.3	39	19	51.3
Total Camps	212	152	28.3	254	219	13.7
Grand Total	511	274	46.3	1044	542	47.9

This record includes a number of injuries which, in reality, did not occur. I have stated we in Mississippi have no compensation law and the limit of

recovery is the sky as stretched by the cupidity of an unscrupulous laborer as aided and abetted by certain individuals who have no scruples at all, and only a license to practice law.

The result is a multitude of claims that are rank fakes—but as we have them to defend, we also include them in the record. This result has been accomplished with the most trivial expenditure for the installation of mechanical guards. It was done by direct appeals calculated to reach and arouse the men on the job. My fixed belief is similar results can be secured in any organization, provided a man is at the head of the Safety Department as capable, conscientious and untiring in his efforts as is and has been our Engineer, Mr. Buchanan.

There may be those present who from lack of opportunity have not learned the value of safety as a fixed policy. These comparisons are commended for their consideration.

Lumber Industry Contributes Much to Human Welfare

The lumber industry has contributed much to human happiness and weal. Unfortunately it has likewise contributed to human woe. Its toll in life, limb and suffering has been great.

To one who has gone through a virgin pine forest with its tall and straight brown columns, its canopy of green and blue, its carpet of green, gold and violet underfoot, the vistas of dogwood and azalea between the columns of pine, he can imagine it was in such a setting the poet stood when he said "the groves were God's first temples," temples of beauty and grandeur such as only the hand of the Creator could fashion, but temples, alas, which for years have been desecrated and profaned by human sacrifices as ruthless and unnecessary as those of the pagan idolaters and fire worshipers.

The lumber industry is necessary to human welfare. No substitute can be found for natural wood in many of its uses, and its production must go on, but, thank God, American industrial enterprise has realized the production and manufacture of timber and lumber need no longer be accompanied by the mutilation of the bodies and the sacrifice of the lives of our fellow humans. This Council has done much to awaken the conscience of the owners of Industry to their own responsibility, and is doing even as much to help them to meet their obligation. May God prosper them and this body in their undertakings.

MR. WALLACE: There are a great many members of this body who have no practical knowledge of the sawmilling or lumbering operations in the south. Our people have had a moving picture film taken of their operations, from start to finish, from the virgin forest to the loading of the finished product. It has been taken as actual operations occurred, there is not a stunt in it, there is not a thing in it, that was attempted to show anything that didn't exist. The cameraman simply went into the woods and through the mill and took things just as they happened day by day, and just as they were occurring in the course of the work.

The photographer who took that picture has kindly consented to bring it up here with him, and it will be shown here tomorrow morning at nine o'clock, and tonight at eight o'clock.

CHAIRMAN FARRA: Mr. Wallace's paper brought out one question that I want you to think over—we will discuss it a little later.

One of the pleasing things in our safety work is that each year it seems that we are able to get into the work bigger men in the safety movement, and we have with us today a man whose face I have never seen at a previous Congress, a man

who is interested in the financial end of the game, and who therefore talks safety with authority.

I have said a number of times that I don't want a job in any organization unless I can work under the man who spends the money because you will get nowhere as a safety engineer in any organization if you have to report to some fellow who has to go to some other fellow and he to some other fellow to sell it from a financial viewpoint.

I am going to ask at this time Mr. J. M. Bissell, of the Marathon Lumber Company, to take the floor and discuss these papers.

General Discussion of Safety

J. M. Bissell, General Manager,
Marathon Wood Lumber Company, Laurel, Miss.

The chairman said he liked to work under the fellow who spends the money. Before you spend the money you have to raise it. Before we go into the discussion of the two papers I want to talk to you from this angle: first that safety work, if intelligently carried on, pays dividends; not some mythical dividend, but actual cash, which ultimately reduces the cost of operation, as in the case of the lumber industry, per thousand feet. Everything is figured, no matter what it is, on the basis of per thousand feet, or in the case of any other industry on the unit of the article produced—unit cost of the article produced. Second: the investment required to produce safety dividends is remarkably small, so that in the average plant employing from 500 to 600 or even 750, it is not necessarily essential to employ a full-time safety engineer or to make any elaborate changes in the method of manufacturing or the type of equipment used. Interest in the safety movement, heads up in the president and those who furnish the money for the operation of the business, whether that be the lumber business or any other business. In other words, the principals or owners themselves must first be sold on safety. Third: that it is a relatively simple matter to interest the supervisory staff in safety, and also to interest not only the better type of your employee, but right on down, as in our case, to the most ignorant negro that we have on the job; and if any of you men have employed much negro labor you will know what I mean when I say, "ignorant." Fourth: that the organized safety and cooperation along safety lines among the employees will increase the safety dividends mentioned above; promote a better understanding of the opportunity for safety work, and finally enable those engaged in industry to render better service not only to their customers, but to the mills in which they operate.

Now with your permission—you don't look like a bunch of hard-boiled men, but to put across my point—I want to try and visualize that I am talking to a bunch of hard-boiled men who want to know: "Where do I come in? Where are the profits?" And that is what I am going to talk to you fellows about right now. I want to say, though, the business men in general in this day and time are more human, they are not the hard-boiled—if you will pardon the expression—don't-give-a-damn type, but they are interested not only in making money, but in promoting the welfare and the happiness of their employees, and there is no better way that it can be done than by studying and using safety.

We have the question of profit in business, and it is every man's right, if he is at the head of the business, to consider what is and what is not profit. We have a right to expect profit in our business, and we have a right to expect a profit out of every branch of that business; and I am telling you men that you can get profit out of safety work, profit in dollars and cents.

Consider for a moment three important factors in the successful operation of

any manufacturing industry. First, there must be an adequate supply of raw material, and with that raw material the necessary finance to convert it into the finished product. Second, there must be assembled suitable machines, buildings to house those machines in, and all your other work incident to an operating business, and to converting the raw material into the finished product, ready to put on the market, to be sold. And, third, there must be assembled men and women who will operate machines and form the personnel of the organization. God provided the first, the raw material; God provided the last, the man; man, in his ingenuity, provided the machinery. Hence, when we consider the raw material which God produced—the man, which God produced—can we do anything greater than conserve that man power? I don't think we can, and I believe you will agree with me.

I happen to have charge of a plant producing from 46 to 47 million feet of lumber per year. To a great many of you men that doesn't mean anything. It is not as large as a great many operations in the south, not as large as many operations in the west, but on the other hand it is considered a fairly good-sized operation. We employ on an average a little less than 500 men. Naturally I am interested in the daily production of the sawmill because what the sawmill produces the rest of the plant must take care of. I am not only interested in the quantity of that production, but in the quality.

The other day, when figures were placed on my desk—and they are put there every morning, where I get them the first thing when I come into the office to see what we have done the previous day—I noticed that our production had materially fallen off. I made inquiry as to why production on the previous day had been so low. I found that the man who operates the jump saw had an accident. A jump saw is a saw that is operated with the foot treadle or a hand lever which comes up through a live roller bed, and as the long lumber passes down it is cut into proper lengths. That roller bed, if it stops, stops the man who saws the logs, and there is where your production begins and winds up. If you have a good man there, if everything is kept clear so that he can continually keep his log in the saw, then you are going to get good production; and I found that this man who operates this saw in the live roller bed had the previous day mashed his finger, and we had to put on a substitute.

We try to keep men reasonably familiar with different jobs in the mill, but no substitute is usually as good as your mainspring man, and we lost production that day.

Compensation Small End of Loss

We paid the man a very small amount in settling with him, really not because there was any liability on our part in that particular case, but we frequently do that for old employees. The money we paid that man wasn't a drop in the bucket to the profit we lost because of the low production resulting from that injury. So for that reason safety pays and pays cash dividends. That was a safety profit, as you might term it, which we did not get.

Another instance: A trimmer operator was injured at home. The next morning his substitute happened to be sick. We had to use a rather inexperienced man. Now, a trimmer is usually composed of from 11 to 13 saws, and is operated by a man on a board, a good deal like you operate a piano, or the young lady is operating that stenotype. The man must know his "onions" because those saws work frequently at the rate of 60 to 70 per minute, and he has to work the keys pretty fast. We lost production that day. Therefore, I say that it is almost as important that we conserve the man-power of our employees through safety measures at home and among our employees' families as it is to conserve this man-power through safety efforts on the job.

It is unfortunately true that I can name several other instances where we have lost production because of some minor injury and that loss amounted to many dollars.

Here is another thing I want you to think of: a serious accident, even, I might say, a semi-serious accident, will frequently so demoralize the fellow-workers in that crew as to lower their efficiency very materially during the rest of that shift; and if the accident is serious or a fatal one your crew is completely demoralized not only for that day, but probably for two or three days to come.

I will give you an example. The first day of this year it was our misfortune to have an old and valued employee severely injured. It at first appeared that the accident might prove fatal, and it was surprising to note the effect that accident had upon our crew for several days. Fortunately the man recovered and is now back on the job, but while he was off we had to break in another. That man was the head sawyer and those of you who know anything about sawmill and logging operations know that your sawyer is a key man. The loss of that man entailed a loss to us that I don't like to think of. I will say that it ran up into several thousands of dollars, not once of which went to the man, but it was lost in efficiency and breaking in a new man.

My father, who has been in the sawmill business for something over 60 years, told me years ago that if you would take two mills, identically the same, with two expert sawyers in each mill, and switch those sawyers from one to the other mill, you would suffer a loss of approximately \$2,000. He figured it out one time. And I, as I grow up in the lumber industry, am beginning to realize that he was right. Therefore, it pays to use all means at hand or what means you can secure in the prevention of accidents.

Dollars and Cents Cost of Preventing An Accident

I am going to pass on now to the dollars and cents cost of preventing an accident. In these days of competition and low margin of profits, there naturally arises in the mind of the man who is responsible for a plant, the question of what it will cost to take part in this safety program, to use it. I have tried to show there is no actual cost, but there must, of course, be an initial investment.

Those of you making furniture, invest in your machines; we invest in our machines, to convert trees into finished lumber. You invest in them to make out of that lumber the furniture. Therefore, in starting on this safety program, don't figure it as cost, but as an investment—the amount that you invest in the safety program.

This initial investment is small and I say that from experience, as well as from what has been told to me by those who have tried it. If I were to take charge of a plant tomorrow, that has never initiated the safety movement, my first investment would be a membership in the National Safety Council. My next investment would be to call my superintendents and my foremen together and drill into them, with the biggest and swiftest drill that I could procure, the ideas of safety. Then I would send them out among the men; and I would call in the men on company time and talk safety to them. We do that—not only when we started the safety program and were just infants in the game—but right now we frequently call our men into the front office, to smoke a while and have a safety discussion. I will tell you fellows that three times the lumber production that we might have had during that time would not have paid us for the benefits in dollars and cents that we have received from those discussions. Those profits are there, you can see them, you can almost put them down on paper and figure them right down to a penny.

I have tried it and I know; and I say that you can afford to give the time to discussion of safety measures with your men; sell it to your superintendents, your foremen, and your men; because in the final analysis, safety is what your employees in the plant make it.

Next I would give a few rewards or prizes for slogans or for safety ideas. I find that pays. I also find that some of the least educated employees give you ideas that are worth many thousands of dollars. At a plant not far from us the slogan they used for years was gotten up by a negro employee. Our slogan was devised by a stenographer in the office. The name of our concern is Mathathon Lumber Company—she combined the letters M, for Marathon, and M for Man; L for Lumber and L for Lives; C for Company and C for Considered, and below those two lines

MARATHON
EN'S

LUMBER
IVES

COMPANY
ONSIDERED

in great big letters, and then underscored the word: FIRST. And I don't know of anything that has done more good than that slogan. We have it displayed all over the plant and the men know it and know what it means, and are interested in it. I venture to say that if we took that slogan down and didn't put up another one, inside of three hours I would have a dozen men running up to my office, wanting to know what is the matter; and I wouldn't blame them.

We get the National Safety Council calendars. We also give a prize for the best slogan that our people could adopt for them.

I think one of the biggest contributing factors in our reducing costs this year in every single department has been through our safety work. A safe man is a more efficient man and a better and a more satisfied workman. And I want to urge you not to neglect the safety in the home, because when a man's wife and children are talking to daddy about safety and about what he did that day, and if he was careful in the mill, that man is going to think a lot more about safety than even the president's talk could make him think about it. Because he knows not only that he is the provider for that family, but he knows that they love him, that if anything happened to him they would suffer financially and every other way. Therefore, when you get the women and the children interested in safety you will have made a long step forward in industrial safety.

Conserve your personnel or your man-power by constantly and everlastingly hammering into your superintendents, your foremen, your department heads and into your men that safety is as essential as the operation of the plant. Don't let safety be subservient to any department, to any operation.

Now I say you don't need a safety man, but you do need someone who is absolutely responsible for that department. My superintendent looks after it—my plant superintendent—there is no duty that he has to perform that takes precedence over safety work. The other duties can wait, safety cannot.

CHAIRMAN FARRA: That is the most outstanding address that has been presented before the members of the Woodworking Section in the eight sessions that I have attended. When we can get business men to come here and give a talk like that, I am confident that safety is going ahead. I feel a lot better than I did when I wrote my paper after reading the statistics of the section for the last seven years.

I see we have with Mr. Wiberg, chairman of the section for last year. He was a very valuable chairman of our section. I am going to ask him to say a few words as to his observations during the year.

H. G. WIBERG (Lumber Mutual Casualty Insurance Company, New York City): I just landed off the train, and I don't know that I am in a position to say anything. This last paper makes me think a good deal of the word "service." I don't know whether you other gentlemen have noticed it, but I think the idea of service is becoming more and more the forward step of progress in all kinds of industry. Competition is very keen in every line and I think most of the heads of large concerns are realizing that service is the medium through which they are going to amplify and extend their operations.

Take for instance the automobile industry. You can buy almost any kind of a car now and get a good car, with a good motor—a vehicle that is put together well, and one that with, let us say, reasonable abuse, will last for a very long time.

I have been driving a car myself for a couple of years, I have had some experience with the service stations, and I am becoming more and more convinced that in a few years the companies that will get the business are the ones that are furnishing real service; the ones that when you have something wrong with your car and you bring it in will really take care of it. After they finish the job they will test it, and before they turn it over to you, they will know it is in absolutely first-class condition again.

Now it strikes me that some of that same idea will have to be extended to industry, in that the people at the top of the organization will have to give some thought to furnishing welfare service to their employees and that, I think means taking care of them from the point of view of keeping them on the job all the time and keeping their bodies whole. That is going to be because of their own interest and also because they feel that they are responsible for the men working for them.

The last gentleman pointed out that the tendency of the present age is to get away from the old indifferent and hard-boiled attitude toward the (as they used to be known) "millhand." It is interesting to note that with the possible exception of one or two industries that term has practically become obsolete. That term in itself conveyed the idea that the workman was considered about on the same plane as a piece of machinery or a piece of the eight-by-ten holding up the floors of the building. The workman is becoming much better known, and is being much better thought of.

We Are Marching Forward Not Backward

I cannot help thinking in that connection of a picture I saw last Friday night, called "Metropolis." I don't know whether any of you have seen it. That picture seems to me to be a complete reversion to old times. It is supposed to be an indication of what is going to happen in the future, but I couldn't see it for a minute.

It showed first a city, supposedly, buildings of a hundred, two, three and four hundred stories high, with elevated railways going from one building to the other, and airplanes flying around like bees, dodging in and out of the buildings. Then it went on to show that there were two classes, the very poor workman, or the slaves, and the very rich people, or the upper crust; and the slaves all lived down in the bowels of the earth, four or five miles below the surface, and the rich people lived on the roofs and had gardens and pleasures and fun of all kinds. It shows these thousands of workers marching in lock step to the elevators and being hoisted to the plants and then in the evening, going down into the bowels of the earth.

Another thing that struck me was somewhat of an anomaly—the fact that in this supposedly advanced age the machines were of the old type, steam-driven, with crank rods and crank disks and connecting rods and all of the stuff which we are getting away from.

My picture of what is going to happen in the future is that machines will pick up the power from the air and there won't be any moving parts at all. But this picture which indicated a condition a hundred years from now, showed machines just as complicated as those we have had in the past, and which in their operation certainly would involve a tremendous amount of energy uselessly spent.

That picture seemed to me to be absolutely contrary to the way in which the world is now going. Instead of the workman becoming more and more a piece of inanimate existence or equipment, he is being given more and more attention. We are thinking of him more and more and we are trying to better his condition. We are trying to get him to take care of himself; trying to get him to live longer;

trying to make him of more use to the world and to his own family; and the employers of this day and age, to my notion, and with the contact that I have had with them are coming to the front in great shape to back that movement.

This safety movement, I think, has had a great deal to do with bringing that around. I think it is going to have much more to do with it. I think it is going to develop into this higher idea, which is that the employers are going to try to give service to their workmen, and that service is going to consist of bettering their condition and seeing personally that when they take a man into their place they are going to provide him with a safe place to work. They are going to educate him in safety and they are going to make him a far better man to himself as well as to everybody else.

CHAIRMAN FARRA: Thank you Mr. Wiberg.

We have one question: How can we get more safety posters pertaining to woodworking hazards?

You can get them by letting your needs be known so that the National Safety Council may provide them.

MR. WIBERG: I think that we could get more of them if all of us were to notice conditions as we go through our plants, and where we see something that could be made use of, make note of it and let the National Safety Council know.

Mr. Homer D. Herron, is the chairman of our Poster Committee—Mr. Herron of the International Harvester Company, Chicago, Ill.—Mr. Herron will have those posters provided.

What you should do would be to send a photograph of the condition and a short story explaining what you are trying to bring out in the picture.

General Discussion of Problems

CHAIRMAN FARRA: Aren't there some questions you would like to ask?

H. A. TOWLE (Western Electric Company, Chicago): I would like to bring out a point in connection with the first gentleman's paper; I wonder if any particular badge has been presented to the committee members, a folding badge such as we wear here or a pocket piece, or something of the kind, to designate each one.

MAJOR STEERE-CLARK (Vancouver, B. C.): We don't as yet, but it was voted upon two or three months ago to have badges or suitable headgear, caps or something, brought out in our industry. We are new at the game and we are here to learn.

MR. BISSELL: I would like to ask a question, Mr. Chairman. I want to know how many men in this room are connected with the logging and sawmill industry?

(A show of hands disclosed fifteen.)

Perhaps some of you may have heard a rumor which has been prevalent for the last eight years, of the sawmill or lumber manufacturing industry wanting to dominate the woodworking industry. The lumber manufacturing problems of safety are not comparable with the woodworking industry, but until the lumberman shows sufficient interest, and I say lumberman, and mean the principals—we need the safety engineers. We need those in charge of the actual safety program at the individual plants at these meetings, but until the principals take enough interest in safety work and in attending safety meetings, we don't want a separate organization. You may have heard that we do; we want it—I want it—yes, I think there are other lumber men who want it, but not until we have organized in sufficient numbers and have a program of sufficient importance to warrant asking the National Safety Council to give us a separate section. That is coming, gentlemen, and when it does I want you to know and believe that we are not trying to organize that section to the detriment of the Woodworking Section, but to promote safety and those precepts which the National Safety Council stands for. It is going to be my endeavor to interest lumber manufacturers in the South, and as I happen to be financially

interested in plants in the North and in the West, I am going to try and interest those men in safety.

They are busy men, they have many conferences, many organizations to attend. I met Mr. Wallace and Mr. Hines this morning. Mr. Hines is president of Mr. Wallace's company. I asked him to come over here and he said: "John I would like to come, but I have just returned from Europe, and I find a lot to do. I have got to attend another meeting, but I want you to know that I would gladly attend if I could."

I said, "Mr. Hines, I am going to tell the Woodworking Section this."

He said, "I want you to know, John, that I am interested in safety and that in no department of our operation does anything take precedence over safety."

When we can get more principals thinking along that line, I think you will agree that we need a separate lumber manufacturers' section.

I want to say this: that Mr. Farra has suggested, or has agreed (and I know it comes from the bottom of his heart) to change the name of the Woodworking Section to Woodworking and Lumber Manufacturing Section, and I want to openly thank him before you fellows, and to thank you for giving us that recognition. I don't want to feel that we are trying to come in here and dominate the Woodworking Section, because when the time comes that we are strong enough I know Mr. Cameron, Mr. Farra and you other fellows, Mr. Grier, and those in charge of the Woodworking Section, are going to help us organize a section of our own.

Re-Naming the Woodworking Section

G. A. ORTH (Claim and Safety Departments, American Car & Foundry Company, New York City): Supplementing what Mr. Bissell has just said with reference to the change of name, that was going to be brought up at the Luncheon meetings. I am in favor of having this change made, and while we are on the subject, I move that the name of this section in the future be known as the Woodworking and Lumber Manufacturing Section.

(The motion was seconded by several.)

CHAIRMAN FARRA: Mr. Bissell rather misquoted my authority, I simply agreed last night, that I would suggest to the Woodworking Section that we do this.

The motion is before the house, is there any discussion upon it?

I think that this is a move in the right direction. I told Mr. Bissell last night that there wasn't an officer of the Woodworking Section, tied up with the remanufacturing part of it, who was not in favor of the logging and sawmill interest having a section of their own when they got enough men to run a section. But gentlemen, it has been the experience through eight years of those of us who have been tied up with this section, that the logging and sawmill interests have not been sufficiently sold as yet, to send their men to the Congress year after year, as the remanufacturing interests have done. We have to get new fellows; outside of Mr. Wallace and Mr. Thompson, most of them have not been here before.

Is there any discussion on this motion?

(The motion was put and carried.)

MR. BISSELL: I thank you gentlemen on behalf of the lumber men, and to all you lumbermen and loggers here I am putting this right under your collars: get out and get busy and get members for the National Safety Council, every one of you.

F. A. MULLET (The Long Bell Lumber Company, Quitman, Mich.): As I remember that compilation of figures on accident experience that came out some time ago, there was some separation of the logging and sawmill industry, but the planing mill end was thrown with the other woodworking establishments, which doesn't give us a clear picture of our experience. I was amazed to note the experience in the woodworking planing mill, and the classification as a whole, because it does not fit our's.

I merely want to suggest, if it is in order, that if we could get any of the statistics that are made up to show the planing mills which are in sawmill operations separate from the ordinary cabinet working, furniture working, and so forth, the figures would mean more to us.

CHAIRMAN FARRA: I am glad of that suggestion. I will pass it on to Mr. Grier. Mr. Grier will try to have that change made.

ADJOURNMENT

Tuesday Luncheon, September 27, 1927

The Luncheon Session of the Woodworking Section was called to order at one-thirty o'clock, by the chairman, E. Ross Farra.

CHAIRMAN FARRA: I give me great pleasure to present to some of you folks who have not been to as many conferences as others, a man who has been connected with this section since its inception, and connected with the National Safety Council work long before there was a Woodworking Section, Mr. G. A. Orth, of the Claim and Safety Departments, American Car & Foundry Company, New York City, the chairman.

CHAIRMAN ORTH: Mr. Farra, ladies and gentlemen, it is indeed a pleasure to have this opportunity of acting as chairman for this luncheon meeting.

This morning you heard reports of various committees, but you might have noticed that there was no report from the Program Committee. As chairman of that committee I purposely refrained from putting in the report because I wanted to see how the addresses panned out, and now that you have agreed that they were good I want to take credit, gentlemen, for getting these men to address you.

Our time is limited. We were supposed to have an hour but we have just 25 minutes in which to conduct this meeting.

The first subject we have is a discussion of the Woodworking Section. That is a broad contract, you might say, to undertake. If there is anyone here who would like to say something with particular reference to his own industry on woodworking we will be only too happy to hear what he has to say.

I think it well to call on some of these officials who have been in this Woodworking Section for a number of years, and I know I would like to hear from Mr. John Grier as to what his company is doing for safety in the Woodworking Department of his plant at Wilmington, Delaware.

JOHN GRIER: (Employment and Safety Manager, American Car & Foundry Company, New York City.): Mr. Orth is only too familiar with our work at Wilmington. If we don't blow our horn no one will know about the Woodworking Department of the Wilmington plant—it is one-fifth of the entire plant, and it employs about one-fifth of the men. We average about 150 men in that department who have worked fairly steady for the past five years.

The last lost-time accident we had occurred August 4, this year. The one previous to that was on February 28, 1923.

This last accident was rather discouraging. We were trying to get a no compensability accident month. I had written to several of the boys of the company asking them to help me on the thing and to try to pull their plants through. Four days later I had an accident on the band saw at the point of contact, with the saw entirely guarded.

We started in January, 1927, on a safety contest in the American Car & Foundry Company, covering all plants. Mr. Dickman offered a trophy for the plant which had the best safety record during 1927. The year is not ended, but up to the present time the efforts along the lines of this safety contest have given us a decrease of 53 per cent in the frequency of lost-time accidents over the first eight months of 1926.

N. C. GOODSPEED (General Electric Co., Erie, Pa.): Gentlemen, speaking of things that we might do to prevent accidents reminds me of a point that happened to us not quite a year ago.

We had a planer in our shop and we hadn't had a guard on it that we could use. We got a new guard and thought it would work in that particular job, put it on and told the fellows we wanted them to use it. At the same time I told

them if they found a job they couldn't use the guard on they were to throw it off.

We had one man in that department who has a reputation for doing what he is told. He had a job he ought to have thrown that guard off, but he didn't and as a result, trying to work underneath the guard, the work slipped, his hand was pulled in and he lost three fingers.

I am telling this story to bring out the fact that if you are putting in a change of work or a new device or a new guard on an old device, see to it that your instructions are explicit, and if you have an old guard to which everyone is accustomed it is safer than trying to make a new guard do the trick of the old one if it isn't properly understood by the men, or if the men are not properly educated to take care of that condition.

CHAIRMAN OWEN: We have with us a man who represents a big industry, the Fisher Body Company, subsidiary, as you know to the General Motors, Inc. Mr. Olsen. He is doing some fine work in Detroit, and they certainly have the safety spirit up there.

Severity Is Important in Wood Mill Operations

O. J. OLSEN (Fisher Body Company, Detroit, Mich.): I was very much interested today to find out the difference between woodworking and lumber manufacturing.

I am going to talk about woodworking.

We fell our own timber, clear all the way through, right to the finished product of an automobile body. On the woodworking, that is, outside of the lumber manufacturing, we have done a lot by mechanical guarding. When you talk about reduction of accidents, reduction of frequency, it is part of the story.

Severity is what interests me, and severity is what counts in a wood mill operation because when you get hooked up on a piece of equipment in a mill you know that something is happening.

What we consider one of our most hazardous machines is a shaper, squarehead and the detail. We have been experimenting for the last eight months with an automatic shaper guard and we believe we have it perfected.

Now in Detroit you know that we are hitting the ball all the time and you cannot put a guard on there unless it is practical, especially for people who have been in mills for years, after they once establish a habit it is pretty difficult for them to change.

We have this shaper guard in four of our mills, in mills where we are working day work, mills where we are working piece work, and the men themselves who are operating these machines are very much interested in it and pleased with it. It hasn't handicapped production.

We haven't been doing so very much safety work until the last year and a half, and we have been pushing it intensely. One of our slogans is, "We are not to get production at the expense of safety." That has the support of the management and we are trying to put that message across right down to the man at the machine.

These shaper guards we thought were an impossibility, we thought it couldn't be done, but we have them, and if any of you gentlemen happen to be in Detroit, we have set up a little room in our experimental department to show this guard in operation.

J. M. BISSELL (Laurel, Miss.): In spite of that safety slogan that you have, is it not true that your production is increasing in the ratio of the diminishing of these accidents?

MR. OLSEN: I haven't any statistics to prove that. So far as I know now, that is more or less of an intangible affair, but we believe—I believe personally and those who are connected with the work believe—the management is sold on the idea that if you have a proper safety spirit it increases the efficiency of your plant. I have no doubt about that. I have been in the safety game for a good many years—

I may look like a young fellow, but I am past forty, and I have met all kinds of experience in all kinds of plants, in power stations, building of magnetos, building of automobile tires. I know that if you run a plant safely, if the housekeeping is right, if conditions are right, your production is going to be increased.

As I say, it is more or less intangible so far as statistics or putting it down in dollars and cents is concerned, but we are working on that. Our safety program doesn't have to ask anything from anybody; it is not an expense, it is an asset; it is not a liability.

You may say it is mercenary, dollars and cents, so far as compensation is concerned, but there is a lot of intangible grief, grief to the man, grief to society at large, that we try to take care of it.

Production Is Increased by the Elimination of Accidents

CHAIRMAN ORTH: If I may make a further reference to our company, I would like to answer Mr. Bissell's question there: whether or not production is increased by the elimination of accidents. That is quite true. I want to give you just one illustration. At our plant, in P (he has since passed on), we had a man who was in charge of making various slings and hooks and who took care of the chains. This man had devised no less than 75 various types of hooks, and these hooks have prevented accidents and incidentally have increased production from 10 to as high as 20 per cent.

We have no slogan in the Car and Foundry, but we have a vice-president in charge of operation who is quite active in safety; and in some of the papers of which I have been the author I have stated that we do not simply command or dictate the policies so far as safety is concerned to our particular plant managers, we suggest and permit them to carry out the policies as they emanate from the New York office.

Our Mr. Dickerman, in a letter many years ago said this in closing, and this letter was addressed to the district managers: "I wish that you would give the same thought to accident prevention that you are now giving to production." That takes in a lot; and from that time forth our district managers and superintendents have taken that to heart. As a result, I think the Car and Foundry have made some wonderful records.

We look back and find that we caused the death of no less than 15 or 20 men every year, some eight or ten years ago; and we have brought it down at the present time to where we only have one or two deaths a year, with nearly twice the number of men employed. I think we are doing something for the sake of the movement.

H. F. WIBERG (New York City): I hope I may be pardoned for coming down to a couple of detailed occurrences which some of you may think unnecessary to refer to. I think, however, that these accident causes are ones on which we cannot place too much emphasis.

We had a man lose a hand on a saw recently. I am not connected with a manufacturing plant, but with an insurance company. The man had been employed two hours. He was put on a rip saw without a protection and without proper follow-up to see that he knew his job. That is one thing that I think cannot be stressed too much, that when you get a new man, find out whether he knows how to do the work that he is going to do—give him not only a test, but actually follow him up for sometime, to make sure of it.

The other circumstance is with regard to the old proposition of shutting a machine down before you make adjustments.

At the plant in Buffalo they had a near serious accident; a man was running a masher with a feed table about eight feet in length. A piece of wood caught in the feed roll. The operator got up on the table and tried to pull it out and got his arm caught. His arm went in to the shoulder. Another man nearby had the

presence of mind to shut the masher. If it had not been for this other fellow this man would have gone right through. It is the old story of keeping after the key fellows to see that they do shut machines down before they make adjustments.

I might also say on that, there was a question involved also of guarding the feed rolls. Most plant foremen will tell you that there is no sense in guarding that feed roll because it is eight or ten feet from where the operator stands. That is all very well if the operator always keeps his feet on the floor. You can never depend on what a man is going to do or where he is going to go.

I just want to leave those two propositions with you; it is the old story of keeping after those things.

CHAIRMAN ORTH: My good friend Mr. Farra suggests that I call on Mr. George P. Eddy, of the Klise Manufacturing Company.

GEORGE P. EDDY (Grand Rapids, Michigan): I think Mr. Farra has rather taken advantage of my lack of experience in some of this safety work. We have only been in it two years, it is a very small plant; some of these people could swallow us up in one corner and wouldn't know we were there.

About the only thing I can say is that about two years ago we came in contact with the National Safety Council, through Bob Haven, who was then our local Council manager, and in getting us into that he got the work enthusiastically started. Since that time we have decreased our lost-time accidents from 30 or 40 days a month, to two or three days a month. Our woodworking plant specializes in a type of product that does not call for a great amount of machinery of the type that carries the biggest hazards.

The work that we are doing has been directly the result of our contact with the Safety Council and the management feels it is the best investment they have made.

So far as any detailed stories, about what they have accomplished is concerned, I can only say that it has been through the efforts of the Safety Council, in getting

enthusiasm into our organization, and then our own work along the lines of education, that has done the work. The guards themselves seem to be a necessary part, but the education of the workmen is the biggest problem that we have got right now, and I think is the answer to the safety work as far as the smaller woodworking plants are concerned.

There is a sad lack of attention to that part of it—I am speaking particularly of the smaller furniture plants, the secondary operations in the woodworking industry.

We think we have a manager at Grand Rapids who is going to put a lot of pep into the plant and we know that we need it badly.

CHAIRMAN ORTH: Thank you, Mr. Eddy.

Our next subject is the election of officers. In the absence of the chairman of the Nominating Committee I will read to you the nominations, and I wish when the names are called that these gentlemen would rise so that all in the room may know who they are.

Report of the Nominating Committee

The committee suggests that the following members be considered for the various chairs to which their names have been assigned:

Chairman, John B. Grier, American Car and Foundry Company, Wilmington, Del.
Vice-Chairman (Sawmills), J. M. Bissell, Marathon Lumber Company, Laurel, Miss.

Vice-Chairman (Manufacturing), E. K. Prichett, Prichett-Powers Company, Grand Rapids, Mich.

Vice-Chairman (Logging), H. Steere-Clark, British Columbia Loggers Association, Vancouver, B. C., Canada.

Secretary, M. C. Goodspeed, General Electric Company, Erie, Pa.

Program Committee Chairman, W. L. Wallace, Edward Hines Lumber Company, Lumberton, Miss.

Membership Committee Chairman, E. Ross Farra, Grand Rapids Safety Council, Grand Rapids, Mich.

Publicity Committee Chairman and News Letter Editor, O. J. Olson, Fisher Body Corporation, Detroit, Mich.

Poster Committee Chairman, H. D. Herron, International Harvester Company, Chicago, Ill.

Engineering Committee Chairman, G. A. Orth, American Car and Foundry Company, New York City.

Executive Committee, The Officers and:

G. E. Sanford, General Electric Company, Schenectady, N. Y.

A. O. Jackson, Aetna Life Insurance Company, New York City.

H. G. Wiberg, Lumber Mutual Casualty Company of New York, New York City.

The committee believes that the offices left open can be better filled by appointment from the floor at the time of meeting.

A. O. JACKSON, Chairman

Gentlemen, this is not a slate that has been thrust upon you. In our democracy we have a right to nominate any man we may see fit to nominate. If there are any nominations, gentlemen, we will be glad to have them, and we will cast our votes for the gentlemen.

Are there any nominations?

If there are none, I will entertain a motion that the nominations be closed.

(Motion was made and seconded that the nominations be closed and upon a vote the motion carried.)

(A motion was then made and seconded that the secretary be instructed to cast the ballot for the nominees as read by the chairman, and upon a vote the motion carried and was so ordered.)

SECRETARY GRIER: The secretary has cast the ballot.

CHAIRMAN ORTH: Is there any further business, gentlemen, before we adjourn this session?

MR. BISSELL: In case some of you gentlemen misunderstood my talk this morning, I don't want any of you to think that I, for one fractional part of a second, place the dollar and cents value of safety ahead of the humanitarian side. I just want to get myself straight before you along that line. That of course is the paramount thing in all safety work.

ADJOURNMENT

Wednesday, September 28, 1927

JOHN B. GRIER, Chairman
Employment and Safety Manager, American Car and Foundry Company,
Wilmington, Del.

The third session was called to order at nine-thirty o'clock by the chairman-elect, John B. Grier, employment and safety manager, American Car and Foundry Company, Wilmington, Delaware.

CHAIRMAN GRIER: Gentlemen, we will start our session without the motion picture, as was the plan before; the picture went awry in some way last night. It will be shown later.

Woodworking Hazards

J. B. Grier, American Car and Foundry Co., Wilmington, Del.

Statistics covering all woodworking accidents can be divided into two distinct classes, which enable one quickly to determine the underlying causes for serious accidents in the woodworking industry, viz.: (a) Mechanical and (b) Non-mechanical. These two general classes are subdivided as follows:

Mechanical: (1) accidents at the point of contact, (2) accidents occurring on other parts of the machine—driving belts, pulleys, shaftings and etc.

Non-mechanical: (1) handling material, (2) bench work, and (3) miscellaneous.

By separating the accidents and putting them into their proper places we are quickly shown the cause of the greater number of accidents, and this will also give us the outstanding reason for the occurrence of these accidents. Our safety program can then be arranged according to the indications of this report.

The method of combating the above-mentioned accidents can be briefly outlined as follows:

Accidents occurring at the point of contact. These are accidents which are caused by the operator coming in contact with cutters, saws, knives, revolving heads or parts of machinery which necessarily must be left exposed in order that the machine may do its proper work. For the prevention of accidents occurring under this classification we must design guards which cover up all of the moving parts as much as possible, permitting the machine to do its full amount of work, and then follow this guarding up with the broad plan of education.

Accidents occurring at places other than the point of contact. These accidents can be entirely eliminated by the proper application of safeguards. When an accident occurs under this classification it should be thoroughly investigated by the committee and a guard designed immediately which will remedy this hazard. I say that these accidents can be entirely eliminated. This is true, if the proper guards are designed. By that I mean, guards which can be quickly removed and quickly replaced, the guards which permit the machine to have the proper attention as to oil, repairs, tightening, etc. After these guards have been designed it should be made a strict plant rule that all guards be in place when a machine is started, and this rule strictly enforced.

The non-mechanical accidents which are classified under handling material are probably the most frequent accidents. Men handling material around woodworking machinery must be carefully instructed to allow the machine operator ample room to work around his machine and feed the material to it. If he is cramped for space,

he will have a considerable number of abrasions, bruises, sprains, etc., which may at any time result in a serious or loss time accident, through the accident itself, or infection developing later.

Bench accidents, those accidents occurring among cabinet makers, bench hands, carvers, etc., do not suggest major accidents. However, I have had two cases occurring on the bench which were of a very serious nature. I will go into the detail of these accidents later, when we take up the woodworking hazards.

In passing it is well to mention that the placing of tools in tool boxes is a large factor in this type of accident. It is necessary to have an educational program to reduce accidents of this class.

Under miscellaneous accidents we place those which cannot be truly classified in the four headings explained above. Splinter wounds, which will be the most numerous under this classification, should be given quite a bit of attention. After workmen handle wood for a considerable period of time their hands become toughened and they feel that a slight splinter wound will cause them no damage. This neglect of a slight injury has oftentimes developed into a serious injury causing dismemberment of part of the body. It is necessary at all times to require workmen to get first aid treatment for splinter wounds no matter how slight they may be.

Hazards of woodworking machines are numerous, and unheard of causes of accidents will develop. In this paper I am limited to cover only the most common causes of accidents. These accidents are the ones which we must combat. Sometimes an accident will occur in an unusual manner; but after we work on this common cause of accidents, as our statistics show them, the unusual accidents will diminish in proportion.

The Joiner a Much Abused Machine

Probably the most abused machine in the woodworking industry is the joiner. Workmen who are not machine hands will use this machine to smooth up material, and their attention being on other work, they do not notice the set up of the machine but lay the stock on the table and push it across the head without determining whether it is too deep, whether the knives are properly adjusted, etc. You might say that permitting this is a poor policy; but, I dare say, it is done in every woodworking mill in the United States today. The result is, if the machine is not properly set up, a kick-back or a near accident. The outstanding hazard on this particular machine is the jointing of small blocks from 6 to 12 inches in length and probably of the same width. This material should never be run across a jointer head unless a plane handle is used to make the operation safe. These short blocks are usually of a twisted grain; and, as soon as the knives come in contact with it the block is kicked from under the workmen's hands and his hands come in contact with the revolving head of the machine. If your safety man has been on the job and a round head installed, the accident will not be as serious as it would have been if the old style square head was used. We must be always on the job to see that the workmen on the machines are always well to the side and the part of the head not being used is covered with a suitable guard. There are several guards on the market for this machine which work very satisfactory. They swing aside as the stock is passing over the head and are brought back into position when the material has passed.

The band saw is also a much abused machine. It is used by workmen who are not employed for this sort of work and cuts are attempted for which the machine is not set up. I mean that circles and curving cuts are made for which work the saw blade is too wide; and, in attempting to follow the line on the board, the blade is given a severe twist which cracks the blade at the base of the teeth. The saw is certain to break and unless your safety man has put the proper safeguards around the saw we have a very serious accident.

Both wheels on a band saw can be entirely covered, and here I might say that I do not like the idea of using an angle iron guard on a band saw without covering it with expanded metal or wire mesh. It has been said that when these wheels are covered with metal or wire mesh, every time the saw breaks it means a new saw. Admitting that it does, band saws are much cheaper than doctor bills. If the saw is guarded in this manner, the broken band will pile up in the upper or lower guard and not on the table or around the workman's neck.

The planer is another machine used like the saws mentioned previously. The newer type of planers are as near "fool-proof" as it is possible to make the machine; and, if necessary guards are placed around the outside when the blower hood is installed, it is impossible, if a man is on the alert, to become entangled in any part of the machine. However, on the old machine, with the old style in-feed roll, there is a distinct hazard. This occurs when feeding more than one piece of stock in the machine. When a thick piece is entered and then a thin one, the thin one is bound to kick back with considerable force and either tear the hands of the workman or hit him in the stomach with considerable force. While operating this machine the workman should be instructed to always stand to the side while feeding material to the head.

Education Has Helped Operations at the Circular Saw

The circular saw is a machine used much as the three previously mentioned. However, education has brought about somewhat of a better condition in regard to the circular saw and not so many men will operate them as will operate the above machines. However, the circular saw is used by men who do not work on it regularly and it will be used when it is not in the proper adjustment. This improper adjustment of wood working machines is the cause of the majority of machine accidents in the woodworking industry. A circular saw should be guarded as above and equipped with a splitter which is fastened rigidly to the frame of the machine and set absolutely in line with the saw itself. There are guards which completely cover the circular saw and will prevent most accidents; however, the use of these guards is severely criticised because most of them do not permit the men to see the saw so that he can cut a line. In other words, "Straighten the board." It is our policy not to permit anyone except experienced woodworking machine hands to operate this machine and we have practically eliminated our accidents on circular saws.

The emery wheels located around the woodworking mill cause quite a few minor accidents and oftentimes they develop into major ones. After we have completely guarded an emery wheel the workmen will continue to dash over to it and shape off a cutter without using goggles. This is a practice which is hard to overcome, and can only be combated by strict adherence to the safety rules by the foremen and other workmen throughout the shop. We are not always about the mill so that we can catch the men doing these things and we must rely on workmen whose machines are located close to the emery wheels to assist us in seeing that the workmen wear their goggles at all times.

The other woodworking machines are nearly always operated by men who are familiar with their job and know the hazards of their machines after guarding them as completely as possible. It is a question of keeping workmen interested and, thus, have them always have their machine in first-class shape before commencing the operation. To take the individual hazards of these machines would be a long and uninteresting paper because, we of the woodworking industry, are thoroughly familiar with them.

I have had or have knowledge of woodworking accidents occurring in the following manner:

A workman was cutting carlins from stock material on a band saw. There were

holes drilled in the side of this material and in order to get a better grip on the stock he put his middle finger into the hole. He pushed the stock through the saw and when he separated the offal from the carlin he noticed some blood on the material; when he removed his hand from the carlin he found that he had cut the end off of his finger. This is a rather peculiar accident, but it actually occurred.

Another accident occurred on a band saw when a man had sawed out a carlin. He had finished the cut and in an attempt to get rid of the offal on the right side of the saw he gave it a violent push toward the back of the machine. In doing this, it struck the remaining piece of stock which he was holding with his left hand and the weight of the stock which had been struck by the offal threw his left hand against the band saw, below the guard, causing a severe injury to his left thumb.

We had a man injured who was working on a glue press. The glue press was a heavy iron frame and in making our inspection we had neglected to notice that the corner of the eye beams were cut square. This man was lifting the heavy piece of work and struck his head against the corner of the glue press inflicting a severe scalp wound. We remedied this by rounding the corner of the eye beams on the press.

Another accident occurred on a mortise machine. This machine was of the conventional type but did not have lugs welded to the table to guide a man's hand and he pushed his hand under the chisel. It came down and inflicted several puncture wounds before he could remove his hand from underneath the chisel. The lugs were placed on this machine and no further accidents have occurred.

Single and Double Head Shapers

The single and double head shapers come in for their share of accidents: but, as this machine is universally known as a dangerous one, only experienced men work on them. There are several guards on the market which will prevent accidents of a certain kind from occurring on this machine, but not all work can be done with these guards attached. A man was shaping carlins when he became interested in what another employee had said and neglected to check up on the grain of the wood he was working. He permitted the cutter to pass the end grain and the carlin split in half, one piece flew in each direction exposing the entire head to the workman's hands. Fortunately he was using the spring holder on this machine and he was not injured—had he not been using this holder, he probably would have had a serious injury.

A man was working on a traveling cross-cut saw. He had made a cut through a board about six inches wide and four feet long. He had cut this approximately in half and was looking around the mill as he reached for the piece of offal. He had not noticed that the saw remained forward and did not return to its rest position. His hand came in contact with the revolving saw, as the guard of this particular machine was of the stationary type covering the saw only when it was in rest position. This was remedied by designing a guard which bolted to the traveling carriage of the saw, carrying a hood which moved forward with it, thus, covering the saw at all times.

The motorizing of the individual machines in a woodworking plant is a big step in aid of the safety movement as well as an economical one in plant operation. One important factor which must not be overlooked when this installation is made is that an emergency stop switch should be located in a convenient spot to where the operator must stand while feeding material into his machine. This oftentimes prevents a serious injury as well as saves machinery from damage when material becomes wedged into it. Workmen will use this switch to stop their machines practically all the time, thus, becoming familiar with its location and can shut down their machines with no loss of time in case of emergency. This type of installation also eliminates the hazard of preventing woodworking machines to run idle while a small job is

being done on a machine nearby. Several accidents have occurred on machines in this manner.

One item which has been considerably overlooked in woodworking safety is that of illumination. Workmen cannot properly set up their machines and do close work if they do not have good illumination in the proper place. We have installed on all of our woodworking machines, particularly band saws and close working machines, individual lights shielded from glaring into the operator's eyes with a small metal shield. These lamps are covered with a wire mesh to prevent their breakage.

A woodworking shop, in order to produce the greatest amount of work in the safest manner, must be warm at all times and employers must not expect production and must expect accidents if they do not have their mill in a comfortable atmosphere at the beginning of the day's work. Considerable time is lost in the morning by not getting the mill in the proper condition.

Bench Hands Have Many Kinds of Accidents

Serious accidents occur to bench hands in different ways. Careless piling of tools in tool boxes is a large contributor to these accidents. A chisel point sticking up always gets a man's hand when he reaches in his tool box hurriedly for another tool, or when he carries a chisel around with other tools he is bound to strike himself on the leg, ruining a good pair of trousers, or inflicting a wound in his other hand when he attempts to get another tool. This can be prevented by taking heavy paper, folding it several times around the end of the chisel, making a sort of sheath which can be dipped in glue and made into somewhat of a permanent cover. It is no trouble to slip the chisel in these sheaths and this hazard is eliminated.

An accident occurred while a bench hand was working with a chisel fitting a tenon into a frame. The chisel slipped striking him on the back of the left hand just at the wrist joint. There was a slight incision, but it was soon discovered that he could not use his ring and little fingers. It became necessary to remove him to the hospital to have an operation performed joining the tendons and he lost six weeks from work. This could have been prevented had he laid the material down on the bench and made the cut toward the bench instead of his left hand. It becomes necessary to educate and keep after the men continually to see that they do not neglect this small item in their daily job.

Numerous accidents have occurred because of slipping. The floor around wood-working machinery and around woodworking benches soon become littered with shavings and sawdust and before long the floor becomes highly polished and very slippery. We have found nothing better than rubber mats to eliminate this hazard and place rubber mats in front of every machine where it is necessary for the men to exert any pressure. All machines such as joiners, shapers, band saw, circular rip saws and similar machines are equipped with this rubber mat as well as the floor in front of the woodworking benches so that the men have a sure footing while making tight fits, etc. We find that this rubber mat prevents slipping even after it has become covered with sawdust, and makes a sure footing for the employee.

A broad plan of education is necessary at all times. This can be carried on in several different ways. Our method is to bring it to the individual attention of each employee some time during the day. As we make our rounds through the shop we notice a man doing something in a dangerous manner and call his attention to it in a kindly way reminding him that he is the one to suffer and not the company, that we are doing this for his protection, also soliciting his assistance in preventing other workmen from doing their work in a hazardous manner.

There will be no discussion on the papers, gentlemen, until after all three have been presented.

The next paper will be given by Mr. E. K. Prichett, president, Prichett-Powers

Company, Grand Rapids, Michigan. Mr. Prichett has also been a director of the Grand Rapids Safety Council for the past seven years.

How Safety Is Practiced in the Manufacture of Furniture

E. K. Prichett, President, Prichett-Powers Company, Grand Rapids, Mich.

As long as men have worked together, industry has had to contend with accidents, but the serious consideration of their prevention has occupied our minds but a comparatively short time. Most industries felt that accidents were necessary trade hazards and because an operative was injured was no reason for additional care nor particularly a matter of sympathy. When a man took the job he knew that he was running certain risks and his chance of accident was in proportion to the length of time he continued in the work.

The woodworking industry, and especially that of furniture making, has always been looked upon as particularly hazardous. A walk through any furniture factory years ago would disclose many hands from which fingers were missing. In some instances the hand was so crippled as to prevent the operator from continuing in his trade and, occasionally, made him a public charge.

Men frequently pointed with pride to what remained of their fingers or hands and often took delight in telling how each particular member was lost. No thought was given to whether or not accidents were preventable. They were trade hazards, and that was all there was to it.

Twenty-five or 30 years ago the National Association of Manufacturers, whose members represented all lines of manufacturing in this country, began to take notice of the great number of men who were crippled through accidents. A committee was appointed to study the subject and a sub-committee was sent to Europe to learn industrial conditions there. They were to investigate particularly the accident situation and how they handled compensation for lost time due to injuries while engaged in the ordinary trades. Upon their return, this committee made an exhaustive report to the next convention. From this beginning industrial accidents have been given the attention they deserve. Progress was very slow at first, but gained impetus as this great National Safety Council took up the movement.

The settlement for accidents had become a profitable field of operation with certain types of lawyers. This was expensive to the manufacturer and, because the sympathy of the jury seemed to be with the injured man, frequently very excessive damages were awarded. This might not have been so had were it not for the fact that often from 60 to 80 per cent of the award went to the attorney while the injured man would receive but from 20 to 40 per cent. This was clearly an injustice. A study was made of these conditions and the present compensation laws were the result. This system places specific values on the various parts of the body and injuries thereto are paid without question at an established rate, which both the employee and the employer know in advance.

At first it was thought that unguarded danger points on machines were the cause of accidents and study of guards occupied the attention of both machine makers and users. This resulted in much safer machines and undoubtedly has prevented many accidents. Still an alarming number, many of them fatal, continued.

The U. S. Steel Corporation made an extensive study of their accidents. They were surprised and shocked to find that after spending hundreds of thousands of dollars to thoroughly guard all machines and dangerous places about the plants, comparatively little reduction in accidents was noticeable.

It occurred to Mr. Arthur H. Young (a past president of the National Safety Council) then in charge of safety in the *Blount Steel Company's* South Chicago plant, that there must be some other reason. He found that at least 20 to

80 per cent of accidents were due to the human element. Men were thoughtless or careless or had their minds on something entirely foreign to their work. In such a condition anything might happen and it frequently did.

With the then existing attitude toward accident prevention and the feeling that no one should interfere with one's liberty to do as he pleased, it was hard to get men to accept safety regulations. Then, again, if a man did accept the advice of the foreman or superintendent to work more safely, he was talked about as being a "sissy" or that he was trying to "stand in with the boss."

With all these and many other things, progress in education of the men was very slow. However, due to the intelligent persistence of the pioneer leaders in safety, a new and favorable attitude of the men (and management as well) was developed with the result that great progress has been made.

For some time the number of accidents decreased each year due to the continued attention being given them. Late reports to the woodworking section of the National Safety Council indicate an apparent increase.

On the face of it, this looks bad and challenges our best thought and efforts to reduce this accident rate. These same reports show a reduction in severity and it is probable that accident records are more accurately kept and we are now counting all accidents, whereas before we only heard of the more serious ones.

Grand Rapids Factories Vitrally Interested

Safety is practiced in the manufacture of furniture in various ways, according to the different views of the management or of the safety director of the plant. Some furniture factories have very thorough and efficient safety measures and some have almost none at all.

Nearly all of the factories in Grand Rapids and elsewhere are vitally interested in accident prevention. Most of them have some one—usually a foreman or a man in some position of more or less responsibility—who leads the safety work, which includes machine hazards, piling and moving stock, sanitary conditions, including toilets, drinking water and even heating and ventilation of the building. This man is charged with the safety of the employees from the time they enter the premises until they leave. All of them know him and are usually glad to tell him of any unsafe or unsanitary condition that comes to their notice.

Unsafe practices are as bad as unsafe conditions, and scuffling, wrestling, throwing objects at others while at work are reported and stopped. This is not done in a fault finding way but in a spirit of helpfulness for the general good.

Generally the safety man is the first aid man of the plant. There is a first aid kit in his office or if he has no office it is kept near his bench and all accidents, regardless of whether serious or trivial, are brought here. Minor cuts, abrasions, etc., may be cared for at the plant but those that are more severe are sent directly to the surgeon.

Many of these safety men in the Grand Rapids plants are graduates of the Red Cross first aid courses fostered by the Industrial Division of the Grand Rapids Safety Council. It may be interesting to you to know that two such classes of 25 each (they are limited to this number) have been held and 47 members received Red Cross certificates in first aid. We find that our women employees take a great interest in first aid also and three graduated in the class last spring.

In the larger and more highly organized factories, accident prevention is usually in the hands of a committee—generally of 3 or 5 members. The personnel of this committee changes regularly. The man who has served the term of his appointment retires and a new member is appointed. In this way there are always at least two men who are familiar with the work and an opportunity is given every man in the plant to at some time become a member of the committee.

The duty of this committee is to make a thorough and impartial inspection of the

plant periodically to find the danger points and suggest remedies. The committee also forms a point of contact between the men and the management. The workmen feel free to discuss dangerous conditions, which come to their attention, with the committee while they might hesitate to do so with the superintendent or manager. Another thing, where these inspections take place at regular intervals, men are on the lookout for points to suggest to the committee. Careless practices are often a greater menace to the employee than improperly guarded machinery and suggestions of this type are recommended.

While prevention of fire may not be considered by some as a function of the accident prevention committee, when you take into consideration the great number of lives lost in fires, the wages lost by employees following a bad fire, also the loss to the company, which may have an effect on employment, suggestions regarding fire prevention are always welcomed by the committee.

The Fire Hazard Has Become More Serious

Now that lacquer or nitro-cellulose finish is so generally used the fire hazard becomes more and more important. The slightest spark may set off an explosion that would injure several men and cause a fire that might consume the plant.

In nearly every finishing room the spray booth floor or the table on which the furniture is sprayed is cleaned with a scraper—usually an old putty knife. This being steel, when it comes in contact with a nail or other metal on the floor or table may produce a spark. This has frequently started serious fires. A brass scraper will not cause a spark and is safe to use.

Broken electric light extension cords are a menace that should be looked for by the safety committees.

A serious fire occurred in a Grand Rapids factory by an operator dropping an electric lamp attached to an extension cord while the floor was being cleaned with naphtha. The breaking of the lamp ignited the naphtha fumes and before the fire department arrived considerable damage was done in addition to the damage by water in extinguishing the flames.

The work of the safety committee is carried on during working hours and its members receive their regular pay. The committee receives reports of all accidents and investigates them, usually making a report to the management. If a change in equipment or operation seems advisable, such recommendation is included in the report. It has frequently been noted how eminently fair and considerate these committees are of both the interests of the employee and the company.

Doubtless every industry feels it has the best method of taking care of its injured men, but I really believe that injuries are treated a little better in the furniture industry in Grand Rapids than anywhere else.

When the Workmen's Compensation Act went into effect in Michigan the furniture manufacturers of Grand Rapids, after careful consideration of the matter, decided to carry their own insurance and organized the Furniture Mutual Insurance Company.

There were no precedents to guide the organizers in this new undertaking, but, with the exceptionally good business and executive judgment of the committee on organization, the company has successfully operated by giving a maximum of service at a minimum of expense and is one of the important factors in accident prevention in the furniture industries of Grand Rapids.

First of all the founders of the insurance company felt that it was most important to engage the very best surgeon possible. Instead of contracting for his time, the company pays the established fee for the service rendered thereby encouraging the best possible attention to the patient.

The surgeon for this kind of work must be a man who combines several very important characteristics. First of all, he must be a good surgeon. He must be

thorough in his work, sympathetic in his treatment of the patient, resourceful to do new things, patient, yet firm with the injured, and, indeed, must possess a rare combination of good qualities. Our surgeon combines more of these qualities than seems possible to find in any one man. His patients like him and nearly all do well under his care.

The office or operating room is located in the heart of the city, as convenient as possible to all factories. Transportation lines from every district come near it. The location of this office was considered from all angles.

The office is equipped with every appliance that will aid in relieving suffering and in the prompt and safe dressing of the wound. The reception room or waiting room is furnished plainly but has a cordial atmosphere that the men like. There is nothing stiff or formal about it.

Few realize the important position held by the industrial surgeon. He represents the company in the eyes of the men who come in contact with him and they often feel toward the company as they do toward the doctor, therefore, the right type of man can do much to engender good feeling.

Another point in accident prevention is the education of the new employee. When a new man is hired he is taken by the foreman to the machine he is to operate, is asked questions and the answers he gives soon demonstrate whether or not he has had experience with this machine. The foreman explains to him in detail the dangerous points, warns him to use care and usually impresses on him the fact that safety must be considered even beyond speed or production. In other words, in case of doubt always take the side of safety.

Employees Are Interested in the Safety of Their Fellows

A cooperative spirit in the interest of safety has developed throughout the industry. Usually if an operative sees another doing an unsafe thing, he will call his attention to it and in most cases the new employee will take the suggestion in the spirit in which it is intended. There was a time when one felt that it was the other fellow's business to look out for himself and he felt equally certain that it was nobody's concern how he worked on his machine. But with the general good feeling that has developed in most plants, both of these attitudes have been modified and anything that can be done to prevent the injury of a fellow-employee and to reduce accidents has gained the ascendancy.

For several years past the Grand Rapids Safety Council has conducted what we have chosen to call the Foreman's Safety School. This is attended by one or more of the foremen in nearly every factory in Grand Rapids. Meetings are held once a week beginning promptly at 7:30 and closing as promptly at 9:30 p. m.

A definite program is outlined and prominent speakers address the meetings on particular topics. After about a twenty-minute talk the meeting is turned into a round table meeting and questions are asked the speakers. Much good has resulted from these round table discussions and many excellent safety men have been developed as the result of the safety school.

A record of attendance is kept and those who have been present a certain number of meetings are presented with a diploma at graduation exercises following the course. I am pleased to say that a large number of the Grand Rapids foremen have a diploma from every course that the Safety Council has sponsored since it was organized.

This year the safety school will be on a rather different plan than formerly. It will meet once a month instead of weekly. The first part will be a general meeting then it will divide into sections—woodworking, metal working, building construction, gypsum industries and possibly a chemical section.

How safety is practiced in another furniture manufacturing center is outlined concisely by Mr. H. G. King, secretary-treasurer of the Jamestown Mutual Insurance Company of Jamestown, New York. He says:

"The New York Compensation Law differs materially from the law in the State of Michigan. The sums of money paid injured employees is materially greater; the method of arriving at each employer's rate whereby the employer is penalized for bad losses and credited where losses are few, is of material help in this state through the fact that the penalties are severe enough to command the attention of all employers. This fundamentally assists in accident prevention work and is, I think, one of the greatest factors in promoting accident prevention measures. This so-called experience rating plan not alone gives credit for good experience but allows credit for good factory conditions; these credits running as high in many cases as 25 per cent and 30 per cent of the normal premium.

"In addition to the above, we organized in 1920 the Jamestown Mutual Insurance Company, of which the writer is secretary-treasurer; this company insures all of the woodworking manufacturers in this vicinity as well as practically all other manufacturers. We employ inspectors to regularly check up safety conditions in the various plants, and call attention of the management to unsafe conditions and practices. We make a careful investigation of every accident which involves any possible permanent injury, fix the responsibility for the accident, and recommend to the management any necessary steps to avoid recurrence. This includes specific recommendations on various types of guards which we know to be adequate and serviceable, and we obtain these guards at a material discount from list prices.

Three Phases of the Key to Accident Prevention

"We of course furnish regular bulletin board service with safety posters, and conduct in many plants safety organizations which are composed of employees and our inspector. These organizations are charged with full responsibility for all safety measures; in fact we have a special plan which is operating to very good advantage, but which we believe would be impossible to outline through correspondence in such a way as to be of any benefit to you. We also furnish pay envelopes with safety slogans. Both these and the bulletin board posters, of course, must be supplemented by something far more tangible.

"Our thought in the matter is that the real key to accident prevention work is:

"First—The penalties imposed under the New York law for bad experience.

"Second—The close follow-up of every serious accident.

"Third—Adequate safety organizations with full authority to impose necessary safety measures."

I have asked a number of furniture manufacturers as to their attitude toward accident prevention and it is very gratifying that, without a single exception, they have expressed themselves in favor of it. To the question of whether or not it retards production, at least 98 per cent state that it does not and many of them say it increases rather than decreases production by giving the operator greater confidence in his safety from the knowledge that both the machine and the methods are safe. Nearly all of the factories replying to my questions use the National Safety Council's bulletins and posters.

To my question, "How do the men take to accident prevention?" in nearly every case the reply is, "The men are very much interested in accident prevention and are very highly in favor of it."

An interesting thought was suggested by Mr. Smiley, factory manager of the Globe-Wernicke Company, Cincinnati. He states, "I will not bother you with the description of the routine safety problems, but in the interest of both safety and productive efficiency, we have established a rule which makes it necessary for all of our employees to have their eyes examined at least once a year. The initial examination of our 1,200 employees showed that more than 30 per cent of them had defective vision and were not wearing glasses. Among those who were wearing glasses, we found that about 10 per cent of them were not fitted properly." They have a licensed optometrist to conduct the examinations in their own first aid room.

He further states: "Although it would be difficult to prove it by actual figures, we are confident that this plan of eye examination greatly reduces the risk of accident in our plant and the productive efficiency of our employees has been increased. In adopting this plan it has been our idea that many factory workers who have defective vision do not have the time or the inclination to have their eyes examined in the ordinary way but readily respond when given the privilege at the factory.

I think you will all agree that the matter of correct vision doubtless has a decided bearing on accident prevention, and also on the quality of work the operator will produce.

Mersman Bros. Brandts Company, Celina, Ohio, stress the point that they have been interested in accident prevention since they started in business 26 years ago and that largely from a humanitarian standpoint. They have a foreman's club in the plant composed of the foremen, assistant foremen and heads of departments. In this club they have an accident prevention committee to report and advise regularly on all safety appliances and accident prevention. This committee encourages suggestions from all employees. Mr. Mersman reports that this has been found very satisfactory.

The Continental Furniture Company, of High Point, N. C., say they have been interested in accident prevention since the factory was built about 25 years ago. They have been unusually successful in this respect for during all these years they have had but one serious accident. This was caused by the operator of a grooving saw wearing an old mitten which was caught by the saw and three of his fingers mangled. They are firm believers in the very safest equipment and safeguards. Like many other manufacturers, they feel that the safety movement is common ground on which both the employer and the employee come together and that it instills a little stronger spirit of loyalty throughout the organization.

A Safety Committee Operating for Ten Years

The Estes Manufacturing Company of Owosso, Michigan, has had a safety committee in their plant for at least 10 years. This committee consists of three men selected by the superintendent, one new member being added every six months and the oldest member in point of service being retired. This committee makes a survey of the plant every month and reports its findings in writing to the superintendent. Every recommendation is promptly acted upon and it has been the means of reducing accidents to a minimum. Out of 26 accidents reported during 1926 but one was compensable. Only \$21 was paid in compensation. Their greatest difficulty is to get the employees to report minor accidents, such as slivers, scratches, etc. The one accident on which compensation was paid was due to a sliver in the finger which was neglected.

The danger of infection from neglected slivers and scratches cannot be overstated. I recall an experience along this line where an employee scratched his finger on a Friday afternoon and feeling it was unnecessary to pay any attention to a slight scratch like this, he did not even report it to the foreman. He did not return to work on Saturday, but as this happened in the slack time nothing was thought of it. On Monday a telephone message from his home stated that he did not feel well and would not be able to work that day but expected to return within a day or so. On Wednesday we learned that he had a bad case of infection and a doctor was immediately sent, but by this time it was too late and on Friday—one week after the slight accident which was too trivial to pay attention to—his death occurred. The doctor advised us that had he been called earlier the man would not have died. The simplest first aid, such as iodine, put on the scratch at once would have saved his life.

A detailed account of the case was placed on every bulletin board in the factory and for many months afterward no scratch or sliver or accident, regardless of how trivial it might seem, was neglected.

It is too bad that it sometimes requires the sacrifice of human life to impress on us the necessity for care, but the death of this man impressed the necessity of medical care on a great many of the woodworking employees in Grand Rapids.

The Kittinger Furniture Company, Buffalo, N. Y., states that their management is highly in favor of accident prevention and gives it full interest and support at all times. They found it difficult to enlist the interest of the men until they adopted a new plan a little over a year ago which has since made their employees enthusiastic over accident prevention. The State of New York gives credit for good conditions and penalizes bad conditions. After thorough investigation the company decided to adopt the plan of self-insurance as outlined by the workmen's compensation law of New York State combining it in a way with their mutual benefit association so that their members would receive greatly increased benefits at no additional expense. The company agreed to stand half the expense of operating the mutual benefit association which pays benefits for all classes of non-occupational sickness and accidents. It is further agreed that on December 15 of each year, all the money saved by the self-insurance and the surplus in the mutual benefit association treasury would be divided equally between the employees and the company. This gave all a financial incentive to become interested in safety and soon the careful workmen were using their influence over the careless ones with gratifying results. For the past year the employees' share of the surplus was greater than the amount they paid for insurance.

A Combined Safety and Sick Benefit Committee

They have a combined safety and sick benefit committee, composed of the foreman and a representative, for each 20 workers in each department. This committee meets monthly to discuss safety, the accidents that have happened since the last meeting, and matters pertaining to the sick benefit association.

They also have general safety meetings with an outside speaker several times each year in order to keep safety before the entire plant. On a large black board, at the employees' entrance, are listed the names of each foreman, the number of days since the last lost-time accident and the number of lost-time accidents since July 1, 1926.

Up to August 17 last they had had but five lost-time accidents in the entire plant. One department had gone 648 days—over two years—without an accident.

Since July 1, 1926, when they adopted the new self-insurance plan there has been a reduction of 30 per cent in compensation insurance expense and 60 per cent reduction in accidents. This is a record that any factory may well be proud of.

I would like to quote many more of the experiences of our good friends who have so kindly and so willingly given them for our mutual benefit but time prevents that interesting pleasure.

I think enough has been developed to show that safety is practiced in a rather intelligent way and with a reasonable degree of uniformity in the furniture manufacturing branch of the great wood-working industry.

It gives me special pleasure to acknowledge the help given me by the many who have aided in the preparation of this paper, by so fully and generously telling of their methods and experiences in this great work.

MR. PRICHETT: I want to digress for a moment. Speaking of the courage to do the unusual thing reminds me of a case that was told by Miss Mill of our Furniture Mutual Insurance office the other day. It seems a man cut one of the tendons on a finger and he was sent to the surgeon and the wound healed, but after awhile the finger commenced to draw around and he couldn't use it very well. This fellow thought more of his compensation than he did of his finger, which is rather unusual, and he wanted the finger taken off at the second joint because if it was taken off at that joint he would get more than if it was taken off at the first

joint, and if he lost his finger he would get still more compensation. And so we sent him to Dr. Denham, and the doctor said he couldn't see any reason why the finger should come off. He thought he could fix it, so he cut in and found both ends of the tendons, drew them together and the last reports were that this fellow is going to be disappointed and not have his finger taken off.

We had another case in our own factory—a man on the rip saw was hit on the end of his thumb and we sent him to the surgeon's office. They X-rayed the finger and found that the bone was split and the thumb had been pushed back into it. Our doctor opened it up, took out a few slivers and bound the wound up again.

This doctor believes in getting men back to work as soon as possible, which is a very commendable thing, both from the man's standpoint and the standpoint of the factory. Three weeks after the fellow was hurt he was back working, and in six weeks he was working as well as ever, and the joint was in good order. Now, a year after that, this fellow doesn't know that there was an accident, except as a matter of recollection.

CHAIRMAN GRIER: We will now have the next paper by Mr. S. Horace Disston, vice-president, Henry Disston & Sons, Inc., Philadelphia, Pa.

The Development of the Circular Saw and Its Relation to Safety.

S. Horace Disston, Vice-President, Henry Disston & Sons, Inc., Philadelphia, Pa.

Modern industrial development, with its demand for greater and still greater production is entirely responsible for the fact that this is a safety problem in connection with the use of saws.

The saw is one of the earliest of tools. Saws have been in use from the beginning of history. But the man of the Stone Age, with his flint saw, working all day to cut through a two-inch tree-branch, had no safety problems. It is in modern times, when saw users are demanding cuts of 200,000, 300,000 and 400,000 feet or more of lumber in a single day that we have any safety problems in connection with the use of saws.

It is fascinating to trace the history of saws. The earliest saws were small flakes of flint, notched by chipping. These saws were rarely more than three inches long. They were used chiefly for making ornaments of bone and soft stone. Saws made of bronze supplanted those of stone. Specimens of these prehistoric bronze saws are rare. Not more than thirty have been found in all Europe.

In Sweden was found a stone mould for casting bronze saws. In this mould, four saws were cast at one time.

The Egyptians used bronze saws with jeweled teeth for cutting the hardest stone. These early Egyptian saws had teeth inclined toward the handle to cut on the "pull" stroke as do the saws of the Orient today. The Japanese sawyer of today cuts by pulling his saw, not by pushing as we do.

Although, as the facts I have just mentioned show, the saw is one of the oldest and simplest of tools, it did not attain any great importance until the last two or three centuries. Stone saws had no real value and those of bronze were little better. Then, too, bronze adapted itself so readily to edged tool construction that the saw was practically supplanted for a time. In many of the later savage races, the trunks of trees were split with wedges into as many thin pieces as possible and the lumber so formed was hewn on both sides to desired size.

Figure 1. Types of very ancient saws.

Iron was necessary for the construction of a useful saw, and the real beginning of saw development came with the invention of steel. The exact date of the first use of steel is not known. In 850 B. C., there were "bright iron" and "black iron." A Greek wrote in 50 B. C. that his enemies were "armed with weapons of excellent temper."

Since I have been asked to talk about circular saws I am going to pass over years and years of hand tool development and speak only of power saws—that is, of circular power saws.

The development of modern power saws dates from the introduction of the power saw mill. The first of these was of the reciprocating "up-and-down" type. Crude as were these old fashioned "up-and-down" mills, they were a great improvement over the previous method of sawing a log with

one man in a pit beneath it, and another standing above, using the old-time pit saw.

The earliest mills were driven by wind power, but a thirteenth century manuscript shows a water-wheel saw. Germany had water-power mills as early as 1322. Holland had saw-mills nearly a century before England. Development in England was retarded by the hand-sawyers, who felt that the introduction of power equipment would put them out of work and when, in 1663, a Hollander erected the first sawmill in England, it was abandoned because of a series of riots by hand-sawyers.

Figure 2. Some of the teeth in ancient saws.

More than a century later another mill was erected by a lumber merchant. Again the hand-sawyers resented the introduction of power saws and this second mill was destroyed by a mob. America's first sawmill was built at the Falls of Piscataqua, on the line between Maine and New Hampshire, in 1634.

Before the arrival of William Penn, in 1681, sawmills had been erected along the Delaware River by the Dutch and Swedes. In 1803 there was built, in New Orleans, a steam-driven sawmill. This mill met the fate of the early English mills—it was torn to pieces by a mob of hand-sawyers.

These sawmills were all of the vertical reciprocating—"the up-and-down" type. The saws were in a strong rectangular frame which was driven along guides by a crank on a revolving shaft. A sliding carriage, which was made to move forward a short distance for each stroke of the saw, carried the log.

At this time, the care of the saw and saw-sharpening was a secret process. The saw sharpener or, as we now call him, the saw filer worked in a locked room and anyone wishing to speak with him was required to ring a bell and wait for admittance until the filer could conceal all evidence of his methods of working.

The next important step in sawing came with the development of the circular saw. It is said that the first patent on circular saws is patent No. 1152, granted to Samuel Miller of England, in 1777. In any event, circular

saws for practical wood-cutting purposes were first used in England about 1790.

The first circular saw in this country is said to have been produced by a country blacksmith—Benjamin Cummings—at Bentonville, New York, about 1814. Two Maine Yankees patented a sawmill in 1820 which produced as much as 1,200 feet of lumber a day—a great output for those times. The saws used on these early mills were crude round sheets of metal with roughly punched out teeth, hammered flat on an anvil.

As saws were developed the requirements were for thinner blades and faster

Figure 3. Method of inserting the tooth.

speeds. To meet these requirements, came the invention of the gullet tooth saw—a saw having round gullets, and providing larger sawdust chambers. Along with this came the development of improved designs of saw-teeth for special work. The old "V" tooth gave way to many new shapes for particular uses. Next came the inserted-tooth saw, also known as the chisel-tooth saw, which provided a way to replace the teeth when worn, without reducing the diameter of the saw.

The difficulty with the early, inserted teeth was that there was no really satisfactory way of holding the teeth in place. However, this difficulty was overcome and progress in this field has been rapid.

The illustration shows the most recent development in this type of saw. It is known as a "log" saw and is used to manufacture or rip lumber from logs.

Circular saws of the inserted tooth pattern also have been developed for the cutting off of logs. We have made saws of this type as large as 110 inches in diameter for use on the Pacific Coast. These are the largest circular saws ever made.

With the old-time, thick saws, running at low speeds, one did not require the factor of safety needed in modern saws. But consider the 110-inch saws, I just spoke of. They weigh 675 pounds each and are made to operate at a rim speed of 130 miles an hour. Here we have a definite problem in safety.

The appearance of saws has not changed greatly since saws were first known. Therefore, it is difficult for those not familiar with saw-making to realize how great has been the development in steel and in the methods of treating steel to produce saws which are withstanding the strain to which they are put in modern sawing.

There are eight important points that a saw maker considers when he supplies a circular saw. Most of these points have a direct relation to safety. Users can secure saws that will do better work and do it with greater safety if they, too, will consider these points when they specify a saw for their work.

The first point is—what type of saw is wanted? This refers, of course, to the work being done—ripping, cross-cutting, mitering, special smooth-cutting, etc. Many types of circular saws are made today to do special kinds of work.

Determine Just What the Saw Is to Do

Do not think because someone else, doing a different kind of cutting, is getting a better production than you are, you should use the type he uses. His saw might not be suited to your work. Be sure of your ground or allow the manufacturer to decide.

Second, what diameter of saw is wanted? There is an old rule governing the size of a circular saw which says "a saw should be just large enough to clear the center, or collar, and still cut through the stock." It is neither efficient nor safe to set a circular saw so that the teeth project too far above the stock being cut. Occasionally, mistakes are made in measuring the diameter of a saw. Diameter should be measured from toothpoint to toothpoint through the center.

Third, what size of mandrel hole is desired? This is, apparently, an unimportant specification. But, when given incorrectly, it causes trouble. What happens when a saw is furnished to specifications but still does not fit the mandrel? Sometimes, I am sorry to say, it comes back to the manufacturer with a claim that he should have known better anyway. Sometimes the saw is put on the machine and, by means of bushings or other makeshifts, is fitted to the mandrel. Then you have a safety problem. The saw wobbles, the rim of the saw is forced out of line by pressure at the center—and trouble is almost sure to develop, particularly where saws are operated at high speeds. Unless the saws fit snugly on the mandrel there will be vibration at high speeds which makes accurate cutting and safe cutting difficult.

Fourth, what style of teeth are wanted in the saw? As mentioned before, there are many styles of circular saw teeth because circular saws are used for hundreds of different purposes. No general comments of any value can be made here on this point. Be sure the type of tooth you select is the right type for your particular work. Do not attempt to make one saw do three saws' work. For example, a rip saw cannot safely nor efficiently be used for cross-cutting. It is not made to cross-cut and may break if used for this purpose.

Fifth, how many teeth are wanted in the saw? As a manufacturer, I am

glad to say that the day of "freak" specifications, as far as the number of teeth are concerned, is passing. The general rule governing the number of teeth in a saw is: the greater number of teeth in a saw, the smoother the cut because the more teeth engaged in the work at one time, the more evenly is the cutting strain distributed throughout the saw. On the other hand, the larger the tooth the faster the cut because with large teeth and correspondingly large gullets, the saw will not fill up with saw dust and "choke down."

A table that embodies the experience of saw makers and saw users has

Figure 4. Details of saw construction.

been developed showing the recommended number of teeth for circular saws of various diameters. It is a good, safe rule not to deviate from these recommendations without expert advice.

Sixth, at what speed will the saw be run in the work? It is well to remember that it is universal practice for saw makers to tension saws to run at a rim speed of 10,000 lineal feet a minute. There has been considerable argument about the most profitable operating speed for saws. Even today experienced operators disagree. Speaking generally, and viewing the practice in all parts of the country as shown by the specifications coming to us, we find the tendency over a number of years has been to increase and increase again the speed at which saws are operated. Not long ago, we began to notice a reaction. The tendency was to cut down speed.

Today, it is not unusual to read an article or to hear a talk by an experienced saw user advocating less speed, not only for greater safety but for greater profit in manufacturing. Definite recommendation has been made governing the speed of circular saws in the National Safety Code for Woodworking Plants, and these recommendations have been adopted in a number

of states. Unless otherwise ordered, saw makers put into saws the proper amount of tension for this speed and there is danger in operating circular saws in excess of this speed.

For example, a manufacturer who was using our saws on his machines complained to us that the saws cracked. Upon investigation it was found that the saws were being run at a much higher rate of speed than was specified. This caused the cracking.

Proper Arrangement of Collars

Figure 5. Details of proper collar arrangement.

Seventh, what kind of wood will be cut? This information will put the manufacturer in position to cooperate with saw users in checking up on the saw, the teeth, the speed, and the other specifications.

Eighth, what is the horsepower that will drive the saw? Particularly in big saws, saws are often specified with a size and style of tooth that cannot be used with a driving force of limited horsepower. There is danger in attempting to use a saw that cannot be properly driven by the engine. This, then, is the first step to insure the safe use of saws—to be sure that the type of saw used is suited to the work to be done.

There are several things that may be watched after the saw is received and

put in use that will decrease the liability of accidents and, at the same time, insure better production from the saw. Briefly, these are some of the points that come up frequently in the use of circular saws, particularly small circular saws. I know that the great majority of you who use circular saws use the small saws and therefore, I will talk particularly about small saws.

First—Circular saws that have been carefully set and filed are often damaged, even before they are used, by pushing them against the slot in the table when turning the mandrel in cutting position. Before turning on the power, saws should be revolved by hand to make sure they clear the slot in the table and are running freely.

Figure 6. Typical crack in this type of saw.

Second—If the material to be cut has been used before, examine it carefully for nails or other metal.

Third—There is only one correct position for the operator of a circular saw. That is to stand to the side of the board to be cut. It is important for efficiency in the work and for safety that the operator does not stand directly back of the work.

Fourth—Use a "push stick" when feeding small pieces through a saw.

Fifth—Bring the saw to a full stop before the angle of the table, the depth of the saw, or other such adjustments, are made.

Sixth—If the saw "whistles" or "sings" when it is up to full speed, this indicates that something needs attention. Some of the first places to look for trouble are:

- a. Is the locking nut on the mandrel loose, permitting the saw to wobble?
- b. Are the mandrel journals smooth and running freely?
- c. Is the saw properly tensioned and are you running it at the speed for which it is tensioned?
- d. Are the teeth properly beveled? The teeth of saws for cross-cutting

should be beveled on both the face and the back—one tooth being beveled to the right, the next to the left, and so on, with the high corner on the outside. Teeth of saws for ripping are filed "straight through" or square across on the face with a slight bevel on the back. The bevel should never extend into the gullets. A saw for cutting hardwood is usually operated with less bevel than a saw for cutting softwood.

Seventh—When the saw "jams" in the work, do not attempt to force the work through. Withdraw the material and go again through the cut. If the saw till binds, stop it and find the cause. A saw suited to the work being done and in good condition will not bind. Examine the saw that binds to see that the teeth have sufficient set and that they are sharp; see that the saw is running in a true line; look for burned (or blue) spots on the side of the saw—such spots indicate that the tension has been destroyed and the saw is running out of line.

Many Causes of the Saw Heating

Eighth—Take particular care to see that the collars which support the saw are true and that only the narrow flat face at the edge of the collar comes in contact with the saw when clamped in position. When the inside of the collar is not machined out properly there is a bearing against the saw, inside of the collar line, which forces the rim of the saw out of line. The result is a buckling effect on the saw, causing heat both on the rim and near the collar line, and, in some cases, causing breakage.

Ninth—Do not run a saw that gets hot in the work. Heat in a saw indicates trouble.

The most frequent causes of heating at the rim are:

- a. Running saw when dull.
- b. Teeth with insufficient set or swage for clearance.
- c. Teeth with insufficient gullet space.
- d. Teeth with too little clearance on the back.
- e. Gum or resin sticking to the sides of the saw at teeth.
- f. Running saw when dished or not level on the face.
- g. Improper tension; i. e., too little tension so the saw is too stiff in the body.

The most frequent causes of heating at the center are:

- a. Improper tension; i. e., too much tension so that the saw is too loose in the body.
- b. Speed insufficient to take up the tension in the saw.
- c. Heating of journal next to the saw.
- d. Saw having too much "lead" in or out of work.

Tenth—It is dangerous practice to use saws after cracks have appeared. At least 60 per cent of the cracks in saws are caused by failure to retain the curved shape of the gullets between the teeth.

Being a saw maker, I have talked only of saws. I shall not attempt a discussion of the many factors such as guards, stops, etc., that also have to do with safety in the use of saws.

It has been our belief that in the operation of saws, as in the operation of other machinery, "the best safety device is a careful man." If the man operating the machine is a careful worker, the machine is apt to be a safe machine. In our company, for eleven years, we have been organized to teach the men who work with us to be careful. We have, of course, guards and safety

devices where we can place them. But a great part of our work has been done through education.

Our organization consists of a safety engineer, workmen's safety committees, a general safety committee and a medical department. Each workmen's safety committee spends one afternoon a month with the safety engineer making an inspection of its division of the plant. The safety engineer makes daily trips of inspection, investigates every accident and reports on ways to prevent a repetition. The general committee reviews all recommendations and suggestions and provides means for carrying out those adopted.

Our work has been successful and has paid us worthwhile returns in money and in happiness as you will see from the figures in the accompanying table, which show the reduction in the number of time-losing accidents in our plant each year from 1916 to date.

Number of Time-Losing Accidents Per 1,000,000 Hours Worked

1916	1917	1918	1919	1920	1921	1922	1923	1924	1925	1926
38.2	18.0	12.6	10.3	8.75	7.7	9.7	9.7	10.3	9.78	5.93

CHAIRMAN GRIER: Gentlemen, I think we all enjoyed Mr. Disston's paper, it is something that much has been said about and probably much more will be said about.

I am told this is the largest meeting the Woodworking Section has ever had; and being my first to preside at, it is very gratifying to me. Let us keep up the good work.

This period of the meeting is given over to the discussion of the papers that were presented this morning. I would like to hear from any one who has any questions he would like to have answered by the speakers at this time.

R. JONES (Surtz Manufacturing Company, Chicago, Ill.): In your discussion of the solid feed roller on the planer to prevent kickbacks—do you know of any method of preventing that.

CHAIRMAN GRIER: Yes, there are guards on the market that will prevent that. There is a sectional guard that consists of a series of dogs that hook on to the frame of the machine ahead of the infeed roll, the material passes under it, this raises the dogs, if there is a kickback the dog drives the material against the table of the planer.

MR. JONES: That was the point I wanted to bring up. There may be some members who are not familiar with articles of that kind and may be under the impression that there is no very adequate way of taking care of it.

Also on the question of getting men to wear goggles when they come up to do any intermittent grinding on a wheel, from my experience it is hard to get them to put their goggles on, and there has been a very efficient machine goggle developed to take away the big end of that careless hazard that you have.

CHAIRMAN GRIER: That is a good point, Mr. Jones. That is what we want to bring out.

MR. JONES: If the members will come down to the exhibit hall I will be glad to explain in detail and show them the models of the actual stuff that will prevent that kind of accident.

CHAIRMAN GRIER: I have a couple of cards that were turned in: "Why as a rule are woodworkers so hard-boiled as to ability to operate machines without guards?"

That is a pretty hard question to answer. I would say that none of the fellows are so hard-boiled but what they can be shown if the proper procedure is gone through.

I might tell you how we handled one fellow who was so "hard-boiled" that he would not use a guard on a shaper. We had two wood mills, one an upper car mill, and one a lower architectural mill; the upper employing 50 men, the lower 150 men. We became very slack in the upper car mill and we had to either transfer our men to the lower architectural mill or lay them off. I wanted to get this one particular fellow and I told him that we had to let him go or transfer him to the lower sash mill. He said, "It is hard times and I cannot get a job, so I'll go to the sash mill."

He went down, and we put him on the shaper. The foreman of the architectural mill will not permit his shapers to be operated without the guard, and this man would not use the guard. The foreman said, "All right, we don't want you; you can go home or use the guard." He went home and stayed there for a couple of days and then came back and asked me if I had a job. I said, "I have a job in the sash mill. When you want to go back there and use the guard you can have it." He said, "No," and went away, but he came back the next morning and asked if the job was still open, and I told him it was, under the same conditions; so he came back and went to the architectural mill. Eventually we got busy in the upper car mill and now he will not operate a shaper without the guard.

That is probably the procedure you will have to go through with some of these so-called "hard-boiled" men, but you will find that they are not all hard-boiled after you get close contact with them.

Employees Approve of Good Safety Work

M. B. GATHMAN (Fisher Body Corporation, Detroit, Mich.): There are two things I think that cause it. In the first place the safety end has not always been an active consideration, it is only in the last few years that the manufacturers are taking a real active interest in this and in putting over these safety programs in the last few years, I think the rules have all been arbitrary. Somebody gets up an idea and it is worked in as an afterthought, and then it is forced upon the man in the plant to use it. Then, as a rule, he doesn't take kindly to it because it isn't adequate.

I find, in developing safety features, that where you get something that is really good, and where the men have been educated to safety, all of them get right behind it and use it and are for it.

R. C. BARR (Lumbermen's Mutual Casualty Co., Chicago, Ill.): I think one of the best arguments I have had in my work is to convince the old time wood worker that the object in the use of guards is that he is not the same man one day that he is another day, that he is liable to have his off days when he is not feeling so good, he is not so thoughtful, he may have had a few words with his wife in the morning, and that may have been on his mind and not his work. I have found it very beneficial in my work, to be able to convince these men that the guard is there to take care of them on days when they may be bilious or have other physically impairment.

While I am on my feet I would like to speak a word about wood slivers. I just finished an analysis of 865 accidents in lumber yards, 25.6 per cent of the accident causes were wood slivers, and from 25 in one operation to 60 per cent in others, these wood sliver accidents resulted in infection.

I went to see our chief surgeon about them and talked to him about wood slivers. He told me the surgeons liked to remove the slivers themselves because they can tell then whether there is any piece left in or not; but the prompt

first-aid treatment of wood splinters, I think, is recommended by every one; and in every case, with the exception of one in the 25.6 per cent of the 865 accidents the men waited four days before reporting wood splinter accidents to the proper authorities.

CHAIRMAN GRIER: In my paper I touched on the importance of keeping an eye on the minor accidents, and this bears out my statement that your minor accidents frequently will develop for you the place at which to direct your safety activity, because that is where your lost time accidents are likely to come on.

B. A. SHROEDER (Hartford Accident and Fidelity Company): I noticed in the slide the picture of a saw guard on which there was neither a splinter nor a kickback guard. We don't ordinarily recommend that type of guard for a rip saw. You generally find them hooked up in position the way they are to be used.

MR. DISSTON: At the moment I cannot recall whether that was a ripping or cross cutting operation.

CHAIRMAN GRIER: I think it is recognized throughout the woodworking industry that the splitter is really the guard on a saw.

MR. DISSTON: On the cracked saw, circular, if the saw is only slightly cracked center punching may help for a time.

HARRY S. NEWTON (Kohler Industries, New York City): In Mr. Prichett's paper he spoke of a self-insured savings, using it for mutual benefit. How do they arrive at a figure for savings for this mutual benefit that the firm has made on the self-insured plan?

Records of the Accidents Are Always Important

MR. PRICHETT: I couldn't tell you a thing about that, but I know that the Kittinger Furniture Company, who operate that plan, will undoubtedly be glad to give you that information.

MR. BARR: I think that one of the most important phases in getting started on accident prevention is to keep a record of the accident. I believe you mentioned that in the beginning of the talk. I have called on a number of risks from Florida to Alaska and I always make it a point to ask the employer if he keeps a record of his accidents. In nine cases out of ten they do not. If you call to their attention specific occurrences of injury to their employees they are surprised when the fact confronts them regarding the number of and the severity of accidents that have been sustained by them.

CHAIRMAN GRIER: The majority of his accidents are probably repetitions of the cause of the first accident.

O. J. OLSEN (Fisher Body Co., Detroit, Mich.): Mr. Chairman, you speak about laying a lot of stress on frequency of accidents in mills. Don't you give severity some consideration?

CHAIRMAN GRIER: Absolutely.

MR. OLSEN: Which do you consider the most important?

CHAIRMAN GRIER: From my own experience I consider reducing the frequency of accidents the most important of our safety activities. I do not mean to overlook entirely the severity of accidents, but if you will follow any statistics on accident prevention work you will find that in 90 per cent of the cases where frequency has been reduced, severity has been reduced in proportion.

MR. OLSEN: While I am on my feet, then, on this that you have either your mills pretty well guarded or you have the men pretty well educated. You say you have guards on your shavers, where are these guards, are they at point of operation?

CHAIRMAN GRIER: We have the transmission of all machinery guarded. That is a first law in our company. We must have our transmission guarded, and

guarded properly. That eliminates the accidents in transmission and other than point of contact. The spring guard which is a circle bolted to the back of the table with an arm carrying the guard, that fits down over the head and the work passes in under this block of wood, and is held down on the work by a spring, and the work is forced against the head, under this, and is held to the table by the spring.

MR. OLSEN: You use detailed shapers—what do you do with the square head top bearing overhead shapers.

CHAIRMAN GRIER: We use there the masher for most of that work, and where we can on the shaper we use this spring guard; where we cannot use it, the best guard is the careful worker.

MR. OLSEN: On this guard that you talk about, the detail shaper guard that serves another purpose, doesn't it, besides a guard?

CHAIRMAN GRIER: It serves the purpose of holding the material solidly on the table as well as keeping a man's hands out of the knives.

An Example of the Hard Boiled Employee

G. A. ORTH (American Car and Foundry Company, New York City): With reference to the "hard-boiled" man in the shop, I would like to cite an incident that occurred many years ago at our Madison Plant. We had in the mill a foreman who was "hard-boiled." When he was asked to put on guards that had been supplied by the company, over saws and gainer heads and various other forms of machines, he would come and tell me: "I have ten fingers on my hands and I don't propose to put any guards on these machines."

He was a valuable foreman and we couldn't dispense with his services. Then the question arose as to how to get around this individual. In order to touch his pride I told him this one day, "Henry, at our B. plant which is the largest of our company, they are not able to develop a guard for a gainer head. I understand that you are a practical man in the mill. I wonder whether or not you are able to devise something that we can get down to Berwick?"

That touched his pride, to think that Berwick had no mechanics to develop a guard and that he would be called into action, and Henry immediately went into his office, and in two days he did develop something, a guard for the gainer head, and we used that. At that time we were publishing a plant paper for all the plants and I had Henry photographed with this guard and of course that was broadcast from there, and from that time forward Henry became a safety first man.

CHAIRMAN GRIER: There are all kinds of methods, gentlemen, that you can employ to win over this so-called, "hard-boiled" operator, and that one was typical.

W. A. WILSON (Frank G. Eares Sash & Door Co., Los Angeles, Cal.): I would like to ask Mr. Olsen, who spoke at the luncheon yesterday, regarding the guard on a shaper. Our difficulty in using guards on shapers in circle-head work is rather extensive. I want to know if either you or Mr. Olsen have guards for shapers that will operate when you are doing circle-head work. I am thinking of the sash work now, where you have circle heads I have found it difficult to get a guard that will operate under those conditions.

E. BRATNY (Pullman Car & Manufacturing Company, Chicago): We have a guard in perfection now, to protect the circle-head work with safety. It will be on the market soon.

MR. WILSON: I am thinking of the circle-head work that is held in a vertical manner, and they feed it in on one side and feed it out from the other.

MR. BRATNY: Ours is for flat work.

MR. WILSON: That is the point.

MR. O. J. OLSEN (Fisher Body Co., Detroit, Mich.): Talking about proper

filling on a detailed shaper we covered it 50 per cent. We don't cover point of operation; we put a casting on top of the spindle, take the nut off and cover the part of the knife that is not in actual contact with the work. In other cases we have just a disk fastened on with a bracket that hangs over the top of the head, but that is only part of it, the point of operation is the important part, that is what we are trying to get at.

MR. JONES: I might say in answer to that, that my company is developing a shaper guard which will be down stairs probably tomorrow—maybe this afternoon—and I would like to have as many men as are interested in shaper guards look it over. In other words I want all the criticism I can get. We have an idea worked through and will have a model at our booth.

MR. OLSEN: May I ask another question? You made a statement that you think

that if we had our table saws—ripping—equipped with the spreader or splitter, that it would answer the purpose. Is there anybody here who can tell us something about kickback on table saws?

MR. JONES: I might answer that if I am not talking too much. There are two points where kickbacks should be placed on the saw guard to be really efficient. The worst kickback, that will cause real injury to an operator, comes from the rear of the saw. In other words the lumber must pass to the rear of the saw. The kickback dog, to give real service, and hold, should be attached to the guard rather than to the splitter so that it automatically remains in the same relationship on various thicknesses of material. In other words if you fasten a kickback dog to a splitter say six inches long to set at the proper angle on one-inch lumber, if you put four-inch lumber in there you are going to have a different angle entirely, and unless it is very sharp you don't get much holding power; if that dog is fastened to the hood of the guard, if the hood is raised automatically the dog should remain in the same relationship, no matter what the thickness of the

slot may be, to give real efficiency and prevent kickbacks. I have found from experience that on ripping short stock lumber it will have a tendency to creep back, as a rule, not with very much force. We have just developed also a very efficient kickback for the front of the guard as well as the rear.

CHAIRMAN GRIER: I think, Mr. Olsen, that a splitter of the proper kind, proper stiffness, located in the proper location to the saw, will prevent kickbacks in the majority of the cases. The great fault is that the splitter is too far away from the saw and not in proper adjustment most of the time. A different size saw is put on with the splitter attached to the table rigidly and we have a gap between the back teeth of the saw and the splitter.

R. G. BUCHANAN (Edward Hine Lumber Company, Lumberton, Miss.): Where a foreman in one plant is not in sympathy with the rules used in another plant, do you force them on him?

CHAIRMAN GRIER: That depends on how far you want to carry on. You have got first to use diplomacy and tact. If that fails, get rid of the man or tell him that he has got to do it.

Each Case Must Be Handled Individually

MR. BUCHANAN: But you do not force the same tactics in various plants?

CHAIRMAN GRIER: You may be able to get something better from the man who is not adopting your policy; if not, see that the policy is put into effect in his mill and see that he works with it. No man is so valuable that he can ignore safety and stay in the employment of any company—he can be replaced and replaced with profit.

MR. BUCHANAN: Here is what I am trying to get at: does anyone try to make one rule apply in all cases?

CHAIRMAN GRIER: We do not.

MR. OLSEN: We have a number of plants scattered all over the country and we do not use this word rule too strongly. We have made up a lot of suggestions for the safe operation in the mills, and we send these from the central office to all our mills.

You will have to decide yourselves when the psychological time comes for these removals.

You also have to take into consideration: are you a salesman? Are you selling it right?

In matters of discipline, changing is the last resort. You can hand the honey out with this hand here, but have the "big stick" down alongside of you.

As far as we are concerned in our mills we can apply the same suggestions in all of them.

Take, for instance, a cracked saw: the code says you shall or you should (use your discretion between should and shall) not use a cracked saw. One fellow says it is all right if you center punch it one side; the other says on both sides; and a third says drill it. We have plainly outlined in our suggestions when we would use a cracked saw; we don't like to use them, but there are occasions on certain kinds of work where we do use a cracked saw and we limit the length of the crack and how it shall be taken care of before we use the saw. We don't say "Don't!" We try to outline in detail the nature of the operation, and that comes through our mills.

MR. ORTH: I would suggest to Mr. Buchanan instead of the use of the word "obey" safety, use "observe" safety—I am like the man in the marriage ceremony—eliminate the word "obey" and he "will marry Mary."

CHAIRMAN GRIER: Gentlemen, we have a moving picture of the logging industry,

Woodworking and Lumber Manufacturing Section 1007

provided by the Edward Hines Lumber Company of Lumberton, Mississippi. We will put that on at this time.

(Screening of "Logging and Lumbering Operations in Mississippi," was shown by the Edward Hines Lumber Company, Lumberton, Mississippi)

ADJOURNMENT

General Session

Educating the Public for Safety—A Symposium

LUCIUS S. STORRS, Chairman
Managing Director, American Electric Railway Association,
New York City

The Public Safety Meeting at the Sixteenth Annual Safety Congress, Hotel Stevens, Chicago, Illinois, was called to order at two-fifteen o'clock by the chairman, Lucius S. Storrs, managing director, American Electric Railway Association, New York, N. Y.

CHAIRMAN STORRS: The program for this session has for general subject, "How can we educate the public for safety?"

The addresses will bring to your attention the activities of various public bodies, public industries and utilities in connection with their work.

As you travel around the country you feel more at ease if you see, as you do, on some of the great railroad systems the slogan, "Safety First." Coming out from New York yesterday I was impressed with the fact that there were banners of safety along the lines over which I was traveling.

It gives me great pleasure to introduce to you Mr. Charles E. Hill, general safety agent, New York Central Lines of New York and vice-president for Public Safety, National Safety Council.

The Viewpoint of the Railroads

Chas. E. Hill, General Safety Agent, New York Central Lines, and Vice President for Public Safety, National Safety Council, Representing the Railroads

There are over 600,000 miles of railroad in the world, one-half of which are within the confines of our own country, and they represent an investment equal to one-tenth of all of the values of the earth. The growth of the railroads in the United States has kept pace with the growth of our nation. They are owned by some 1,800,000 stockholders. They constitute one of the basic forms of business of our country.

Efficient transportation as provided by the American Railroads has had more to do than any other agency or combination of agencies in establishing good citizenship, and also that high standard of living which is not equalled by any other country in the world. Therefore, it is only natural that in keeping with progress along other lines, the railroads of this nation should have a keen interest in any suggestive remedies having for their purpose the saving of human life, for the railroads have long since recognized safety as essential to successful railroad operation.

Quite successful safety performances are being made by the railroads of the country today due to the systematized manner in which safety is being conducted.

The steam railroads of America were among the prime movers in the inauguration and promotion of organized safety in the United States, and as a result, railway employment today is less than one-third as hazardous as it was fifteen years ago.

Organized Safety Is a Vital Factor

Organized safety has indeed been, and still is, a vital factor in railroad operation. In 1913, which was prior to the time constructive safety work had an opportunity to make itself appreciably felt, there were upon the railroads of the United States—based upon reports made to the Interstate Commerce Commission—10,964 persons killed and 200,308 persons injured. In 1926 there were 7,090 persons killed and 130,293 persons injured, representing a reduction of 35 per cent in deaths and 35 per cent in injuries. It must be remembered that this reduction in casualties—which refers to all classifications—was made in the face of a material increase in the number of railroad employees, an increase in the volume of freight and passenger traffic, and what is of still greater moment, an increase of 125 per cent in the number of casualties at railroad highway crossings.

Confining ourselves to employees, we show a reduction from 2,353 deaths and 170,239 injuries in 1913 to 1,587 deaths and 111,241 injuries in 1926, or a reduction of 33 per cent in deaths and 35 per cent in injuries. In 1913 there were 350 passengers killed on the American railroads as compared with 155 deaths in 1926, or a reduction of 56 per cent. The reduction in the number of casualties to employees and passengers during the past thirteen years has been nothing less than phenomenal, and while the hazards incident to railroad employment have been materially reduced during this period, the safety of passenger travel has been greatly increased. Of the 155 passengers killed last year through the operation of the American railroads, only 79 of them were due to train accidents, the remainder being due to causes largely beyond the railroads' control. During the same period there were 23,000 persons killed due to automobile accidents occurring in the streets and highways of this country, of which number 7,600 were passengers in the car. This comparison serves to cause a further appreciation of the splendid safety achievements of the railroads of this country, and this feature is further emphasized when we know that the railroads of the United States last year carried 860 million, 343 thousand passengers, or the equivalent of 35½ billion passengers a distance of one mile.

Therefore, travel by railroad train in this country has reached a position not only of comfort, ease, and enjoyment, but also of security and safety. In fact, there is only one place today that may possibly be considered safer than when traveling as a passenger on a railroad train, and that is when you are asleep in your own home. However, an accident that occurred in Nebraska recently has

caused me to be somewhat skeptical as to the safety of your own bed. Two women were driving along the highway in that state, and from some unknown cause lost control of the steering wheel, and drove their machine up over the curbing, striking a three room bungalow, knocking the wall down, continuing on into the bedroom and across the bed in which two bachelor brothers were quietly sleeping, not stopping until their machine arrived at the kitchen sink. While the two men were not killed, their sleep was somewhat disturbed.

The hazards occasioned through the operation of the American railroads have, for many years, challenged the attention of men whose vision has been broad enough to visualize the necessity of placing into effect a definite program that has resulted in a downward trend in accident frequency.

Fifteen years ago, or about the time organized safety began functioning on the railroads of this country, our progress at first was measured almost wholly in the elimination of the physical conditions that were contributing to the nation's casualty toll. We were then primarily concerned with a situation that was obvious to the layman. While the work of accident prevention at that time was of interest, yet it had a touch of the inanimate, for we were dealing with the physical side of safety.

As time went on, we gradually passed from the physical aspects into the realm of the human equation. Man has kept pace with progress in that he has modernized machinery, he has renovated our industrial plants, he has put his house in order so that accidents from the proper use of these agencies have been rendered almost negligible.

Man Made Machines Are Ahead of Mental Training

The progress of things which are inanimate brought about through the ingenuity of the human mind, has been greater than the progress of man himself. While he has been busy delving into the intricacies of the things which are for the betterment of mankind, he has neglected to train the mind to meet the new order of things as they exist today. Thus we find the human element as the potent factor in our safety program, and this being true, we must of necessity train the mind so that man in the performance of his duties will pursue the course that is efficient and safe.

To carry on accident prevention work successfully, it matters not whether it is in the industry, the home, the street, or elsewhere, we must proceed along orderly and intelligent lines, following a preconceived, definite program. We must not only know how many people are killed and injured annually through accidents, but we must know where they occur, and how they occur, always having in mind that a careful analysis precedes an intelligent remedy.

As already stated, the railroads of the country have been quite successful in accident reduction, particularly as it is related to employees and passengers—accidents which, in a measure, are under their control; but while these accomplishments have been made, there has been a marked increase in accidents involving the public at highway crossings. This has been due to a large increase in the number of automobiles, which, together with the extensive mileage of improved highways, has immeasurably increased the volume of traffic on the highways and over such crossings.

It is worthy of note, however, that motor vehicle accidents in the streets and highways have increased three times as fast as they have at grade crossings, which evidences the fact that the application of safety measures has been effective in the prevention of crossing accidents.

The Safety Section of the A. R. A. recognizing the importance of this problem, organized a committee on the prevention of highway crossing accidents five

years ago. The efforts of this committee, plus the safety work of the various railroads, have borne fruit, for while the number of automobiles in 1926 as compared with 1923 (the year this campaign became effective) increased 46 per cent, and the number of casualties resulting from automobile accidents in the streets and highways increased 29 per cent, the number of casualties at highway crossings during the same period increased only 10 per cent. The work of this committee has been made more effective by reason of the splendid cooperation of the various organizations and agencies most directly concerned.

The crossing accident problem is a subject within itself, and will not be discussed at this time excepting to say that our immediate remedy is through a cooperative procedure as between the railroads and the public. Our chief success in the prevention of accidents to our employees lies in the spirit of cooperation between employer and employee, and if our contact with automobile drivers was as close as it is with our employees, and the response toward cooperation was proportionate, we would materially reduce crossing accidents immediately, and eventually bring them down to an infinitesimal number.

A Problem of Constructive Education

Our experience in industrial safety teaches us that after our engineering work has been done—after we have ascertained the causes and corrected the conditions—that our problem is one primarily of constructive education. Since education is the real fundamental upon which effective safety work can be based, we must learn how our employees and also how the public can be educated. The railroads have a keen sense of their responsibilities, not only to their employees, but to the public as well. The strides they have made in accident prevention prove the efficacy of their plan. If a similar procedure were followed as regards accidents that more directly involve the public, it would mean the weeding out of a large army of incompetent and reckless motorists that infest our streets and highways, thus assuring a greater degree of safety for the large majority of motorists who are careful. This would immediately bring about a marked decrease in the number of street and highway accidents, and would result in the saving of many thousand of lives each year.

The consummation of such a plan is essentially a problem for the community as a whole. We have our responsibilities as citizens. We owe our allegiance to our flag and our country. We adhere to this allegiance not through compulsion, but rather through a desire to serve the citizenry that go to make up this great nation of which we are so proud to be a part. If we are disloyal to our country, we, in a measure, disrupt the moral fabric of our citizenship. To be good citizens means to be good safety men and women, for good citizenship and safety go hand in hand.

The American railroads are now engaged in the greatest safety campaign in their history. Their goal is a 35 per cent reduction in accidents by the end of 1930. A large number of railroads have already reached this goal, but they are pressing on and on, not content that they alone have succeeded but desiring to aid those who are less fortunate.

The railroads would have no greater satisfaction than to have the realization that their efforts will also be instrumental in inculcating in their hearts and minds of the men and women of America a full appreciation of their individual responsibilities in the conservation of human life so that through this medium there will be a greater spirit of cooperation upon the part of all organizations and agencies, ultimately resulting in the establishment of not only a safe place in which to work but also a safe place in which to live.

Public Safety Sessions

CHAIRMAN STORRS: The utilities, so known, have touched intimately the daily lives of the largest portion of the public.

We will be favored with a brief talk by Mr. H. F. Webb, general safety director, West Penn System of Pittsburgh, Pennsylvania.

The Viewpoint of The Electric Railways and Utilities

H. F. Webb, General Safety Director, West Penn System, Pittsburgh

The progressive public utility is interested not only in safe-guarding its employees by all available methods, but also in the protection of the public, residing in, or traveling through territory occupied by the railway, light and power systems. Most of this protection is afforded by high standards of construction and operation, the safe equipment, or the recommendation only of safe equipment, by careful maintenance of properties and prompt service to customers. But having attended to all this, the Public Utility company realizes the need of a well sustained system of safety educational publicity.

The West Penn System, Pittsburgh, Pa., developed an interesting and productive Public Safety program beginning the year 1925, and the result of its application brought a reduction of fatal accidents to the public from 27 reported during the year 1924, to 7 fatal accidents the year 1925, or a 74 per cent reduction. The methods used which may have been partially possible for this reduction are as follows:

(a) *Safety Talks and Lectures* given wherever the opportunity was afforded to Kiwanis, Rotary, Lions, and other clubs.

(b) *First Aid Talks and Demonstrations* given in all cases where manufacturers and fire-departments requested this service.

(c) *Newspapers* cooperated to the extent of publishing all copy furnished.

(d) *Car (railways) Cards* helped to inform car-riding patrons precautions that might be taken to insure greater safety.

(e) *Dash (railways) Posters* displayed on front and rear ends of cars were helpful in bringing safety to the attention of pedestrians and automobile drivers.

(f) *Public Schools Plan* designed for teaching children the fundamental principles of safety.

The importance of public school safety work should not be over-looked, for it is among children that the need is greatest, and once a young mind is impressed with the great need for carefulness, gratifying returns may be expected. There is little question that children are the best advertising mediums to be found and where printed matter would be wasted effort, insofar as adults are concerned, a child will carry the whole story home to the willing adult ear.

During the spring semester 1927, the speaker personally visited 93 schools, gave 203 talks, ranging from a ten minute to a forty-five minute school period, and carried the safety message to 52,170 school children from the primary to the highest grades. The safety talks were given in a language understandable to the grade of pupils addressed. A stiff, stilted, grown-up manner of address would be entirely lost on school children, and the successful speaker must be as changeable as to age, action, talk, etc., as a chameleon. The "Always Be Careful" clubs were formed in each school and the members were given buttons and printed folders containing a safety pledge and rules. The motion picture film "Ask Daddy" was shown at each opportunity as the scenario ties in with the formation of the club.

It is of course necessary to enlist the cooperation and sanction of school authorities before such work may be started.

The West Penn System has found this last named treatment of the public safety situation by far the most productive of results, and heartily endorses this plan of attack to other utilities, industries, etc., interested in public accident reduction.

CHAIRMAN STORRS: Another phase of the public transportation problem and one which I think we all recognize as being a most vital one, is that of the service rendered by taxicabs.

We have the pleasure of having with us this afternoon Mr. W. W. Cloud, president of the National Association of Taxicab Owners, and president of the Yellow Cab Company of Baltimore, Maryland.

The Viewpoint of Cab Companies

Wm. W. Cloud, President, National Association of Taxicab Owners, and President and General Manager, Yellow Cab Company, Baltimore, Md.

The particular subject assigned me covers two separate and distinct passenger transportation industries. Different as to their equipment composition, operating methods and business conduct. Both however have grown to tremendous proportions in recent years, representing vast capital investment, employment importance with mileage performance and passenger carrying records which have earned for them a deserved position in the great scheme of passenger carrying industries of our country.

Charged with the responsibility of transporting a goodly percentage of our population year by year, those of us actively engaged in this work realize that the small percentage of accidents and fatalities against miles operated, is not a condition of chance but has been accomplished through proper business conduct and the adoption of safety methods applied to operations, together with the education of and cooperation with the public.

Referring to the standardized cab industry, for which by reason of an active identification with it of 19 years, I can speak from experience and with some degree of authority, I know that its operators consider safety a business fundamental, without which success would be impossible. To this end, they each year, either appropriate a definite lump sum or set same up from mileage run to be used for educating their employees and the public as to the value and importance of safety. To succeed in the role of educator, one must be educated, particularly when one's pupil happens to be the public.

Therefore, the cab industry some years ago started to put its house in order, and the good work has continued. Hiring and firing methods of the old days were abandoned. Careful selection of employees, with physical examinations and psychological tests for drivers was introduced. These drivers were proclaimed to the public as safe, honest and courteous and by like token were the improved conditions emphasized in the public mind. Many thousands of dollars in newspaper publicity were spent throughout the country to carry this educational propaganda. Safe drivers schools and safety contests were promoted within the organizations. Of these the public were told about through convincing newspaper advertisements, booklets, pamphlets and other media. Out of the campaigns safety contagion has been spread.

Through the convention activities of the National Association of Taxicab Owners, with which many of the standardized cab companies of the United States are affiliated as members, a number of cab operators have become actively associated with their local Safety Councils and by reason of their knowledge and experience in safety work, have been of practical help in the development of these Councils and the carrying on of their activities.

The officials of our association have consistently urged these affiliations,

realizing that with the adoption of public safety as an important part of the work, representative organizations, such as the National Safety Council and local Safety Councils, have a definite function for them, reach the public in an educational way and should be supported.

Time does not permit a brief on what the bus industry is doing to educate the public as to safety, nor am I qualified to give same; however the great importance of this industry and knowing the caliber of men who are identified with it, we can rest assured that they are doing their full part and can be counted upon to cooperate and help further the usefulness of this great movement.

In conclusion, this short brief would be sadly lacking were it not to emphasize the fact that these of us who by virtue of our occupation are from time to time brought close to the great tragedy of accident, fully realize our responsibilities to the public and are conscientiously striving to bring our operations to a higher degree of safe conduct. Out of which not only comes the material compensation of greater efficiency and more orderly procedure but the higher humane reward of helping safeguard life and limb.

CHAIRMAN STORRS: Private transportation, which almost killed off public transportation until it came to life again, is one of the vital factors in our public life because about 25 per cent of us use private instead of public transportation. The motor clubs of the country are doing a wonderful job in connection with safety work and we are fortunate in having with us Mr. Charles M. Hayes, president of the Chicago Motor Club of this city, who will present the matter to you. Mr. Hayes.

The Viewpoint of The Motor Clubs

Charles M. Hayes, President, Chicago Motor Club, Chicago, Ill.

Long before there was any serious accident problem, the Chicago Motor Club was engaging in active safety work, for we could see that the growth of the automobile industry would bring with it a stupendous accident problem. In those early days the danger of grade crossings was stressed. Motorists had not learned the high degree of danger that exists at these crossings, and at that time the railroads had done little to protect the motoring public. Today the grade crossing danger has by no means passed, but motorists are more aware of this danger. The railroads are doing great work in protecting and in eliminating dangerous crossings and are deserving of credit for their endeavors in trying to reduce grade crossing accidents.

The next stage of development was the sign erection stage. Like the grade crossing stage of safety development, this sign posting stage is still here. Our progress in accident prevention has brought additional needs, but we have by no means outgrown our dependence upon warning signs—in fact, the need is more pressing today than ever before. As soon as the club in the early days, with its small membership of a few thousand, could afford to pay for warning signs, we saw to it, that they were erected at dangerous crossings. (In fact, I used to go out on sign boarding expeditions myself.) This work is being carried on today on a scope that the limited finances of the early years could never have permitted.

Our accident prevention department maintains a large map of Chicago on its office wall, and whenever a fatal accident occurs the location and nature of the accident are indicated on the map by the use of colored pins; and the large numbers of pins clustered in certain spots bring up vivid pictures of the tragedies that have happened there. An unusual number of accidents in one spot

indicates some unusual hazard, and just what this is we try to determine. If it is in a school district, we find out whether or not there is a schoolboys' patrol, and, if not, why not.

This department concerns itself with the saving of life, and uses many methods in promoting the cause of safety. The erection of warning signs is one method. Warning and direction signs are erected everywhere. A sign at a dangerous spot might some time save a life. The actual work in connection with this phase of accident prevention is carried out by the highway department. In 1926 the Chicago Motor Club erected a total of 2,894 signs, classified as follows: 148 Caution; 771 School; 126 Danger; 48 Railroad; 7 Left turn.

Another method is general publicity, and this method is carried on by means of motor news, articles sent to the press, radio talks, and literature showing how accidents are caused.

Today we are in the third stage of safety development—the stage of safety education. We believe that safety education must begin in the schools, and that this is a most important part of the child's curriculum. The club is now engaged in the work of helping school authorities to educate children in the fundamentals of safety. This work is accomplished by means of several agencies. The School Boys Patrol is one of these agencies, and the Chicago Motor Club has fostered this work everywhere in the territory of the club. The engineer in charge of our accident prevention department supervises this work in the schools.

The Safety Habit, Once Developed, Will Remain

Habits of caution can be built in childhood's plastic age that would be difficult if not impossible to instill in later years. In the early years the child can build up what the psychologists term patterns of reaction. These habits, once formed, are difficult to eradicate. The child who is taught safety from the first year of his school life will scarcely develop into a careless motorist or pedestrian. The safety manner, once developed, will remain for life.

What is being done to develop the safety manner? The automobile clubs have entered into the problem seriously.

Most of the public and parochial schools in northern Illinois and northern Indiana, in the territory of the Chicago Motor Club, now make use of the poster system of teaching children safety. The club supplies the posters and the data used by the teachers in talking to the children about the posters. Each month the club prepares a new poster to be hung in the various classrooms. A safety film owned by the club and a victrola record are used in teaching lessons of safety.

This continuous plan of safety instruction has been in force a little more than a year, and the results have been remarkable. The fatalities among children for the first five months of 1925 were computed. There were no posters used during this period. The fatalities for the first five months of 1926 were then computed and it was found that the fatalities during this period, when the safety posters had been used, were 11 fewer than for the same period of the previous year. And this despite a tremendous increase in the registration of automobiles and a similar increase in school attendance. The plan has been so successful that it is now being used by a number of other clubs affiliated with the American Automobile Association. It is a practical safety plan because it is not a plan for a day or a week, but one that is constantly engaged in putting over the idea of safety throughout the year.

Closely allied with the poster plan is the work that the club is doing with the school boy patrols. These patrols render invaluable safety service. Where

the boys of the patrol are well organized and thoroughly drilled in their duties, a noticeable improvement in the conduct of children on the street will be noticed, and with this improvement will come a reduction in accidents. In order to encourage the boys, the Chicago Motor Club once a month issues a bulletin to all members of the patrol in the territory of the club. An interesting event in connection with the work of the Chicago Motor Club in schools took place last June when the Chicago Public School patrol teams met to compete for the Chicago Motor Club trophy.

On some of our early inspection tours we found that, contrary to instructions, boys were standing in the middle of the street to direct traffic. This practice caused the school authorities a great deal of worry. We tried to impress on the boys that traffic should be directed from the sidewalk; that the principal duty of the patrol boy is to keep the children from running pell-mell across the streets; that the boys are charged with the safety of the children and should not concern themselves so much about the flow of the traffic. We have in most cases found the boys amenable to suggestion, and this practice of standing in the street has been practically stopped.

Accidents can be reduced by day in and day out attention to accident prevention. Spasmodic attention to safety, hysterical and emotional campaigns, are useless. With motor and pedestrian traffic on the rapid increase, closer cooperation between the two bodies should be fostered. This can be brought about by a campaign of education directed toward motorists and pedestrians, alike, and toward adults as well as children, and by a sense of the obligations of courtesy on the part of all. The need for uniform courtesy and consideration is urgent. Children should be taught that the street is a dangerous place to play as they are taught that fire will burn.

We already have enough laws. Additions to those now in effect may do more harm than good by bestowing upon the pedestrian a false sense of security.

Science has made tremendous progress during the past 25 years in cutting down fatalities from children's diseases. Specifics have been discovered for diseases that formerly had a high fatality rate. What the scientist has done in his laboratory, in his calm, unemotional way, we who are interested in accident prevention must do. We must use laboratory methods. The day of the emotional, sob-sister campaign has passed.

CHAIRMAN STORRS: You have heard the public utility and private transportation agents. In this problem the education of the future generation as well as the present generation is what we look to for final success.

We have the great privilege of having with us Mrs. Walter H. Buhlig, president of the Illinois Council of Parent-Teacher Associations.

The Viewpoint of the Community Organizations

Mrs. Walter H. Buhlig, President, Illinois Council of Parent-Teacher Association, Chicago, Ill.

The last speaker said he was acting from the standpoint of conservation. So, too, are the parent-teacher organizations throughout the country. It is an evident fact that we shall not have the children to educate and to train if we do not conserve the lives of the children, and as we emphasize different activities with children we are beginning to emphasize more and more the ramifications that come under the head of safety.

Our national organization and the National Safety Council have cooperated to

the extent that the National Council has prepared three questionnaires to be distributed to the parent-teacher associations in every community. Questionnaires are frequent and not very popular and it is going to take a double push from our organization and from your organization undoubtedly to bring these questionnaires back in large numbers.

I want you to know the National Congress of Parent-Teachers is offering co-operation of this sort. We have over 1,000,000 members. We have a branch in every state of the union except Nevada. We have 26 parent-teacher associations in the island of Hawaii. If you want to get in touch with the state organization and don't know to whom to apply, write to our national office, the National Congress of Parent-Teachers at Washington, D. C., and you will be told just who is the president, or some one with whom you can get in touch.

The parent-teacher associations are made up of men and women. We are not just a woman's organization. We realize that dad has much more to do with the family than just provide the financial end of it and we are very anxiously urging the dads of the communities to come into the association in full membership, not just to pay the small dues, but to participate. And because this is a democratic organization, organized in every school where we can have it, without respect to race, to color or to finances, we feel that we have the avenue through which all of those things which concern the welfare of the children may be promoted. Since you are, each and every one of you, interested in this particular phase that has to do with children and with child welfare in the community life, I want to ask you to get in touch with the parent-teacher association and help make it stronger and make it an avenue for safety education.

CHAIRMAN STORRS: We are fortunate in having with us a representative of the movement in the schools of the land in Mr. Thomas F. Power, assistant superintendent of schools, Worcester, Massachusetts.

The Viewpoint of The Schools

Thomas F. Power, Assistant Superintendent of Schools, Worcester, Mass.

Before attempting to answer the question, what the public schools can do to help educate the public for safety, I feel that in all justice to my conscience I should recognize the indebtedness of the school people to the work of the National Safety Council.

Without the initiative of this safety work by the National Safety Council, working indirectly through local councils in their management, it is undoubtedly true that safety education would not be in the school systems of a great many cities of our country.

If there are school people present they can recall that in the history of the educational movement in America the initial sponsoring of many projects was carried on by outside agencies. The enthusiasm of those agencies is responsible for the initiation and the justification of the work which school people later have gathered to support. The history of America is full of instances justifying the work of these so-called outside agencies.

In answering the question as to what can the public schools do to help educate the public in safety, I am going to make a rather challenging answer.

The most direct and useful opportunity for educating the public for safety is through the public school children. You cannot have an army of school children singing safety songs, writing about and discussing dangers and safe practices, acting out pantomimes, playlets, computing problems in arithmetic that deal with the atmosphere of safety, without having some of the educational results carry over into the lives of adults of the community. An interesting, small piece of evidence

of this is found in the attempt of a child to prevent his father from cutting corners on a main thoroughfare of our city. "You must go to the next corner," said the child. "We are taught to cross at street crossings."

The introduction of safety patrols of school children commands the respect of adults. This orderly crossing of highways by school children marching, two abreast, under the direction of their patrolmen and captains, is an impressive sight. To my positive observation in our city where almost all of our seventy public and parochial schools are thus organized, the safety patrol makes a very psychological impression upon automobile drivers. During the spring of 1926 one court conviction of an autoist for failing to slow down while approaching the school patrol, and three cases of suspension of automobile licenses for thirty days each by the Massachusetts Registrar of Motor Vehicles, for refusal to recognize the rights of school children as pedestrians, made such an effect upon autoists of the city that during the subsequent school year of 1926-27 not one case was discovered of any autoist in our city of 200,000 population who failed to recognize the rights of school children to cross the streets in orderly formation.

A Long Record Without a Child Injured

During this time from March, 1926, to June, 1927, not one child was injured fatally or non-fatally at dismissal time in our city. Such dismissal formation includes approximately 35,000 school children twice a day. To create such general respect for the rights of school children as pedestrians on our highways requires the support of all newspapers. The above results could not be achieved without a generous amount of space in the news and editorial columns by all local newspapers.

The introduction of Safety Education into the public and parochial schools of our city has been, in my judgment, the prime factor in reducing fatal accidents to children on the highway by approximately 50 per cent. Statistics from January 1, 1927, to August 1, 1927, show a reduction of approximately 50 per cent of fatalities to children on the highways in our city. We believe that, in the main, this high result is due to the teaching of safety by approximately 1,000 teachers to about 35,000 public and parochial school children. These statistical results are due in part to direct instruction given by the teachers and to the indirect results in the homes created by this general atmosphere of safety resulting from the introduction of the subject into the public schools. This period of reduction corresponds exactly to the time when formal education in safety was put into the school system. By formal education, I mean not only the orderly dismissal of school children under the organization known as the "Safety Patrols," but the teaching of proper attitudes of mind, correct safety habits, through the three R's and the other subjects of the grammar school curriculum. All this work can be done without crowding out anything, as has been proved by the formal Worcester Course of Study in Safety Education. The material to be used follows modern school procedure. Because so much of it is taken from the lives of children, it is well motivated. Teachers are eager to use it, because it is highly social. All in all, it places a new emphasis or interpretation upon existing material.

Safety was introduced into the Worcester schools through an experimental or laboratory school during the spring of 1926. After the teachers had spent several months organizing, selecting and compiling material, parents, members of the executive committee of the Worcester Safety Council, city officials, citizens, generally, were invited to view such demonstrations. The work was altogether praiseworthy. In my judgment, this, too, contributed towards educating the public for safety.

Another practical means of arousing the public to keener consciousness of danger and to safe habits is to present to the public a demonstration of the work done in

the schools. This was done in Worcester during the Spring of 1927. The several thousand citizens who saw the display in the Chamber of Commerce Building were very favorably impressed with the attempts to develop safety practices in the children. Psychologically, it is evident that a display of posters, graphs in arithmetic, hand work, compositions, penmanship exercises and evidences of work done in all other subjects from Kindergarten through Grade 8 would make the public, generally, stop, reflect and conclude favorably. This is all apparent and there is no need to go into ramifications of the effect upon human minds.

It may be rather challenging to say that education of the public can best be accomplished through the children. This is not the only reason why education for safety should be in the schools. One who has studied the causes of accidents and analyzed the material used to offset those causes must admit that this material is proper educational matter. Ignorance of conditions, or facts, improper attitudes of mind, improper physical habits, dangerous personal tendencies, lack of control, irresponsibility and such have been the causes of thousands of accidents. In offsetting these causes, the material used is educational. On the face of things, supplying information, forming correct habits of body, correcting improper habits, forming correct attitudes of mind, correcting faulty attitudes of mind, developing control—all have been, for ages, proper educational material.

It would appear from this brief summary of causes and procedure just listed that one could go on pedagogically and psychologically to justify the teaching of safety in the schools. It is not my desire to attempt to justify the teaching of safety in the schools from an economic point of view. That is undoubtedly being done in other sections of this convention. But, it is my opinion that the slaughter of humanity and wastage of physical property, which has become so absorbingly a part of our economic organization, must be offset in part by teachers. Modern conditions of life have made this demand upon our schools. This is one respect, wherein the complexity of modern society, has demanded a changed conception of public school education.

CHAIRMAN STORRS: You have had presented to you the various phases of the safety movement from the standpoint of personal and humanitarian interests of the utilities and private automobile agencies, the home and its appeal for the conservation of infant life. You have yet to hear of the great possibilities of the National Safety Council offered through the movement in the local safety councils.

I have the great pleasure of introducing Mr. A. Hardgrave, past president of the Kansas City Safety Council, Kansas City, Missouri.

The Viewpoint of The Community Safety Council

Arthur Hardgrave, Past-President, Kansas City Safety Council; President, City Ice Company, Kansas City, Mo.

It was a little less than a quarter of a century ago that American industry became interested in the prevention of accidents. The purpose then was, and the purpose today still is, based on economic principles. Industry coined the slogan "Safety First," and, notwithstanding that in the drift of years slogans have come and slogans have gone, the humane appeal incorporated in "Safety First," has caused it to be translated into many tongues and has carried its work into practically every civilized country on the face of the globe.

At the beginning many agencies worked independently in their respective fields. A little later these agencies were grouped together under what ultimately became local councils. With the further recognition of the importance of safety work, a national head, or fount, under the title of the National Safety

Council was formed. By this method and through this channel, it has been possible to coordinate the efforts of all agencies and to bring about almost complete cooperation.

Coordination of ideas and cooperation of effort backed by men—human individuals deeply concerned in safety—are the fundamental factors contributing to the great success of safety work in this country.

We are making great strides in safety work in this country, both industrial and public and especially in the industrial line.

The big field before us is public safety. While we have just begun the great work, to succeed in this branch of safety we must reach down into the uncontrolled public mind.

There is a message—a universal message—that must be carried in a convincing manner to the 115,000,000 people in our country. This can best be accomplished through the medium of the local or community Safety Council. With the National Safety Council acting as a clearing house of ideas and methods, these Community Councils are able to carry a uniform message and progress with a unity of thought and of purpose. By no other method would this be possible.

Coordination of Effort Through the Council

It has been demonstrated beyond question of doubt that the local Safety Councils can best function in this manner. There are many agencies doing effective and most commendable work and this work should be carried on and further developed. However, to obtain the maximum results, the work of these various agencies should, where possible, be coordinated; and this coordination is most effective through the local Safety Council where the work is of a local nature.

The local Safety Council is a cooperative organization providing the facilities to which the work of all agencies interested in safety can be tied together and duplication of effort eliminated.

There is another fact which should be seriously considered in discussing the value of Community Safety Council work and that is the attitude of the public toward National organizations. However extensive may be the National Safety Council program of educational work, nevertheless it is sometimes discounted, owing to the fact that their organization, representing, as it does, a specific general purpose, cannot expect to be accepted by the local public as representing a disinterested attitude.

When the Community Safety Council presents a recommendation to the community it is accepted as being a recommendation which represents the combined interests of the many units which go to make up that particular community. How can it be otherwise when the Board membership of the community council includes the representation of practically every phase of community life and its respective organizations? They should be sold on the idea that any movement which they desire to have sponsored would be much more effective if they would lend their support to the Safety Council and ask their cooperation in sponsoring the movement rather than trying to conduct an individual educational campaign. For example, how could the Motor Club be expected to put on an effective campaign for pedestrian control? How could the railroads put on a campaign for the protection of grade crossings and for the enforcement of the rule that motor cars should stop at the hazardous grade crossings? How can the electric railways put on a campaign for the preservation of the rights of the citizens when standing in the safety zone? How can the schools put on a program including safety in their curriculum?

without being criticized by some of the citizens for introducing a fad into the schools? All of these campaigns would be deserving of the support of the Safety Councils and could be effectively consummated because the public of the community recognizes that the Safety Councils not only represent the interests of the individual organization or corporation, but that it also represents the interests of the other 85 or 90 per cent of the community.

Educating the public for safety cannot be accomplished by the Safety Council assisting the motor club, the railways or the other organizations, but it will only be accepted by the public when it is sponsored by the Safety Council, and following such sponsoring, the cooperation of each of these organizations can materially add to the effectiveness of the campaign.

Experience has demonstrated that three distinctive lines must be pursued in community Safety Council work; namely,

1. Engineering,
2. Enforcement,
3. Education.

In developing the program of the Community Safety Council, we must, therefore, give consideration to each of these three fundamental factors and drawing together the various activities in the community, feel sure that the program is properly coordinated and properly proportioned. The installation of automatic signals or the creation of through streets without adequate enforcement spells failure. On the other hand, strict enforcement without proper education does not obtain the proper and necessary support of the public. Assuming it is possible to obtain the coordination of agencies interested in the engineering and enforcement factors, then it would seem the major problem of local Safety Councils would be along the lines of education, and experience has shown that this is, indeed, a difficult part of the Safety Council work, for here we must deal with the uncontrolled, unorganized public mind.

As a general rule the average citizen braggingly states he is not interested in the work of safety. He speaks from the conscious and not the subconscious viewpoint. It cannot be questioned that the work of safety, both industrial and public, is rooted deeply into the subconscious mind of the public, so deep in fact, that it cannot be eradicated or washed out by mere idle statements. This is due to the very nature of the work—the human appeal—the inherent characteristic of humanity to save and protect.

The Adult Is More Difficult to Educate

The education work of safety becomes more difficult when dealing with the mature person, because of the difficulty to reach the fixed conscious mind. It is upon the adult subconscious mind that we must depend to obtain the results desired in public safety.

In the case of the child or youth, we deal with the receptive conscious mind which, contrary to the mature mind, recognizes its knowledge is limited and is grasping for enlightenment.

The work of educating both the conscious and subconscious mind of the public can best be accomplished by and through local Safety Councils for reasons which are obvious. The work of public safety must be national in scope and made effective locally. A uniform national message must be handled through local agencies.

It is only the local agency or the Community Safety Council that thoroughly understands the problems of its respective locality. The National Safety Coun-

cil. as a national body, can plan and outline and advise, but it is only the Community Safety Council that can mould these thoughts into action.

CHAIRMAN STORRS: I find that your very efficient Program Committee has down as the conclusion of this portion of your program on the agenda today, the suggestion that your chairman sum up the salient points of the various addresses so that the audience may be left with some definite, coherent impression.

Your chairman hesitates to impose upon you any further, as you must have a very definite, coherent impression (to use the quotation) of the matter that has been so ably presented in all its aspects. The magnitude of the task, the efficiency of the labor and the results that are being obtained mean much. They are good results, but not good enough. Only those can come by a continued cooperative effort.

You are to be favored with the presentation of a playlet by Mr. A. W. Whitney, whom you all know as the Chairman of the Education Division of the National Safety Council and head of the National Bureau of Casualty and Surety Underwriters.

Mr. Whitney is an enthusiast and has a real, fundamental philosophy of education.

For the presentation of the play you are greatly indebted to the Chicago Board of Education, the staff of the school system, the Nathaniel Pope School in particular and its teachers, also to the Academy of Dramatic Education.

For an explanation of the little play these booklets are available. To quote from it, "The present play undertakes to interpret the transition in a child's life from the dominance of fear to the dominance of knowledge."

(A morality play, "How Knowledge Driveth Away Fear," by Albert W. Whitney, was presented by the pupils of Grade 6A, Pope School, Chicago, Illinois, Frank A. Fucik, principal, Helen Oleksy, teacher, directed by Irene Skinner and Donald Marye, Academy of Dramatic Education.)

ADJOURNMENT

Wednesday Morning, September 28, 1927

COLONEL JAMES SINKE, Chairman
Director of Public Safety, Grand Rapids, Mich.

The second session was called to order at nine forty-five o'clock by the chairman, Colonel James Sinke, Director of Public Safety, Grand Rapids, Michigan.

CHAIRMAN SINKE: We have for our first topic this morning a subject that has been creating a great deal of interest throughout the country. There has been much said pro and con relative to the advisability of pedestrian regulations. I know it has been discussed to a great extent in my city for the past three or four years, but we have never done anything about it and have been watching the success of other cities to have a precedent to fall back upon. Some of the cities in the South and some in the West, I understand, have had a great deal of success with it. Some of the older communities have found it harder, I believe, to put those regulations into effect.

We hear a great deal of fine comment about Los Angeles' pedestrian regulations out our way, and I think we are exceptionally fortunate in having Mr. Lefferts with us this morning to talk on the subject. Mr. Lefferts has not only been with the Automobile Club of Southern California for several years, but prior to that time he had been a Safety Council manager. He has been in quite close contact with the development of the traffic movement for a considerable time, and it is my pleasure to introduce him to you.

Regulation of Pedestrians

E. B. Lefferts, Manager, Public Safety Department, Automobile Club of Southern California, Los Angeles

The subject assigned to me for discussion is one of the great problems confronting everyone interested in municipal traffic regulation. For many years this holding of pedestrians for the "Go" signal, as has been practiced so univervally with vehicular movement at heavily traveled intersections, has seemed to be practically impossible of attainment. To all who have observed the confusion as well as danger resulting from mixing these two classes of traffic no argument is necessary to convince them of the desirability of definite and effective segregation.

This ideal of so controlling pedestrians that danger is minimized, and the maximum vehicular capacity of an intersection is obtained through uninterrupted flow of travel during the "Go" interval, has been realized in Los Angeles. I shall endeavor to outline the high lights as to how and why this has been possible. Aside from the apparent benefit of such control, engineers who have given serious study to this realize that this is a matter of life and death, because statistics show that 70 per cent of all traffic fatalities result from collisions between motor vehicles and pedestrians.

Our experience in Los Angeles is to me proof positive that pedestrian control is like practically all other safety measures, a matter of education. This has been proven by the long and torturous path this plan had to travel before it finally was enacted as a law. During a period of three years it was introduced three different times in our City Council and each time it was vetoed by the Mayor.

Naturally, each time it came before the Council it attracted a great deal of attention in the newspapers and was quite generally discussed on the street. Finally sentiment had been developed in favor of this regulation to such extent that it was

possible the third time to pass it over the veto of the Mayor. The third time, in addition to pedestrian regulation, the entire ordinance was revised and simplified. This gave a splendid opportunity to furnish articles regarding the provisions of the ordinance to all of the daily papers, and they gave the necessary space because the interest and discussion aroused gave added news value to these regulations.

The radio broadcasting stations also helped, and as a result of their cooperation we were able to have every station in the city broadcasting the same information regarding provisions of this new ordinance at eight o'clock each night during the week before the ordinance became effective. Each speaker was furnished with the same copy, consequently during this period if a person tuned out of one station and into another they would receive the same message. In other words, the radio audience had no escape from the informative talks on this regulation in our city.

During this same period the Automobile Club of Southern California, the police department, oil companies and similar agencies having direct contact with the public, printed and distributed over a quarter of a million copies or summaries of the ordinance. Therefore when the ordinance became effective there was no need to do other than remind our citizens of its provisions because there was no valid excuse for ignorance.

Lanes Provided at Each Street Intersection

This complete control of pedestrians and automobiles followed a series of experiments in dividing the right of way between the motor vehicle and pedestrian. For a long time we have had on our statute books, like most other cities, a regulation compelling automobiles to stop behind standing street cars, which provides protection to pedestrians desiring to board and alight.

Next, primarily with the thought of protecting the school children of our city white lines were drawn across streets where large numbers of children regularly crossed, and motorists were required to stop before crossing these lines. This experiment was not successful, as it compelled many motorists to come to a full stop during hours when there was no need for this precaution. As you all realize, any law to be observed must be reasonable. This was not a reasonable regulation, with the result that compliance was not obtained in the majority of instances unless a police officer was present.

We finally decided upon our present regulation which calls for the prolongation of the sidewalk lines across the street. These lines are divided in the center by another white line, making in effect an elongated letter "H" between the curbs with the cross bar of the letter in the center of the street. A motorist is compelled to stop and remain standing while a pedestrian is in that half of the lane on the side of the street upon which the motorist is travelling, until the pedestrian has passed beyond the path of the vehicle.

Our next proposal was to separate pedestrian and vehicular traffic through the construction of pedestrian tunnels. A bond issue for \$350,000 was submitted to the voters and passed with the largest majority of any issue submitted at that election, showing conclusively the interest taken by the public in this question of protection child pedestrians.

Upon passage of the bond issue we were confronted with an interesting problem of properly locating these tunnels. Naturally every parent wanted a tunnel across the thoroughfare where his child would cross in going to and from school. Our original estimate showed that 35 tunnels could be built with this money, which naturally meant that some parents would be disappointed. It was therefore necessary to study in detail the proposed locations to determine which were the most dangerous crossings. I therefore undertook for the Automobile Club of Southern California a detailed traffic survey of all crossings in the vicinity of schools, which included traffic counts of vehicular and pedestrian movement at 150 of the most dangerous

locations. Through the amassing of this data we were able to suggest to the constituted authorities tunnel locations which would give the maximum protection to the largest number of children.

After starting construction it was found that these tunnels could be built at a lower price than was originally estimated and when this year's building program has been completed we will have over 40 tunnels in operation which have been financed entirely by our original bond issue of \$350,000. In addition to providing protection for pedestrians, these tunnels greatly facilitate vehicular traffic movement by eliminating interruptions in its flow, as well as relieving police officers for duty elsewhere.

In Los Angeles County alone there are 645,549 automobiles, or one to every two and a fraction persons, which of course means that the largest majority of our people either own or ride in automobiles, with the result that we have a population which is "motor minded." Possibly this is another reason why the regulation of pedestrian travel has been so eminently successful in the city of Los Angeles, as it is not particularly difficult to sell to a motorist the idea that pedestrian regulation is a necessary adjunct to the expeditious and safe movement of traffic. It is a fact that the regulation of our pedestrians has expedited vehicular movement in our congested areas and the vehicular capacity of intersections has been materially increased since pedestrian movement has been synchronized with vehicular movement.

The question of enforcement has always loomed large in everyone's mind whenever this regulation has been contemplated and I know you will be interested in hearing how this phase of the problem was worked out in Los Angeles. To the best of my knowledge, but two arrests were made. These occurred soon after the regulation became effective and it was generally accepted that the violators were simply publicity seekers.

The Policeman Makes the Pedestrian Obey

The procedure in general is that when a person steps off the curb when the signal is against him, the police officer gives several sharp blasts of his whistle and beckons the absent minded individual back to the curb. When this person turns and goes back to the sidewalk he is facing a large gallery of amused people and he shamefacedly takes his place with the waiting group. Of course some persons are headstrong and refuse to be deterred by the officer's whistled warning. In such cases the officer simply escorts them back to the side of the street from whence they started. Arrests are not made except when persons become abusive and refuse to obey orders. We have found in both of these situations that the ridicule of their fellow citizens is far more effective than any other means which might be adopted.

We have in our city 371 mechanical traffic signals of which 81 are in the down town or central traffic district. We have given considerable thought to the time intervals at all intersections so controlled. The "platoon" or "wave" system is being used, which from the standpoint of the motorist causes the minimum amount of delay, but we have also given careful consideration to the pedestrian phase of the problem.

There are 16 different cycles in use in our down town area. The "wait period," or that represented by the amber interval where the three light signal is used, varies from six to nine seconds. In the early morning and late evening hours the intervals are short, while at noon and during the five o'clock peak hour the nine second interval is used. The "Go" period for vehicles is never longer than 36 seconds, giving from 68 to 90 seconds for the complete cycle. I know that in some cities the "Go" interval has been set at as long as 180 seconds. There the pedestrian control is not effective. Try standing still in one location for three minutes some time when you are in a hurry,

and you will see why 180-second intervals make it almost impossible to control pedestrians.

We have recognized that in controlling traffic we must take into consideration the study of human psychology, rather than approach it solely as an engineering problem. As American citizens we believe in fair play. The pedestrian does not resent being regulated when he realizes that he is getting a fifty-fifty break with the motorist, which is the case if he is not required to wait an unreasonable length of time on the corner and is given some protection when he happens to be in the center of the street when the signal change takes place.

In conclusion I want to say that in the city of Los Angeles we do not have any different type of people than is found in any other community in this country. Our population is very cosmopolitan, having been drawn, as you know, from all over the United States. We find that even our visitors, after one or two false starts, fall into step and observe our regulations just as willingly as do the residents. I feel that this same regulation, with the consequent decrease in hazards to pedestrian traffic, can be effected in any community, provided the necessity for giving the pedestrian an even break with the motorist is recognized.

Pedestrian Regulation Effective Throughout the City

CHAIRMAN SINKE: Mr. Lefferts, I would like to ask if the pedestrian regulation with your automatic signals is effective throughout the entire city?

MR. LEFFERTS: Yes, Colonel, it is. Possibly one reason why it has been so effective is because we have a heavier vehicle crossing in our outlying areas than in our downtown areas. Seven thousand vehicles passing through an intersection in one hour make it hardly necessary to argue with the pedestrian that he should wait until all of those vehicles are stopped.

CHAIRMAN SINKE: Is this regulation effective throughout the 24-hour period of time?

MR. LEFFERTS: The regulation states that the pedestrian shall move with the signal "Go" for vehicles. If there is no traffic officer on the corner, or a traffic signal is not in operation, the pedestrians naturally are not regulated. We have a basic regulation that pedestrians shall cross at intersections. That is quite rigidly enforced in our downtown area. You see very little jaywalking there. In the outside area the regulation is, pedestrians shall not cross except at intersections if so doing interferes with the free moving of traffic.

WM. R. MILLER (Rochester Police Department, Rochester): Regarding the time on the amber light, did I understand you to say it was nine seconds? If the pedestrian is moving with your signal is it necessary to have the amber light on that length of time?

MR. LEFFERTS: Yes, that is in the most congested pedestrian period, for instance, in the noon hour. It is necessary in order to give the pedestrian who has gotten ten feet out into the street when the signal changes, a chance to continue his crossing safely. The wait period, or the amber period, of necessity must vary with the width of your street. Nine seconds is the maximum interval, down to six seconds, depending upon the volume of pedestrians crossing. We have pedestrians crossing 35,000 and 37,000 an hour on our busiest intersections, so we have to give them a little chance to get across the street after the signal has changed.

MR. MILLER: We have found we can't keep the amber on that length of time. We eliminate both left and right turns, which allows our pedestrian traffic to go with the light.

MR. LEFFERTS: That is a local condition depending upon your own particular

locality. We tried that for a while, but we got more congestion by prohibiting the right turn.

CLARENCE SPAYD (Brooklyn Safety Council, Brooklyn): I am very much interested in the work which the Automobile Club of Southern California has done and I would like to ask just what position the club took as an organization when this ordinance was passed. Did you do any propaganda work other than what you mentioned over the radio, or how did the club perform?

MR. LEFFERTS: We helped with the radio broadcasting. It was not a proposition of the automobile club alone. Civic organizations throughout the city were interested in putting this over. We helped with the drafting of the ordinance. We furnished summaries to our members. We have about 126,000 members and we circularized them quite generally with summaries and propaganda in favor of the ordinance; and also furnished, as did many other organizations I mentioned, the police department, the newspapers and others with summaries of the ordinance so as to try to disseminate this information in every way possible. I think there was nothing that could be done that was neglected in helping to make the ordinance effective and insure its passage, and then the acknowledgment of the people of its provisions after the ordinance was passed.

A. C. BURNETT (Bexar County Safety Council, San Antonio): You haven't given any information concerning the accidents prior to and after the enactment of this legislation. You mentioned the fact of the speed of motor traffic.

Many Things Affected the Accident Reduction

MR. LEFFERTS: The year after the passage of the ordinance there was a reduction in the fatalities in the city of Los Angeles from pedestrian motor vehicle collisions. There were a good many things that took place simultaneously—the pedestrian regulation, the change of the ordinance, the provision of lines across the street, giving the pedestrian very definite rights. There was a general education program calling to the motorist and pedestrian the fact that there had been some consideration to both of their rights. We had a reduction from 155 to 129 deaths in collisions between motor vehicles and pedestrians, in the period of one year.

REYBURN HOFFMAN (City Traffic Engineer, St. Louis, Mo.): May I add in support of Mr. Lefferts' figures, and also to answer the request of the gentleman on the left for some figures as to reduction of accidents, one small experience in our city? We have anticipated this question of pedestrian regulation at signalized corners; so based upon two years of experience at signalized intersections, one year before and one year after the signals were installed, we found this: We took a dozen typical intersections, some on very busy streets and some on relatively minor streets but where signals were located because of proximity to churches and schools. We found that the total accident reduction was 75 per cent after the signals were installed. We found the reduction in which pedestrians were concerned was somewhat less, only 55 per cent.

The logical conclusion to draw from that would be that the pedestrian still needed a good bit of regulation, and we are building up this data so we will have quite a complete file at such time as this subject comes up for serious consideration.

MR. SPAYD: How do the courts deal with those who violate this new pedestrian ordinance?

MR. LEFFERTS: I tried to make that clear in my paper. We have had but two arrests, to the best of my knowledge, where the pedestrians were hauled before the court. The people who are absent-minded and start out into the street are whistled down by the police officer and they are compelled to turn around and come back, and everybody thinks it is a great joke and they laugh at the poor unfortunate devil who has forgotten that he should stop. He doesn't like to be laughed at, none of us do.

and as a result the officers have not had to make any arrests. If we have a rather hard-boiled individual who is going to go across after the signal, the officer sometimes meets him on the other side of the street; and I have seen them go down 40 or 50 feet (because they lose their tempers the same as the rest of us do) get this individual and bring him back, escort him back to the place from whence he started. Everybody gives him a good laugh, to which he is entitled, and that is much more effective than any other measure that could be adopted.

I have a few pictures here I would like to pass around. They will give you an idea of how the pedestrians are controlled.

CHAIRMAN SINKE: Mr. J. W. A. Bollong, street maintenance engineer of the city of Seattle, is with us this morning. He has with him a reel of pictures taken in his city showing how they regulate pedestrians. It is a special feature not provided for in the program, but we will be very glad to give Mr. Bollong about five or ten minutes to show those pictures.

An Excellent Experience Also in Seattle

MR. BOLLONG: Our experience in Seattle has been almost identical with that of Los Angeles. Our regulations and ordinances are similar. We had two or three arrests. One of them was a woman. It was given very wide publicity and it sort of put the fear into everyone else's heart in regard to the disobedience of traffic signals. These pictures were taken primarily for the education of the traffic officers so they might all act alike. One could see what the other did and then govern himself accordingly.

(The film of pictures was here shown.)

J. H. LYONS (Toronto): In what period, as to time, do you get the best results?

MR. BOLLONG: Our changes are made 10 or 12 times a day to meet the conditions, in the same manner as they are in Los Angeles. The pedestrian change is from six seconds to twelve seconds in order to give them time to cross.

CHAIRMAN SINKE: We have a very interesting program this morning and the speakers on it are men of prominence in traffic studies throughout the country. We are exceptionally fortunate. Our next speaker is one whom I think you are familiar with and whom you all have heard on various occasions. The subject he has is another subject of great interest to us throughout the country, because we are interested in uniformity, we are striving for it; we know what the Hoover Conference has done, and Mr. Miller McClintock, director, Albert Russell Erskine Bureau of Street Traffic Research, Harvard University, Cambridge, Mass., is going to speak to us. He is eminently qualified to speak authoritatively.

Uniformity of Traffic Regulations

Miller McClintock, Director, Albert Russell Erskine Bureau of Street Traffic Research, Harvard University, Cambridge, Mass.

Uniformity of traffic regulations is a subject which would seem to need no discussion. The logical course would be to give a eulogy of uniformity. But sometimes it is more interesting and valuable to do the thing that isn't so obvious. Instead of a eulogy I am going to ask some embarrassing questions.

We are often too prone to believe in iron-clad adherence to a fetish regardless of varying conditions. But in the adoption of regulations in our cities and states it is highly desirable that we should have more than a mere standard to go by. The mere fact that somebody has said it is a good thing or that other jurisdictions have adopted the regulations is not enough. So the first question is, "Why is uniformity desirable?"

The Need for Uniformity

One of the oldest mottoes I know for getting on with people, and one of the most valid, is, "when in Rome do as the Romans do." That is merely a reflection of the fact that every community must have community habits if its people are going to live together without constant friction. The ability of people to get along with other people is their ability to abide by certain customs of movement and activity which have been found to possess social utility.

That is why we are interested in uniformity of traffic regulations. Uniform regulations are not new. Out of the Middle Ages there came two very basic principles of traffic regulation. They were the only two uniform rules controlling the acts of people on public highways. One of those rules was this: That all users of a public highway are mutually and equally responsible for maintaining the safety and convenience of the other users of the highway, and that they must so conduct themselves that other people will not be inconvenienced and endangered. Subject to that rule they may use any part of that highway at any time they please.

Another great rule which came out of common law practice in the English court was this: That when two people meet head-on on a highway, each shall bear to the proper side of the roadway. In English practice, that meant the left side. That common law rule was adopted in America to this effect. That instead of passing upon the left, people should pass upon the right. That rule is the most basic rule of traffic uniformity. If it were not in existence we would have almost complete chaos upon our crowded highways and streets. The significant point about these two rules is this: That common law principles are always based on acceptable community customs, and that I believe to be the proper basis for uniformity.

A quarter of a century ago there was no pressing need for uniform habits as between various communities of the nation. People rarely went from one community to another. The absorption of 23,000,000 automobiles by the American public has changed that situation entirely. It has freed us from geographical limits and we are no longer citizens of Chicago, or Grand Rapids, or New York. We are citizens of the United States very definitely, and in a very short space of time we may move from our community through several states or even across the continent. In any city you will see many cars from other states.

In other words, instead of a habit for Rome we need a habit for the world. It is not sufficient to have rules which can be understood by the people of Chicago; they should be recognized by motorists from all parts of the country.

The Basis For Uniformity

What is the basis for uniformity? Common law practice was satisfactory because it was a rule which the courts reflected as a customary and community habit. I think it is fair to say that the only validity which a traffic rule has is its ability to be accepted as a community habit.

Present practice in the United States, even in the better cities, is something like this. There is about one traffic officer to every thousand vehicles; sometimes it runs one to every two thousand vehicles. In other words, it is perfectly obvious that the ability of the police to enforce traffic laws is an impossible problem, if we are going to depend strictly upon police enforcement. The only rule that has any validity is one which will be adopted as a reasonable rule by at least 95 per cent of the motoring public and therefore will be self-enforced.

One needs only to look over the country to see rules which are, in the abstract, very desirable, but which because of their means of application are unreasonable in the community, and therefore subject to a great deal of disobedience. Disobedience to a rule which has been established in the community is not merely an inconvenience, it is frequently a very grave hazard. It would be my conclusion that it would be better to have no rule whatsoever than to have one which presumed to give protection but did not because it was generally violated.

I want to give a few examples. Unreasonable application of perfectly sound principles in traffic regulation are known to all of us. Speed regulations furnish the most notorious application of a desirable principle improperly administered. There is still a state in the Union which requires in all cities a maximum speed limit of 12 miles per hour, and six miles an hour through all intersections in the state.

Do you suppose that regulation is obeyed? Yet there are people in that state who complain because other people violate that law, even though they themselves do not obey it. Since the rule is on the statute books people come to believe that other people will abide by it. Therefore a false sense of security and a lack of uniformity exists.

Another example is the misadministration of the through-street regulation. I know of no single law better designed to facilitate traffic flow and give protection to motorists than the boulevard-stop or through-street regulation, yet because of its merits it has been used in such a way as to spoil its adoption in many cases. The over-use of a boulevard-stop regulation or its application to those arteries which obviously need no such protection will result only in one thing—a lack of sound community habit and repeated violations, regardless of police power.

So we come to the administration of traffic signals. The installation of signals at outlying intersections where traffic is never heavy, and where the driver feels the need of no control, will tend to break down the authority of the signal. What might be a very desirable habit of strict obedience to automatic traffic signals begins to diminish.

Pedestrians will willingly obey traffic signals at intersections where signals are so regulated as to make them seem reasonable. If you should change the cycle by only ten or fifteen seconds at some time of the day so that pedestrians must wait at the intersections with nothing but a red signal to hold them back and with no physical reason in front of them to make them stay on the curb, you will find pedestrian regulation breaking down.

You might even put eight, ten or twelve officers on the curb, as they do in New York, and you couldn't hold the people back. The reasonableness of regulation is the only basis for establishing the most essential thing in public safety—uniform habits on the part of the people.

The Limits of Uniformity

How far can uniformity go? As we talk about it glibly we assume that uniformity can be made a great deal more iron-clad than actual conditions would indicate. For example, it is a great deal easier to draw up a uniform vehicle act designed for adoption by the states, including general rules of the road which can be practically identical throughout the country, than it is to draw up a uniform ordinance for American cities.

For that reason I hope we shall not expect too much or be too greatly disappointed if we find that the regulations which are being drafted at the present time as a basis for uniform regulations in American cities are not too

elaborate in detail and leave something to the discretion of the communities.

I can think of nothing more disastrous to the program of sound traffic control than some arbitrary power which might force down on these cities a uniform code from which no variation would be tolerated. We are only beginning the development of a sound technique of regulation and it is necessary for us to experiment. For that reason I hope that any attempt at uniformity of local regulations will be a moderate one that will deal only with general principles.

There is a pressing need not only for an agreement upon some of the general principles of traffic movement but also for greater uniformity in the indication of those regulations. A great deal of the sting of local regulations which vary from uniform standards can be eliminated if motorists are given due indication and notice of local variations. If this principle is followed I can see no great harm which may result in general conditions from local experimentation.

Progress Toward Uniformity

The Hoover Code, or the National Uniform Code for the regulation of highway traffic, has been adopted in practically all of its details by ten states. Probably half of the remaining states have adopted the main essentials of the code, and I believe that within the next decade we shall see a general uniformity of standards of regulation throughout practically all of the American states.

There are a number of interesting movements toward uniformity which will serve not only as a basis for the ordinance which will come out of the Hoover Committee, but will likewise be a great stimulus to the movement. In Los Angeles the city drafted a simple traffic ordinance. The Automobile Club of Southern California, the California State Automobile Association, and the California Conference on Public Safety took up the remodeled ordinance and have obtained its adoption by about 50 of the larger California cities.

There was no attempt to force the ordinance on any city. All of the cities that have adopted it did so because they believed that it was desirable to be in line with the general practice and because some of its principles were better than those which had been in effect. As you drive through California cities you are rarely aware of any lack of uniformity in regulations.

Michigan and Minnesota Have a Uniform Ordinance

Some eighteen months ago Michigan drafted a uniform ordinance which has been adopted by more than 200 cities in the state. Minnesota, likewise, has a uniform ordinance, not yet sent out to the cities in view of the meetings of the Hoover Committee. Likewise the work which has been done in Chicago is being made known throughout the entire regional district by the Chicago Regional Planning Association. In many localities there is a movement toward unification, which, I believe, will greatly stimulate the adoption of whatever ordinance comes out of the Hoover Committee.

CHAIRMAN SINKE: The first part of Mr. McClintock's talk was very interesting philosophy. I was much impressed with what he said because he made brief mention of some underlying basic principles that govern all our conduct when we attempt to regulate traffic or regulate any other human action.

We will pass on to our next subject. Mr. Kopf, the speaker, represents the Metropolitan Life Insurance Company, is a member of the Statistics Committee of the National Safety Council, and is a specialist on this question.

What We Learn From Statistics

E. W. Kopf, Metropolitan Life Insurance Company, New York City

Each year it is the privilege of some members of the Statistics Committee of the National Safety Council to give you a summary of the report prepared for the year, and to bring before you a number of problems wherein the members may assist the committee in furthering its work.

We estimate that there occurred last year in the United States about 90,000 accidental deaths. That is an increase of about 10,000 over the figure of 79,350 which occurred in 1911. Motor vehicle deaths amounted to approximately 23,000 in 1926, which is an increase of 21,000 over the number which prevailed in the year 1911. Accidental falls last year approximated 15,300; railroad accidents a little more than 8,000; burns and scalds 7,300, and drownings 7,100. There was, of course, an increase in automobile fatalities. There also was an increase in the number of falls, there being 1,200 deaths in excess of the 1911 record. Railroad accidents decreased by 4,000 deaths in 1926 over the number which prevailed in 1911. The number of deaths from burns and scaldings was about the same in 1926 as it was in 1911, and we saw in our figures a decrease of some 1,700 deaths from accidental drowning.

Each one of you who has been associated with this safety work for the past 15 or 20 years can see in these figures gains and losses, the loss from motor vehicle accidents and the gains from increased safety on the railroads and from the decrease in the drowning hazard. The death record against population, of course, ought to be taken into consideration. The death rate per hundred in 1911 from all accidents was 84.7 and in 1925 it was 78.3. The Statistics Committee does not particularly care whether the death rate is going down or up, but what they are interested in is the number of persons killed. We often hear a remark that the number of deaths per thousand automobiles is going down. But it doesn't make much difference to the man who is killed.

We do wish you to take more cognizance of the absolute number of deaths which occur. As far as the United States and foreign countries is concerned, there is a very wide margin between the accidental death rate in the United States and that in other countries similarly situated. In 1925 our death rate was 78.3; in England and Wales, 35.9; Scotland, 49.2; New Zealand, 46.7; Australia, 52.6. Strangely though, while the accident rate for the United States between 1925 and 1926 increased 2.1 per cent, in England and Wales it increased 4.8 per cent.

Automobile accidents on a national basis also afford an interesting insight. The United States 1925 death rate was 17.0 per 100,000 population. That figure may be compared with the rate of 6.8 per 100,000 for England and Wales; 6.5 for Scotland; 8.7 for Australia, and 5.0 for Canada. Canada has a death rate of 5.0 per 100,000 and we have a death rate of 17.0 per 100,000. The accident death rate by sex shows a very marked difference between males and females. Males showed 108 deaths per 100,000 and females 42 deaths per 100,000.

The facts in respect to age are also of interest to the safety movement. For all accidents combined some 22 per cent occurred among children under 15 years of age. Eight per cent of all the deaths from falls occurred among children in this age group. A quarter of the automobile fatalities occurred among children under 15 years of age. Fifty-four per cent of the deaths from burns and 31 per cent of the deaths from drowning were of children under 15 years of age.

The comparison between accidents and other causes of death shows that all accidents combined are the sixth cause of death, preceded only by heart disease, cancer, tuberculosis, cerebral hemorrhage, and chronic nephritis. Accidents are the leading cause of death in the age period 5 to 9 years, and in the age group 10 to 14 years; they are the second cause of death in the age group 15 to 19 years.

The urban and rural data are also of some interest. In the cities of the United States the accident death rate was 83 per cent per 100,000, and in the rural districts, including communities of 10,000 or less, it was 69. About two-thirds of the automobile deaths occurred in the cities, 41 per cent of the railroad fatalities, 79 per cent of street car fatalities, 38 per cent of drownings, 33 per cent of firearm deaths; nearly 60 per cent of the falls occurred in cities, 59 per cent of the burns, and strangely enough, 53 per cent of conflagrations or fire deaths; that is to say, 57 per cent of all the deaths in conflagrations in the United States occur not in the cities but in the country. Of the deaths from poisons 49 per cent occurred in the cities, which is about an even break between city and country.

Then there are data on the relation between the accident death rate and the density of population. As the density of population increases the accident death rate decreases. That is quite contrary to what most of us have assumed. We have assumed that the accident hazards are concentrated in the cities both large and small, but as the density of population increases the accident death rate decreases. There seems to have been no difference, however, as between cities and country, or as between dense and less dense populations in the increase in the automobile death rate.

Statistics Tell a Detailed Story of All Accidents

Considering season of the year in connection with automobile accidents, the low point occurs in February and the high point in October. The high points are reached on Saturday, the lowest point on Thursday. We have taken these figures from the New York State Motor Vehicle Bureau and we hope that the statistical system which is there employed will be shortly extended to other states.

As to the types of vehicles, some 69 per cent were private passenger cars, 15 per cent trucks or commercial vehicles, 14 per cent taxicabs, busses less than 1 per cent, and motorcycles 2 per cent.

We have also gathered some data on the detailed type of hazard which gives rise to public accidents. Considering all public accidents as 100 per cent, deaths from transportation hazards make up 23 per cent of that total; deaths from pedestrians using the streets, 42 per cent of that total; sports and recreation, 6 per cent, and the use and occupancy of public buildings about 2 per cent. Other public accidents 27 per cent.

Public accidents considered by the type of injury show 55 per cent were automobile accidents, 18 per cent drownings, 9 per cent railroad accidents, 5 per cent falls. We also analyzed the different types of public accidents, which show that 71 per cent of transportation accidents were automobile accidents; 70 per cent of sports and recreation accidents were drownings; 74 per cent of pedestrian accidents were automobile accidents, and 44 per cent of public building accidents were falls. That is a figure that ought to be of interest to building managers and persons interested in the safe operation of buildings.

You will notice that elevator accidents do not rank first. That is the impression one receives by talking to building managers.

We also gathered what there was available in the reports of the Interstate Commerce Commission for 1926. We have found that of all the railroad fatalities in the United States last year, 73 per cent occurred to persons who were neither passengers nor employees, that is, trespassers; 25 per cent of those deaths occurred to employees, and only 2.2 per cent of railroad fatalities were those of passengers.

The committee has given extended consideration to home accidents. We are unable to quote an estimate for the number of home accidents in the United States, but we guess that possibly 20,000 to 25,000 fatalities occur in this country each year which arise out of hazards in and about the home. We are likely also to

issue an estimate that fatalities in the home are at least as numerous as fatalities in industry, if we can ever find how many there are in industry. Estimates prepared by responsible persons range all the way from 13,000 to 30,000 a year. I suppose we can take it to mean between those two figures that from 20,000 to 25,000 fatalities occur out of or in the course of occupation in the United States each year. That tremendous toll of home accidents is being attacked now on the basis of facts. The committee is endeavoring to secure information from men such as you, from the schools, from the homes, insurance companies and their agencies with respect to the types of accidents which occur in the home according to the specific hazard existing therein. Perhaps by the first of December we should be able to outline a simple statistical program for the study of domestic accidents. Perhaps at the next meeting we may have some reliable and extremely useful information in the home accident field.

We have some data gathered by the National Safety Council on home accidents. A third of the accidents were due to falls, about one-quarter to burns, 15 per cent to asphyxiation and suffocation, 8 per cent to poisons, 6 per cent fires and explosions, and 3 per cent to the use of firearms. We have had in this home accident study the cooperation of the largest insurance companies, such as the Travelers, the Aetna, and Metropolitan, and others, and we hope to supplement that insurance data with data directly gathered by the committee's staff, through the plans which the Committee will outline this winter.

"Accident Facts For 1927"

We should like to direct your attention to the report which was prepared this year. Five hundred copies were printed as a preliminary edition for this meeting, called "Accident Facts 1927." A few minor adjustments are going to be made in the figures and then an extended edition will be printed.

This last year the committee also prepared what I believe to be the most important publication in its history, a little pamphlet called "Public Accident Reporting." If you have not received this pamphlet get in touch with Mr. Williams or Mr. Forney. Read the pamphlet. Inquire locally whether your police and safety departments are using this standard system outlined by the Council's Committee. You ought to have that standard accident reporting system in every important city and, of course, in the states. New York State has had three years of experience with it and it has experienced no important difficulty in administering the system. It has produced data for the use of the Motor Vehicle Commissioner which have led to modification of his rules and edicts. The New York data was in such condition that when a traffic and safety survey was made in Albany a year ago, the state provided not only the data for Albany as a whole but also detailed facts on accidents in the city of Albany. Intersection accidents were plotted, deaths were segregated, and the data arranged according to age. If you have this system not only can you get out general reports monthly, semi-annually, and annually, but your material will be in such shape that when you want to tackle a specific situation in a given city the data are there for the use of the traffic engineer.

The committee has in mind that the Statistical System has two uses: First, in providing data such as we quote here and such as we publish, data used in generalized discussion of the safety problem. But we don't think that is the most important use for it. We do think the chief use of the system is the local study of cards prepared for specific areas, the utilization and the subdivision of that material, its plotting and spotting and rearrangement locally to point out specific traffic hazards that need to be abated.

Colonel Sinke has made such use of the system in Grand Rapids. He gets out splendid reports, not only reports that tell us what is going on in Grand Rapids, but he makes wider use of the material by having the data segregated, arranged

according to specific locality in the city and then he studies a specific problem and solves it. Thus the wider and deeper use of the statistical reporting system lies in making available information to the practical engineer who sets forth to abate public accident hazards.

The Safety Council System is now at work in its full array in some 59 communities and in New York State. The motor vehicle information becomes available from a population of 37,000,000; data on public accidents from a population of 18,000,000; non-vehicular accidents from 10,000,000; and home accidents from 12,000,000.

Only 20 years ago we had to get our automobile accident data from newspaper clippings and from almost any source, so you can see that marked progress has been made in providing actual basis for public safety work.

Cooperation in Securing Reliable Statistics

We have also been able to secure from the Census Bureau data which they did not in prior years publish. We have had exceedingly good support from W. H. Davis, Chief Statistician. He has shown in his annual reports facts which we called for and which we found to be useful in public safety work. They are also issuing every four weeks a summary of the available data on automobile accidents.

We have received support also from state motor vehicle bureaus, state highway commissioners, insurance companies, and state health departments.

Don't forget "Accident Facts, 1927," nor "Public Accident Reporting," a description of the standard system. Send to Mr. Williams for them and let us see when we come back here next year not only 59 cities but possibly 159.

We are greatly indebted to Colonel Sinke for suggestions which lead to the inclusion of nearly all the rational elements of this system. He has used a reporting system in Grand Rapids for quite some time and has had a lot of experience with it. We had a rather academic outlay at first, Colonel, and it was entirely due to the fine criticism which you offered that the excellence of this system stands as it does today. We also have had some splendid comment from the Chicago Police Department, from the statisticians and from public safety officials all over the United States. You may be assured that the accident reporting system is good and has gone through the fire of actual trial both in Grand Rapids and New York State, and if you apply it in your town you will have something which is absolutely solid and good. It is not new, there is two years of experience back of it.

CHAIRMAN SINKE: The National Safety Council is the only organization that is doing anything in a really large way in this field. In accident prevention, as much as in industry or any other place, we have got to have facts upon which to base our judgment and our actions.

The Program Committee has saved until the end a subject and a speaker which in the final analysis supersede all other topics. We can spend all the money we wish for control devices, we can hire as many police officers as we see fit, but unless the final authority for imposing penalties is in accord with the principles being followed, little can be accomplished and much time and money will be wasted. The enforcement phase has to do with the element of fear in the individual, and while through education we are trying to dispel fear, yet we recognize that it is necessary to appeal to that human trait of character which is concerned about fear. We have our courts for that purpose.

Last year Judge Bartlett talked to us in Detroit. We in Michigan are very familiar with Judge Bartlett and his work and know that when he took the bench in the city of Detroit and began sending violators to jail and treating them rough, they had a big reduction in the amount of reckless driving and casualties upon the streets of that city.

I am informed that the speaker is one of the pioneer traffic judges, that his specialty

is giving jail sentences to traffic violators and that he is also a member of the Executive Committee of the Brooklyn Safety Council. So on behalf of the National Safety Council I want to welcome Judge Lawrence C. Fish, of the Traffic Court of Brooklyn, New York, to this gathering, and to assure him that it gives me personally, and I am sure the gathering as a whole, extreme pleasure in having him with us and hearing what he has to say.

Traffic Law Enforcement

Judge Lawrence C. Fish, Traffic Court, Brooklyn, N. Y.

It has been said of me that I am the highest priced orator in Kings County because every time I open my mouth it generally costs \$25.

I have been greatly interested in listening to the remarks made here this morning by eminently qualified experts who discussed their specific subjects in an able manner. I think it does a judge good once in a while to get out where he can hear what the other fellow has to say, because most citizens are unkind enough to say that they must remain discreetly silent when in the presence of the court.

It was my good fortune once to be in Los Angeles and if the people fail to elect me municipal court judge this fall in Brooklyn, I think I will move to Los Angeles, because that must be the nearest place to heaven. Unfortunately, in New York with its cosmopolitan crowd, we do not find either motorists or pedestrians so thoughtful. About a year ago I was attempting to cross the street with a lady. The light was in our favor but it was suddenly changed when we got about two-thirds across the street. I tried to be gallant and save the woman's life, and put out my hand. You know sometimes judges, even when they are off the bench, seem to think that people must know who they are.

This taxicab driver said something to me that must not under any circumstances go on the record. I started to take his number, and again a vile remark. It has been said of me that I am a quiet worker between the acts. I looked up the name and address of this driver and telephoned the station house nearest to where the driver lived that I would like to have the pleasure of meeting him face to face in the morning. My friend appeared and told the lieutenant of the police station that he had received no summons but the nearest police station had told him to report. The lieutenant said, "Do you recall any violation that you made?"

"No," he said, "except that a little fellow was attempting to get a woman across the street and I said something to him that I am sorry for."

When the lieutenant told him that little man was Judge Fish, I thought he would have to give him special aid for the injured, because he seemed to collapse all of a sudden.

Sometimes I have grown weary in participating in these gatherings, but on the whole I think it is worth while for men and women who love to serve others to give of their time and money in movements of this character. I was pleased to note that as a result of the Hoover Conference various state legislatures have adopted (and others will adopt it) the recommendations of the Hoover Committee as to uniform traffic regulation. I don't think that we fully appreciate all of the good work that has been done by the National Safety Council.

When I first was called to preside upon the Brooklyn traffic court bench the number of deaths was appalling and I urged upon the patriotic citizens of that borough to form a Brooklyn Safety Council. Reliable statistics daily obtained from the police department of the borough of Brooklyn conclusively show that after the formation of the Brooklyn Safety Council the death rate decreased over 137 in one year's time. And so, as I said before, it is gratifying that in this pleasure-

crazed age, when everyone is seeking pleasure and in search of the dollar, that over 6,000 patriotic men and women will attend this National Conference and individually and collectively do their part in doing away with this wanton slaughter of our fellow citizens.

Of course, I have come in contact both with the policemen and the offending motorists, and as you know, there is nothing in common between them. I was amused a short time ago when a strapping Irish policeman had arraigned a diminutive Hebrew on a charge of driving on a one-way street, and when called upon to plead the Hebrew said, "I was going one way, Judge, what more does he want?"

I think it has been a fine thing that our engineers have devised and are giving thought to traffic signals. But, my friends, if we are honest, let it be said that the American people love to take a chance; and unless the bluecoat, the man with authority is there, all of us unconsciously take the chance.

Unfortunately, most of us look at this problem from an extremely selfish viewpoint. Shortly after going on the bench I received a postal card from a friend of mine who likened me to President Coolidge. He said I was not severe enough, and that was the first compliment that I had received after my appointment. He came to court the following morning, and to show my appreciation of his kindly expression of thought I had him sit alongside of me while at the bench.

The Root of the Evil Must Be Plucked Out

The following morning I received a letter from him that a very dear woman friend of his had received a summons for speeding and would I be kind enough to suspend sentence? It makes all the difference in the world whose ox is being gored?

Friends, I fear that I have not touched on the serious side of the problem, but I simply want to say this: That in my judgment the thing for us to consider is whether or not the state authorities in all of the states of the Union are careful enough in demanding a physical and mental test of applicants before they are turned loose upon the public highways. All the safety talk imaginable, all this talk about regulating pedestrian traffic, is not getting to the root of the evil. When we consider that before a railroad company will permit an engineer to take out a train he must serve an apprenticeship of at least seven years as a fireman and then submit to a physical and mental test, is it unreasonable for us to ask and demand that before the state grant the privilege of operating a car—it is a privilege—the applicant shall conclusively prove his capabilities, physically and mentally?

In all large cities throughout the country we find this deplorable condition prevailing. Take, for instance, in our own Brooklyn court. Last year over 53,000 persons were arraigned for various traffic violations. Thousands of policemen were taken away from busy street crossings, the judges were compelled to listen to every case, and in the great rush and in the desire of the court to get the policemen back to their posts and the citizens to their place of business, the court was unable to consider properly the more serious charges brought before it.

I am inclined to think the plan that I understand is in vogue in Chicago is a step forward, and that is this: That when a ticket is given, on the back of the ticket there is the prescribed fine that will be charged for every violation, and the citizen can, if he desires, waive his constitutional right, appear before the clerk, and pay the fine. A method of that kind does not clog up the court calendar and it does not take away from important posts the policemen.

I do hope that as a result of this conference and of other conferences, there may be an awakening in the heart and conscience not only of the motorist but of the pedestrian. I think Judge Cardoza, of our New York State Court of Appeals,

stated it ably in these words: "Mutual forbearance is the supreme rule of the road," and that is so hard for us to do.

Just one illustration and then I am through. A short while ago one of the leading officials inadvertently got into the private chamber to intercede in behalf of a doctor, and I said: "I don't try cases in chambers, I try them in the courtroom."

"Well," he said, "I am afraid that he won't get a chance to say all he wants to say."

"Well," I said, "I will tell you what you do. You sit right in the front row and I want you to listen to everything that takes place between him and me."

So when this doctor was arraigned he confessed he was going 45 miles an hour. I said, "Doctor, have you any excuse for going so fast?"

"Yes, I was summoned to a hospital to assist in an operation to save a human life."

One of the Typical Cases Before the Court

I said, "Sit down and we will try the case in a few moments." The officer who issued the summons was sworn in and, I suppose, bearing in mind the anxiety of his superior officer to be of service to the doctor his mind suddenly became a blank. Then the doctor went on the stand. The summons indicated that he was served at 7:40 p. m. "Doctor," I said, "did you receive a telephone call from the Bushwick Hospital to assist in an operation between 7 and 7:45 p. m.?"

"No, sir."

"Did you receive a call from that hospital between 6 and 7 o'clock?"

"No, sir."

"As a matter of fact, Doctor, did this doctor from the hospital telephone you to assist in that operation?"

"No, sir."

"Then do you want the court to understand that what you said was a deliberate untruth?"

"Yes."

I called my official up and I said, "Are you satisfied that your friend had his day in court?"

"Yes."

"What do you think of him?"

"I think he is a little nervous."

"He is more than that, he is a liar of the first type and I gave him a few days to study medical jurisprudence in the county jail of Kings County."

Talking about law enforcement, I simply want to say this, friends: That I believe and I hope that you citizens as you go back to your respective places will bear this in mind. The members of the police force are maintained at a great expense. They are not all honest men, they are not all brilliant men, but if they are honest, and if they are trying to do their best to safeguard your lives and your property, then in Heaven's name, back up the judges who support them in that move!

I read an article only a short time ago that impressed me wonderfully. It spoke of the difference between the enforcement of laws in the United States and Great Britain. A desperado had with impunity held up men in western cities (far removed from Los Angeles) and got away with it. However, this desperado had inadvertently got over the borderline into Canada and he whipped out his pistol and demanded that people dance at his command. A small, undernourished deputy sheriff appeared with a little tin shield on his breast and said, "Go down the street and leave your gun at headquarters," and this desperado was about to shoot when his friend said, "Don't be a damn fool; perhaps you don't know, but you

are over the border, you are under the English law. You will get a fair trial but you will pay the penalty within a very short time."

My friends, what we need in America today, not only in the enforcement of the traffic laws but every other law, as long they remain on the statute book, is honest enforcement of the laws; and whether or not we like them, as long as they remain there let us, as American citizens, have the courage to back up the judges.

ADJOURNMENT

Wednesday Afternoon, September 28, 1927

CHAS. A. HARNETT, Chairman
Commissioner of Motor Vehicles, Albany, N. Y.

The third session was called to order at two-twenty o'clock by the Chairman, Charles A. Harnett, Commissioner of Motor Vehicles, Albany, New York.

Opening Address

Charles A. Harnett, Commissioner of Motor Vehicles, Albany, New York

The Empire State regards it as a duty to be represented at this most important annual Congress of the National Safety Council. We desire to record our appreciation of the invitation, and at the same time, give public expression to the splendid assistance and cooperation rendered by your organization to New York State in its attempt to properly solve the all important problems arising from present traffic conditions.

The thing I want to emphasize most is this: This is my first occasion to be present personally, and I am sure we will all learn a great deal from these deliberations. We couldn't let the occasion pass without paying our respect and our tribute of appreciation to the National Safety Council for the work they have rendered us in New York State. Modest men as they are, Mr. Williams and his associates have been ever at our beck and call, ready to help and assist us in any way that we saw fit to call on them, and we want to in the most formal way express our appreciation for the help they have rendered us.

No more enlightened nation exists—or one in which there is more intelligent interest in the alleviation of suffering and the prolonging of human life—than our own. We have been uniformly free from devastating plagues and yet we have before us in this country a condition arising from the use of the automobile which is hard to understand. I refer not alone to the ever increasing appalling loss of life and property damage occasioned by accidents on the highways, but to the apparent indifference of the nation to this yearly toll which is being taken and which is killing so many of the youth of the country. If it were confronted by an epidemic causing 70 deaths a day, for even the brief period of one week, every governmental agency and the entire resources of the nation would be immediately coordinated in an effort to wipe it out and remedy the condition which produced it. The press of the country would demand its conquering, and study as to the best methods to prevent a recurrence. Today there is an agitation for the control of aviation—caused by the loss of half a hundred lives during the past summer months—and yet automobiles are killing more people daily than were killed in airplanes all summer.

It is estimated that more than 24,000 lives will be taken and a property damage of \$700,000,000 ensue before 1927 comes to a close. New York State has its particular share of this unfortunate condition. With a total of 2,000,000 automobiles and two and a quarter million drivers, the Empire State is confronted with a peculiar problem due to the vast congestion in a few great cities within its confines. In 1901 we registered 954 automobiles and in 1923 the number had increased to 1,204,000. During all this time the motor vehicle and its operation officially were viewed largely as a source of revenue. Little or no attention was given to the necessity of properly supervising and regulating the machine and its operator.

It was imperative that the increasing loss of life and waste of property be materially reduced, if not entirely eliminated, and in a special message to the Legislature Governor Alfred E. Smith, reviewing in a very comprehensive manner the conditions largely created by such an apparent policy, urged in no uncertain terms that legislative action be taken providing a means of supervision and control of motor vehicle operation that would bring about an immediate reduction in our annual loss of life. A joint legislative committee intelligent and alert to the problem—appointed as a result of the Governor's message—recommended amendments to the then existing laws which were adopted and resulted in the establishment of the Bureau of Motor Vehicles.

The value of a complete statistical division was apparent from the outset, and it is through the information thus compiled that we have been endeavoring to control the accident problem in our state, and it is a matter of satisfaction that slowly but surely other progressive states are about to adopt similar methods.

A Statistical Unit Is Essential

Let me depart a second and say to you who are so deeply interested in this automobile problem, that if you are attacking it in your local communities in any way and are attacking it without the establishment of a statistical unit, you might just as well stop. The gathering of statistics in an intelligent, comprehensive manner to indicate the way in which accidents occur, why they occur, and how they occur, and when they occur, is the whole soul of the question of traffic safety.

Through the establishment of a proper tabulation of statistics you will be able to then disseminate your information for pointing out the various phases that need correction. As I go along you will see, if you bear with me, how New York State is able to tell in an intelligent way how they are attacking the problem, mounting as it is in our state.

A comparison of our statistics shows that in the first seven months of this year automobiles killed 1,118 people as compared with 1,032 in the same period in 1926. The saddest feature of this loss is that 40 per cent of those whose lives were crushed out were children under 16 years of age.

Accidents in that time increased from 30,153 to 37,294 although in the same period there has been an increase of 10 per cent in the number of cars in operation in our state. Therefore accidents have not increased in proportion with the number of machines on the highway. In this period 44,330 people have been injured as compared with 35,057 in 1926, and it is important to note that of those injured and killed 84 per cent were pedestrians. We have developed the fact that Saturday and Sunday are the worst days of the week for accidents and that five o'clock in the evening is the danger hour of the day. Railroad crossings at grades continue to count high in the percentage of fatal accidents. Eighty-eight of these accidents caused 61 deaths and 121 injuries this year as against 79 accidents, 70 deaths and 85 injuries last year. This brings to mind very forcibly the campaign instituted by Governor Smith for the elimination of these grade crossings. On private driveways of homes, automobiles were responsible for 18 deaths, eight of which were children killed on property belonging to their own parents, showing to what extent care and caution must be exercised. Taxicabs represent but 3 per cent of the motor vehicles of our state and yet figured in 17 per cent of the accidents although it must be conceded, particularly in New York and other large cities, that these machines are in operation practically 24 hours a day. One hundred eighty-one lives were taken through machines striking fixed objects such as elevated railroad pillars, girders, cars overturning and skidding because they were being

driven at such excessive speed that they were out of control when it was necessary to make a quick stop.

In this connection I would remind the automobile manufacturers of this country that they have a duty to perform beyond the manufacture and sale of automobiles. Recently in our state two advertisements appeared proclaiming the fact that two different makes of cars passing through important cities from Buffalo to Albany had eclipsed the running time of the famous Empire State Express, and as a result the two drivers quoted as operating these cars have lost their licenses. This has a tendency to create a lust for speed among youthful drivers, particularly those who do not use their cars for the comfort, convenience and safe transportation of families dependent upon them. The average purchaser of an automobile—and I say this because I am satisfied that 94 per cent of the motorists of our state never in any one year get into the slightest difficulty with the law—is not influenced in the purchase of automobiles because of their ability to operate at 100 miles an hour. Automobile manufacturers must, in my judgment, give careful attention to this question lest the day come when by legislation the speed producing power of automobiles be regulated.

Ten per cent of junior operators between 16 and 18 years of age were involved in fatal accidents, while among adults there was but 3 per cent. I again reiterate that the most important feature of our statistics is that which shows the loss of life among children under 14 years of age. These youngsters have not the ability to think quickly, and it is a sacred duty imposed upon every automobile driver to exercise exceptional care when he sees them in the roadway.

How then shall we intelligently attack the problem?

The Examination of Drivers Has Become More Stringent

In our state this year 470,000 prospective automobile drivers have appeared for license examination. Step by step we have made more stringent the practical examination of drivers and in addition this year we have included an eye test which we regard as all important, and further, we plan to include in the near future a color test, believing it is quite as important on the highways as it is in the operation of railroad trains. We believe the power of suspension in cases involving serious personal injury and revocation of licenses when deserved is a forward step. We further believe the publication of the names of those who are responsible in these cases has a salutary effect.

In addition, the utmost care is given to applications for reinstatement of those who have been disenfranchised for serious offenses in the past. The automobile clubs and local safety councils in our state are rendering intelligent cooperation in solving the problem. The police agencies in our cities and the State Police through strict enforcement on the highways will eventually prove of great assistance in controlling the situation, and it is a matter of personal satisfaction and pride that I can refer to the progress in the control of this vexacious question by the Police Department of the city of New York in which the death rate not alone has been controlled but is slowly but steadily being decreased.

The courts can do their share in properly adjusting the punishment to meet the circumstances. Drivers operating at 30 or 40 miles in cities over streets in which children are playing should be severely dealt with. We are satisfied that except in minor cases fines have little deterrent effect. In our state the motorist has but one fear, and that is the loss of his license. The adult pedestrian can assist in reducing accidents by crossing at the crosswalks and other-

wise using care and judgment on the highways, for children are born imitators and if adults show a good example children are bound to follow.

Municipal authorities can assist by the extension of traffic lighting systems, increasing the number of traffic officers, providing oneway streets, eliminating parking where necessary, establishing uniform signals for traffic officers, and maintaining adequate playgrounds for children so they may not be forced to resort to the streets for their games. We utilized our inspectors by their giving short talks to the children in schools on the subject of safety on the highways, and we suggest that local police agencies adopt a similar program.

We commend to the attention of our sister states the adoption of a "Save-a-Life" Campaign, such as we have just concluded in New York State in which more than a million motorists voluntarily submitted their machines for examination for possible mechanical defects. Carefully compiled statistics reveal that 39 per cent of the cars thus examined were defective in some important respect such as the steering wheel, the brakes, the horn or the headlights. This campaign we believe brought home to the motorists the necessity for frequent inspection of these important parts of the automobile. We believe our state will soon have a compulsory insurance and compensation law similar to our present Workmen's Compensation Law, so that regardless of responsibility, injured persons and dependents of those killed in automobile accidents will be compensated.

CHAIRMAN HARNETT: The next speaker is a man who doesn't regard this subject in any degree as a plaything, he has lived with it, worked with it, and slept with it for years. He is a representative in an unofficial way, and possibly in an official way of the National Government. He is what we might describe in the human body as the heart of the Hoover Conference, which has had as its main endeavor the establishment and the adoption of the model Motor Vehicle Code in all of the states in the Union. There is no one whom I know in my contact in the official automobile world who has a better knowledge of the subject that has been delegated to him than the next speaker, and I take great pleasure in introducing Colonel A. B. Barber, the Director of the National Conference on Street and Highway Safety.

Plans of the National Conference on Street and Highway Safety

A. B. Barber, Manager, Transportation and Communication Department, Chamber of Commerce of the United States, and Director, National Conference on Street and Highway Safety, Washington, D. C.

Commissioner Harnett made some very nice remarks about me which I don't deserve. As for my heart to this conference, it consists of Secretary Hoover and of the great number of official and unofficial people from all parts of the country who gave their experience and their service. My part was simply to keep them spurred up to the good ideas which flow up to the top, so that there might be crystallized out of that a better understanding among the people at large throughout the country of what is needed to cope with this very serious problem that we have been discussing.

I would like to pay my compliments to Commissioner Harnett and his associates in the other states who are doing a similar work to what he is doing, by saying that to my mind, after being in fairly close touch with this whole movement for bettering the handling of traffic, I don't believe there is any more essential thing than the establishment in each state of a responsible official to whom the person can look for

light on this subject, Commissioner Harnett has mentioned with repeated emphasis the matter of statistics. New York State is to be congratulated in having a man who isn't afraid to let the light of statistics into the problem. He is conscious of the fact that the measures which he and the Governor and the Legislature of New York have taken are going to produce results, are going to get the accident rate down. They are not afraid of the statistics.

A year and a half ago the National Conference on Street and Highway Safety developed an extensive program of recommendations for dealing with many different phases of the traffic problem. These recommendations were based primarily on the reports of 12 committees that had studied various phases of the problem in the preceding two years. At the general session of the Conference in March, 1926, at which the program was adopted, however, there was opportunity for discussion of every point, and amendments were in fact made to the recommendations of the committee, although on most points the Conference found the committee recommendations to be sound. It could therefore be said with confidence that the program represented the most advanced thought on street and highway safety. This confidence is confirmed by the fact that in the year and a half which has intervened the recommendations then made have almost without exception stood the test of detailed scrutiny and application in many different parts of the country. A very few minor modifications might now be made if the entire program were to be again reviewed but these are so insignificant or so easily adjusted by local action that they in no way impair the value of the program as a whole. On the other hand, there were a few uncompleted items in the program on which, as I shall explain later on, work is now in progress.

Closing Words to the Hoover Conference

In dissolving the National Conference in March, 1926, Secretary Hoover referring to the reports which the conference had just adopted, said:

"Our work is not completed with the formulation of these results. You have already resolved that we should proceed in our next step through state conferences, and you have set up certain committees to continue the work of the Conference.

"It is not our purpose to create here an additional organization for safety, but rather to secure cooperation between the many agencies that are working throughout the country to that end. It is not our purpose at the moment to call another Conference of this character, but to hold ourselves ready at any time, so that if the representatives of the different states and the voluntary bodies of the country should wish it, we can again convene for the further advancement of thought."

The situation which then existed remains largely unchanged. As Mr. Hoover indicated, the Conference looked to the participating organizations to further the execution of its program; and this is a large task. Excellent work has been done along some lines. Along others there has not been much accomplishment. The fact that the accident rate continues to increase is indication enough that there should be no thought that the job is done. On the contrary, most of the work of execution is yet ahead, and every organization interested in street and highway safety has a large opportunity and a larger responsibility.

A program of recommendations of the Conference was divided into eight general headings, as follows: (1) Traffic Laws and Regulations, (2) Enforcement, (3) Education, (4) Statistics, (5) Causes of Accidents, (6) Design and Maintenance of Motor Vehicles, (7) Street and Highway Traffic Facilities and (8) Elimination and Protection of Grade Crossings.

Traffic Laws and Regulations

Under this first heading the major recommendation of the Conference was the adoption by states of uniform vehicle legislation, and as a basis and guide for such legislation the Conference in collaboration with the National Conference of Commissioners on Uniform State Laws developed the Uniform Vehicle Code of four acts.

This Code was brought formally to the notice of the various Governors, the designated State representatives at the Second National Conference on Street and Highway Safety were asked to work for the adoption of the Code in their states, and there was much concentrated effort by various organizations; to bring about the adoption of part of all of the Code in the states ripe for such legislation. While we have not yet complete information on all states, we know that this year North Carolina, North Dakota and Idaho adopted all but the licensing act; that Pennsylvania, Michigan, Minnesota and Washington adopted supplementary legislation bringing its laws into line with the Code; and that other states added to or amended their existing laws more or less in the direction of the Code.

On the other hand, in at least two states bills based on the Code were passed but vetoed. In several the bills were defeated by close margins, or lost in the final legislative congestion. Opposition developed in some quarters apparently due to misunderstanding which it is hoped may be cleared away before the next legislative sessions. Next year is an off year for State Legislatures and action will be concentrated in some ten states, but 1929 will see all legislatures meeting except four states. If all the organizations represented at this Congress will get behind the legislative program in the various states great progress should be made in the next two years. Besides education of the public as to the benefits of modern vehicle legislation there must be intensive work in adjusting the Code to state constitutional and other legal requirements, and in properly presenting it and following it up with the right legislative groups.

The Conference program recommend that the Uniform Vehicle Code be supplemented by state administrative regulations, local traffic ordinances and local regulations as nearly uniform as practicable. It was the consensus of opinion at that time that uniformity in local ordinances could best be worked out by state or regional conferences of officials and other persons or organizations interested. Since then, however, the belief seems to have been growing that regional conferences alone cannot produce the uniformity desired, and in response to a widespread demand Secretary Hoover recently appointed a committee to deal with this problem. I shall later on speak further of this new activity of the National Conference.

Enforcement

The First National Conference on Street and Highway Safety emphasized the great importance of uniformity both in the traffic laws and their enforcement, and enforcement was made the subject of a special committee study. The recommendations of that committee provide, in summary, that state laws should prescribe a uniform system of enforcement, through adequate trained police departments, adequate courts and adequate means for collecting evidence and maintaining records; that the courts and the police through vigorous enforcement and evenhanded treatment of offenders should instill respect for the laws and regulations; and that public opinion should be enlisted in support of enforcement.

The International Association of Chiefs of Police has been in close touch

throughout with the Conference and its findings. Secretary Hoover, as chairman of the Conference, has sent the report of the Committee on Enforcement to more than twelve hundred traffic judges and judges handling traffic cases. It is evident, however, that there is much opportunity for local effort in impressing upon the public the benefit to them of vigorous enforcement, in ironing out differences of opinion between police and courts, and in convincing that the public desires enforcement.

Education

The educational program of the Conference embraces instruction in safety and accident prevention in schools of all types; education of the driver through the compilation and distribution of a uniform manual; education of the general public through the newspapers, motion pictures, radio talks, public gatherings and special campaigns; and standardized plans for the selection and training of traffic officers.

School educational work has been making rapid strides, and the efforts of those engaged in the development and promulgation of the safety curricula are greatly to be commended. The initiative taken by the Education Section of the National Safety Council has borne fruit in securing active cooperation of the various educational groups. The Highway Education Board, the American Automobile Association, and more recently the American Road Builders' Association, have also greatly contributed through essay contests and otherwise. The general public is now receiving safety instruction of many kinds mostly of considerable value. The newspapers have a difficult task to reach the minds of great numbers who have not adapted themselves to twentieth century conditions and to keep the message before them.

The uniform drivers' manual recommended has not yet been compiled. This is a definite piece of work waiting to be done.

Apparently not all of those in charge of the police departments are alive to the importance of careful selection and training of police officers. Hence we find at important intersections officers with evidently very inadequate conceptions of the things to be done to expedite the traffic without endangering the public; some of them pressed into service from the regular force with little or no special instruction. The authorities should be persuaded that traffic control requires special ability and training.

Statistics

The Committee on Statistics made reports to both the First and Second Conferences. In both it pointed out the inadequacy of existing methods of reporting accidents, and the Conference recommendations include a standard form for reporting accidents as proposed by the Statistics Committee of the National Safety Council which is actively following up the subject and has secured the adoption of substantially the same forms in about sixty cities. The National Conference program also includes a recommendation for a comparative index rating of all states and communities and one for a contest in accident reduction. The index rating is in part being carried on by the Census Bureau, but no practicable plans for a contest in accident reduction have been worked out.

The Uniform Vehicle Code prescribes the reporting on approved forms of all serious accidents, and as adoption of the Code is extended to additional states adequate and uniform reporting of accidents will doubtless become a fact.

The Conference Committee on Statistics met recently with a view to following up some of this unfinished work.

Causes of Accidents

Since our traffic accident statistics are incomplete and inadequate, obviously our information as to the real causes of accidents is also inadequate, but even the available information has not been thoroughly analyzed. Nor have obviously needed original studies been made. The Conference Committee on Causes of Accidents reported in favor of a comprehensive program of research to be undertaken by a national body qualified for the purpose; and a recommendation to this effect is included in the Conference program.

This is much needed research which the National Research Council undertook to organize and sponsor. The understanding was that a special committee to be organized by the National Research Council would investigate particularly the human factors in accidents and that a Committee of the Highway Research Board, which also operates under the auspices of the Research Council, would specialize on a study of the physical factors in accidents.

Design and Maintenance of Motor Vehicles

The Conference program recommends continued effort on the part of manufacturers with a view to further improving the design and construction of motor vehicles and accessories from the safety standpoint. It also recommends the preparation of a simple and practical inspection chart and code applicable to all makes of motor vehicles.

The automotive manufacturers and their engineers are their own most severe critics, and we may rest assured that they will continue their efforts to make the vehicle as safe as possible when it leaves the factory. We have not the same assurance that after it is sold and put into operation its owner will maintain it in a safe condition. They are many vehicles on the road with improper lights, inadequate brakes, defective steering gear. One of the recommendations of the Conference yet to be carried out is the preparation of the inspection code.

In connection with this matter of maintenance, the automotive engineers realize that they need not only to make the vehicle safe as to design and construction, but to make the adjustments easy to understand and make. There has been material progress in this field in the more recent models of cars.

Street and Highway Traffic Facilities

The Conference recommendations urged that every community or metropolitan area confronted with a traffic problem should adopt a comprehensive traffic improvement program—this program to be based on a thorough traffic survey and to include a transit plan, a street and highway plan and a traffic control plan and to be carried on a sound financial program to insure properly balanced progress. To accomplish such a program the Conference holds that there must be a traffic planning organization consisting wherever possible of an official traffic commission, with preferably also an unofficial advisory committee of representatives of utility, business and citizens groups, and, for metropolitan areas, a joint official board and a joint advisory committee representing each community.

These Conference recommendations have been brought to the attention of the mayors of all cities and towns, to the automobile clubs, the chambers of commerce, and the safety councils. Reports indicate excellent progress in the past year or two. But this is a field for continuing effort. Despite widespread publicity and repeated circularizing of different groups, we have frequent indications from communities that those who ought to be are in no way familiar

with the findings of the Conference, and that the communities are struggling along without adequate plans or with no plan at all. It should be kept before those in authority locally that the Conference recommendations are based on what is succeeding in other communities.

On the more technical side the Conference program also includes recommendations relative to street and highway widths, curves, grades, bridges, clear view, illumination and other features. Highway engineers are generally keenly alive to these matters and improvement is constantly going on. Our consciousness, however, that there are still many miles of improved highways dangerously narrow, dangerous combinations of curves and steep grades, blind intersections in the city and the open country, one-way bridges on highways of considerable traffic, and a vast mileage of unimproved highways and unpaved streets over which motor vehicles are operated should lead us to support reasonable programs for alleviating these conditions.

An aid to traffic of perhaps greatest importance in comparison with the costs involved is afforded by proper signs, signals and pavement markings. Since the National Conference was organized in the spring of 1924 great progress has been made in this field. The Joint Board on Interstate Highways, made up of representatives of the American Association of State Highway Officials and the United States Bureau of Public Roads, after most careful study, has developed a manual of best practices in highway signs, and this manual is already being followed in the signs being installed in a number of states.

In general the state and federal highway departments do not have jurisdiction in cities and towns. With a view to promoting uniformity here also, not only in signs but also in signals and pavement and curb markings, safety zones, methods of marking turns and so forth, a committee of the American Engineering Council, working under the general auspices of the National Conference, has been studying this entire matter for several months. Detailed information as to the practices in about a hundred cities has been obtained and analyzed, part of the committee's report is in preliminary form, and it is hoped that the entire report will be available by the end of the year.

Elimination and Protection of Grade Crossings

The Conference program, recognizing elimination of grade crossings as the only perfect solution of the problem, but one which can only be approached gradually due to the enormous costs involved, recommends the carrying on of such work under a proper program, eliminating the most dangerous crossings first. It urges due regard to the relative costs and advantages of elimination and other forms of protection, and avoidance of the creation of new grade crossings. It also urges that crossings remaining at grade be safeguarded in every reasonable way, and that properly designated commissions be empowered to designate dangerous grade crossings at which motorists must stop. The Uniform Vehicle Code contains the latter provision, and a number of states have enacted it into law.

The American Railway Association and other organizations directly affected have done much to impress on the public a consciousness of the dangers of grade crossings. The grade crossing problem has so many ramifications, however, that there is need for much intensive cooperative effort to work out the remedies for specific situations.

Summary of Uncompleted Business

The foregoing makes clear what I stated at the outset, that, while much effective work has been done along certain lines in carrying out the program of the National Conference, on Street and Highway Safety there is far more yet

to be done—communities to be organized for more intelligent traffic planning; police authorities to be prevailed upon to provide special training for traffic officers; the general public, the police and the courts to be impressed with the vital necessity for adequate traffic law enforcements, better collection and analysis of traffic accident statistics, and a thorough research into the real causes of accidents; development of a manual for drivers and an inspection code for maintenance of the vehicle in safe condition; intelligent cooperative study of the grade crossing problem in general, and intensive study of local situations; and as important as any of these, continued and in many cases better thought out effort to bring about uniformity in motor vehicle laws and regulations.

Model Traffic Ordinance

As you know, it has been felt that most of these things must be brought about by the various organizations and groups, official and unofficial which participated in the Conference, not by the Conference as a body. It was understood, however, that the Conference should remain available for any further study the future might show to be desirable; development of plans for securing greater uniformity in municipal traffic ordinances and regulations comes in that category.

The committee recently organized to report on this subject has some 20 members, under the chairmanship of Mr. William E. Metzger, of Detroit. It has the same wide representation of interests that has characterized the other committees of the Conference and the Conference itself. The work has been distributed among six subcommittees, whose subjects are as follows: I—Vehicle Movement and Regulation; II—Pedestrian Regulation and Control; III—Traffic Signs, Signals and Markings; IV—Parking, Terminals, Garages, Loading Facilities and Street Obstructions; V—Public Motor Vehicles, Railroad, Street Cars and Emergency Vehicles; VI—Traffic Organizations and Enforcement.

It can be seen that every one of these subcommittees has a real subject. The subcommittee work is well under way, and it is believed that reports from all of them will be ready for consideration by the full committee so that a completed report can be made before the end of the year.

At its organization meeting those present recognized the need for determining in what matters precise uniformity and in what a considerable degree of flexibility in ordinances is desirable: to what extent the ordinance should supplement and to what extent repeat the language of the state law; what matters should be covered by a model ordinance, and on what the committee should merely make recommendations as to best practices. They also felt that the ordinance and recommendations should be supported by appropriate explanation. It is not for me further to attempt to forecast the findings of the committee.

I think you will generally agree, however, that this is one of the most important pieces of work undertaken by the Conference in the three years of its existence. The report of the committee should strengthen the cause of the Uniform State Code. The states that have the Code will see the need for the uniform ordinance to supplement the Code. The two will work together for the uniformity that all agree will be one of the greatest factors for street and highway safety.

Summary

Stated briefly, the plans of the National Conference on Street and Highway Safety are to complete in certain features the comprehensive program of recommendations developed by the Conference during the years 1924 to 1926 and look to the various groups—official and unofficial—who participated in the Confer-

ence to see to the execution of their respective portions of the program following within the field of their several responsibilities or interests. There are present at this National Safety Congress representatives of many of the groups which are able to carry a great part of the burden of this much needed work. I therefore venture to hope that this brief outline of the program of the Conference and the additions to it which are now being worked out will suggest to many opportunities to play a part in putting the program into execution.

CHAIRMAN HARNETT: The next subject is one that is very important to all of us, the question is "Who Is Responsible for Lack of Law Enforcement—Courts, Police, Prosecutor, or Public?" It was intended that Mayor Victor J. Miller, of St. Louis, speak on this question, but we learn now that the Mayor couldn't attend. He has, however, sent a very able representative and I know you will all be glad to hear from the Director of the Streets of St. Louis, Mr. Robert Brooks.

Who Is Responsible for Lack of Law Enforcement— Courts, Police, Prosecutor, or Public?

Robert B. Brooks, Director of Streets & Sewers, St. Louis, Mo.

Is there a lack of law enforcement? The homicide rate in the United States is double that of Italy; four times that of Australia and South Africa; eight times that of New Zealand and Spain; nine times that of England and Wales; twenty-four times that of Holland, and thirty-six times that of Switzerland.

The word of law means, a rule of conduct established by an authority able to enforce justice. The above comparison of homicide in various countries shows there is a lack of law enforcement in the United States.

Senator Wm. E. Borah, of Idaho, says, "Lawlessness is the insidious disease of Republics." It would seem then that a lawless person is one not obedient to law, such as an anarchist who recognizes no law except his own pernicious self-will. In short, government divides itself into two classes—those who obey the law and those who disobey the law.

It is essential that our government be maintained by the law abiding element, expressed in terms of courts, police, prosecutors and good citizens. Consider these four a chain which bars our national door to a flood of lawlessness. Any chain is only as strong as its weakest link.

Let us confine our talk on lack of law enforcement to traffic laws. Within twenty years St. Louis traffic has increased one hundred and twenty times. This phenomenal growth has made comparatively recent traffic laws out of date. In a large Iowa city there is still a law which requires anyone driving an automobile on a public street to send an outrider several hundred feet ahead ringing a bell. To us of the present generation this is as ridiculous as the law passed in Massachusetts within the present century, making it a penitentiary offense to own a bathtub.

Traffic laws to be enforced must be practical, the kind that will be respected by the riding public as well as the walking public, for their own safety and convenience.

Statistics compiled by the American Road Builders' Association show a five-year toll in highway accidents in the United States of about 115,000 killed, 3,500,000 injured, and an economic loss of nearly \$3,000,000,000.

Carelessness and recklessness caused nearly 90 per cent of all accidents. Rigid law enforcement will reduce this gigantic total of the last five years. Assuming that every death or serious injury affected, either directly or indirectly, five persons, nearly one-sixth of the nation's population suffered.

The first step is securing the right kind of traffic laws. The next is to secure the absolute cooperation of the Police Department in the enforcement of these traf-

fic laws, particularly the hazardous offenses such as driving while intoxicated, reckless and careless driving, speeding, leaving the scene of an accident, etc.

The Traffic Squad in St. Louis, headed by a capable captain, such as John H. Glassco, has done much to bring about law observance on the part of our citizens. When arrests are made the next important step is that our police judges let it be known by their judicial acts that violators of traffic laws can expect no favors at their hands. The result is a watchful attitude on the part of the driving public.

At this point comes the prosecutor's responsibility. It is up to the prosecutor to take steps to see that his case and his evidence are in proper shape. Without this the judge must give the benefit of the doubt to the defendant. It is very important that the prosecutor in the Court of Appeals have as much information of the testimony in the lower court as possible before him in the trial of the case on appeal.

Often a strong case is made in the lower court and heavy penalties imposed upon by the judge, but due to improper records taken, witnesses may be tampered with and when the case comes up on appeal their testimony may be changed, causing a reversal of sentence of the lower court. Written records should be taken.

Unless the prosecutor has his full case, even though the judge may be anxious to deal out stern penalties, many guilty violators will escape the meshes of the law.

The Law Is for Us as Well as the Other Fellow

The fourth link in the chain is the public itself. That group of individuals who have the greatest responsibility generally assume the least. They are the drivers themselves. Most of us take the position that the law is for the other fellow. Let us realize that we all have a Dr. Jekyll and Mr. Hyde complex, one personality being the driver and the other the pedestrian.

As to establishing responsibility of our courts, police, prosecutors or the public for laxity of law enforcement, I emphatically decline to indict any of these groups as such, for that would manifestly be unfair.

The really criminal indictment rests against those individual judges, prosecutors and police officials who are solemnly sworn to enforce the law and yet for fees or favors prostitute the law and perjure themselves. Law breaking Anarchists are not all in overalls. There are, on the other hand, thousands of honest and courageous judges, prosecutors and policemen (all honor be to them) who do enforce the law and remain true to their oaths of office.

Policemen will do their duty in direct proportion to the support received by way of convictions from the courts and cooperation from the driving public and voluntary compliance with the law. Judges and prosecutors will do their duty and return convictions after the police have reasonably enforced the laws, using a certain amount of discretion. Police, prosecutors and courts will assume their proportion of responsibility, inasmuch as the laws are reasonable. Therefore, there is a big responsibility resting upon the legislative branch of the City Administration. Ordinances should not be passed which are unreasonable and oppressive.

In St. Louis the Traffic Division of the Department of Streets and Sewers, headed by Reyburn P. Hoffman, City Traffic Engineer, develops, through an investigation, all the facts pertaining to pending legislation, thus giving the Board of Aldermen this benefit before legislation is passed.

Two and one-half years ago Honorable Victor J. Miller was elected Mayor of the City of St. Louis on the platform of economy, efficiency and enforcement. The Police Department, believing that he meant what he said, made a strenuous effort, and in 1925 had tried in the City Courts 50,000 cases as compared with 38,000 the year before his incumbency. In 1926 there were 70,000 cases tried. In 1925 the judges of two courts assessed and collected fees amounting to \$155,000, as compared with \$94,000 collected the year before Mayor Miller put into practice the enforcement plank in his platform.

To reduce the gigantic total of fatal accidents on our highways, two things are necessary; a program of education for the general public and strict law enforcement.

The St. Louis Safety Council, under the efficient direction of Girard C. Varnum, has welded into a unit the legislative, administrative and enforcing officials of the city, the trucking companies, public utilities, taxicabs, the School Board, and individual influential citizens. This nonpartisan group, without cliques, is working with an eye to the fact that each one of us is his brother's keeper.

The secret of educational success has lately been impressed upon the educators. The school children must early learn their responsibilities, both for their own preservation and for their future responsibilities as good citizens. Through the efforts of the St. Louis Safety Council, and through study and consideration on the part of Superintendent of Public Instruction Dr. John J. Maddox, and members of the Board of Education, the curriculum in our St. Louis public schools includes a definite course of study on safety, which should include law enforcement.

This program of education inaugurated by the St. Louis Safety Council, together with the law enforcement plank in Mayor Miller's platform, as practically carried out in City courts 1 and 2, with the 100 per cent cooperation of the Police Department, under Col. Joseph A. Gerk, has brought St. Louis to the fore. With its record of 192 fatalities and 6,434 injuries in 1925, the reduced record of 174 deaths and 6,011 injuries in 1926, and on the basis of its present nine months record an estimated 124 deaths and 5,625 injuries in 1927, St. Louis on a pro rata basis for these three years is recognized, on account of its record, as the safest city in the United States.

An Aroused Public Opinion is Effective

You representatives from other cities have seen what public opinion aroused through an educational program and a law enforcement platform rigidly enforced, can do.

It is rightly said, "A man's opinion is like a snowflake. It may fall upon our coat-sleeve and we may lightly brush it away; but if it is a real snowflake, many other flakes follow until soon they cover our coats, the roads, the whole countryside, and even the most powerful locomotive cannot burrow a way through."

After all, that is just what public opinion does with any subject, and lack of law enforcement is no exception. Christianity, Equal Rights, Religious Freedom, the Abolition of Slaves—every vital topic of world discussion since the beginning of time started as a solitary snowflake from the mind of a solitary man. It was brushed aside rudely, carelessly or lightly, but there were more flakes to follow. The bringing became more vigorous, oftentimes frenzied; great crews of "snow shovelers" were summoned to battle with the drifts. But eventually the single flake evolved into a mighty blizzard—and the opposition was smothered.

Business, finance, politics have their summers and winters. It behooves us to remember the power of the snowfall.

Let each one of our individual opinions be merged through our Local Safety Council into a campaign of education, so that lack of law enforcement on the part of individual judges, police, prosecutors and citizens will be a thing of the past.

A. K. GAGE (Detroit): I see nothing on the program of the Public Safety Section in relation to the lighting of automobiles. Last year, as I recall in Detroit, Colonel Barber had something to say about the lighting of automobiles on highways. I presume he has some progress to report in reference to the standardizing of automobile lighting. There are others here who would like to hear what progress has been made in that direction.

COLONEL BARBER: That is a very interesting question, but I don't believe I can say we have gotten very far with it. There are two schools of thought, one of

which is that the regulations now developed are O. K. All we need is a thorough enforcement of those regulations. The other school of thought among the automotive engineers and lighting experts is that the entire present system has got to be scrapped and some entirely different methods of handling the headlighting must be adopted. If you ask for my personal impression, I would say, that I question the latter view. I am inclined to think the course we ought to pursue is rigid enforcement of the present headlighting requirements. The great offenders in the headlights are on the cheap cars, where instead of paying \$5 for a good headlight the manufacturer puts on a dollar pair of headlights that won't stay in adjustment very long. That is why you see a lot of cheap cars come along that look like Rolls Royces, but when they buzz by you know they are not.

The automotive engineers after the 1926 conference undertook to take up a number of these important questions. I can say as far as lighting is concerned, the lighting experts have taken it up and they have been doing a lot of work on it, but there is that divergence of view as to the direct, ultimate solution.

The Unit Headlight Might Be a Vast Improvement

CHAIRMAN HARNETT: The Eastern Conference of Motor Vehicle Administrators, which comprises about 13 of the eastern states and the provinces of Canada, meets quarterly and has a lighting committee which has been struggling with the headlight problem. There is no question but that it can be to a great degree simplified, if not remedied.

We in New York state believe that one of the great factors in advancing the situation would be the construction of a headlight as a unit. We believe that the headlight should be constructed as one single unit and not be the collaboration of six or seven or possibly eight different manufacturers. We think if the headlight were made an integral part of one manufacturer's job that we would get a better headlight. We also think that the day may come when we may get a bulb of 21 candle power that will be made so that no other bulb of higher degree will fit into it. One of our great problems is that 75 per cent of the automobiles on the highways of New York State in or out of adjustment are carrying candle power of 32 instead of 21.

Of course, you never will eliminate the condition of headlights getting out of adjustment until you remove all the jars and bumps in the road, but in New York State under our law we established probably 5,000 headlight testing stations and up until last January they were to a great degree very effective. That was where a motorist could go and have an official inspection of his headlights and have them remedied at a nominal charge by the state. Now we have adopted a campaign of education, and I believe that of itself will be a factor in the future of educating the motorist how to adjust his own headlights, because it is a very simple matter to adjust your own headlights. In fact, every set of license plates issued in New York States carries with it, directly on the face of the envelope, simple instructions on how to adjust your own headlights. I think if all the states adopted that it might help a great deal. The headlight problem is still an acute one in New York State. We are getting a great many complaints about it.

G. F. H. WYSE (Toronto): It is a very simple matter for a motorist to adjust his own headlights, but a very small percentage of them have mechanical skill enough to do it. I would like to ask you, what percentage of success you have had in your scheme of having those headlights adjusted by your stations established for that purpose?

CHAIRMAN HARNETT: We had up to January of this year a great measure of success. It wasn't until about twelve months ago that we began to attack the problem from the viewpoint of teaching the motorist to adjust his own lights. I am sorry to say I do not agree with you that it is a technical matter, it is purely a

layman's job. A schoolboy could adjust headlights if he is told how to do it. It isn't a hard job.

CLARENCE SPAYD (Brooklyn Safety Council): When the request was made a few weeks ago to inspect the cars of New York State with respect to brakes, headlights, steering gear, and so on, the Brooklyn Safety Council, made a close check-up on how that was done and how the people owning motor trucks and private cars responded, and I think if I can depend upon my memory, about 90 per cent of the cars inspected were found correct so far as headlights were concerned. I think it was in a large measure due to the campaign of education which the Commissioner referred to, that has convinced the operators of automobiles in New York State that it is a thing which means much to the individual. Therefore, they all try to comply with the suggestion that their beams be turned down.

Any one who examines an automobile headlight knows it is a simple matter to turn it down or up. I realized this myself last summer when I made a little trip through New Jersey and Pennsylvania, out through Ohio and Indiana.

When I reached Pennsylvania—and I am not trying to throw any stones at that good, old state where I was born and lived for a good many years—I discovered myself off the paved part of the road. All the cars I met at night had their beam on so high I couldn't drive in the middle of the road. I had my beams according to New York regulation and they drove me off the road. Up above Harrisburg I stopped and turned my beams up as the rest did and I got my half of the road. When I was stopped by a state trooper above Harrisburg he wanted to know what I was trying to do. "I thought I was in a lot of good company because everybody else was trying to see how far they could shoot the ray in the road."

A Campaign of Publicity Is Advocated

"You're from New York, you ought to know better," he said.

I told him then that I thought it was largely due to the fact that they don't take them in. He hadn't issued a summons to anybody. He simply picked one up here and there and tried to argue with him. That is all due to the fact that in Pennsylvania they do not enforce that headlight law.

When I came back I forgot to change my headlights and came into New Jersey. I was stopped by an officer who wanted to know how far I had been driving with those headlights up as they were. I told him where I came from and he said, "That is the only reason I will let you go, because in Pennsylvania they have the beam up; but please turn them down because when you get into New York you will surely be locked up."

Not many of our accidents in New York State or Brooklyn are caused by the glaring headlight. We don't have many of them, but we have had during the past year some 18 or 19 cases where serious accidents resulted from that glaring headlight.

I would like to suggest when the Safety Council representatives go back to their own towns, that they get in touch with the newspapers and explain to the individual city editors just what this headlight thing means and what the lack of law enforcement means. I believe in that way they could get a campaign up without any trouble, in spite of the politicians who want to reach the judges and get them off. You can make public sentiment, and I would like to tell you a story if I were nearer home of what we did in New York State about law enforcement in the way of making public sentiment.

There was considerable opposition to the judges carrying out the law as they saw it, and only when a little campaign was put up by a few well-known citizens; but the judges were overwhelmed with letters (one man, I believe, received 10,000 letters of protest because he did not enforce the law) that something was accom-

plished. The result was in a few days we had jail sentences and suspension or revocation of licences.

SI MAYER (Chicago, Ill.): I happened to be one of the delegates at the Hoover Conference and I would like to ask Colonel Barber what has been done with the red light, the rear light. I know that a majority of the delegates who were at the Hoover Conference voted for the amber light, but because a few manufacturers' representatives were there they asked to defer action one evening until next day. It finally went back again into the hands of the committee and there is lying dormant.

COLONEL BARBER: Mr. Chairman, that matter was referred by Mr. Hoover to the Bureau of Standards for an investigation and report thereon. That report was very thoroughly gone into, and as you might expect, a good many conditions that weren't evident in that large gathering came up in the investigation by the Bureau of Standards. That report has been received but I don't think it is a final report. After the Conference terminated, the interest in the red versus amber light seemed to fade away in such a degree that I think it was felt best not to attempt to get up another session of the conference to consider that question, but to leave it until other subjects might call for another session.

The Law on the Rear Light is Clear

R. I. CATLIN (Aetna Life Insurance Co.): I should like to ask Colonel Barber whether any real study has been given to the matter of rear lights, especially on commercial trucks? We find in the insurance business a great many accidents are occurring because of the failure to have lights on trucks, especially those that get out of commission at night and have to be pulled off the side of the road for repairs. We have had some of the most serious accidents occur in just that way.

COLONEL BARBER: I guess you know more about that than I do. Commissioner Harnett. All I can say is that the code recommended by the Conference has been adopted by a number of states. It calls for a truck to be marked with two lights in the rear. The law is very clear on the subject of marking of such vehicles whether they are moving or standing, so the question is simply a matter of enforcement.

MR. CATLIN: That is true. I have noticed while a certain number of lights are required and while quite frequently they are lit, that it only means the lowering of a tailboard to cut off that light entirely. So many of the rear lights on trucks are hung right underneath at the rear end, and if there is any obstruction at all by way of a tailboard being lowered, there is no benefit at all from it. In view of the strides we have made in providing rear lights for busses, we have kept far behind in providing suitable lighting systems in the rear for commercial trucks.

COLONEL BARBER: The Society of Automotive Engineers appointed a small committee of three men, consisting of their president and two of their former presidents, and I will be very glad to convey to the chairman of that Committee your suggestion.

MR. CATLIN: At the close of your address, Commissioner Harnett, you stated that you believed that the next Legislature of New York would possibly pass a compulsory automobile law which would be built up somewhat along the lines of the Workmen's Compensation Law, which I would take to mean that persons injured would be compensated irrespective of the liability of the automobile owner. I believe I am correct in saying that the Hoover Conference in passing on the question of compulsory automobile insurance indicated quite clearly that they did not believe that that was the solution to the problem of automobile accidents. I also believe that since the Massachusetts compulsory law went into effect the first of this year, there have been more fatalities and more injuries in the state than for the same period last year, and with fewer cars registered. I should like to know, therefore, your opinion as to the benefit which might be derived from your proposed law in New York as having a bearing upon the matter of improving the traffic situation.

CHAIRMAN HARNETT: Speaking for myself, I will be very frank to say to you at the Hoover Conference I had the opportunity to speak for a moment on the subject and I took the stand that you have just taken that compulsory insurance is not the answer to the question of safe driving. I gleaned my information from some comments of legislators who comprise the Legislature of our state, of which I am not a member. I simply think from the trend of comment and opinion expressed that they are prone to pass such legislation.

Whatever means will be taken to work it out we are not certain at this time. However, there is no question but that something must be done, because a committee of the Bar, appointed by Judge Dowling of the Appellate Division, made a report which you probably read, that the calendar in New York State is congested to such an alarming degree that an ordinary action can't be tried for four or five years due to the fact that 70 per cent of the cases involve motor accidents, and he has urged, as others have urged before this committee, that there be a separate bureau for the handling of them, and in addition to that, some form of compensation be provided for the dependents, or those left behind.

MR. CATLIN: It seems to me that compulsory insurance is attacking the problem from the standpoint of the effects rather than the cause, and I believe we should lay far more emphasis on the necessity to study the problem of the cause than the effect. I think in speaking on the necessity for compulsory insurance we should analyze very thoroughly and carefully the matter of non-compensated cases, and I firmly believe that if any compulsory law is established which agrees to pay irrespective of liability, it is going to tremendously increase accidents.

There are at the present time three plans, in Massachusetts, New Hampshire and Connecticut, each of which I believe has some merit. I believe that it will require at least two or three years to get any real benefit from the application of the laws. Personally, I lean strongly toward the New Hampshire law, because I believe it is far more practical to leave it an optional measure as to whether the responsible people of the states should provide for the irresponsible ones. If the irresponsible don't provide it then I claim the sooner they are barred from the highways of the state the better.

GEO. E. CLARKSON (Pittsburgh): I would like to ask Colonel Barber whether or not the Conference on Street and Highway Safety has given attention to the emphasis that the automobile manufacturer is placing upon speed in their general advertising.

COLONEL BARBER: This Conference on Street and Highway Safety is not a continuing body that is having opinions about everything all the time. I would certainly join with others in saying, it would be detrimental if advertising is used to such a degree in regard to speed that it would be disastrous.

ADJOURNMENT.

Thursday Morning, September 29, 1927

A. C. GODWARD, Chairman
City Planning Engineer, Minneapolis, Minn.

The fourth session was called to order at nine-forty-five o'clock by the chairman, A. C. Godward, City Planning Engineer, Minneapolis, Minn.

CHAIRMAN GODWARD: We are fortunate this morning in having the best program I have ever known to be arranged in a matter of public safety, and I consider it quite an honor to be able to preside at this particular program, and more than that, I can assure you that all the men on the program are here and all ready to go. Each one wants more time than he can have, which is rather encouraging.

The chairman isn't going to take up any of the time that these men wish for themselves and I will try to reserve a little for discussion.

The first paper will be given by Mr. H. W. Eldridge, president and manager of Geo. Wyman & Co., South Bend, Ind. Mr. Eldridge is able to discuss his subject through personal experience, in the study of conditions in his own city, and in the making of surveys. I take pleasure in introducing Mr. Eldridge.

Taking Stock of the Community Accident Problem

H. W. Eldridge, President and Manager, George Wyman & Company, South Bend, Ind.

South Bend is a typical middle west city of something over 100,000 inhabitants. It has had a continuous and uniform increase in population of 50 per cent, or a trifle more, each ten years for the last seven or eight decades. Two or three hundred years ago this region had its traffic problems. At that time and many centuries previous the traffic was principally canoes. The chief accident problems were logs, sunken trees and Indians. This vicinity, or as it was later called, South Bend was the connecting link between Lake Michigan and the Gulf of Mexico by way of the St. Joseph, Kankakee, Illinois and Mississippi rivers. A portage was established about four miles in length between the south bend of the St. Joseph river and the Kankakee, over which were carried canoes, supplies etc., from one water system to the other. This portage was used by all the various tribes of Indians, even by the Peruvians in their traffic for Lake Superior copper, also by the early explorers, LaSalle, Marquette and many others. The traffic at this time was not quite so swift as that we now have, nevertheless the safety problems connected with it were of the greatest importance.

The early founders of South Bend laid out its principal streets five and six rods wide, wider even than many cities that were built at a later period. This excellent width of streets has helped in deferring the actual need of traffic regulations to a later time than many cities who are supplied with narrower streets. However, the time finally did come when the traffic became so heavy that it was necessary to scrap the many and various ordinances and regulations for traffic that had been gradually accumulating month by month. Our mayor, Mr. Montgomery, called together several citizens and laid this entire matter before them. The citizens had a fair idea of what was wanted but were not, of course, expert in supplying traffic regulations that were at least for the time up-to-date and workable. A number of meetings were held, some of the

members attended the National Safety Council convention at Detroit. The matter was discussed up one side and down the other but still could not come to a constructive plan that would displace the many regulations then in use.

The traffic committee finally sought the assistance of the National Safety Council, and Mr. Earl J. Reeder, supervising engineer, was sent to South Bend. After several meetings it was decided that time would be saved and a better traffic system could be evolved were we to work with and through the National Safety Council. The working out of the plan was quite simple. There were three important committees appointed by the mayor.

First—Committee on Statistics.

Second—Committee on Traffic Engineering.

Third—Committee on Public Education.

Both the citizens' original committee and the National Safety Council believed that large committees in the beginning would be more helpful than smaller committees, inasmuch as there would be the constant education of each member of these committees together with taking advantage of the experience and outlook of so many different men in different employments. The Committee on Statistics consisted of 20 members. The Committee on Traffic Engineering consisted of 25 members. The Committee on Public Education consisted of 30 members.

Committees Are Made Thoroughly Representative

When you consider that each of these committees was selected with reference to a wide distribution of employment and business interests as well as organization connections and location of their homes and businesses, you can readily see that the public education on traffic began with the very first meeting and helped materially to create public sentiment in favor of whatever plan might be adopted. While the present speaker had been chairman of the original citizens committee it was deemed best to have the Mayor general chairman of the three larger committees, and then the chairman of each one of the three committees would work with the Mayor as an Executive Advisory Committee.

The committees having been formed as explained, their meetings and deliberations began covering a period of two weeks. Collection of data was of course the first work and preceded the work of the other committees several weeks. Mr. Reeder met with each committee each time. Perfect freedom of expression of all members of each committee was the rule. The first thought concerning committees of the size that were chosen would be that the attendance would be poor and the interest divided. Exactly the opposite was the actual result. I have never attended public meetings where the attendance was so excellent and the interest so great. It appeared that nothing but absence from the city or appointments of great importance kept members from attending these meetings. They were mostly held at noon time with a luncheon and continued until the work of that day was accomplished, although several of the meetings were in the afternoon and evening.

I have neglected to mention that on all these committees the city was well represented by the various city officials working along with the citizens on matters that would later come directly under their care. This was helpful in the extreme as it enables the impractical things to be disposed of. It also helped to bring in the constructive and practical ideas. Preliminary reports were submitted after several meetings and gone over carefully by the committee and especially by those who would have to enforce the ordinance that was later to be passed.

While fundamentally the principles underlying traffic and safety problems are practically the same, each city has its individual problems. In South Bend the main north and south business street parallels the river, making it more difficult to handle traffic as the approach is mostly from one side. The tendency was for much unnecessary traffic to be attracted to this street. To relieve this condition a "By Pass" route was laid out about four blocks wide and six blocks long, making the streets that bounded the vehicular loop preferential streets. Much traffic being thus diverted from the three north and south streets within the vehicular loop.

Angle or diagonal parking had existed in South Bend on the wider north and south streets within the business district, which were the streets that carried the heavier traffic. This was changed so that all parking became parallel within the vehicular loop and practically throughout the city.

Due to parallel parking two lanes of traffic each way were possible on the wider streets and two lanes were enforced at street intersections by pavement markings. Right and left turns were permitted only from the right or left lanes respectively. At several chief intersections left turns were prohibited.

Results of the New Rules and Regulations

The time of the amber light of the automatic signals was lengthened from three to five seconds, and no driving into the intersection was permitted while the amber light was being displayed.

Additional street car safety zones were established. Discharging or receiving passengers at congested intersections, except as incidental to waiting for a go signal, was prohibited.

There were other rules provided relating to No-parking Zones, Loading Zones and the like. A number of minor regulations were inaugurated such as preventing U turns within the vehicular loop, rules applying to extra passengers in the driver's seat, embracing while driving, removing, or trimming to a certain height, shrubs or plants at intersections, and other regulations of like character.

In a brief way this furnished an idea of the changes that went into effect in South Bend the first of this September. That moving of traffic on our streets has been expedited there can be no question. The total cycle of traffic signals has been materially reduced which had not been possible before. The cycle at present is 65 seconds, five seconds for the amber and 30 seconds each for the green and red lights. We believe it can still be further reduced, except possibly at the more congested hours of the day. A much greater volume of traffic is now being moved in a shorter period of time, than heretofore, with less congestion.

No actual control of pedestrians was attempted in South Bend in the present ordinance, although certain minor rules were provided both as to pedestrians and as to vehicles, tending to promote greater safety for pedestrian traffic.

Two separate booklets were printed and simultaneously distributed prior to the ordinance becoming effective. These were given a wide distribution through the medium of gasoline stations and in other ways. One of the booklets contained the ordinance set out in full. It also emphasized the changes over former ordinances. The other booklet explained the traffic survey and stressed the point that the traffic problem is a growing menace and must be met by continuous study and by cooperation from the public. It also contained caution and safety rules and reminders. The booklets were eagerly sought and well received by the public.

South Bend, the first part of this year, installed a new system for keeping

more complete records of accidents, by adopting the National Safety Council record cards. This should materially aid, after a time, in accomplishing a reduction of accidents by reason of furnishing an additional and more reliable basis for deductions and conclusions for future action.

Many checks and counts were made of traffic at various intersections throughout the congested district. A considerable amount of data of this kind assisted materially in developing the vehicular loop district and the necessary regulations in the new traffic code. There is considerable doubt and confusion as to the exact proportion of conveyances used by patrons of stores in the down town district. The Chicago, South Bend and Northern Indiana Railway Company on March 19 of this year made an exhausted and careful check of this question. The hours chosen were from nine until seven. 25,863 persons were interviewed on a carefully prepared plan to avoid duplication. The results were as follows:

Street Cars	56.2
Interurban Cars	2.1
Busses	5.5
Automobiles	19.4
Walk	13.6
Taxi	.1
No reports	3.1

This emphasizes the necessity of amply guarding safety zones in the congested district, inasmuch as in South Bend 58.3 of all patrons in the down town business district arrive and depart on street cars. It is quite true that this percentage will vary according to the population of the city and its transportation facilities. The proportion using street cars being much greater in the larger cities and less in the smaller cities. All of this needs to be taken into account as a basis not only for reduction of accidents but moving of all kinds of traffic in any city.

Study of the Parking Problem

The parking problem is, of course, a difficult one. It has by no means been solved. If merchants want to make the most of their location it will be necessary for them either individually or collectively to provide parking space with or without service, near their stores. It will be far better to realize this in the beginning before their customers have formed other parking habits in less congested trading districts. Our own store is located at the center of the down town district. Realizing the probable growth of traffic and the very condition just described our store has furnished free parking space for customers' automobiles within a block of the store for the past three years. Several months ago we started a "parking at the curb" service where a customer drives to the curb, a Wyman attendant takes car to garage and returns it later to the curb for customer when it is wanted. Service of this kind established now will bear its greatest fruit as traffic and congestion increases. The new traffic regulation makes a far greater turnover of cars that can reach the central business district and will, when understood and observed be helpful to all those having business to transact in this district.

I have tried to relate briefly the story of South Bend's effort to put into operation modern street traffic regulation. Changes will become necessary, of course, as facts or conditions warrant. It is gratifying to know that results have already demonstrated that we are moving traffic more readily. We believe that results will also demonstrate in a short time that the cause of safety in South Bend has been promoted by the new traffic plan. Of one thing we are

quite sure and that is that the best thought of city officials, of the citizens of South Bend as represented by committees, and of the National Safety Council of Chicago have all gone into this work.

CHAIRMAN GOWARD: Thank you, Mr. Eldridge. Mr. Eldridge has covered problems that are common to all of us and I am sure that there are members who would like to ask him some questions. I know there are some I would like to ask. The Chair will take the liberty of postponing the discussion of this and other papers until all the papers have been given.

The next speaker on the program wouldn't need any introduction if he were farther west. There may be some here from New York who don't know him. He is well-known through the Middle West and Western cities. He has studied and knows, I believe, as no other person in America, the American city. He is familiar not only with the city itself, the officials of the city, but with its ambitions, its aims, and its hopes. He has helped many of them in answering their problems not only through his magazine, but through personal consultation. I have known him as a writer and a thinker for a long time. However, it is my first opportunity to know him as a speaker. I believe he can give us an answer to the question: "Have Our Cities Fallen Down on Their Traffic Job?" I take pleasure in introducing Mr. Harold S. Buttenheim, Editor the *American City Magazine*, New York City.

Have Our Cities Fallen Down On Their Traffic Job?

Harold S. Buttenheim, Editor, "The American City," New York City.

"You can walk over to Seventh Avenue, but don't go across. You hear what I tell you, Rosie, don't go across! You may get killed."

This warning, which the writer overheard a tenement house mother shout at her little daughter on the sidewalks of New York a few weeks ago, may well serve as the text for a discussion of the traffic job of our modern cities. Perhaps Rosie obeyed her mother and came home safely. But perhaps she was the little one who that day, as traffic fodder, helped to meet New York's average quota of three persons—one of them a child—killed by motor cars or trucks in the streets of that city every day in the year.

The terror of wild beasts under which the cave woman struggled to bring up her children in bygone days has its all too real counterpart in the terror of motor-driven juggernauts under which the cliff-dwelling mother in the tenements of our big cities is struggling to keep her children alive. Are we doing all that we might to remove that terror, or have our cities fallen down on their traffic job?

If Rosie was run down and badly injured, she probably had good hospital care; and if she did not recover, and her parents were poor enough, her doctor's bills and funeral expenses were probably met from public or charitable funds. Maybe her parents were even able to collect some cash damages from her slayer—though the failure of most of our states to pass compulsory accident insurance laws makes that relief, as yet, problematical.

The Motorist's Mental Attitude

In general, however, it may be said that our states and cities have fallen down less in providing some measure of relief *after the event* than in the adoption of preventive measures *before the event*. And in the preventive work thus far done, as is usually the case in our efforts for human welfare, palliatives have had more attention than the removal of causes.

As this is a *safety congress*, doubtless it is expected that I shall place the main emphasis on safety rather than on the facilitation of traffic. With this I am in hearty accord. No study of traffic problems is adequate, however, which does not recognize the fact that many persons prefer to drive in haste and possibly "see our jail" than to drive carefully and "see our town." If driving at high speed has slain its thousands since the automobile was invented, a foolish mental attitude of haste, when driving at comparatively low speed through traffic congestion, has doubtless slain its tens of thousands.

Next to the impulse of foolish haste I should place lack of courtesy as a primary cause of traffic accidents where the driver is at fault. The same man who invariably rises from his chair when a woman enters a room or removes his hat when she enters a hotel elevator—neither of which actions has any value other than courtesy—will too often forget courtesy entirely when he is at the wheel and she is a pedestrian or in another car.

The mental attitude of most motorists and of some lawmakers appears to be that pedestrians who still survive as such, are a well-nigh intolerable nuisance. We hear a good deal of the need of pedestrian *control* on the highways, but mighty little of the *consideration* which pedestrians, as a temporary or permanently inferior order, should receive from their betters. But there is a ray of hope for them in the recommendation made last year by the National Conference on Street and Highway Safety, that pedestrians be accorded a safe and *dignified* use of the highways.

Safety Education the First Essential

But do these factors of haste and discourtesy belong in a discussion of the subject assigned to me—"Have Our Cities Fallen Down on Their Traffic Job?" I am sure that they do, for statistics appear to prove that pedestrian fatalities constitute about two-thirds of all fatalities in which motor vehicles are involved, and that more than 90 per cent of the traffic accidents in cities are due not to defective mechanical equipment but to defective mental or moral or physical equipment of individuals. Some of these shortcomings can be reached by law, but for most of them education is the only hope. The most serious indictment, therefore, which can be made against our cities in relation to their traffic job is their failure to regard this job as primarily one of public education. Here, as elsewhere, the schools are the greatest potential force, but adult education through press and platform, and through local Safety Councils and civic organizations, demands much greater attention than it has yet had.

In addition to attacking haste, discourtesy and carelessness in drivers and pedestrians, a well-organized campaign of traffic education would seek especially to combat

(a) Ignorance of the mechanics of the automobile and of the laws and ordinances governing its operation.

(b) Lawlessness—failure to obey the rules of the game, such as no public opinion would tolerate on the tennis court or the golf links.

(c) Selfishness—often shortsighted—such as that which causes farmers to fight the enactment of drivers' license laws or merchants to oppose reasonable restrictions of parking in congested city streets.

Indictment number 1 is, therefore, the lack of a consistent and comprehensive educational policy directed against such human factors in the traffic problem as the foregoing.

Failure to Coordinate Local Efforts

Indictment number 2 relates to the failure of most municipalities properly to coordinate their own local efforts for traffic control and facilitation.

Perhaps no other municipal problem demands such intelligent and unselfish co-operation of the various branches of a city government. The traffic problem is not

merely a police problem; it is also an engineering problem, a legal problem, a city planning problem, and, as has already been pointed out, an educational problem. It involves, moreover, intercommunity relationships of a difficult and delicate nature. One of the essentials of effective traffic control is a much closer approach to standardization of traffic ordinances than has yet become the general practice. This involves one of the hardest things which we human beings have to do—the relinquishing of some of our own pet ideas in the interest of harmony and progress.

Compromise often plays an important part in human progress. When after months of debate there seemed danger of a deadlock in the convention which drafted the Constitution of the United States, Benjamin Franklin helped to bring harmony into the gathering by a speech in which, conceding certain points for which he had previously held out, he told his fellow-delegates that he had come to believe in the combined wisdom of many as against the infallible judgment of one.

Are not many city officials hindering progress in traffic control by stubborn insistence on their own infallible judgment or on the prerogatives of their own departments, instead of getting together with their fellow-officials and with local civic bodies in a joint effort to solve this well-nigh insoluble problem? A few cities have organized traffic commissions through which some approximation of such cooperation has been brought about; but comparatively little use has yet been made of the valuable suggestions on Organization for Traffic Planning to be found in the 1926 report of the National Conference on Street and Highway Safety.

More Engineering Skill Is Needed

A conspicuous result of this lack of local cooperation in many cities is that, in the control and facilitation of local traffic, too little use has as yet been made of engineering skill. This has been due largely to too strict an adherence to the tradition of police control of movement on the streets. Traffic officers are, and doubtless should remain, under the control of the director of public safety or the chief of police, but a much more effective coordination is needed in most cities between the police and engineering departments. The limits of this paper do not permit a detailed discussion of this problem; but emphasis should, perhaps, be given to the importance of expert-engineering skill in the selection and installation of signal systems and the marking of highways, as well as in activities generally recognized as of an engineering character, such as street opening, paving and widening.

During the last two or three years some progress has been made in the installation of signal lights operated on the so-called "progressive" or "coordinated" plan. Properly installed, this system makes possible an approach to a continuous flow of traffic at a predetermined speed, the lights changing from red to green as the motorist traveling at this speed approaches them. The result is the handling of traffic at a higher average rate of progress through congested sections than by the more common method of synchronized control; and the factor of safety is greater than on streets where all lights flash green at the same time with the result that the motorist is tempted to travel during the "go" period at a dangerous rate of speed in order to "beat" the lights for an extra block before they flash red and bring him to a stop again. Obviously, the grouping and timing of the lights in such an installation is a rather technical engineering problem. Would the chief of police or even the city engineer in the average municipality lose caste if he were to admit that it is beyond him, and call in an expert consultant to advise on this and other problems of traffic control?

As I have pointed out in my paper on "The Problem of the Standing Vehicle," in *The Annals of the American Academy of Political and Social Science* for September, 1927, there is need for a fundamental attack on the traffic problem through city and regional planning, and through much more drastic limitations of building heights and of density of population than American cities have yet adopted. Here

the efforts of city officials must be coordinated with those of city planning and zoning boards and of the regional planning organizations which are gradually beginning to function in our metropolitan districts.

Lack of Adequate State Laws

A third way in which most of our cities have fallen down on their traffic jobs is in their failure to insist on adequate state laws for the control of motor vehicles.

There has been available this year for enactment by the several states a Uniform Vehicle Code, drafted with great care under the leadership of Secretary Hoover, by committees of the National Conference on Street and Highway Safety. Some states have already adopted the code or important features of it, and several other states have laws previously adopted which are so good as hardly to require wholesale revision; but most of our forty-eight commonwealths are still without an adequate motor vehicle code—or any at all.

It may be said that this is not a municipal problem, and that it therefore has no place in the present discussion. My belief is, however, that the lack of adequate and uniform state laws for motor vehicle registration, and for the licensing of operators and the regulation of vehicles on the highways, is of such outstanding importance that every city, in states where such lack exists, has but two proper alternatives—to use every effort to secure the enactment of such laws, or to meet their lack as far as possible by writing into local ordinances features which, in the more progressive states, are to be found in state codes. The courts would, I believe, sustain such ordinances as a proper exercise of a city's right to protect the lives of its citizens; but the complications involved in local enforcement would be so many that cooperation with other municipalities in a vigorous campaign for adoption by the state of the Standard Vehicle Code would be much the wiser course.

The Grade Crossing Problem

Another traffic job of the first magnitude on which our cities and states have as yet largely fallen down, is the abolishing of railroad grade crossings. There were, on December 31, 1926, according to records of the Interstate Commerce Commission, 234,280 highway grade crossings. Of these, more than 88 per cent—206,433 to be exact—were unprotected with any gate, signal or watchman. At the 27,847 "protected" crossings the kinds of protection afforded and the number of casualties during 1926 were

Crossings Protected by	Number of Crossings	Number of Accidents	Persons Killed—Injured	
Crossing gates	6,148	227	100	175
Crossing watchman	7,760	603	195	718
Audible and visible signal	6,427	216	143	270
Audible signal	5,308	406	216	460
Visible signal	2,204	262	119	269
Total protected crossings	27,847	1,714	773	1,892
Unprotected crossings	206,433	4,148	1,718	5,099
Total grade crossings of highways with railroads	234,280	5,862	2,491	6,991

An analysis of these figures shows that at the protected crossings the average for the year was one accident for each 16 crossings as against one accident for each 50 of the unprotected crossings. This is due in part, of course, to the fact that the more heavily traveled crossings are as a rule the protected ones, but the fact that 773 persons were killed and 1,892 injured last year at "protected" grade crossings in the United States is a strong reason for preferring abolition to protection.

Analyzing the 5,862 grade-crossing accidents of 1926 as to persons and vehicles affected, we find the following totals:

	Number of Accidents	Persons Killed—Injured	
Pedestrians	519	293	241
Passenger automobiles	4,078	1,766	5,350
Autobusses	31	15	106
Autotrucks	861	281	902
Motorcycles or bicycles	26	18	13
Trolley cars	36	1	151
Animal-drawn vehicles	153	49	126
Other vehicles or machines	10	2	12
Pedestrians passing over or under trains or cars	27	7	20
All other grade-crossing accidents	121	59	70

The figures here quoted are from the forthcoming Accident Bulletin for the calendar year 1926 of the Interstate Commerce Commission, and have been furnished to *The American City* through the courtesy of M. O. Lorenz, Director of the Commission's Bureau of Statistics.

Automobiles Run Into the Side of the Train

An amazing fact disclosed by another of the Interstate Commerce Commission's tabulations is that of the 5,862 accidents listed above, more than 1,100 were caused by vehicles *running into the side of trains*.

Our automobile marksmen are evidently fairly expert in attacking a locomotive or railroad car, whatever may be their skill in hitting the side of the proverbial barn!

Another surprising fact disclosed by the Commission's figures is that there was an actual increase in number of highway grade crossings on Class 1 railroads last year. Grade crossings to the number of 1,184 were constructed on these roads during 1926, while the number eliminated was 1,158, of which only 195 were eliminated by the separation of grade.

It has been estimated that to abolish all the grade crossings of railroads with streets and highways in the United States would cost at least \$20,000,000,000. No one, of course, advocates any such expenditure in the immediate future. But New York has made an excellent start towards a state-wide program by the adoption, in November, 1925, of a constitutional amendment authorizing the Legislature to issue bonds aggregating \$300,000,000 for the elimination of railroad grade crossings, the expense of the work to be borne 25 per cent by the state, 25 per cent by the municipality and 50 per cent by the railroad company affected.

Separation at Grade Is Many Times Advisable

Any comprehensive program of grade separation, to accomplish the greatest good in saving life and expediting traffic, ought not to be restricted to railroad crossings. In many cases the separation of grades at intersections of highways with other highways would have much greater economic and humanitarian value than the abolition of crossings of minor railroad lines. Accidents and delays at street crossings are responsible for so many of our traffic ills that we must look forward to large and increasing expenditures throughout the United States for the separation of grades at the intersection of vehicular ways.

A nation-wide impetus that will grip the popular imagination and open the public purse must be given to the campaign for grade-crossing elimination before any substantial progress can be made. There is one way, at least, in which with the backing of the National Safety Council and other powerful organizations, I believe this could be done:

Unless the past is no guide to the future, the generally prosperous conditions now prevailing throughout the United States will be followed, some time within the next few years, by a period of business depression. One of the best means of minimizing such "hard times" when they come, and of re-stimulating industry and employment, will be to have a well-planned program of public works ready to set going with the aid of state and municipal funds. Why should not the abolishing of grade crossings be made a major factor in such a carefully prepared plan? Engineering studies; determination of proper division of costs between states, municipalities and railroads; the voting of funds to be available when the emergency arises—these and other measures of preparedness in times of prosperity are dictated, I am sure, by a sound public policy.

Revocation of Drivers' Licenses

As indictment No. 5, most of our states and cities have fallen down on their traffic job by undue leniency to persons guilty of reckless driving. The average American of today would, I believe, rather lose his right to vote than his right to operate an automobile. If the latter were made by law in all of our states not a natural right but a privilege to be exercised only by persons able to pass strict mental and physical tests, and if the license were always revoked by the courts for driving when under the influence of liquor and for chronic carelessness or disobedience to traffic rules, the effect would be very wholesome.

Many otherwise well-balanced advocates of personal liberty, in persuading themselves that the eighteenth amendment ought either to be repealed or nullified, have apparently overlooked the folly of allowing any or all of our more than twenty million motor cars to be operated by potential drinkers. There is a large measure of truth, I am sure, in the remark attributed to Henry Ford that the era of the automobile is necessarily bringing to an end the era of intoxicating beverages. That the manufacture and sale of intoxicants can be assumed to be a matter affecting only the persons who consume the stuff, is one of the most amazing examples of rationalization of which the human mind has ever shown itself capable.

This list of "indictments" might be further extended, but I have already exceeded the time limit assigned to this paper. In closing, may I make clear to the many friends of *The American City Magazine*, among the municipal officials and civic organizations throughout the United States, my realization of the suddenness and speed with which the traffic problem has come upon them. It was only eleven years ago that Henry C. Wright, in a treatise on city government, was able to write that "cities of less than 200,000 seldom have traffic congestion that requires regulation." During the interval the problem has spread to every village Main Street. The marvel is, not that so little has been accomplished, but that on the whole the traffic problem has received so much intelligent study. But redoubled efforts are necessary to the end that "civilization may outrun catastrophe." If in the five directions above outlined, and in other needed ways, substantial progress is made during the coming years, is it too much to hope that some National Safety Congress before the end of the present decade may be able to record an actual lessening of the traffic hazard over large areas of the United States? Perhaps, even in New York, Rosie may grow to womanhood!

A Paper Worthy of Quotation

CHAIRMAN GODWARD: You have heard a paper that I know many of you will want to quote in your home towns and in papers which you in the future wish to read and give. I hope your natural modesty does not prevent you from publishing that paper in the *American City Magazine*. I seem to have several seconds on that

I now take pleasure in introducing Mr. H. S. Simpson, Traffic Engineer, Essex County, N. J., who will talk to us on "Accidents as Symptoms of Traffic Ills."

Accidents as Symptoms of Traffic Ills

Hawley S. Simpson, Traffic Engineer, Essex County, N. J.

Progress of any sort in this world has always had its price, and it is an immutable law that the price must be paid. Aviation, for instance, is progressing but it is taking an enormous toll in human lives much of it seemingly unnecessary, but nevertheless every accident is teaching a lesson, which if properly studied can be used to prevent a recurrence of that particular type. New methods of transportation, whether by water, land or air, develop new ways in which human lives are sacrificed. This fact is regrettable but nevertheless true and cannot be ignored. The automobile is no exception to the general rule and in furnishing a new and more convenient form of transportation has exacted and continues to exact its toll. Keeping the loss within the bounds of reason and effecting reductions where possible is the duty of everyone concerned in the street accident problem. The price now being paid is admittedly too high and strenuous efforts will be required before any great reduction becomes apparent.

It is needless to quote statistics indicating the loss in life and limb sustained by this nation as a yearly tribute to the motor vehicle. All are familiar with the figures, which are so staggeringly large as to be almost beyond comprehension. And the condition is annually becoming more aggravated; fatalities are increasing rapidly, as is the fatality rate, while on the other hand the rate in fatalities per thousand motor vehicles is decreasing yearly. It might be assumed on the basis of the latter figures that the street accident problem was being conquered, because of the fact that 10,000 motor vehicles now cause only about 9 fatalities per year, as against approximately 24 fatalities per year caused by the same number of vehicles in 1915. But the assumption is erroneous. Statistics for the whole of the United States covering a period of 13 years prove conclusively that the motor vehicle fatality rate is increasing with a definite relation to the rate of increase of motor vehicle density.

The problem has not as yet been met and will not be met until it is faced squarely and attacked intensively by other methods than those now generally used. Misinformation and misinterpretation of accurate information must first be eliminated and a science of public accident prevention established proceeding in a logical manner towards the desired goal. Misconceptions of accident information may be illustrated by absurdities such as the distribution by well-meaning individuals of data tending to show that women are better drivers than men because the former are involved in less accidents, that straight roads are more dangerous than curved by reason of more accidents, or that wet pavement is safer than dry for the aforementioned reason. All of these fallacies have been given publication but each neglect the relative proportion of the factors involved, and tend to distort the viewpoint of the public in regard to the accident problem. Such erroneous ideas are typical of what might be called accident "frenzies" and are typical of many commonly held tenets arising from improper or incomplete analyses.

Street accidents and human illnesses are very much alike. The former attacks the community as a whole, while the latter attacks the individual. But how much better prepared is the individual to resist disease than a group of similar individuals to resist accidents. The mass may be swayed by "frenzies" and mob psychology, while the individual acts decisively, and in addition the individual has at his service the science of medicine which combats disease with certain tried remedies which have proven their value in cases of similar symptoms. The science of accident preven-

tion such as it is, is only now in the formative period, but as surely as the practice of medicine has developed from its progenitor, the witch doctor, so will a science of accident prevention develop through a period of "tom-tom" beating to establishment upon a firm basis of fact. This era has not yet arrived and regardless of whatever may be said to the contrary, the average official charged with protection of the public safety is extremely apathetic in his attitude toward public accidents. Deploring the loss of life and injury to the public and, feeling that some concrete action must be taken, accident statistics are collected and published, persons responsible for accidents are apprehended and attempts made to bring about convictions when the circumstances warrant.

But after this has been done—what then? Have you ever stood in a room in which were reports of a hundred thousand traffic accidents, in filing cabinet after filing cabinet containing information which had cost thousands of dollars to collect, and wondered to yourself whether this invaluable data had actually been used to the fullest extent in preventing a recurrence of any particular class or concentration of accidents? If you have, I am sure you will agree with me that not every use to which the information could be put has been exhausted.

Peculiarities of the Congestion Problem

The connection between traffic and traffic accidents is more or less disordered, or does not appear as one might expect on casual study. Great concentration of vehicles and persons does not produce the greatest accident hazard. It has been stated that one of the safest places in the world is at the corner of 42nd street and Fifth Avenue in New York during the rush hour, and the reason is readily apparent. Assume a street closely packed with pedestrians and vehicles so that no movement is possible. It is corollary that no accidents are possible. Reduce the concentration and allow movement and accidents begin to occur, the hazard increasing as the congestion reduces. Accidents are occasioned by the occurrence of the unexpected and the unexpected occurs with relatively greater frequency when the street or road is comparatively deserted. Proof of this fact has recently been made available in figures released by the Pennsylvania State Highway Department.* During the 6 hours—10 p. m. to 4 a. m.—traffic is at an ebb. Yet traffic hazard, measured in accidents per vehicle, during these hours average four times that of the remainder of the day, reaching a peak between 12 midnight and 1 a. m. approximately six and one-half times the average hazard of the other 18 normal hours. Further proof of this fact is furnished by the same authority in showing that there exists a sort of inverse relationship between accidents and traffic volume. The day of greatest traffic volume, Sunday, is not the day of greatest hazard, but Monday, the lightest traffic day of the week, is the highest in point of vehicle hazard. The relative hazard to the individual vehicle on Monday is nearly twice the hazard on Sunday, although Sunday traffic is twice as heavy. There is no apparent reason for the belief that concentration of persons and vehicles is the cause of accidents, or that decentralization will relieve the situation, since statistics show that the reverse is actually true.

In the central business section of Detroit, into which come and go half a million persons and 150,000 vehicles during the business day, there occurred only 13 traffic fatalities in 1925, and seven of these happened after business hours during periods of comparatively light traffic. Accident hazard in the same downtown area on the basis of number of persons and vehicles on the street is only about one-half that of the residential area three miles from the nominal business center. Comparing city fatalities in the 10-mile circle with a like area in a scattered residential section shows seven times more frequency in comparison to injured accidents than in the downtown business section. And probably, although general statistics are not

*G. G. Kelcey, on "Automobile Hazard and Its Reduction"—Proceedings Am. Soc. C. E., August, 1927.

available, the seriousness of the individual accident increases as congestion decreases in about the same ratio as that just quoted, so that the absolute seriousness of accidents is even higher in residential districts as compared to business districts.

These examples indicate only in a general way where some of the danger points in a community may lie. More detailed information regarding concentration of accidents at points of extra hazard is required before a solution can be attempted.

A city of 750,000 persons found that 28 per cent of all accidents occurred at only 64 intersections. In a smaller city 33 per cent of all accidents occurred at but 56 intersections. In a survey which the speaker has just concluded 59 per cent of all accidents in a certain area occurred at 22 per cent of the intersections. In another survey over 12 per cent of all the accidents in a built-up area of 3.2 square miles occurred at only one location. In a survey now being conducted in Detroit the 20 intersections of greatest accident frequency, estimated to be but 2/10 of one per cent of the total intersections in the city, were the scene of 4 per cent of the accidents to date this year, with an accident hazard 20 times the average. Similar cases are on record but the above are undoubtedly indicative of the relatively large concentration of accidents at a comparatively few intersections. It certainly appears logical that the angle of attack which has been generally neglected points to the individual extra hazard intersection.

Detailed Analyses of Extra Hazardous Locations

If in addition to the preventive work now being carried on, detailed analysis were made of all extra hazard intersections, it is reasonable to believe that progress would be shown. Certainly, if it is possible to attack, say 60 per cent of the accidents at only 25 per cent of the possible places of occurrence, concrete results can be achieved in a much shorter space of time than if the entire accident situation is attacked as a unit.

Elimination of disease in the human body is accomplished in two ways which may be classified as preventive and curative. Disease in general is prevented by the promotion of more sanitary living conditions, and the elimination of disease producing bacillus from food and water before being taken into the human body. But when an individual has been so unfortunate as to contract disease a physician is consulted and a remedy prescribed for the *particular* form which the disease may have taken, and a cure attempted.

The first, or more general attack is being used to considerable extent in the prevention of street accidents and is largely responsible for the results already achieved. It includes safety educational work, elimination of unfit operators, improvements in roadway and lighting conditions and work of a similar nature. But while this has been going on, too many of us have lost sight of the second line of procedure. An ounce of prevention may be the equivalent of the proverbial pound of cure, but when prevention fails curative measures should certainly not be neglected even though the methods are more involved and require more careful analysis to be effective. A "sick" location, meaning a place of occurrence of more than the normal number of accidents; is an indication not perhaps of failure of preventive measures but rather an admission that preventive work does not cover the entire field. "Sick" locations then require just as skilled treatment as a sick individual, and more, it might almost be said, for certainly more is at stake.

The individual is able to make his needs known to a physician. The intersection is not. Attention is usually called to a serious condition, not by accurate accident data, but by popular petition and invariably the remedy is prescribed by the residents of the neighborhood, usually taking the form of a "stop and go" traffic signal, when this may be the worst possible solution.

We are fully aware that most up-to-date police departments keep some sort of

spot map indicating the place of occurrence of accidents, but the records are not always such that it is possible to immediately list the 10 or 20 most dangerous intersections either in number of accidents or in point of total loss involved. Previous mention has been made of the variation in individual accident seriousness in different area and at different periods of the day. Similar variations are found when comparing different intersections. Studies of personal injury accident reports reveal the fact that a large number of very minor accidents are included in the total, each having the same weight in a numerical compilation as accidents causing total disability. Accidents represent actual losses to the community in property and productive ability of individuals, which can best be expressed by a common denominator, the dollar. Who knows what the trend of loss per accident is? We all know that the number of reported accidents is increasing but what of the individual accident? It may actually be that the individual accident seriousness is decreasing and the increased number of accidents is due mainly to better reporting. With estimated accident losses running into the millions, it seems that some effort should be made to close the last gap and determine actually what this loss is. It is a safe conclusion that the amount of the losses involved in accidents and not the number of accidents should be the basis from which the accident situation should be analyzed.

Keeping the "Account With Death"

There thus appears to exist a largely undeveloped and very fertile field for the analysis of each extra-hazard intersection, the degree of hazard being based upon a computed monetary loss dependent upon the seriousness of the injury or amount of property loss involved. Because of the fact that there is the possibility of reducing the majority of accidents by remedial measures instituted at a minority of locations, it seems that this procedure might offer the outstanding hope for the amelioration of a very serious condition. This work is now being spasmodically carried on in several localities under the urge of public pressure, but not in an orderly, careful and unbiased manner.

Successful prosecution of a plan with the foregoing as a background is dependent upon the establishment of a department which might be called the Bureau of Public Accident Prevention under the Department of Public Safety and entirely divorced from the regular accident department which functions in an investigational capacity more especially from the criminal angle. The sole duty of such a department should be to keep a record which might be called an "Account With Death" for every intersection in the community and prepare analyses of particular locations with recommended measures tending to reduce the death rate at the location.

How this account is kept is not material. Any of several methods might be used, the essential difference between this record and the various forms of accident "spot" maps and records being that a monetary standard is known for various types of injuries is used. Briefly for each intersection at which has occurred a certain minimum number of accidents the "Account With Death" should be established, showing the date of each accident, the actual number and the total monetary loss suffered, divided as between fatalities, personal injuries and property damage. An accumulative total should be kept so that the average loss per month or year can be readily determined.

Assume that such an accident prevention bureau has been established and records have been kept for six months upon 30 intersections which have proven to be especially hazardous. The procedure would be to first classify the locations in regard to the amount of loss involved so that analysis would begin with the most dangerous locations, progressing systematically towards those of lesser hazard. Starting with the most hazardous location, the accident records for this location should be subjected to a most careful analysis to determine if possible the underlying cause back of the majority of the accidents. The exact details of such a study

may vary materially at different locations and cannot be accurately forecast in advance, and should be entrusted to a competent engineer or person trained in this particular work. From the information will usually appear a predomination of accidents, perhaps at certain hours, perhaps from vehicles moving in certain directions or in any one of a dozen other classifications. If a field study of particular location were made, keeping in mind the data assembled from the office records, some form of remedy would undoubtedly be developed. Apply the remedy and record the details upon the ledger record for the intersection. Compare the accident loss per month following the change with that preceding and whether or not an improvement becomes evident can be absolutely proven. Continuation of these studies to cover more and more hazardous intersections will undoubtedly reveal certain more or less standard remedies which can be applied to like intersections, and the progress of the work materially advanced. That this can be done has been proven in many instances throughout the country, so that the ideas brought out here are not essentially new, except in so far as indicating a more exact and orderly method by which this type of work may be carried on.

This State of Connecticut, after having gathered and compiled accident records for, I believe, five years has recently announced that it is embarking upon just such a curative campaign by applying the information which has been collected. The results which may be achieved are fully realized by them and should be very valuable to the country as a whole. But we must not sit back and "let George do it." Other states and municipalities should begin to make practical use of the information which has been collected and, rather than using accident statistics for round-table discussions, someone must take the records and put them to work.

Facts About the Situation in Detroit

To refer again to the city of Detroit, with whose work the speaker is most familiar, it might be stated that Detroit's accident record has been most unfavorable. But strenuous efforts are put forth to bring order out of chaos. Detroit has used the standard report form of the National Safety Council for some time, and this present year is using the system of Hollerith mechanical tabulation, with excellent results, not especially in the preparation of the monthly report, but in detailed analyses of special classes of accidents. One investigation of this sort concerned accidents on protected safety zones of which Detroit has many. It was found that in the first four months of 1925 and 1926 no accidents occurred on protected safety zones between 5 a. m. and 4 p. m. approximating the border line between dusk and daylight. Additional information was indicated and immediately provided, and the average number of accidents per month decreased from 29 to 21. This may appear to be a small item, but not on a city in the 21 persons who possibly have been saved from injury within the four month period, and it does indicate that the procedure is correct.

As an added method of accident study, the department has kept, for two years, a location record, giving a cross index on all accidents occurring at every intersection in the city, so that each extra location intersection may be studied as a separate problem. The 25 intersections with the highest accident total are now in process of analyses along the lines just discussed, and although but one has been completely analyzed, it is interesting to know the survey showed that most of the difficulties lay in confusion caused by large volume of irregular turns, essentially again the unexpected. Efforts are now under way to re-plan the intersection, to eliminate as many as possible of the unexpected movements and to confine them to their proper channel. I have with me a few of the sample tabulation sheets given to the field investigators who have been trained in this type of work by the survey bureau—a continuing adjunct to the police department—with instructions not to return the sheet until some solution has been discovered. Whether or not it will

be correct on first analyses, will remain to be determined by its effect on the accident records; the effect cannot be determined around the table, it must be put into practice and given a fair trial. If correct, it should be continued and amplified. If incorrect, perhaps it will point the way to the correct solution.

I hardly feel that the title of this discussion has been fully justified. Accidents may or may not be symptoms of traffic ills. We would rather like to believe that accidents are symptoms of lack of information, or lack of use of such information as is available. Yellow fever was not conquered by compiling and filing records of deaths. General Gorgas took upon himself the task of analyzing the information previously collected and after sifting it all, arrived at the cause and knowing the cause was able to practically wipe out the dreaded plague. Sufficient traffic accident information has been collected in most communities, but too often it has merely been compiled and published, with little or no concentrated effort to make use of it. After this has been done, we shall be better able to discuss whether or not accidents are symptoms of traffic ills.

CHAIRMAN GODWARD: The next subject on the program is "A Community Safety Program at Minimum Costs," by Mr. A. C. Burnett. I take pleasure in introducing Mr. A. C. Burnett, president of the Bexar County Safety Council, San Antonio, Texas.

A Community Safety Program at Minimum Cost

Arthur C. Burnett, President, Bexar County Safety Council, San Antonio, Tex.

I am quite sure I can cover the subject assigned to me within the twenty minutes allowed. I am to talk to you about maintaining a safety council at a minimum cost. Having had four years experience in the operation of a council with a very small budget, those of us who have been interested in it have learned to economize in time as well as in money, so that what I have to say will be directly to the point. I shall not attempt to tell you how we organized our safety council in San Antonio or the many disappointments we encountered. It is enough to say that the public demonstrated very little interest at first.

We, of course, realized that 95 per cent of the results we would obtain would be through education. We then set out to see how we could come in contact with the people so that they might become interested. Our first job was to get the San Antonio public schools to teach safety. That cost us nothing, except that we could not get the School Board to buy the pamphlets and periodicals from the National Safety Council. We bought them.

The main problem was to get a little money. We found, as everyone else does, that the Public Service Company and four or five of the largest industrial concerns were willing to help support the movement. That, however, required constant solicitation and was abandoned when the financial committee of the Community Chest decided that we were entitled to a share of the chest, by reason of the fact that our activities would tend to reduce the calls on the charity organizations of the city for help. We have been receiving from the chest \$270 a month.

We could not hire a manager for that small sum, but we cast about for a man to undertake the work and found him. He was making \$10,000 a year. His work was such, however, that he did not need to devote all of his time to it. We started out with him at \$300 a month on a temporary basis, having some reserve funds in the treasury, and after he had worked for about three months, giving most of his time, we pointed out to him that we could not continue on that basis. We calculated correctly, that if he was the man we wanted, he would be sufficiently interested in the work to be willing to go on with it

even at the reduced salary. He accepted \$100 a month and has been working for that ever since. He had an office and a stenographer for his own business. He also had a telephone. We paid for a listing in the telephone directory, reimburse him for such time as his stenographer would have to put in on the safety council work, and after having paid for postage stamps we have a sufficient amount left each month to devote to various educational projects.

I have already spoken of the work in the schools. That has continued without interruption and I can refer you to the various representatives of the National Safety Council as to the efficiency of this work in San Antonio. You would be interested to see Mexican children from seven to ten years, who, without prompting, can be called on in class to answer almost any question about protecting themselves in traffic and answer intelligently, promptly and clearly. They also have a better idea as to the emergency measures necessary when a fire occurs, when a live wire falls, or when a companion is drowning, than a great many American grown-ups. These children have had absolutely no home training along this line and all of their knowledge of English has been gained in the schools, but they absorb knowledge of this sort more rapidly than our native born children.

Organization of a Chauffeur Class

The next work in the schools was the organization of a chauffeur class. We found a man who had been in the public schools for fourteen years, whose training qualified him to conduct a class of this sort. He solicited the owners of automobile fleets and met with encouragement in almost every instance. This chauffeur school started about a year ago and has cost us nothing. We charged the employers \$1 a man for the course of ten hours. We use one of the high schools and we discovered that we could obtain a certain amount of help from the Federal Government through the Smith-Hughes Bill, which with the \$1 paid by the employers was sufficient inducement to Mr. Peavey to continue his work. He has graduated, now, 218 chauffeurs of whom 26 were colored. I attended one of the first sessions of the colored class and instead of finding a lot of tired, sleepy men, I found 30 negroes intensely interested, volunteering information and answering questions at every opportunity.

Our main difficulty, however, was in interesting the public as a whole. We tried meetings of the Council at noon at the hotels, and averaged not over eight or ten business men, who came rather reluctantly, tardily and irregularly. Then, we found the answer. We went to one of the leading industrial concerns and suggested to them that we have a night meeting in their plant. We picked the Mistletoe Creamery, manufacturers of dairy products. We suggested that they furnish us with a room large enough to hold a meeting for 400 or 500 people, and, more or less by our suggestion, they agreed to serve a lunch after the meeting. They also furnished music. It was easy enough to get speakers, and by a notice to the owners of other plants, educational institutions, public service companies, etc., urging the managers, themselves, to come and bring the heads of their safety departments and all other employees interested, we had a successful meeting of about 400 people. It was a very complete cross section of San Antonio citizens, including presidents of the largest corporations, members of the fire and police department, heads of the safety departments, chauffeurs, mechanics and their helpers, and other interested citizens. It is true, of course, that some of them came because we were going to serve refreshments, but we were not interested in why they came, because we felt that we could put out propaganda and make converts. This you will see cost us nothing also. I have given you the story of only one meeting, we have had a great

many of them, averaging one a month except during the summer when the meetings aren't held quite so regularly.

We got the Police Department to standardize the method of keeping records of accidents as suggested by the National Safety Council and on forms furnished by the Council and paid for by us. We have on various occasions suggested to the city authorities that certain dangerous street intersections be made safe. This, of course, cost nothing. We helped organize the Texas Council of Safety and participated in the quarterly meeting in April. The city authorities gave us the free use of the city auditorium, in the basement of which we conducted sessions all day; here also were placed exhibits by various local industries, the police and fire departments, our own safety council, and others who had safety appliances for sale or display. At our night meeting we had about 3,000 people, the largest meeting of that sort that has been held in the South. We worked up interest in this meeting by employing a man to speak in the schools, to conduct demonstrations in the streets and to test automobile brakes. He tested the brakes on 3,145 automobiles, with the aid and cooperation of the police department. This man, of course, cost us several hundred dollars, but it made possible a very successful, satisfactory day.

At an expense of not over \$75 we have equipped the Chamber of Commerce with a safety library, obtained, of course, from the National Safety Council. This library is available, particularly, for manufacturers and has been found extremely useful and helpful on many occasions.

What I have had to say, today, I am sure would be of more interest to men from cities about the size of San Antonio than to men from larger cities. I hope that I have made the point that any town, regardless of its size, can have a Safety Council and can keep it going at a very small monthly cost. If there is no such organization in your city, start one now on your return, even though you have nothing but the idea.

St. Louis Created a Traffic Council

R. B. BROOKS (St. Louis): Mr. Chairman, Mr. Battenheim's paper appealed to me very strongly, on whether our cities have fallen down on their traffic job. I think everybody here likes to think that his city is the exception to the rule, but one of the observations I have made in these meetings so far is that all of us have been going after a bear with a shot gun instead of a rifle. One thing we have done in St. Louis, and inasmuch as it received the personal approval of Mr. Hoover I am going to tell it to you. We realized that the various agencies in our official life might have petty jealousies or might want to do it all themselves. We realized that there were three divisions of our city government that had to do with traffic regulation. There was the legislative branch which passed the laws, the board of aldermen; the administrative branch; the department of streets and sewers; and there was the enforcement branch. We conceived the idea of passing an ordinance creating a traffic council, composed of the president of the Board of Police Commissioners, representing the enforcement end, the chairman of the committee of the Board of Aldermen, representing the legislative end, and the director of Streets and Sewers, representing the administrative end, and later adding to that the traffic engineer, Mr. Hoffman, as the secretary of that council.

Through that ordinance we meet once a week. We had authority to put into effect anything that we thought would better conditions in St. Louis traffic. Our decision was law for a maximum period of 90 days, from which there was no appeal. For instance, we wanted to make a one-way street out of Ninth Street from Olive to Locust. We three would simply get together and say that shall be the law, and if at the end of three days we decided that it didn't work out very

well, why we met and said we would cut it out. But within that 90-day period if we thought that it was good for the city of St. Louis we would introduce into the Board of Aldermen an ordinance to that effect. It didn't make any difference whether the Board of Aldermen passed that within six months after that time or not, it was still the law. It was the law until they killed it.

We had no trouble with our enforcement because every single patrolman knew that if he didn't carry out the orders of the Traffic Council he had to answer not only to his chief, but to the president of the Police Board. We had no trouble in getting our laws through the Board of Aldermen because the Board of Aldermen was represented, the chairman of their own legislative committee had passed on it.

The Supreme Court knocked this out temporarily on the basis that it was delegating legislative power to other than a legislative body, but I asked the Supreme Court to give us some constructive criticism so that we could pass a law that would get by the Supreme Court of the State of Missouri. I am giving you this for your own information because you may want to do it yourselves sometime. The Supreme Court said this: If the enactment carries with it a clause that this fact-finding authority will extend to the city as a whole or to certain general conditions covering the city, we will approve it. It was a minor item and we have taken care of that situation. We are going to call it the Traffic Commission so as to make some change in the old law. The Traffic Commission will have this power on all streets in St. Louis where the traffic exceeds 100 vehicles per hour. So that covers practically every condition that we would want to cover and, after all, the proof of the pudding is the eating of it, and if you get a chance to try out something it may be foolishness, it may be all wrong, but the best way to prove it is to try it out.

The Outline of An Extraordinary Accident

GEO. HERROLD (City Planning Engineer, St. Paul, Minn.): I want to speak on Mr. Bittenheim's paper, which I think is the most scholarly and the most practical treatise on the subject that I have ever had the pleasure of listening to. He spoke of the number of accidents through people running into railroad trains. I think it was Carl Gray, president of the Union Pacific, who called attention to the appalling number of accidents of that character at the Cleveland conference two years ago, and I know my reaction at the time was that there must be a lot of incompetent drivers. It seemed impossible that a man could run into a train. We drove back from Cleveland to St. Paul, and in crossing the line between Illinois and Indiana, just south of Chicago, we ran into a train, or at least we took the ditch in preference to a train, and a little analysis of that situation shows that it is possible to run into a train; that is, it is possible for good drivers to do it, and especially under certain atmospheric conditions. In this particular instance there was a haze, it had become dusk and the lighting of this haze with our lamps had blended so with the train that it was impossible to see it until we were right onto it. That is a situation that needs to be analyzed, as Mr. Simpson has brought out in his paper. The analysis of these things are the things that are going to cure it. There were four men in this car and all of us perfectly awake and alive to the situation, and yet not one of us saw this train.

I also want to say in speaking of grade crossing separations that many cities are accepting and putting on record plats of additions that are creating grade crossings much faster than we are eliminating grade crossings, and some publicity should be given to this phase.

I want to compliment my old friend, Mr. Simpson, on his very wonderful diagnosis of the accident situation, and his emphasis of the necessity of more careful analysis. It is quite remarkable how a close study of some of these things develops almost unexpected results. For instance, in our own city we had at some intersections flashing beacons and at others we had "stop" and "go" signals. The police

department took out the flashing signals because they didn't think they were efficient. An analysis, however, showed that in the case of the "stop" and "go" signals we were passing 4,000 vehicles per accident through the intersection, but in the case of the flashing beacon we were passing 13,500 vehicles per accident at the intersection.

B. N. WHEELER (Duluth Safety Council, Duluth): Mr. Bittenheim's list of indictments was exceedingly interesting. I think he had them correctly listed. Lack of education was the biggest one in the group. We realized that in Duluth when we tried to get into some kind of an educational program for adults. The children are taken care of through the Junior Safety Councils. Ten policemen in uniform visited all the high schools. We took a speaker with us and we talked to 10,000 children in the course of a month or two. Duluth is a city 25 miles long. It is a hilly city and in the winter there is a lot of coasting. Many children were killed in coasting accidents the year before. As a result of this campaign we didn't have a single death in the months of January and February.

A Pledge Was Secured From 1,500 People

Then we went on into regular schools for adults and we had four sessions of the safe driver's school. We worked with the automobile club and had a pledge-signing campaign. We got 1,500 people to sign a pledge in which they solemnly promised to drive carefully during the entire year of 1927, and especially as far as children were concerned. Once a month we sent out postal cards telling them what was going on in the city. We even ran display advertisements calling attention to the necessity of careful driving and careful walking. We had a campaign for pedestrians as well as for drivers, and as a result, at the end of our first eight months we had only killed seven, whereas the year before we had killed fifteen or sixteen during the same length of time.

It was nothing but a deliberate campaign using the Chamber of Commerce, the Parent Teachers Association, speakers and writers and every conceivable idea of publicity that we were able to use.

NEAL FUNK (Louisville, Ky.): I heard Mr. Bittenheim's paper and I thought it was wonderful. There was one indictment I have heard at every convention I attended in the last three years. I have constantly heard how reckless and negligent the automobile driver is at crossings, and that is probably true. I am with the railroad company myself and I hold no particular brief for motorists, but I do know this, and I am sure all the gentlemen will agree with me: Anyone who has toured through the states of this country, not in all states, but in the majority of states, has no doubt noticed the way railroad crossings in a tremendous number of localities are allowed to be blocked by shrubbery, by debris, and by various things of that sort, which an active safety director could correct.

After all, the finest safety device, better than watchman, better than the gate, as long as we have grade crossings, is the human eye, and it is no more than fair that we remove all obstacles that obscure the driver's view. He is an ordinary human being. As he goes along the road perhaps he is not at all times thinking about a train, perhaps he may not see a wig-wag, and that doesn't signify that he is a terribly careless fellow. Before we talk so much about what the other fellow does, let us go home and clean up our own crossings, especially those on the interurbans. People have beautiful country places and they want to have beautiful foliage around their homes. That is natural. I think if the safety director or someone in the community visited these people in the fall and pleaded with them from a humanitarian standpoint, he could clear up these places along the crossings.

H. O. ROUNDS (Detroit): I am very glad to hear the remarks of the brother, but he is about six months behind Wayne County. I will say that the Road Commissioner of Wayne County has hauled about 5,000 loads of cut-down trees. They

have men constantly doing that. They have cleaned up about 40 crossings, and as time goes on they are going to clean up all of them.

R. W. WORM (Traffic Division, Toronto): I would like to tell you some of the things we are doing on the Toronto police force in connection with the examination and testing of brakes on commercial vehicles. This year the chief constable, S. J. Dickson, inaugurated a system of brake inspection on all motor vehicles, especially motor trucks. Two men were detailed for this duty with a set of loadometers for weighing trucks. These men were chosen for their courtesy and also for their firmness in carrying out whatever duty they were set to do. They would stop the truck and weigh it, at the same time speaking to the driver in a courteous manner and telling him what they wished to do. When the truck had been weighed they examined the brakes. Then they checked up on his steering, his horn, his whistle, or whatever it might be, his muffler, if he had one on, and also on his chauffeur's license. All of these things were done in the one operation.

We found in the first month especially, there was a tremendous number of trucks going around the city overloaded. We found after the first week there were fewer trucks being overloaded. We also found that in the design of a number of these trucks, when they had the load on, their brakes would not function properly, and when we weighed them the drivers would make the excuse, "Well, the brakes were all right before I put the load on." In that case we would weigh them after the load was taken off and very often we found the brakes in perfect condition. We came to the conclusion that these trucks must have been designed improperly.

I am not an expert by any means—we just approached this thing in Toronto in a quiet, practical, common sense way. We have had very little trouble with the truck owners or drivers. They have been asked in a nice manner to cooperate with us and in so far as possible I think we have been very successful. We have told them that it is not a revenue-producing scheme at all. We don't bother to summon them to court if it is at all possible. But where we found both brakes on a truck not working, or any motor vehicle, we took the car off the road immediately. We have the power to do that. The car or truck is taken to the nearest police station and the owner, if he is not the driver, is at once notified to come down and have his brakes put in proper condition before the truck is allowed out on the streets again. If the brakes are found in a deplorable condition we also inform him when he comes after his truck that he will be summoned and the minimum fine for a first offense is \$10, and so on up to \$50, as the case may be, or the truck may be confiscated. The law is very clear on this point and needless to say we get splendid backing from the courts in carrying out all these little laws.

ADJOURNMENT

Thursday Afternoon, September 29, 1927

CHAS. M. UPHAM, Chairman
Director, Highway Research Board, National Research Council,
Washington, D. C.

The fifth session was called to order at two-ten o'clock by the chairman, Charles M. Upham, director, Highway Research Board, National Research Council, Washington, D. C.

CHAIRMAN UPHAM: Our first speaker has taken it upon himself to do quite a job. If anybody can tell why some people have had luck I think he is undertaking a very big task. It gives me a great deal of pleasure to introduce at this meeting Dr. Knight Dunlap, of Johns Hopkins University, Baltimore, and also an officer of the National Research Council.

Why Some People Have Bad Luck

**Knight Dunlap, Chairman, Division of Anthropology and Psychology,
National Research Council.**

The collection of reliable statistics on the causes of automobile accidents, is still a problem, but I believe we have at present enough information to serve as a source of guidance in the work of making traffic progressively more safe. There are, of course, two main groups of causes of accidents: (1) defective cars and equipment, and (2) inefficient drivers. Automotive engineers are taking care of the first group rather effectively. The second group pertains to the problems of the psychologists, and I believe that it is now the important factor in danger. The enormous improvement in the efficiency of the automobile and its equipment during the past few years has not been paralleled by any improvements in the human beings who drive them. The human machine remains the same as it was when the automobile was first invented, and we cannot change it within the next few thousand years. With the increase in number of cars, and the steady increase in the speed of traffic, the demands upon the human machine are vastly greater than they were a few years ago, and these demands will become greater year by year. With these increasing demands comes an increase in the accidents, until we devise means of employing the human machines more efficiently.

The real problem of safety, therefore, is: What can we do to make the driver use his capacities more efficiently?

Now, we know that some drivers are efficient, and are therefore relatively safe drivers; others are extremely inefficient, and therefore dangerous to themselves and others. What we have to do is to increase the number of efficient drivers, and decrease the number of inefficient ones. A pertinent question, therefore, is what makes an unsafe driver? Why are so many drivers inefficient? To these questions there are several answers.

In the first place, the drivers who have certain organic or bodily defects are unsafe. Cases of accident through heart disease are known. It is possible that other accidents have been due to epileptic attacks; at any rate, the driver subject to epilepsy is obviously unsafe. Such causes of accident are, however, comparatively rare, and it is perhaps not possible to guard against them. Really adequate medical examination of drivers is practically impossible, so that this source of accidents is not a highly important matter. Whether the man with an arm or a leg missing should be allowed to drive is another matter, and the answer depends on conditions which are not difficult to analyze. It is possible to equip cars for some of these

drivers so that they are safe; and a practical test of ability to manage the car under different conditions should tell the tale.

Defects of vision and of hearing offer a somewhat more serious problem. There has been controversy over the effects of deafness, but up to date, it does not seem to be shown that the deaf man is more unsafe than the man with normal hearing. Very little dependence is normally placed on hearing, and the man who does depend on it is surely unsafe. The deaf man is less apt to cross the railroad in front of a train because he does not hear the train, and he is more apt to use his mirror to see whether there is a car behind him, than is the man who depends on his ears. The deaf pedestrian is really the man who is out of luck, and perhaps we ought to compel him to wear a distinguishing costume.

Defective eyesight is a much more serious matter, and here we have two sorts of defects: (a) unclearness of vision, and (b) defects of color vision. Theoretically, it is possible to examine the eyes of all candidates for drivers' licenses, and pass only those who have clear vision; or whose vision is sufficiently corrected by spectacles, but practically this amounts to very little, since changes in vision may occur subsequent to examination, and there is no way of compelling drivers to wear their spectacles. On the other hand, the evidence that any serious accidents are really due to unclearness of vision is small. The vastly more serious problem concerns the man whose vision is clear, but who doesn't look.

Defective color vision, at first, seems to be a definite factor in danger, and in some states all candidates are required to take a color test, and are rejected if they fail the test. In this case, the danger has not been definitely made out, and the remedy is certainly worse than the disease.

Defective Color Vision Found in Many Persons

Defective color vision, or color blindness, as it is popularly called, exists in several types. But the only color blind persons who occur with any considerable frequency are those unable to distinguish green from red where the colors are dim: or rather, those who are apt to have difficulty in distinguishing these colors under certain conditions. Since perhaps two per cent, or slightly more, of the population are defective in this way; and since safe driving depends more and more on color signals, this defect might appear to be an important source of danger. Really it is not. There is no evidence that the color-blind man is more subject to accidents than the man of normal color vision. Furthermore, all persons are color blind in peripheral vision; one sees colors properly only when he looks directly at them. If you want to see how a green light looks to the color blind man, all you have to do is to fix the center of vision on a point about fifteen degrees to one side of the light. Now, it is not advisable that drivers should keep their eyes directly on the signals. It is much more important that they should watch pedestrians and other cars. We must assume, therefore, for purposes of safety, that all drivers are color blind, and arrange our signals accordingly. Analogy with railroad practice, where conditions are quite different, has been a source of fallacy which we must take care to avoid.

Fortunately, there are two colors which the color blind man can discriminate as readily as the man of normal color vision, and moreover these two colors are the best for distinguishing in peripheral vision. These colors are orange-red and blue-green. The best signal practice is in the direction of these two colors, which are the safest for all persons.

Testing color vision as a measure of safety is especially fallacious for several reasons, aside from its needlessness. The color blind do not really constitute a separate class, but there are all degrees of defect, ranging from the normal to the worst cases. Tests as ordinarily administered do not even catch all the worst cases. To catch these requires a prolonged test, sometimes an hour in duration for each candidate, and a high degree of skill on the part of the tester, skill which it is hardly possible to obtain for testing large numbers of candidates. Even with

the best test, it is impossible to say whether the candidates that just get by are any more secure in their color estimations under traffic conditions, than those just excluded. The testing, moreover, tends to obscure the real needs for color signal work, namely, the securing of colors which shall be safe for all.

A second cause of inefficiency in driving has been alleged to be low intelligence, and it has been urged that all candidates for driver's license should be given intelligence tests, and only those above a certain grade should be passed. While it is true that intelligence is required for safe driving, a great deal depends on the kind of "intelligence" that is meant. Intelligence, unfortunately, is an ambiguous term. In the one statement it means ability to drive; in the other case, it means whatever an intelligence-test tests. Now it is by no means certain that what is tested by so-called intelligence tests is important for driving. What these tests really test is a group of skills of certain sorts; skills which are important for the college student, and for many other lines of work. But that doesn't mean that they are skills needed by the ordinary auto driver. It is probably true that the man who is very low in an intelligence test probably isn't skilled in anything, and can't acquire skill in anything. The idiot and the imbecile are not safe drivers. But even the low grade moron may be an excellent and safe driver. I don't say that he is, but that he may be. In fact, I suspect that shutting out the morons would work havoc with commerce, which needs many drivers for trucks and delivery wagons.

Intelligence Tests Not Always Just

Here statistics are exceedingly fallacious. If you are employing taxi drivers, and have no better means of selection, and have plenty of applicants, you are wise in taking only those who stand high in an intelligence test. You will accept some inefficient drivers, and will turn down many efficient ones; but on the average, your selected drivers will be more efficient than your rejected ones. The man high in one kind of intelligence is more probably high in others than is the low man. But in the licensing of drivers, the problem is an entirely different one. You can't turn down a lot of people who have every right to be licensed, in order to catch a few who have not that right. Nor is it probable that public safety would be essentially increased. I think that intelligence tests as a means of selecting drivers must be frowned upon as ineffectual and unjust.

On this account, the suggestion has been made that we should test candidates on the kinds of skill that are believed to be actually required in driving. There are two alternatives here. One is to test candidates on their actual ability as drivers under traffic conditions. The other is to test them more exactly in certain kinds of elementary skill which would seem to be required in driving. A number of ingenious devices have been put forward for this latter purpose, mainly depending on the measurement of the reaction time; namely, the quickness with which the candidate can make a hand or foot movement in response to a sudden signal. I believe all these methods are fallacious, and dangerous if they are depended upon. Quickness of response, for example, is not a requisite in driving. The requisite is to do the proper thing. Very frequently, safety depends upon making the responses slowly. The man who sets his brakes with a snap may cause a serious accident to the man behind him. More complicated tests fail, because the responses under test conditions are no index of what the driver will do when on the road or street, where conditions are entirely different.

As for tests of actual driving, such as are now employed in various places, where an officer accompanies the candidate in his car, and directs his operations in traffic, these are unquestionably useful, but not as means of selection. All candidates eventually get by. The real value of these practical examinations lies in the fact that they compel the learner to really try to learn something, or at least to practice driving, before he starts out as a full-fledged driver. It is a good thing for the examiner to flunk a few candidates, to stimulate to more practice on the part of

candidates generally. Even if he flunks the wrong ones it makes little difference, as a week or so more of practice is not a serious hardship.

This consideration brings us up to another factor in the improvement of drivers, namely, training. This is the most important factor in safety. The drivers who are by nature incapable of learning to drive safely are relatively few, and may be eliminated. The important thing is the proper training of the others. Unfortunately, a large number of drivers are not properly trained. Many of them are untrained in the elementary details of controlling cars. They don't know how to apply their brakes properly, how to change gears properly, or how to start their engines, how to avoid skidding, how to manage their cars at a railroad crossing. These may be minor matters, seeming to have little to do with the matter of safety of life and limb, but I believe they are important indications, not of incapacity, but of ignorance of the conditions of driving, and of dangerous inefficiency. A campaign for better driving should start at the bottom, with learning how to perform the essential details of operation properly. These operations are a more potent factor in safety, or in danger, than might be supposed.

The more important feature of learning, however, is learning to drive in accordance with traffic rules, and here the greatest source of danger exists. The man who has not learned to obey the rules is to be considered as ignorant, just as the man who has not learned to shift gears. But in both cases he is fully responsible. He has neglected to learn something that he can learn, and should learn. For obeying the rules, or not obeying them, is a habit, like gear shifting, and should be as automatic on the part of the driver. What are the rules the unlucky drivers do not follow? They are very numerous. To slow down on corners; to keep to the right going around corners; not to overtake on a hill top; to hold out the hand before stopping or turning; to give pedestrians the right of way; to approach all intersections cautiously, and so on. These are the lucky rules. The man in trouble has usually broken one of them, or some other driver has broken one and made him the goat.

Training the Driver to Be More Careful

There are no simple cures for carelessness and recklessness, the two grand divisions of unsafe driving. Yet, from the general store of psychological facts and principles, we can point out certain types of training of the driver which do conduce to safe driving; and we can suggest, tentatively, at least, certain ways in which such training may be applied.

1. The rigorous examination of the candidate does conduce to his training, and this examination needs to be insisted upon. In some instances, the examination is casual. It needs to be systematic and carefully planned, so that candidates will fully understand that a considerable degree of competence will be required. This examination should be largely practical, but I believe that a certain amount of theory also should be demanded. Theory is of no use by itself, but as an aid to practical knowledge it has unmistakable value. Many boys learn to drive before they ever touch the controls of a car, just by watching drivers, and analyzing their performances in different situations. The case of the 9-year-old colored child who drove a car successfully in Baltimore traffic, after having merely watched others, is not exceptional. Most women, it would seem, acquire little in this way, and drive solely by rule of thumb. The problem of women drivers is really an important one, and we cannot accept the statistics which have been compiled to show that they are as safe drivers as men. Many men, however, have but vague ideas as to the reasons for the various operations in starting the engine, shifting gears, and applying brakes, and their learning is much accelerated by being made to study the principles.

2. Schools for drivers who show signs of incompetence should be seriously considered. There are great numbers of borderland cases, in which the driver shows

slight incompetence, and is either reprimanded by the officer or taken to court and made to pay a small fine, where the better plan might be to sentence the suspect to a training school or training course, with no prejudice to his record. The organization and administration of such a program will be indeed difficult, but it is worth considering.

3. The habit of obeying traffic rules is the most important desideratum. This is a matter of learning, just as much as the habit of stopping without stalling the engine, shifting gears smoothly, and avoiding skidding are matters of learning. The man who is sloppy about traffic rules has failed to learn a habit which he can certainly be required to learn.

In connection with the formation of the habit of driving safely, it is worthy of remark that while it is possible for a driver habitually to obey certain safety rules, and habitually disregard others, the certain tendency is for the habits to ooze through these distinctions. If the driver is in the habit of breaking certain rules, there is a strong tendency to break them when he thinks he can get away with it.

Necessary Qualities of the Enforcement Rules

The enforcement of the general safety habit is a complicated and difficult matter, but although the training school plan for some offenders seems worth trying, law enforcement is not the only end. The important preliminary and supporting factor is in the rules themselves, and the accessories of the rules. Little can be done towards the attainment of safe habits, until certain requirements are met by the rules.

1. They must be uniform.
2. They must be reasonable.
3. They must be consistent.
4. They must be clear and unmistakable.
5. They must in all ways be easy to follow.

With regard to the first two demands, it would seem that little need be said. These have been well emphasized by the National Conferences on Street and Highway Safety. Yet there is a great deal to be done in these regards. It is, however, the other points which I wish to emphasize. Too much confusion exists at present both in rules and in the signs and signals accessory to the rules. For example: on many roads, signs indicating "dangerous curves" are placed at various points. But the curve may actually be a gentle bend, or a really dangerous one. On many roads some dangerous points will be marked and many other equally dangerous ones not marked at all. What is the result? Drivers pay little attention to any of these signs. In many cases the signs are direct sources of danger. In all cases, the habit of disregarding rules is fostered. Every time a driver disregards a rule of the road, he increases his tendency to be an unsafe driver.

The laws requiring a full stop at a railroad are undoubtedly causes of unsafe driving. For 90 per cent of these signs are disregarded, and will be. They are merely breeders of unsafe driving.

The confusion of signals and rules in cities is perhaps a more serious evil. Here traffic is being impeded, and made dangerous, by drivers needing to take attention off the prime conditions of driving, in order to read words lettered in the street, read signs stuck up in various places, and hunt for traffic lights. The worst part of them, however, is that drivers are constantly being bawled out by officers for minor errors due to confusion which might be prevented. Every bawling out for a dereliction not intentional increases the tendency to be an unsafe driver.

For example: a driver starts to make a left turn where it is prohibited by an obscure sign, and is bawled out. He passes a red traffic light which is located in an unusual place, and is bawled out. He goes around the officer at some corner where he is expected to cut behind him. And so on, through a long list of mistakes due to confused rules and signs. In every case the driver is sore, and says,

"Hell with the signs," or "How can anybody follow their fool rules?" and his unsafe driving is increased.

Simple principles of signals are plain. They should always mean the same thing. They should always be in the same places. They should be visible without hunting for them. There may be no accidents at points where these conditions are not fulfilled, but the deficiency inculcates unsafe habits. We can never get drivers into the *habit* of obeying rules, signals and marks, until the present confusion is cleared up.

Running through all our requirements in the way of safety is the basic principle that we don't want drivers to have to *think*. We want them to act from habit, that is automatically, so far as the conditions are possible. We don't want drivers to stop, or slow down to read signs when it is possible to avoid it. The Baltimore system of no-parking signs is a splendid example of the possibilities in the way of signs which can be quickly learned, so that reading is unnecessary.

We don't want drivers to look around for stop-go lights or no-left-turn signs and to think of the possible places where they might be, at busy corners.

We don't want drivers to think whether a sign means one thing or another. In Colorado, this summer, I came to a railroad crossing marked as such, at which in addition there was a blinking red light. I stopped and waited for the train. Soon I found there was no train for an hour; the red light was kept blinking constantly. I learned to disregard this sign, and perhaps some time later I will have to think, in some other state, whether a flashing red light means stop, or proceed cautiously. And I may think wrong.

At Loveland, a lady driving a small coupe *thought* a red light on a street obstruction was a tail light on another car. Her thinking wrong cost her her life, and serious injury to several other people. There is no excuse for the confusion. Drivers ought not to have to decide what a red light means. Thinking a red stop light on a car to be a red tail light has caused many crashes.

The maximum safety is secured, when drivers are not required to think, or speculate, or guess. All rules should be consistent and uniform. Every signal should mean one thing and one thing only. When this is attained, the driver can learn to obey them automatically. Until we reach this point, the habit of guessing, and driving unsafely, will stay with us, and eventuate in accidents.

The Red Light Should Always Mean Stop

J. T. PRATT (Reading Co., Reading, Pa.): What sort of a signal did you have flashing at a grade crossing?

DR. DUNLAP: A one-light signal. I haven't seen that thing before, immediately associated with two flashlights.

MR. PRATT: That does cause some confusion because there are many advertisements along the highways in the east that have flashing signals. The standard in the east is a double flasher and they only flash when trains are approaching.

J. H. LIEGLER (Racine, Wis.): May I ask whether you consider the red light the proper signal at a highway, railroad crossing?

DR. DUNLAP: The whole problem of the red light is a very complicated thing. My opinion is, the red light should always mean stop. A man should never have to decide whether it means to stop or to go along. Where the signal does not mean actual stop some other light should be used. The practice of putting a red light at the end of a strip where an ordinary street turns into a boulevard, or putting it on a division of a bridge, leads to a great deal of trouble. There may not be trouble there; except in smoky conditions people stop to see what that light means. However, it has something to do with the accidents at other points. There is no excuse, it seems, for using a red light in a position where it might be interpreted to mean other than stop.

MR. LIEGLER: Isn't the red sign overburdened with duties?

DR. DUNLAP: Yes.

MR. LIEGLER: Might there not be established something which traffic hasn't at the present time, a positive stop? In other words, instead of having a red light at a highway grade crossing, why not get away from the railroad's idea of the use of the red and install something distinctive, by the use, we will say, of the two other colors which you mention in your paper, your orange and your green?

DR. DUNLAP: The simple solution which I believe we are headed toward is to relieve the red of everything except positive stop. It is a very difficult matter to remove the red sign from that position. It now means in the most important cases "stop." The red should stop a driver before he thinks.

H. D. WOOD (Yellow Cab Co., Chicago): I would like to ask the Doctor if he doesn't consider the ability to concentrate, on the part of the driver, a very important part?

DR. DUNLAP: I don't know whether I can answer that question. The trouble with many drivers is they concentrate on something other than the important thing at the moment. The driver with a keen mind happens to concentrate on something over here and fails to note something over there. The ability to concentrate when required is a valuable asset. I don't know how that compares with the ability to distribute the danger. For ordinary driving purposes, the driver who can distribute his attention over the whole range, so he will notice pedestrians darting into the street, is, I believe, a safe driver.

Nothing Should Distract the Driver's Attention

MR. WOOD: I am interested only in taxicab drivers. Their job is to transport individuals from one place to another. Sometimes the address may be confusing. He may not know where the particular street is. While going down the thoroughfare he will be wondering in his mind as to the best way to get there. That, of course, hinders his ability to concentrate on the most important subject—the safe operation.

DR. DUNLAP: I think his operations should be so automatic he wouldn't have to think about them. Your taxicab driver should not have to think about ways of getting there; that should be automatic. Without further reflection he automatically should know the proper route. If he is thinking about something other than the driving situation it is dangerous driving. Of course, emergencies arise, but the most useful thing to provide against those emergencies is to drive automatically to his destination.

B. N. WHEELER (Duluth, Minn.): Isn't there a third factor in these accidents? Isn't there the efficiency of the pedestrian in the crossing of the street? Two-thirds of the people that are killed are walking, not driving.

MR. WOOD: I think probably the best answer to that is the ruling of the Supreme Court, which contends it is up to the automobile driver to look out for the pedestrian. The pedestrian doesn't have any responsibility.

DR. SNOW (Yellow Cab Co., Chicago): Dr. Dunlap, you gave a very illuminating and interesting talk. I quite agree with everything you said because I have spent a little time working along the same line. I find that education is of tremendous importance, there is no doubt about that, but it is also a tremendous task to educate anyone. Some, of course, we can educate with greater ease than others, but even the ones that learn very quickly we have some difficulty in educating.

I know at the Yellow Cab Company schools it takes two weeks or more to educate the best, and then we cannot be sure that he has really learned to respond unconsciously the way we want him to. We doubt very much whether two weeks of constant driving in traffic can educate one where he can automatically respond properly. If you take a class of taxicab drivers who have difficulty in mastering any habit, this period is prolonged sometimes a month or two months.

These methods of responding to certain situations do not become automatic with them. We find that these individuals can be classified if tested by certain methods.

There are few, but nevertheless they are a problem in the taxicab industry. I am speaking of individuals who are trained carefully for a long period of time and when they go out to drive get into trouble invariably. Even if they attend safety schools afterwards and are sent back to the driving school again, they come out and have difficulty.

Dr. Dunlap was quite right in saying that intelligence, as it is measured today by pencil and paper, is no indication whatsoever of man's ability to master these necessary habits. In fact, we have a lot of data to show where simple reactions are no factors. At least, they do not weed out the incompetent from the competent, they do not weed out the man who has accidents from the man who has no accidents. There are, however, certain measurable behavior types. You can assign a man a certain task and measure his response and see if he belongs to a group who has difficulty in mastering these necessary habits, or a group who with comparative ease can master these important habits.

Therefore, I think, it is imperative that we should segregate them. We should have a law licensing the small group of individuals who are found incompetent to master these habits properly.

The Discharge Sword May Be Wielded Too Much

DR. DUNLAP: You are speaking of the taxicab driver now. Can you apply that to the general field of licensed drivers?

MR. SNOW: I am not prepared to say. I can realize a tremendous task in testing a large group of individuals.

DR. DUNLAP: I didn't mean to imply anything to the contrary with regard to employee driving. I know exactly what you are up against there. My question is in regard to the licensing of the regular driver.

MR. WOOD: I believe that the discharge sword is wielded too much at times. As the Doctor brought out in his paper, the majority of individuals have the capacity to grasp things, and if you hire a man to drive an automobile and he measures up in other qualifications, then it is your obligation to spend some time with him in finding his faults and training him and educating him to a point where he will be efficient.

A discussion came up the other day that was very important. It was in connection with a driver who had a fatal accident. Some people are very quick in saying, "Why that man should be discharged! There is no question about his guilt." His record may show in many cases just the contrary.

I have in mind a serious accident we had about two months ago. Two cabs, one of our cabs and another cab, met at an intersection, a wide, open intersection. There was no excuse in the world for them to meet there if the drivers had had their eyes open; but owing to the fact that our driver had his last load and was in a hurry to get back to the garage to have his morning coffee and doughnuts, that man had a very serious accident. That man has been with the company for over five years, I think, and I can vouch that during the past three years he has not been involved in what we would term an avoidable accident, and still he makes that fatal mistake once and has that terrible crash. Unless the accident has had too much mental effect on the driver, you are not taking a chance by taking that man back and putting him back to work. You might be criticised for it in some cases, but it is unquestionable that that man is going to make a good man for you from then on. He is too valuable a man to lose, probably.

CHAIRMAN UPHAM: They say in order to teach a person the correct methods you must catch him young, and I do not know where that is any more applicable than in highway safety. We have a very important subject on "Reducing Accidents Through Junior Safety Councils," by Mrs. C. C. Owen, of the Dallas Safety Council, Dallas, Texas.

Reducing Accidents Through Junior Safety Councils

Corita C. Owen, Secretary, Dallas Safety Council, Dallas, Texas.

The most effective educational processes are those which enable the learner to participate actively in the thing being mastered. By his own action he makes the thing learned a part of himself, and thus acquires not only the theory but also the habits which come from doing.

The Junior Safety Council offers an excellent opportunity for the school to teach safety, and at the same time build up safety habits that will persist long after the actual instruction has been forgotten.

With such an audience as this Congress provides it is unnecessary to "sell" the idea of teaching safety in the schools. More important is a practical illustration of how safety is being taught in a given case and the results that accrue. The school conditions, as well as the general types of hazards met by children, are much the same the country over, and the experience of the Dallas Safety Council in bringing safety to school children through the Junior Safety Council applies almost directly to similar situations everywhere.

In Dallas an unfortunate accident record, particularly as to traffic accidents, several years ago resulted in the formation of the Dallas Safety Council in 1920.

For three or four years this Safety Council used traditional methods of committee activity, publicity, etc., to interest Dallas citizens in safety. Much good was accomplished, but the results were not satisfactory. The number of fatalities from traffic accidents steadily increased, and among them were many accidents to children.

The next step taken by the council was to gain the cooperation of the Dallas Public Schools. It was thought that by working through the schools the safety lesson could be given to children and they in turn would take it home to their parents.

✓ In 1924 the Dallas Junior Safety Council movement was started. At first only a few schools undertook our safety program. By the close of the school year the success of safety work with children through the schools had become so evident that plans for the next year included its extension to all white elementary schools in Dallas.

The move toward educating the child along safety ways proved to be the best move that we had made. We soon discovered that though we couldn't properly impress the driver that he should watch the child, it was more effective to caution the child to be on the lookout for the reckless driver and to stay out of his way. We found the children were considering the dangers very seriously and were responding immediately to our advice. They were carrying home the safety messages as we had hoped. Children and parents were soon discussing the proper ways to cross the street, and many a father was reprimanded when he told his child to *hurry* across. One young child told her father that she had been told to *walk* across the street, never to run, and when in doubt to stop and let the driver see that she was waiting for him to go around her, so that there would be no danger of her confusing him.

In 1925 the Dallas schools designated Julius Dorsey, supervisor of elementary education, to have charge of the Junior Safety Council activities, and he was instructed to work closely with the Dallas Safety Council. Mr. Dorsey threw himself into safety work and much of the splendid record accomplished is due to his wholehearted cooperation. One of the first essentials for success is that the schools actively cooperate with the local safety council.

Junior Safety Councils were organized in each elementary school. One teacher, usually the principal or auditorium director, was designated to head the work in each school. The Junior Councils elected officers and named

numerous committees. An effort was made to give safety work assignments to as many pupils as possible.

A premium was placed on membership in the Junior Safety Councils by requiring pupils to earn it. This was done by learning the safety code and pledge and by following safe practices. When proficient in these, pupils were admitted to membership in the council and given an attractive membership button. The price of membership was adherence to all safety practices.

If a member of the council is seen violating safety practices he is brought before the School Council and his case is discussed. If the action is serious enough his button is taken from him and he is placed on probation for a certain period of time. This is the most humiliating thing that could happen to a boy, to have his button lifted before all of his classmates and fellow members. This tends to make the child stop and think before he commits any act which might be dangerous. We find as a result that children do not hop on the back of trucks or on street cars and are very careful about going into the street, and in this way many accidents which result from carelessness have been eliminated.

No School Children Were Killed in 1925 in Dallas

The results of this work were at once apparent. In 1923 nine children of junior safety council age were killed in traffic accidents on Dallas streets. In 1925 no children of this age were killed, and no Junior Safety Council member was involved in a traffic accident.

Our Junior Safety Councils are self-governing. The teacher has little to do with them, other than to give such assistance as is requested and to lend a steadying influence. More than that, the Dallas Junior Safety Councils have become the student self-government bodies in their respective schools. In most cases the principals and teachers allow the safety patrols to control discipline in the halls, on the stairways, on the playgrounds and on the streets about the school. This practice has become so prevalent that the Junior Safety Council is the most important student morale force we have.

These Councils consist of the student body of the fourth to seventh grades, inclusive. These children have patterned themselves upon older organized bodies as much as possible. The Dallas Safety Council gave them their original organization plan including a constitution and by-laws. Their meetings are carried on in perfect order even to the smallest parliamentary detail. Their work includes inspection of school premises to discover accident and fire hazards, studies of traffic safety, home safety, play ground safety, etc. Children are organized into Safety Patrols to aid younger children across the dangerous streets.

These patrols control traffic in and near the school buildings. In the smaller schools their duties are confined mainly to the buildings and grounds, but the larger schools have a real problem to face because of the heavy traffic in front of their buildings. Sometimes patrols are placed several blocks from schools. The patrols are equipped with attractive arm badges, police whistles and red flags. They are instructed to keep out of the street as much as possible, but to control traffic and clear a safe passage for children.

At the beginning of the school year police officers of Dallas go to the different schools and talk before the children on safety practices and habits. The man in the uniform is a big man to the child and his every word is law. For a couple of weeks the policeman often stands on the walk with the child and together they direct traffic while he explains many of the dangers to the child and impresses it upon him to stand on the walk and never allow the children to cross the streets while a stream of traffic passes. It is a real sight to see

the little lad of twelve years control traffic by blowing his whistle and waving his red flag—the cars stop while he takes the smaller children by the hand and leads them across the street. Then he blows his whistle and traffic moves on. Motorists usually give friendly nods to the “little officer.” Often business men stop their cars at the curb and watch these little fellows perform their duties. Then the Safety Council office gets a call telling us about the good work the children are doing. The fathers take as much pride in the work of their children as do the children themselves. We have received much favorable newspaper publicity and the public seems enthusiastic over the work.

We have had only a few cases when the motorist failed to cooperate with the patrols. In these few instances the car license number is taken by the patrol and turned over to the Auditorium teacher or principal, who calls the Dallas Safety Council. We locate the owner of the car. If he cannot be reached by telephone we write him a letter, though when it is possible we always talk to him personally. The purposes of the Junior Safety Council and patrols are explained to him and we give him an opportunity to go to school and apologize to the patrol, otherwise he is called into Police Court. In every case we have found the driver willing and even glad to make this apology. No one thing probably has given the children more confidence than to have a grown man come to them and admit that he was wrong and apologize, then offer his cooperation in the future. To know that he is right and is being backed by the citizens of Dallas gives the little patrolmen increased confidence in themselves. We have found that the patrols never abuse their privileges. Responsibility brings thoughtful and considerate action.

The Fire Prevention Committee Cooperates

The Fire Prevention Committee of the Dallas Chamber of Commerce has worked closely with the Junior Safety Councils. The efforts for fire prevention have been very successful. The Junior Safety Council members have inspected and cleaned their home premises so thoroughly that no fires of preventable nature have occurred in their homes during the past two years.

The excellent safety and fire prevention record established during the first year of Junior Safety Council operation has been repeated each year since. During the last three years in Dallas, no Junior Safety Council member has been killed or seriously injured in an accident of any kind, and our records show no instance of a preventable fire in their homes. Surely this is sufficient evidence of the value of Junior Safety Councils in bringing about greater safety and reducing fire losses.

Each Junior Safety Council holds meetings at least once a month, often more frequently. These meetings are under the supervision of the Auditorium teachers and the students themselves have charge of the programs. The Dallas Safety Council furnishes them with safety plays, slogans, songs, etc., which they learn and give at these meetings. Often these plays are put on before luncheon clubs in the city, so that the man who is too busy to visit the schools may know the work they are doing.

During the past spring when the National Education Association met in Dallas one of the Auditorium teachers in the city was asked to put on a program which would show the visiting teachers what the Dallas schools were doing along safety lines. This program was attended by members of the association from all over the United States. They seemed much impressed with the safety program enacted by the children. Especially was the audience pleased with the Schaefer Prone Pressure Resuscitation demonstration, put on by the children who had been instructed by the employees of one of the local power companies.

Following this N. E. A. convention in Dallas, more than 100 requests for additional information and material were received from those who had become interested in school safety work.

We feel that our children are greatly responsible for the reduction of accidents in Dallas during the past four years, mainly through their "ounce of prevention," but we recently have had cause to learn that they are doing even more than that. They are approaching the problem of accident prevention from a constructive point of view and doing much to eliminate accident causes.

In one of our Dallas schools which is located in a cotton mill district a boy was brought to our attention because of an act which he performed in the interest of safety. This boy, a member of the Junior Safety Council, had not been a very active worker in the Council. The boy had unfortunate influences in his home. His father was a fighter and a trouble maker and the boy seemed to have inherited the same tendency. One afternoon he was standing on the banks of a river watching two boys on a raft. Suddenly the raft was overturned, and he discovered that only one of the boys could swim. Without a moment's hesitation he jumped in and rescued the drowning boy. When this act was brought to the attention of the Dallas Safety Council we awarded the boy a Distinguished Service Certificate. Later, at a mass meeting of all the Junior Safety Councils in the city, this certificate along with a membership in the Y. M. C. A., was presented to him. Though the boy was very timid and did not want to discuss his act, one could see that it was probably the first praise he had ever received and he appreciated it greatly. The wholesome Y. M. C. A. environment is proving very helpful.

The Junior Safety Council Has Been Most Valuable

Many other acts of merit have come to us during the past year, but this one, coming from such a source, stands out as the most valuable safety service rendered during the year.

The Dallas Safety Council feels that its Junior Safety Council program has been the most valuable activity it has undertaken. We give the schools entire credit for the work they have done in the prevention of accidents and we are glad to have had the opportunity and privilege of fostering such a movement.

It is surprising how easily and cheaply Junior Safety Council work may be carried on. In 1927 the Dallas Junior Safety Councils enrolled more than 25,000 active members in the grades from the fourth to the seventh, inclusive, in thirty-five elementary schools. Using the facilities of the National Safety Council—especially the Education Section, we were able to supply teachers with numerous helps in the form of multigraphed copies of lesson outlines, slogans, playlets, etc. We printed the safety code and pledge on large 18 by 24 inch posters and placed them in school rooms. National Safety Council safety posters were distributed and the children themselves made many posters. We provided 500 arm badges for patrols, 500 red flags and police whistles. The total cost of all these supplies was less than a thousand dollars.

Each year the Dallas Safety Council holds several mass meetings in large down town auditoriums where Junior Safety Council members gather to listen to programs arranged by various schools. We also show safety pictures, comedies and have prominent speakers. Capacity audiences always attend.

Success in Junior Safety Council work depends wholly on the adoption of a constructive program and willingness of the schools to cooperate. The Safety Council must stand ready to give aid and assistance whenever possible. Children must be made to understand that safety work is worth while and that it is their job. They must be allowed considerable freedom in carrying out the plans they make. Good work must be suitably recognized.

This done. Junior Safety Council work will succeed and the lesson of safety will be learned by the children, and by them will be taught to adults.

CHAIRMAN UPHAM: This is very important work and it has grown in every city in the United States. How susceptible the younger people are to work of this kind is evident in the safety campaign that is now being carried on, starting October 1, where the children in the schools are asked to sign a pledge, a simple pledge; and while that is not supposed to start until October 1, already we have thousands of pledges sent into the office. In one school 1,400 have signed the pledge, making it 100 per cent for that school.

E. R. FARRA (Grand Rapids Safety Council): How do you expect to tie in the local safety council?

Adopting the Slogan "Courtesy and Caution"

CHAIRMAN UPHAM: That safety campaign as run by the American Roadbuilders' Association is nothing new. Last January, when the American Roadbuilders' Association met at their annual convention they wished to contribute something toward highway safety. After talking it over with Mr. Williams and two or three others, we decided to start a highway safety campaign beginning October 1. We summarized all the rules that we could find in about 25 or 50 pamphlets into two words, "Courtesy" and "Caution," feeling that if everybody would be as courteous and as cautious when they are on the highways as they were at other times, it would help the cause of highway safety to a great extent.

We find that 90 to 95 per cent of all the accidents originate with the individuals. The mechanical devices play a very small part in highway accidents. Knowing that our problem was in the individual, we decided to appeal to the individual. If you go to the individual with a lot of complicated rules and regulations you don't get as far as going to them with very simple rules, so that is the reason we selected the very simple rule of Courtesy and Caution to appeal to the individual.

Then the question came up, how should we appeal to the individual? We tried to appeal in groups, the Rotary Clubs, the Civic Clubs, Kiwanis, Lions. Then we appealed to the schools through the principals of schools, the Parent-Teacher Association, and so forth. The Federal Council of Churches became interested. We got the information to them, made a direct appeal to about 25,000 churches in a little prospectus that was printed based on the simple rules of Courtesy and Caution. In all we sent out 100,000 of these prospectuses to these civic clubs, schools, country departments, highway associations, and everybody that has to do with the masses. In some of the cities the safety councils have written in and said they would like to conduct a campaign within their city. In that case we simply sent them all the literature and they are conducting the campaign in their city.

For a background, we appealed to nearly 1,500 newspapers and magazines, and I should say we had at least 1,000 letters from newspapers and magazines stating that they would be pleased indeed to help in this campaign, to send along the copy and they would print it, so beginning October 1, there are over 1,000 newspapers in the United States and some two or three hundred magazines that will print this copy every day for two weeks. That will be the background for the campaign.

Then in order to have an appeal to the individual, we used what we call our pledge card. It is a very simple pledge card which pledges the signer to courtesy and caution while on the highways.

It is evident from the results that have followed from this campaign that the public right now is eager for a full-fledged highway safety campaign, and I believe the press of the country and the magazines are more than willing to help in a large, well-organized, well-timed, safety campaign on the highways.

In addition to what I told you, the Roadbuilders started a highway safety contest

open to everybody. They gave a thousand dollars in prizes. It has yet to run for six weeks. One of the manuscripts that came in said something like this: that if the motorist would use just common, ordinary, everyday, barroom courtesy a lot of our accidents would never happen. That is about so. When a person gets behind the wheel he assumes a dual personality and he is not as courteous or as cautious as he is at other times.

R. M. ARUNDEL (Washington, D. C.): I, too, am connected with the American Roadbuilders, and one of the things I would like to mention is the education of children as to the following of traffic rules: We have an idea that we think would be very good, and that is of installing on the stairways of each school a regular traffic signal. When the boys and girls came in in the morning we could have them march into their schoolrooms according to the traffic signals. When they are dismissed they could march out under the green signals, and have that repeated day after day during the entire school season. We believe that that will bring about habitual obeying of the traffic lights.

R. M. SHERRARD (Board of Public Education, Pittsburgh): We are using the "stop" and "go" signs in a great number of schools under the direction of our junior safety patrols at the interchange of classes, so the idea isn't new to us, and the children are very much accustomed to that sort of thing.

A Junior Safety Council in Every School

J. M. MORRILL (Frisco Railroad, Pacific, Mo.): At Memphis they have a police lieutenant who is paid by the city but reports to the safety council manager, and he organizes a junior safety council in every school, public and parochial, and has meetings arranged after the close of the school hours, so as not to interfere with the school work. He is a scout master and he is a man that the boys love, and he is doing a wonderful work.

F. C. LYNCH (Kansas City Safety Council): I would like to ask Mrs. Owen about one part of her paper, the part about the motorist disobeying the regulations of the patrol. How did you bring the motorist back to apologize, and to whom did he apologize, and in case he refuses to apologize, who enters the complaint to have him arrested?

Mrs. OWEN: The first thing we did was to either call or go to the highway commissioner and get his name and address from his number. Then we look him up and call him immediately, usually within an hour or two, and we ask him to call at the Dallas Safety Council office. When he calls there we tell him about it and ask him if he would like to apologize, telling him we would be very glad to give him a chance; otherwise, he would be turned over to the police court. Our police judge said he believed in enforcing the law. When a motorist is brought up to him he is fined usually, and they really have a fear of the judge. So in every case the man went to the school and apologized. He apologizes to the officers of the patrol, or once in a while he talks to the whole assembly and tells them he is sorry. He usually says he didn't understand, of course, and would not have committed such an offense if he had known in advance.

MR. LYNCH: Our police department will not issue a warrant unless someone is willing to volunteer as a complainant or witness.

Mrs. OWEN: The manager of the Dallas Safety Council puts in the complaint. So far we have never had to go to court.

E. R. FARRA (Grand Rapids Safety Council): We have gone one step further in going into the high schools. We bring together the representatives of the high schools once a month and analyze the accidents that have occurred the month previous, and in a couple of weeks I am going to have one of those high school boys or girls broadcast over the radio on Wednesday night the

findings of that board. In the Children's Hour they get more kick out of hearing those youngsters over the wire than they do me.

NORMAN ANDERSON (Ohio Bell Telephone Co., Cleveland): I don't see that I could let this opportunity go by without introducing to you Sergeant Roth, who spends all of his time on this school work. I think perhaps he could tell you in a few words some of the things he is doing.

SERGEANT A. ROTH (Cleveland Police Dept., Cleveland): I have organized safety patrols in all the schools in Cleveland. Each school has a safety council. They make the laws for that school. If a child runs out into the street or hops on a truck, or a street car, or anything of that kind, and one of the patrol sees this boy or girl, as it may be, his name is taken and sent into this legislative body. They decide what is to be done with this child. Then they have a judge, a prosecuting attorney, a defense attorney and a jury. That child is brought up to this court and tried the same as any offender would be tried if he had violated a traffic regulation. In that way, the children do not only get the idea of safety, but they also get their civic lessons through this court.

I have also made up a set of stereopticon slides of actual accidents, and also some of the things that children do on the streets. I lay in back of billboards and places of that kind probably for a day or a day and a half trying to get these children in the act.

I also started to work with the commercial drivers, the general drivers of the road and the taxicab companies, of which I think there are four in Cleveland. They were running as high as 25 accidents a week in four companies, making 100 taxicab accidents in a week. I went to these men and pleaded with them. I showed them these pictures and in that way I reduced the accidents to four slight accidents in a month.

CHAIRMAN UPHAM: The next subject is "Safety at Grade Crossings." It is something like the weather, there has been a lot of talk about it, but not much done about it. I don't know of anyone who is better equipped, on account of his previous experience, to begin solving that problem than Senator Drexler, of Delaware. He is the President of the Delaware Safety Council. I have great pleasure in introducing Senator Drexler.

Safety at Grade Crossings

**Senator Louis A. Drexler, President, Delaware Safety Council,
Bethany Beach, Del.**

The grade-crossing problem had its beginning with the advent of the railroad at a time when the highways were used almost, if not entirely, by pedestrians and animal-drawn vehicles. While the traffic on both railroad and highway has changed in many particulars with the increased number of trains, the advent of the motor-driven vehicle on the highway, the increased speed of both and many other elements which enter into the problem, one feature remains to challenge the best efforts of all concerned, the railroad and highway officials and the public. It is a fact that of all forms of highway accidents, the grade-crossing accidents are, in proportion to their number and the number of persons involved, the most deadly. This cannot be otherwise as long as such accidents occur, owing to the great forces and weights involved in grade-crossing collisions.

The fatal character of railroad grade-crossing accidents is evidenced by the facts regarding such accidents. For example, in Delaware, during 1925, there was a total of 14 such accidents with four deaths and nine persons seriously

injured. No figures as to those slightly injured or the property loss were available. During 1926, in the same state, a total of 22 such accidents have occurred with 25 deaths and eleven persons seriously injured.

In the State of New York, during the year 1925, the Bureau of Motor Vehicles reports the number of railroad grade-crossing accidents as 148, with 103 persons killed and 178 injured, or about one death and one injury for each accident. A similar report for New York State for 1926 shows 161 railroad grade-crossing accidents, with 151 killed and 158 injured, showing such accidents to be extremely fatal. These figures are only for accidents where automobiles are involved. Other vehicles using the highways and pedestrians are also victims of railroad grade-crossing accidents. Such data as can be studied from various sources warrant the statement of the Connecticut Department of Motor Vehicles, "That the most dangerous hazard known to motor vehicle traffic from the standpoint of serious damage and death is the railroad grade crossing."

Highway Accidents Challenge Our Best Efforts

In view of the greatly increasing number of vehicles using our highways and the larger number of persons involved in such use, the number of accidents may seem comparatively small; but, like other menaces fatal to mankind, they challenge our best efforts to eliminate them or by protective measures reduce their extremely hazardous nature so far as is humanly possible to do.

A study of the grade-crossing accident reports of the various states and the several railroads reveals a certain number of accidents due largely, if not wholly, to the carelessness and recklessness of drivers of motor vehicles.

The mental attitude of drivers toward the potential danger of a crossing differs greatly. There are those who always take a chance whether at home or abroad in respect not only to railroad grade crossings but to all crossings and other road circumstances. The elimination of these wholly reckless drivers through appropriate legislation and strict vigilance by patrol officers may never be complete but should be a matter of constant effort upon the part of those officials charged with the duty of making and enforcing traffic laws and regulations.

In any effort to reduce the fatalities at railroad grade crossings, through the drivers of vehicles (motor or other types) or pedestrians, we are confronted with all those elements of mind and body which constitute the human factors which enter into the problem, and herein is the great field for the work of those interested in public safety to remove, by education, publicity, etc., as much as possible this human factor.

However, we cannot place responsibility for the large toll of deaths at grade crossings wholly upon the reckless class of operators. The hazards which the railroad grade crossings present everywhere are too real to pass over lightly. Many a well-balanced and a reasonably careful driver has come close to disaster, and others have met fatal accidents through seemingly no fault of their own.

Almost every motorist can recall some nerve-racking personal experience encountered in approaching or crossing a railroad at grade. He recognizes that serious attention must be continuously directed to the extreme hazards which these crossings present. He expects that a definite program for the gradual elimination of the most dangerous and heavily traveled crossings shall be planned and financed through the cooperation of the railroads and the proper public officials. Recent fatalities are focusing general public attention upon the necessity of such a procedure. Sentiment also is being crys-

tallized into the demand that adequate protection be provided within a very reasonable time to safeguard human life at every railroad grade crossing in face of the present day railroad and highway traffic conditions.

A considerable number of grade-crossings might be eliminated by the diversion of a slight amount of vehicular traffic using same to more important and better-protected crossings and the crossings from which the traffic has been diverted should be abandoned. This requires the cooperation in many instances of local authorities and the state and country highway officials with the railroads and should receive careful thought and attention. At a number of points, especially in some of our smaller communities there occur an excessive number of grade crossings within comparatively short distances of each other. Additional safety might be provided at the price of slight inconvenience to the few for the safety of the many by the diversion of traffic as heretofore suggested. Local opposition in some instances has prevented the carrying out of this feasible and reasonable solution of such cases.

A Definite Program Should Be Laid Out

Elimination of grade crossings, either by relocation of highways or rail lines, or by grade separation, which constitutes the only perfect solution of the problem, should be carried on under a proper program, first eliminating the most dangerous crossings on thoroughfares carrying heavy traffic and with due recognition of the enormous costs involved, which if elimination were attempted on a wholesale scale would impose an excessive financial burden resting in the last analysis upon the public. Elimination is impossible of accomplishment at every location; however, a comprehensive survey of the physical circumstances and traffic conditions of railroad and highway in detail at every crossing will supply the necessary information to permit a classification of the various crossings.

A very admirable survey of the railroad grade crossings in Memphis, Tennessee, was made by a committee appointed for that purpose by the Memphis Safety Council at the request of the Mayor. All crossings were scientifically rated as to the degree of hazard, having regard for the following factors: Topography, visibility, traffic on highway and rail, possible means of protection, and recommendations for improving conditions were made in accordance. The program should have due regard to the relative costs and advantages of grade crossing elimination and other methods of protection and should be given the most thorough joint consideration by the proper authorities. The elimination and protection of grade crossings are of such importance and involve to such extent the public safety as to require that priority be given to them in the allocation of capital funds by the railroads and of public moneys by public authorities over expenditures for other safety measures designed to protect the public.

In locating new highways or railroads, or re-locating existing highways or railroads, grade crossings should be avoided or eliminated wherever practicable. Re-location of highways offers many possibilities not yet fully developed which should be worked out by the State authorities in cooperation with the railroads. In eliminating grade crossings, narrow or obstructed underpasses and sharp turns in the approaches thereto should be avoided. Authority to order grade separation at grade crossings in Delaware is vested in the State Highway Department and Chancellor. The State Highway Department plans the improvements and initiates the proceedings for all highways under its jurisdiction, the Chancellor having authority to determine finally the practicability and the proper division of costs between the railroads and the public. A like

authority should be vested in some State agency in each state to determine and prescribe the proper protection at grade crossings. Time is an essential element and a prompt decision should be provided in the law. Railroad crossings remaining at grade should be safeguarded in every reasonable way.

Present protection at railroad grade crossings consists of a variety of forms and devices. Some grade crossings are guarded by watchmen; at others gates, bells, flashing light signals (both island and side road, either blinker, wig-wag or fixed) and signs of various types; at a number of grade crossings a combination of the above are in use.

Standard warning signs and pavement markings should be used to mark the approaches to all public railroad crossings. Where the volume of traffic requires it additional protection should be afforded by the use of flagmen, gates, or approved electric or mechanical devices standardized as far as practical. So far as possible a clear view along the track in both directions from both sides thereof should be maintained. The placing of railroad cars near grade crossings so that the view is thereby obstructed should be discouraged. Sharp curves, abrupt changes of grade, roughness of the pavement, or other conditions at or near the tracks, which tend to divert the attention of the motorist should be avoided. Properly designated state authorities should be empowered to indicate dangerous grade crossings at which motorists must stop. Of possibly greater importance than the elimination of grade crossings to the motorists of today is the adequate protection at an early date for every grade crossing. Removal of physical dangers as far as possible and the installation of suitable warning devices are of paramount consideration. Without question, the sign "STOP, LOOK & LISTEN," and the signal bell warnings placed immediately at the railroad crossings are out of date. They must be discarded and replaced by visible as well as audible signals located so that the motorist, traveling at an average rate of speed, has sufficient time to come to a halt through "due and timely notice." Signals or signs depending on the light from automobile headlights for their visibility should be regulated as to location and height with due regard to legal restrictions on elevation and power of such headlights.

Adequate Warning and Information of Danger

In approaching a crossing a motorist desires first to be advised "Railroad Grade Crossing . . . Feet Ahead," and, secondly, to have answered the question, "Is it safe to cross this crossing now?" The first signal as to the presence of a crossing is unnecessary for the alert, frequent user of a highway. He is wholly concerned with the answer to the second consideration. To the transient traveler the former is more important for if he were unaware of the existence of a railroad crossing, the answer to the second would be too late for his guidance. As far as practicable such warnings should be uniform in character without regard to state or county lines. They should, we believe, be so located as to serve their purpose effectively without detracting the attention of the motorist from the crossing itself or obstructing his normal path of travel. It must also be recognized that in this day, when motorists are roaming everywhere, even the remote and little-used byways may attract a wanderer from some distant place. No crossing can be neglected. At some locations where railroad or highway traffic is heavy and also possibly visibility of the tracks is poor, no series of advance signs and mechanical warning devices may be deemed adequate. Here it would seem that the watchman and gates are appropriate to follow the advance signs or supplement the mechanical warning devices. The watchman then holds the position of highest trust. He is

custodian of the lives of the traveling public. He should, therefore, meet the same high qualifications of other traffic officers and be deserving of the same public confidence. The highway user, generally, we believe, is opposed to relieving the railroads of any portion of their responsibility, relating to railroad grade crossings of public highways; but he also realizes that the magnitude of the problem makes necessary financial participation by the public to secure any degree of relief commensurate with the exigencies of present conditions. Human lives must be conserved regardless of expense.

We cannot be unmindful of the excellent work carried on by the several railroad companies in their endeavor to educate the public as to the dangers of grade crossings. For six years they have conducted during the summer months a "National Careful Crossing Campaign" designed to bring forcefully to the public's attention the necessity for care at grade crossings, and to impress upon railroad employees the necessity for doing everything in their power to prevent such accidents.

A List of Railroad Obligations

These National Careful Crossing Campaigns have been carried on under the guidance of the American Railway Association's Committee on Prevention of Highway Crossing Accidents. This committee in its report of March 28, 1927, reminded the member railroads of the committee's suggestions (which they term railroad obligations) made in a letter of March 1, 1927, as follows:

- "Early re-inspection of all grade crossings.
- "Removal of unnecessary obstructions to highway traveler's view of trains.
- "Adequate, suitable protection at crossings.
- "Proper maintenance of signs, signals, gates, lights and other warning equipment.
- "Proper maintenance of surface—approach—drainage conditions.
- "Check up on efficiency of crossing flagmen day and night.
- "Adequate sounding of locomotive crossing whistle signal.
- "Proper Maintenance of whistles and bells upon locomotive.
- "Adequate ringing of locomotive bell.
- "Proper protection in backing movements and when trains are out, particularly on multiple tracks.
- "More than ample space between crossing and cars when latter are stored on sidings.
- "Special attention should be given where crossing casualties have recently occurred.
- "Improvement in the record of crossing accidents can be attained by all concerned faithfully performing every duty.
- "It is hoped that railroad executives will give further prompt and full consideration to those features of crossing accident prevention other than the separation of grades, being prompted therein by motives of humanity, expediency and economy."

Further, the following language in the conclusion of this report is most emphatic and impelling: "The continuous presentation of a logical plan of safe action at crossings must ultimately impress even the most unwilling mind. We, as railroads, must do our full duty in suitably safeguarding our crossings: go beyond our duty in warning the highway traveler of his hazard at the crossing, and endeavor to encourage him to constant watchfulness and an intelligent understanding of the various protections thrown around him."

We agree most heartily with the suggestions and conclusion as quoted

above and believe that if they are harkened to and carried out in sincerity and positive action, and with the cooperation of such organizations as the National Safety Council and kindred bodies in energetic and sustained campaigns of public education, railroad crossing accidents will be yet further reduced, and death and suffering eliminated.

In conclusion, gentlemen, let me say, I have not taken up your time with a battle of figures and statistics, for in my judgment to argue around such statements as "only 6,991 injuries at grade crossings occurred in a given time as against 800,000 injuries on the highway in the same period" is like trying to set up an alibi, to ease our conscience.

In a study of the various reports obtainable on railroad grade-crossing accidents, one cannot fail to note the almost universal attitude more or less defensive as regards the interests of the railroad. This is probably owing to the fact that most of the information and data have been compiled by those whose position gives them the railroad point of view and contact. Many of these reports go so far as to try to establish an alibi based entirely on figures which would almost lead one to believe that grade-crossing hazards had been or could be entirely eliminated by mathematical juggling, intending to show how few fatalities occur at grade crossings compared with other causes.

The viewpoint of the public, however, is that of an eminent jurist of one of the eastern states who stated that the hazard is inherent in the railroad grade crossing as a physically existent fact, the duty being imposed upon the railroad of giving "due and timely notice" of such danger.

"Contributory negligence" in approaching or entering within the zone of hazard is an entirely different thing. The elimination and placing of safeguards around such hazards is the especial duty of the railway, aided by highway officials and engineers. The elimination of "contributory negligence" upon the part of the users of the highways should be the constant effort of the various safety organizations, and the cooperation of all should bear fruit in robbing this menace of its victims.

Let us always remember that the victims and those to whom they are near and dear are the great losers. Only those who have experienced the sudden taking from their midst of a dear one can fully realize what such fatal hazards as grade crossings really mean. To these and the public generally who are confronted with the reports and details of such accidents there can be no answer but the elimination of the hazards, or full and adequate protection where such hazards exist.

Safety at Grade Crossings

Chas. E. Hill, General Safety Agent, New York Central Lines, and Vice President for Public Safety, National Safety Council

In discussing safety regulations at railroad highway crossings, we must do so from a broad standpoint, having in mind not only the problems with which we are confronted today, but must take into consideration the conditions we may reasonably expect to exist in the future. This subject is a vital one, and is of tremendous importance in any plan we may adopt in our efforts to reduce what are commonly termed "Grade crossing accidents."

We must approach this subject from a national viewpoint, for it has indeed become a national problem, one which has perhaps created more discussion than any other question in which the railroads of this country and the public are mutually concerned. While the crossing accident problem is but one of the many types of problems with which the railroads have to contend, it is no less

important, and today is being given greater consideration by the carriers than ever before.

The Extent of Crossing Accidents

During the ten year period from 1917 to 1926, inclusive, in the United States there were 20,021 persons killed, and 55,771 persons injured through accidents at railroad highway crossings, or an average of 2,000 deaths and 5,570 injuries per year, the increase in deaths alone during this period being 28 percent.

As a result of automobile accidents in the streets and highways of this country, there were 23,000 deaths last year, as compared with 6,000 ten years previous, an increase of 283 percent. In other words, during 1926 there were more people killed through automobile accidents than were killed at grade crossings during the entire ten year period. We must always look to the future, and in doing so, upon the assumption that the same increases will obtain, we see history recording during the year 1936, the deaths of 65,000 men, women and children, through automobile accidents in our streets and highways, of which number less than 5 percent will be the result of grade crossing accidents.

We do not deprecate the seriousness of the crossing accident problem, and it is not our purpose to minimize the tragedies due to such accidents. Our only purpose in making these comparisons is to undertake to focus attention on where the difficulty lies, and to this your attention will later be more specifically directed.

The Physical Situation

We have in the United States at the close of 1926, 234,280 crossings at grade. In seeking a remedy we must do so upon the theory that the future holds no panacea in so far as the physical situation is concerned, for it has already become an acknowledged fact that a solution of this problem through crossing elimination as the *immediate* remedy is unthinkable, by reason of the prohibitive expense which is conservatively estimated at 20 billion dollars, and the time required to perform such a stupendous task. Twenty billion dollars is equal to the preliminary estimated value of all railroad property as made by the Interstate Commerce Commission. It is almost equal to the combined resources of the national banks of our country. It is a little more than our public debt. Certainly no further argument should be necessary to show the utter inability of the railroads and the municipalities to shoulder such a financial burden.

A gradual process of crossing elimination has been, and still is being carried on by the railroads, but they have been seriously handicapped by the addition of many more new crossings. For example, in one recent year, while the railroads of the country were eliminating 972 crossings at a cost of about 100 million dollars, during the same period 3,065 new crossings were constructed under conditions over which the railroads had no control. We fully agree that the final solution of the crossing problem lies in the elimination of the crossings and that this is the real remedy. The point we desire to make is that it is not the immediate remedy for reasons heretofore stated.

A progressive plan of crossing elimination should be carried on. Even so, we could not hope for a solution of the problem by this means for many generations to come. Therefore, it is our duty to face the situation as we find it.

The Motor Vehicle

We have, in the United States, 81 percent of all of the automobiles of the entire world. The state of Illinois, alone, has more than Germany, Italy, Spain and Australia combined. In fact you could take the automobiles in Illinois and match

them with the four countries named, and still have enough left to supply the city of Chicago.

We had, at the close of last year, 22,100,000 automobiles, as compared with 5,000,000 ten years previous, an increase of 340 percent. The saturation point is far distant. If the same rate of increase continues, we will have 40,000,000 cars by 1936, one for every four persons. In fact, by that time, there might be a sufficient number to supply one car to each individual who is old enough to reach the steering wheel. The automobile is here to stay, and progress will demand not only a continuation of its use, but a greater extension of its services. Therefore, these facts also should be taken into consideration when we are attempting to find a solution of this problem, and this should include *a regulation of the use of the motor vehicle so that it will serve the purposes for which it was intended*. The automobiles play an important part in our crossing problem, for they will be involved in 90 percent of our crossing accidents this year.

Analysis of Accidents

We must know the causes of crossing accidents before any real progress can be made in their reduction. This plan is followed successfully in connection with accident prevention work as it relates to other classifications, and there is no reason why it should not be applied in this instance. In making this analysis we find that a large majority of crossing accidents occur in daylight where there is an unobstructed view of the approaching train, and in the locality where the driver resides; which indicates that the motorist is either so familiar with the situation that he lulls himself into a feeling of security and drives on without any thought of the consequences, or he sees the train approaching and attempts to beat it over the crossing. What is of still greater moment—more than 22 percent of these accidents result from the automobile running into the side of the train. The large number of accidents due to this cause is so appalling that recently I mentioned the matter to an eminent psychologist, thinking perhaps he could give the answer. He replied that it was not a problem for the psychologist to determine, and referred me to the familiar story of the farmer's mule. The farmer purchased this mule upon the representation that it was in first class condition. No sooner had he turned it loose in the pasture than it immediately began to run into trees and knock down fences. He took the former owner to task, claiming that the mule was evidently blind. The reply was that the mule was not blind, but he didn't give a damn.

About 95 percent of the motorists of this country are reasonably careful. The remaining 5 percent, however, represents a large army of more than a million reckless and incompetent drivers flitting about the country without any regard for the safety of themselves or their fellowmen. They include drivers who are deaf, blind, of immature age, enfeebled condition due to old age, those who are intoxicated, and then there are those that are analogous to the farmer's mule.

A Contrast in Qualifications

Contrast the comparative qualifications of the driver of an automobile and the driver of a locomotive. The former, as a rule, needs no qualifications other than his ability to possess a car. He is not only unfamiliar with its operation and mechanism, but is wholly lacking in a knowledge of our laws governing its use on the highways. In many instances his responsibilities are such that he is weakened in his regard for the rights of others, whereas the locomotive engineer has earned his right to a seat in the cab of his engine by virtue of many years of training. He is not only familiar with its mechanism and operation, but also with the rules governing its movement over the road. His responsibilities are

a part of his make-up. He sits in his cab not only with these qualifications but with a steady hand, a clear head, a brain that is nowise affected by anything he may have drunk, and with a keenness. He is so alert that he is, in fact, a part of the locomotive being operated under his guidance.

What is the Remedy?

There is a joint responsibility between the railroads and the public. The railroads have a duty to perform. We must not lessen our efforts toward increased efficiency in the maintenance and protection at highway crossings, and in the manner of train operation as it applies to accidents of this character. Our every act in the discharge of our duties in this regard must carry a sincerity of purpose of such positive character as will convince the public of our real devotion to a most worthy cause.

The immediate remedy lies largely in a constructive campaign of education. We must find some means to curb the reckless motorist, and at the same time make driving safe for the great majority of motorists who are careful.

As a further aid to this plan, the following suggestions are offered:

First, see that advance warning signs are properly maintained.

Second, require school busses and trucks carrying explosives or flammable liquids to stop before passing over railroad tracks at grade, the same as is required of revenue operated motor vehicles.

Third, prevent the building of unnecessary highways crossing railroad tracks.

Fourth, eliminate crossings through the re-routing of highways whenever possible.

Fifth, eliminate obstructions to view on the highway within 500 feet of the crossing.

Sixth, enact uniform and stringent laws in the various states requiring a proper standard of qualifications so that operators of motor vehicles will be required to meet a mental and physical test, including penalties for violations, that have a real effectiveness.

The carrying out of the latter suggestion, alone, would result in a marked decrease not only in crossing accidents, but also in other accidents in which automobiles are involved.

It is our hope that all organizations and agencies, civic, political, and otherwise, that are in any manner concerned in the conservation of life and limb, and whose aid is so essential to the success of this movement, will unite in a common enterprise, and that as a result our cooperation will become more extensive, so much so, it will assume a force of such magnitude and power as will serve to wipe out this needless slaughter of human life.

Friday Morning, September 30, 1927

W. M. COLLADAY, Chairman
Superintendent, Motor Vehicle Department, Des Moines, Iowa

The sixth session was called to order at ten o'clock by the Chairman, W. M. Colladay, Superintendent, Motor Vehicle Department, Des Moines, Iowa.

CHAIRMAN COLLADAY: There has been in session this week, as well as the Safety Council meeting, a meeting of the Mid-West Conference of Motor Vehicle Administrators which consists of different states of the Mid-West. We have been discussing safety matters as well as reciprocal relations between states. These meetings have been held in Chicago for the last two or three years and we have arranged numerous items in regard to reciprocity. We want to go on record with you people as favoring the driver's license. Driver's license we think is about the only way we can rid the road of the undesirables by being in a position to revoke their license. We have in numerous states now a revocation proposition but it is only for driving while intoxicated. If the judges would only recommend it we could go through with it, but in some cases they will not recommend it.

It has been suggested in the legislature that they organize a safety or motor vehicle division with proper enforcement officers, to be operated by a fund; instead of using all the license fees for building highways to use a part for the enforcement of safety after we get the highways constructed.

We have on our program this morning for our speakers men who are leaders in their line of work, a work that is fast becoming a necessity. Our first speaker, Mr. K. W. Mackall, is engineer for the Crouse-Hinds Company of Syracuse, New York, who are one of the leading manufacturers of traffic signals. The subject which was assigned to Mr. Mackall is one with which he is thoroughly familiar, and one in which the general public is vastly interested. Mr. Mackall!

Recent Developments in the Control of Traffic

**K. W. Mackall, Engineer, Crouse-Hinds Company,
Syracuse, N. Y.**

Any discussion on the subject of the control of traffic by electric traffic signals, or by any other means, must be of vital interest to the National Safety Council, since its activities are solely directed toward the elimination of accidents.

It is in this phase of the subject that we are most interested, since it is of the most importance. City authorities may assign other motives for the installation of signals, and yet there is no denying the fact that signals are actually installed today for the very same reason that the traffic squad was created—namely safety. Other results may be, and usually are, accomplished by the installation of a well-designed signal system, but were it not for the prime consideration of safety there would be no signals, nor would there be any traffic squad. It was owing to the desires of the municipalities to protect life and property, that the traffic squad was created—which also sponsored the installation of the modern traffic signal system.

Most of us think the traffic squad was created to handle the automobile problem, but I can assure you that such was not the case, for many cities had traffic officers before the automobile became a factor in our daily lives.

It is quite true that the automobile enhanced the problem and caused the enlargement of existing traffic squads. As the traffic problem became more acute, traffic officers were given mechanical aids, such as whistles and semaphores, but even with these aids, the traffic officer was unable to cope with the problem, because of his limited vision and complete lack of coordination with traffic officers at adjacent intersections.

Let me make this quite clear—I do not mean to imply that the existing traffic officer is inefficient. As far as one particular intersection is concerned, the intelligent traffic officer is far better than the best traffic signal, because the traffic officer can observe traffic conditions within the range of his vision and act accordingly. It is only because he is concerned solely with his own particular intersection that he becomes inefficient in the broad scheme of traffic control. He may clear his own particular intersection most admirably and yet do a very bad job of traffic control since he may send traffic to adjacent intersections which are not ready to handle it.

In the original scheme of things, the traffic officer's job was not only the direction of traffic, but he was also a bureau of information and of great assistance to the aged and infirm and was more or less able to move around and enforce traffic rules. He was really efficient. The dense traffic created by the automobile turned the human traffic officer into a human semaphore—an automaton, with no time to do other than direct—and oftentimes dodge—vehicular traffic. He could not give information, since no one could get to him, and he dared not leave his post in the center of the intersection to assist anyone or even to enforce traffic regulations. He blew his whistle and sometimes the violator stopped—sometimes not.

Reasons For the Installation of Signals

Let me, for a moment, briefly review the reasons why signals are installed and the results to be accomplished. The reasons for the installation of signals are three and they are very simple. They are tabulated below in the order of their relative importance.

1. Safety.
2. More economic utilization of the police force.
3. Expedition of traffic.

Analyze these three reasons carefully and it will be seen how closely they are inter-related. The first—safety—is of the utmost importance and were it not for this consideration of safety to life and property the police force would not be involved at all.

The third—speeding up of traffic—is really the result to be accomplished, if it can be done with safety.

Granted now that the result to be accomplished is the speeding up of vehicular and pedestrian traffic with safety—what is the best means of accomplishing this very desirable result? If it were actually possible to accomplish this result with traffic officers; unaided by other means, such as traffic signals, it would still not be economically possible to control traffic solely by means of traffic officers. We are past the days when a few intersections in the heart of a city's business district constituted the "traffic problem." The problem today is almost the entire city and it will gradually become more and more acute until the point of automobile saturation is reached.

Unfortunately, the city fathers and planners of other generations could not foresee our problem of today and plan our streets accordingly. Only a few cities—such as Salt Lake City, Utah, and Birmingham, Alabama, were laid out with thoroughfares sufficiently broad to handle modern traffic, and even

with their broad streets the use of a traffic signal system materially assists in accomplishing the desired result—expedition of traffic with safety.

The economics of the problem are quite simple and they are convincing. An intersection of signals will cost between \$700 and \$3,000, depending upon the type of signal and the method of installation.

The expense of a policeman for an eight-hour shift, including his salary, his supervision and his maintenance is upward of \$3,000. For some intersections this means \$6,000 per year when an officer is required for two shifts. A safe average for signal cost is \$1,500 per intersection, which means that for the cost of one traffic officer, two intersections of signals may be had. After the first cost of the signals has been paid, there is only the maintenance cost of say \$150 per year. Thus, 20 intersections of signals may be maintained for what it costs to keep one traffic officer.

Please do not misunderstand me. I am not recommending the complete signalization of a city and the elimination of the officer. With human nature what it is, that would be impossible. I am merely pointing out the economics of the thing and showing how a city may economically spend its budget money for greater protection to life and property. Signals at all bad intersections, traffic officers at the worst ones and officers mounted on motorcycles patrolling all others. This will solve the problem economically. No city has sufficient funds available to place traffic officers at all bad intersections.

Systems of Control

The subject of this paper is "Recent Developments in Automatic Control." To the engineer, designing control apparatus, the word "recent" means the thing he hopes will solve the problem while he is looking for something better. That may seem strange, but it is, nevertheless, a fact. The development of control apparatus has been very rapid, during the past two years and will, in all probability, be more rapid during the next two. It is not the purpose of this paper to enter into a description of the mechanical and electrical features of timers, but rather to describe briefly what degree of flexibility may be had. Early timers performed a set traffic cycle without any variation. Then followed a timer capable of performing two set cycles. In order to use them an accurate traffic count had to be made and it had to be predetermined just how many seconds traffic should be permitted to go in each direction. These were followed by timers which could be varied at will both as to total period of the traffic cycle and the split in each direction, keeping the amber of change period constant. This seemed to be all that was needed—and in fact a timer of this nature will meet most problems.

However, a further refinement in timers has been developed during the past year and it is the last word in flexibility, whenever such control is really needed. This latest timer will vary the north-south GO period at will, it will vary the amber period between the north-south and the east-west GO periods at will, it will vary the east-west GO period at will, and it will vary the amber period between the east-west and the north-south GO periods at will. With this new timer any of these four variations may be made independently of the other three, without the use of tools and without shutting down the system. Surely that is all that will ever be required.

The mechanism to accomplish all this is small and pretty reliable. There will be improvements in design—that is to be expected. The same engineer who designed such a mechanism will not be content until it has reached a stage of perfection equivalent to a grandfather's clock.

So much for the timer itself.

Now for a moment let me explain systems of control and their relation to the broad scheme of traffic control.

During the last year or two there have been many improvements in the control apparatus for signals and even more particularly in the methods of control. I shall briefly review these improvements and endeavor to point out when the various systems of control may be applied to advantage and possibly predict the trend of future development. In order to make the matter perfectly clear, let me name the various systems of control now in use together with a description of each. They are:

1. Synchronous control.
2. Progressive or modified progressive control.
3. Coordinated control.

These types of control have very definite meanings, at least to traffic signal engineers, and it is important that each system be thoroughly understood, together with the accomplishments and limitations of each system.

When the Traffic Moves Simultaneously

Synchronous Control means that traffic moves simultaneously on all north and south streets while all east and west traffic stops—followed by the simultaneous movement of all east and west traffic while north and south traffic is stopped. Such a system is accomplished by a very simple timing device, located at a central control point which may be varied as to total period of the traffic cycle and the split in each direction. The outside wiring is very simple and no controls are required at each intersection. Synchronous control may also be accomplished with synchronous motor timers located at each intersection, dispensing with the inter-connecting signal cable. However, with this latter method, it is not possible to vary the total period of the traffic cycle. Such timing devices, when connected to a common A. C. Supply line, will remain in step indefinitely.

Progressive Control is the simplest method of attempting to provide a continuous movement of traffic without the stops that are inherent in synchronous control. An ordinary synchronous system may be changed to progressive control by simply reversing the signal colors at the beginning of each traffic block. This is a straight progressive control system and is open to the objection that the split in time between north-south and east-west timing must be even. The total period may, however, be varied at will. The more up-to-date modified progressive control does away with this limitation and provides the same flexibility as the synchronous control. This may be accomplished by a duplicate set of interconnecting cables, connecting the signals of each alternate traffic block to corresponding cables, or by using a special progressive timing system consisting of a central station timer and sub-controls at each intersection. If no variation in the total period is wanted progressive or modified progressive control may be accomplished with synchronous motor controls at each intersection, dispensing with the inter-connecting cables.

Coordinated Control is the perfection of timing since it gives the utmost in flexibility. So far as I know, it originated here in Chicago and has since been used in several other places. With such a system the total period of the traffic cycle may be varied at will and the split in time between the north-south and the east-west directions may be varied for each and every intersection, if desired. The only limitation being, that the total period of the traffic cycle must be the same for all intersections. Here in Chicago this system of control was accomplished by means of a very elaborate central station timer and separate cables

running from each intersection back to the central control station. This made a rather expensive installation. Since the system was put in traffic control engineers have been working on the problem and have developed new control apparatus which will accomplish the same result with a very simple central station controller and simple sub-controls at each intersection, dispensing with all but a single cable between intersections.

Improvements in control systems are coming not so much in results accomplished but in the methods of accomplishment such as the reduction or total elimination of connecting wires.

The problem before any city is, therefore, the selection of the proper system of control to fit its needs. Off-hand, a city would be sure to select the coordinated system of control, owing to its extreme flexibility. Unfortunately the question of first cost and maintenance expense is a troublesome problem for most cities to face and the selection must only be made after a very careful study of conditions. The speed and density of motor vehicle traffic, the speed and number of street cars, the volume of pedestrian traffic, block lengths, width of streets, boarding platforms for street car patrons, right and left turning vehicles, parking, etc., all affect the selection of a system. All of this must be nicely balanced against initial cost and maintenance—and—against the phase of ever changing volume of traffic throughout the hours of the day—remembering always that the result to be accomplished is speed with safety.

A Real Need For the Traffic Engineer

It may readily be appreciated, then, that there is a real need for each city to employ a traffic engineer, whose sole duty is to study the problem from every angle. It is not a part-time job, nor is it a problem which will be solved for any fair-sized city in a day, a week, or a month. It is a permanent job for an expert.

Let me cite an extreme case where the most elaborate system of coordinated control will not work one bit better than the simplest synchronous system. On a narrow street, carrying one lane of traffic in each direction; where, due to parking, all traffic must follow the back of street cars and stop with the cars. The street car schedule, with its extremely variable periods of loading and unloading, will absolutely govern the speed of all traffic and upset any prearranged attempt at the continuous movement of traffic.

The one cardinal principle necessary for the continuous movement of traffic is the presence of at least one lane of moving traffic in each direction — a lane of traffic not affected by street car stops and not affected by other cars pulling into and out of a parking space. Unless there is such a lane for continuously moving traffic, no elaborate system of control will work.

One of the things most overlooked in traffic control is the number of vehicles in any given block. It is thought by some that the full block is ideal, but such is not the case. Let us assume for a moment a street with 400 foot blocks and cross-street widths of sixty feet from property line to property line, making a running distance of 460 feet per block. During the rush hours, when streets are taxed to capacity, an average speed of 12 miles an hour is good and 15 is the most to be hoped for, though the usual result is much less. To illustrate the point let us take 12 miles per hour as the average. If there are five vehicles in line waiting at each intersection the speed of get-away of these five vehicles will control the running speed of the street. Each standing vehicle takes approximately 15 linear feet of street and takes approximately two seconds to get started. At 12 miles an hour the first car in line will travel the 460 feet in 26 seconds; it will travel 460 feet minus 75 feet (the space consumed by the five

waiting vehicles) in slightly less than 22 seconds, or will before the fifth car in line has started. This applies to synchronous control of traffic.

With a continuous movement of traffic afforded by progressive or coordinated control the street loading is about the same. Vehicles moving continuously in line at 12 miles an hour will string out, each one occupying about 35 linear feet of space. Since, however, with the progressive or coordinated systems each alternate traffic block must be entirely free from running cars to allow for cross traffic, the figure of 35 feet must be doubled, thus allowing 70 linear feet for each vehicle. Seventy feet per vehicle will permit only six cars per block of 400 feet. (Actually there would be 12 cars in every other block). It would, therefore, seem that there is no great advantage for any system so far as effective utilization of street length is concerned. Actually, however, the average speed of cars under a coordinated system will be better than 12 miles an hour, particularly on streets which do not carry street cars, but the street loading of one car for every 70 linear feet is seldom bettered, since at higher speeds, vehicles require more rather than less space.

Uniform Traffic Laws

The crying need of the day is for uniform traffic laws and many states are now at a point of passing state-wide laws to apply to the control of traffic by means of electric traffic signals. The creation of such laws is a laudable ambition which, however, is utterly impossible of accomplishment, except at a sacrifice of individual city efficiency and safety, merely because what is excellent for one city may bring chaos in another, and what may be accomplished on wide streets, cannot be done on a narrow street.

Let us consider only two of the points which are under discussion in the formation of uniform traffic laws. First—when and how should the right turn be made? Second—when and how should the left turn be made? There is enough disagreement about these two points to show the uselessness of endeavoring to create uniform traffic laws. And yet uniform traffic laws are most desirable.

The right turn is made with the green light only or with either the green or the red light. Some cities permit it at any time—even when the amber light is showing. It is quite easy to say that the right turn should be made only when the green light is showing, and yet in some cities, like New York City with a very large number of very short blocks, traffic would soon become completely blocked were this rule enforced at all intersections.

Under ordinary conditions, with reasonable length blocks, it is far safer to permit the right turn only when the green light is showing—safer for pedestrian traffic and safer for vehicular traffic moving at right angles to the turning vehicle. The best law that could be possibly made for the right hand turn would be to permit it only when the green light is showing and only when the turning vehicle is in the lane of traffic nearest the right hand curb. When the physical layout of streets demands that the right turn be permitted on the red light also, that particular intersection should be clearly marked as an exception to the general rule.

The right turn is relatively simple—since there are only three or four ways in which it may be made. The left turn, however, presents a far more difficult problem. During the careful study of traffic, as governed by the three-color traffic signal, I have found 17 different methods of making the left turn. I'll not enumerate them but instead I'll cite a particular street condition which is all too frequently found in our cities and then apply to it the only rule for the left-

turn; and the right turn, too, for that matter; which may be applied. Assume a street which has just sufficient width for one lane of moving traffic in each direction. It may be a 20 foot street without parking or street cars, a 40 foot street with parking but without street cars, or a 60 foot street with parking and a double line of street cars—all provide just sufficient road width for only one line of moving traffic in each direction. On such streets, of necessity the left-turn must be made with the green light. No special signal for the left-turn may be used, for there is no place in which to store the cars temporarily awaiting any special left-turn signal.

With this in mind, the only uniform law which may be applied to the left-turn is to permit it only with the green light and from the lane of traffic nearest the center of the roadway. At that, such a law is reasonably safe, since the driver of a vehicle, approaching an intersection where a green light is displayed, has only one thing to guard against and that is the possible left-turn made across his path from the opposing parallel lane of traffic. And yet in a city like New York City, with its one-way streets, it is not the best nor the safest. New York makes its left-turns when the north and south traffic is stopped and thus all left-turns into and out, of the one-way streets are made without cutting any lane of traffic.

Color Sequence

Perhaps the place where a uniform traffic law is most needed is in the standardization of the sequence of color—the color of the lights to be used and the order in which they are to be displayed. At the present time there are about 20 different color sequences in use, some of which are good and some are bad. There is much debate at the present time over the amber light—whether or not it is necessary or even advisable. This argument immediately divides the signals into two main classes, viz: the three-color signal and the two-color signal. It is not the province of this paper to take sides in this argument, but rather to analyze the claims of both, hoping that the immediate future will settle the point.

Regardless of the number of lights per signal, it is universally agreed that traffic shall move on the green light and stop on the red light. It is only as to the change period that there is any disagreement.

The following Table 1 gives the color sequence in use with three-color traffic signals.

This table lists eight color sequences and when the double bell is used, four more are added to it. All twelve are in use throughout the United States. It will be noted that in all these color sequences the signal to go is the same and the signal to stop is the same. It is only in the change periods that there is any variation. For the purpose of comparison it is possible to eliminate those color sequences employing the bell, leaving only numbers 1, 3, 5, and 7.

Numbers 1 and 3 are the color sequences most generally used. Number 1, involving the display of colors in rotation without overlap was perhaps the original color sequence. It was superseded, in many instances, by number 3, having a complete overlap of the amber with the preceding signal. This change was made for two reasons; first, to prevent stopped vehicles from "beating the amber light" and second, to give immediately an indication of what color is to follow the amber. With this color sequence, traffic stopped by the red light gets the red and amber signals during the change period and is presumably held back by the red light until both these colors disappear and the green light is shown.

Of late, color sequences 5 and 7 are being used. Both are effective and both prevent the "beating of the amber" by stopping traffic, since those vehicles see only the red light during the entire change period. Of these two, number 7 is

COLOR-SEQUENCES WITH TWO-COLOR SIGNALS					
NO	FACES OF SIGNALS	"GO" NORTH-SOUTH "STOP" EAST-WEST	CHANGE	"GO" EAST-WEST "STOP" NORTH-SOUTH	CHANGE
1	North-South East-West	Green Red	Lights Out Lights Out	Red Green	Lights Out Lights Out
2	North-South East-West	Green Red	Bell Bell	Red Green	Bell Bell
3	North-South East-West	Green Red	Red Red	Red Green	Red Red
4	North-South East-West	Green Red	Red Bell Red Bell	Red Green	Red, Bell Red, Bell
5	North-South East-West	Green Red	Green, Red Red	Red Green	Red Green, Red
6	North-South East-West	Green Red	Green, Red, Bell Red	Red Green	Red Green, Red, Bell
7	North-South East-West	Green Red	Green, Red Red, Green	Red Green	Red, Green Green, Red
8	North-South East-West	Green Red	Green, Red, Bell Red, Green, Bell	Red Green	Red, Green, Bell Green, Red, Bell
9	North-South East-West	Green Red	NO INTERVAL	Red Green	NO INTERVAL
NOTE: Four other sequences are obtained by ringing Bell					
only at beginning and end of "Change Period." Crouse Hinds Co. K. W. M.					

COLOR-SEQUENCES WITH THREE-COLOR SIGNALS					
NO	FACES OF SIGNALS	"GO" NORTH-SOUTH "STOP" EAST-WEST	CHANGE	"GO" EAST-WEST "STOP" NORTH-SOUTH	CHANGE
1	North-South East-West	Green Red	Amber Amber	Red Green	Amber Amber
2	North-South East-West	Green Red	Amber, Bell Amber, Bell	Red Green	Amber Bell Amber Bell
3	North-South East-West	Green Red	Green, Amber Red, Amber	Red Green	Red, Amber Green, Amber
4	North-South East-West	Green Red	Green, Amber, Bell Red, Amber, Bell	Red Green	Red, Amber, Bell Green, Amber, Bell
5	North-South East-West	Green Red	Amber Red	Red Green	Red Amber
6	North-South East-West	Green Red	Amber, Bell Red	Red Green	Red Amber, Bell
7	North-South East-West	Green Red	Green, Amber Red	Red Green	Red Green, Amber
8	North-South East-West	Green Red	Green, Amber, Bell Red	Red Green	Red Green, Amber, Bell

NOTE: Four other color-sequences are obtained by ring Bell only at beginning and end of "Change Period"

the one more generally used. Either of these two color sequences give a clear, positive indication for the movement of traffic.

There is a sharp disagreement between those who advocate the three-color signal and those who advocate the two-color signal. Those latter claim the amber light is unnecessary—and in some cases confusing.

The color sequences in use with the two color signal are shown in Table 2. This table shows nine combinations, but four more are added by ringing the bell only at the beginning and the end of the change period.

Here again, the signals to go and stop are the same in all cases and also the same as with the three-color signal. For the purpose of analysis let us eliminate those color sequences involving the bell and consider only numbers 1, 3, 5, 7, and 9.

Of these, number 1 is the simplest to attain, but the "lights out" change period of five or more seconds is apt to be confusing and there is some question as to its meaning and legality. Number 3, having an "all red" change period is much better and yet has one rather serious objection: namely the sharp transition from green to red, displayed to moving traffic. Red is a positive command to stop and should be obeyed. With swiftly moving traffic it is impossible to obey the stop command immediately, since certain vehicles are just about to enter the intersection and could not be brought to a stop short of the cross-walk.

Vehicle drivers may know that the "all red" change interval is to last for five seconds and try to be guided by that, but it is most difficult to judge five seconds correctly and the main objection to this color sequence is that vehicles will be found entering the intersection after the five second change interval is up, since there is no clear indication of the duration of this change period to moving traffic. With color sequence number 5, the green and red lights are overlapped to moving traffic to indicate the duration of the change period, while stop traffic goes sharply from red to green. This color sequence is better than number 7, which indicates the duration of the change period to both moving and stopped traffic, thus giving stopped traffic an opportunity to start before cross traffic has completely stopped.

It would seem, therefore, that color sequence number 5 is by far the best of those obtainable with two-color signals, since it gives a distinctive change period to moving traffic, while holding stopped traffic with the red light. Its principal objection is that the change period involves the use of the two other signals, one of which, the green, is a positive command to go and the other, the red, is a positive command to stop.

Color sequence number 9 shown in this Table 2 has little or no value, since with it the change period is entirely eliminated. It was formerly used, but so far as I know has been abandoned everywhere.

Marking Intersections and Aligning Waiting Cars

I would like to bring one other point to the attention of this meeting and that has to do with the proper pavement markings, particularly at intersections. Paint is a wonderful aid to safeguarding traffic. On streets where there are no street cars, the marking of the center line does wonders to align traffic and keep vehicles on the proper side of the roadway.

Pedestrian cross-walks should be clearly defined with two lines, one in line with the curbing and the other in line with the property line. Cross-walks so marked will be more generally respected by both stopped and moving traffic.

One of the great delays in traffic is due to the incorrect alignment of stopped vehicles at intersections. Streets wide enough for two lanes of traffic in each

direction may be rendered less efficient by bad alignment. If the first car in line straddles the two lanes, the second car must wait behind it. If the first car goes into the proper lane the second car will be right beside it and when traffic starts, both will cross the intersection together. Therefore, to assist in aligning cars, traffic lanes should be indicated by white lines or some other means. If it is not possible to indicate these lanes throughout the entire length of the street, they should be marked far enough behind the pedestrian crosswalk to take care of the number of vehicles usually held by the stop signal.

One more thing may prove very helpful and that is a clear indication of the turning limits. If the center spots of the crosswalk lines, which continue the property lines, are marked with a single or a traffic button, it will materially assist in correctly aligning both left-turn and right-turn vehicles and thus eliminate much confusion at intersections.

Where the National Safety Council Can Help

If the National Safety Council is to fulfill the function which the general public expects it to fulfill, it must add to its already large staff of engineers, at least one competent traffic engineer for each state or regional district. It should be the duty of each such traffic engineer to study traffic conditions in the cities under his jurisdiction and be prepared to assist the local safety councils and city authorities in the solution of the problem. Each city should in turn employ a competent traffic engineer of its own, who should have complete supervision of all phases of traffic within the city, consulting with the police department, the city electrical department, the safety council, the city planning commission, and the engineers of companies making traffic signals and control apparatus. Only by some such procedure as this, can any city intelligently plan a signal system which will meet present conditions and permit extensions to take care of future demands.

It is quite a job to ask your organization to undertake, and yet there is no organization better qualified to undertake the task. You have the machinery—a national organization serving without profit and which is nationally respected. You have been useful and successful in so many other fields of endeavor, that I sincerely hope you will undertake this one. It will be a long, hard battle, for many cities have already installed signals, governing traffic with a multiplicity of conflicting laws. But, if we are to have that very desirable feature—namely, uniform traffic laws, with reasonable exceptions—we must begin immediately to attain it. Only competent engineers will solve the problem. There are already entirely too many amateur traffic experts who can only see one phase of the problem, and that none too clearly.

F. C. LYNCH (Kansas City Safety Council): We have an intersection where the traffic movement is about 12,000 per hour, north, east, south, west. The question is whether a light would work better than a circle.

MR. MACKALL: I don't like to pass an opinion on it until I see the intersection.

MR. LYNCH: What would be your suggestion if you used the light, would you use a center light with the lefthand turn inside the pivot or outside?

MR. K. W. MACKALL: I would use the left hand pivot. They can't be made simultaneous around the pivot.

MR. LYNCH: If there is chance for storing cars in the street, would you recommend a turn on the amber light?

MR. MACKALL: I don't like any movement of traffic on the amber light. If there is any chance to store cars on the street make them turn when the signal turns either ahead of or following cross traffic.

There is one thing I would like to bring out here. Regardless of what signals or what orders you give for the change interval, unless the city authorities or police force make it clearly understood at the outset that that change period must be respected, you are going to have careless drivers beating the amber light or beating the change signal. In some cities they are very lax. In other cities if you attempt to beat the amber light it means a trip to the police court. Until cities let it be known that any violation of that change period means an arrest, you will not get the full advantage of that change period. The change period to my mind, whatever signal is given, is the heart of safety in mechanical or electrical signalling.

F. M. ROSELAND (Newark Safety Council): I would like to ask the speaker how the traffic control lights are used in the pedestrian control.

MR. MACKALL: Any traffic signal system which doesn't take care of the pedestrian is not doing its full duty. Pedestrians are a large part of the traffic problem; I may say here a major part. Pedestrians who get off the curb, stand out in the street a few feet or dodge between vehicles, are not only endangering their own lives but they are endangering property and they are materially slowing up traffic. Some people advocate a very long period to permit pedestrians to walk. The length of the pedestrian period is not of real great importance, because your pedestrians come continuously, they are moving all the time on the sidewalks, they are approaching that intersection and all the while the pedestrian period is on they are going to walk. If the pedestrian period is 10 seconds and some fellow takes the first step off the curb at just the end of that period, he is going to try to complete his journey. The pedestrian period if it were properly observed would mean that no one should step off the curb after the amber light has been shown or the change period.

Walking With the Green Light Is Safe

Pedestrians are reasonably safe walking with the green light, particularly if the laws read that all turns should be made on the green light, because then the pedestrian knows exactly what to expect. He is about as safe under that ruling as any ruling at all. There are elaborate traffic cycles which will give a special signal for both right and left turns, a separate time for pedestrian control, which will absolutely give safety, but any of those is going to slow down your vehicular traffic so that a city will not tolerate them at all.

Perhaps the best pedestrian controlled city I know of is Dallas, Texas. In order to enforce the regulation which was very new, they got the boy scouts with their staffs at each intersection. When the traffic changed they held their sticks out in front of that line of traffic. When the traffic changed again they walked around to the other sidewalk. After a period of about two weeks and several arrests, they put the fear of God enough into these people of Dallas that today when you walk in Dallas you don't see a single person put their foot off the curb. They move only with the green light. If you attempt to step off the curb Mr. Cop will put you back. The boy scout idea was a good one.

The point I would like to make if you are contemplating putting in pedestrian control is at the very beginning let it be known that it is going to be enforced and you will have no trouble. The short traffic cycle will help.

CHAIRMAN COLLADAY: The next speaker, Mr. W. B. Powell, is consulting traffic engineer to the city of Buffalo as well as chairman of the Committee of the American Engineering Council which is studying the subject of signs, signals and pavement markings for the purpose of preparing a national standard. This work is being done under mandate from the Hoover Conference and in cooperation with the National Safety Council and others.

Progress Toward Standardization of Signs

W. B. Powell, American Engineering Council, Buffalo, New York

There is no feature of the traffic problems that has so completely impressed everyone as the tremendous confusion in the traffic signs, signals, and markings that we depend upon to control traffic in the different cities and towns of our widespread country. At the time of the Second National Conference on Street and Highway Safety, which was held about a year ago, this was one of the outstanding points that developed in the discussion. When the Conference set up a series of sub-committees to carry out various functions, made a proposition to the Committee on Metropolitan Traffic Facilities that if they felt that something could be accomplished in that direction, the American Engineering Council, which I had the honor to represent and which is a national body composed of engineering societies throughout the country, would be willing to undertake to carry forward an investigation in that direction, with the hope that eventually we might develop a standard code of practice.

The entire committee and later the entire conference accepted that offer with a considerable degree of enthusiasm, and as a consequence we set about such a research effort. We appointed, as we generally do in such matters, a committee of some leading traffic engineers of the country, and after several months of correspondence and work we developed a sixfold questionnaire, two questionnaires on each one of the three fields. One of these in each case was simply a statement of the facts of existing practices; the other was a statement of the experience that each community had had with the various devices and particularly their reasons either for approving of certain devices or for having abandoned them because of there not being satisfactory. It was our thought that the experience part of the program would be of greater help in developing a code of standard practice than the actual development.

We all know that when we send out questionnaires, nine times out of ten we get very little real value from the returns. We knew before we began that if we wanted to get any real facts of value in this investigation we would have to pursue some extraordinary method of getting those questions answered in a satisfactory manner. Before we sent them out at all we sent to our member engineering societies, and also in cases where there were no existing engineering societies, to the local safety councils or to the local chambers of commerce, or to the local automobile clubs, and we succeeded in each place where we were going to send the questionnaire for answer, in developing a local committee of men, either engineers or those that were related to the traffic problem in such a way that their judgment would be worth having, who assumed the responsibility of seeing to it that those questionnaires were adequately answered. Then we sent them out.

We attempted to canvass altogether about 200 cities, and up to the present time we have had returns from approximately 100 of those cities, and in those we have all of the principal cities in the United States, with one exception. In addition to that, we have cities of varying size, clear down to a few small towns of not more than 10,000 or 15,000 inhabitants. These cities are scattered throughout the country so we have a fair cross section of the traffic practice of the entire country, including all the varying conditions that have to be met in the different places.

That data was secured during the past spring and early summer. We have had some people at work in Washington during the summer compiling the information in large tabulations and getting it into shape so that our committee could get something out of it. Just recently we have reached the stage where we have gotten statistical tabulation done; we have developed certain general conclusions and have undertaken to prepare a tentative report of recommendations.

While we must take into account the fact that a majority of the cities are

doing a particular thing, and have organized it to the best of their ability and their circumstances. we have to take into account in some cases the fact that the development of the art has shown that those particular practices are not the best.

Throughout this whole work we have been attempting to develop a code which would represent the best possible practice, and in doing that in a field that is developing as rapidly as traffic control has developed in the last few years, you have to be very alert to see that you do get the very latest and best scheme in each individual case. We are not yet prepared to present the result of our findings to the public.

There are two or three items of research that we think are deserving of more attention than they have ever received by any community. I have in mind the obvious fact that most communities today are beginning to suffer from oversignalization. I think you will all agree with me that most of our American cities today have too many signals rather than too few, and particularly the smaller cities and the rural communities are oversignalized. I don't mean to say by that that signals have been put at places where there is no need for them at all. But I do mean to say that signals are frequently put in places where the need for them is very occasional, once a week perhaps, or once a day at the most, and that at other times the use of the signal at that particular place is a detriment rather than a help, even for the preservation of safety.

Bad Time Cycles May Be Found In the Country

I frequently come in contact in my state, in the rural communities, with a signal at a country cross road at which during the time cycle there would be no other vehicle in evidence at all but my own. Of course, that is not a good condition to have because the tendency is to encourage the motorist who is impatient to go on with his journey, to violate the signal. Frequently he gets into a state of mind where he exercises his own judgment. I am gratified to say in general at the present time our American motorists are obeying the signals very well indeed. A great mass of them do observe signals even when there is no particular reason why they should. If we continue to install signals we are going to arrive at a time when there will be a very strong public reaction against it. Our committee feels that this is the proper time for a definite research to be made as to what volume of traffic justifies the use of a traffic control signal, and we are hopeful that through some field investigation which we expect to inaugurate almost at once, we can bring forward a recommendation on that point which, if observed, would change the current practice to signal operation only at such time when the traffic volume is sufficient to warrant it. At other times it would go out of service.

That seems the most hopeful way of meeting the problem unless our friends, the signal engineers, will develop a timing device which will operate the signal on small volumes of traffic and large volumes. I know that that involves some very difficult electrical and mechanical problems. I am not particularly hopeful they will get it, although some efforts are being made in that direction. If we can't develop a timing device that will measure the volume of traffic the necessary thing is to arbitrarily cut out the signal at the time when the volume does not justify its use.

That is one of the several problems we have undertaken to get some real scientific data on, so we can make a recommendation that is worth while. The outcome of our work if it is as successful as we hope it will be, will be substantially this: Mr. Hoover last winter recognized not only this confusion as to signs and signals and markings, but also the great confusion in city ordinances, and so he established a committee for the drafting of a model city ordinance to supplement the model state

law which was already well in the course of its advancement toward adoption by the various states of the country. That committee divided up into subcommittees and appointed our American Engineering Council Committee as one of their subcommittees. When we get through with this job our first duty will be to report back to the Hoover Committee such features of our work as have to do with the drafting of a model ordinance. That, I think, will happen some time during the next few months. Then our next move will be this: Having gotten our proposed standard code into what we think to be its best shape, it is our expectation to go to the American Engineering Standards Committee, and to promulgate the code as a code under their jurisdiction. In other words, it will come out under the authority of the American Engineering Standards Committee as well as the American Engineering Council.

The Hoover Uniform Vehicle Code

I have a strong expectation that another conference will be convened next year, at which time this model city ordinance will come up for final adoption. Also, our proposed uniform code of practice will be offered for adoption, and should that prove to be the ultimate result we would then go before the country with this code with the authorization of the Hoover Conference behind it as well as the engineering bodies that have directly sponsored it. It is a pretty tough job to get all of the American cities to adopt the same practice in traffic control when each one of them thinks the method they have developed is the very best, and where in many cases it might involve the sacrifice of a considerable volume of equipment that has cost real money. Nevertheless, we are encouraged to believe, in the light of what has been done by the states so far in the adoption of the Hoover Uniform Vehicle Code, in the course of reasonable time we can expect the cities to gradually change their practice as they have to make renewals or modify their plans one way or the other, and to move in the direction of the Standard Code.

Take the question of signs, for instance. Signs as a general thing are not permanent; they deteriorate quite rapidly; they are frequently spoiled in one way or another. It wouldn't be a very difficult thing if the cities in making renewals should adopt a standard that we propose to find, so all cities within, say a period of five years, would come around to the standard signs. That is equally true as to markings, because markings deteriorate the most rapidly and have to be renewed more often.

When it comes to signals our problem is much more difficult. Nevertheless, even there, while there are a great number of different time cycles in use the variation between them is not so very great. They are all attempting to accomplish the same thing and the method they go about doing it is one of minor detail rather than of principal importance. I am hopeful that even in that field we can get sufficient concessions from one source or another so that as time goes on we can get a practically uniform system of signals. If that can be accomplished in a period of ten years the result will be so tremendously helpful that every driver of a motor car will have had a real service.

E. R. FARRA (Grand Rapids Safety Council): I would like to know if there are any other cities of any considerable size in the country that are making the right-hand turn on the red light, outside of a few in the state of Michigan.

MR. POWELL: I can't answer that question. The secretary of our committee has all of the tabulations of the questionnaire with him and if you will see him after the meeting I am sure he will show you the tabulations and show you just exactly what all the cities are doing. The great mass of opinion among the cities we have canvassed is in favor of going on the green alone. Buffalo used to operate on the red and now is operating entirely on the green, much to our satisfaction and to the

betterment of the safety of our citizens, having less accidents than they have had before.

T. G. BRABSTON (Birmingham Electric Co., Birmingham): In Birmingham the street cars turn right on the red; automobiles do not. As a result, there have been practically no collisions.

MR. POWELL: I can easily see under certain circumstances that a special movement of that kind is the best solution you can get, and in our attempt to draw a standard code of practice we naturally would not attempt to cover any special cases; we would only be able to go so far on a standard intersection under average conditions. Then you have got to apply that as best you can so those very peculiar conditions which are local in their character can each be treated as a separate problem.

CHAIRMAN COLLADAY: The next thing on our program this morning is a debate, the subject being "Should the Speed Limit Be Abolished?" The affirmative is to be handled by Mr. John N. Mackall, Chairman of the State Roads Commission of Maryland, who is one of the best known state officials interested in the highway traffic situation. He is a believer in the abolishment of speed limits on highways and the substitution of a general rule prohibiting reckless and unsafe driving. Mr. Mackall!

Debate—Should The Speed Limits Be Abolished?

The Affirmative Presentation

John N. Mackall, Chairman and Chief Engineer, State Roads Commission of Maryland, Baltimore, Md.

Today marks the greatest progress which has so far been made toward the efficient and satisfactory use of the highways. The very fact that this National Safety Council is willing to have discussed the matter of increased speed, in itself, marks great progress in bringing this about. Those of us who believe that orderly and efficient movement of vehicles over the highway is essential in the development of highway transport, and who believe that this can be brought about only by the abandonment of the present ridiculous speed requirements, have been greatly handicapped because of the fact that whenever even an argument was made in favor of it, the opponents took the position that we were in favor of the killing of more people.

I remember only a couple of years ago, when I attempted to discuss briefly the matter of abolition of minimum speeds before the Hoover Safety Conference, I was not mobbed, simply because no one felt like doing bodily injury. Those at the Conference for the most part, however, did think that it was necessary in the interest of safety to give a pretty good "panning" to any man who would dare to speak of the thing most sacred to them, namely, the maintenance of present speed limits. When I finished talking it seemed that every one in the room wanted to answer me, and those who were permitted to do so pointed to the man who was willing to sacrifice human lives to save a few minutes of time. They entirely missed the point and most of the advocates of the retention of the present speed limits have also missed the point.

A few figures are necessary to show the magnitude of the highway transportation system of the nation. For these, I am indebted to the Bureau of Public Roads and to the National Automobile Chamber of Commerce. I am sure the figures which they furnished me are accurate and serve the purpose and I wish to express my appreciation for their courtesy in furnishing me with them.

The public highway system of the nation, exclusive of city streets, is composed of 3,006,000 miles of road, of which only 521,260 miles have been improved with any kind of surfacing and of these 360,518 miles are gravel, so that we have 160,742 miles of improved roads of macadam or better. The value of the right-of-way and improving of all the highways is in excess of ten billions of dollars. The state highway departments expended \$621,744,210 for the construction of 19,492 miles of road in 1926. The counties, towns and townships brought the total expenditures up to \$1,288,939,707, so that it will be seen that the expenditures for roads aggregated more than one and one-quarter billions of dollars in 1926, which is a very sizable sum of money.

On the other hand, the paving of but less than 20,000 miles of the main roads of the nation shows that great progress is not being made in the construction of the highway system. At this rate, we are just about providing parking space for the new cars. As a matter of fact, the addition to the highway system is slightly in excess of one-half of one per cent of the total mileage of the nation yet to be completed, at which rate it will take 200 years to complete surfacing these highways, but long before this is reached the sums needed for maintenance will equal the total resources available for road construction.

Highways Not Keeping Pace With Automobile Construction

Now, if we turn to the figures of the motor vehicle industry, we find that they are certainly impressive in their size and it is evident that the highways are not keeping pace with the automobiles which are being placed upon them. There were registered in 1926, 19,237,171 passenger cars and 2,764,222 trucks, having a combined value of twenty billions of dollars. We find in the same year that there was produced and sold 3,936,933 pleasure cars having a wholesale value of \$2,730,385,507, and 491,353 motor trucks having a wholesale value of \$433,371,169.

The accessories and tires for these vehicles amounted to another 200 millions. It seems quite evident that the so-called saturation point has not been reached and the problem of moving vehicles over the highways is greater today than ever before and is likely to become greater and greater as the years go on.

The total deposits of all banks and trust companies of the United States for 1926 were \$52,499,960,000. Of these less than eight billions were in the Mutual Savings Banks. The value of automobiles and trucks of 20 billions is two-fifths of the value of all the bank deposits and two and one-half times as great as the savings banks, and is one of the greatest businesses of the country.

In highway transport we have invested, as I have shown, more money in public roads than we have deposited in all of the savings banks of the nation. We have invested in vehicles to run over these roads twice as much money as we have invested in the highway system. We have an automobile in the hands of every 6.1 persons in the United States. We have a business that virtually affects the health, prosperity and happiness of every man, woman and child. Certainly it behooves us to make the maximum use of these facilities. It seems to me quite remarkable that a business of this magnitude should not have the sympathetic regulation which it deserves. It seems to me incredible that those charged with the regulation of this great industry have made no study as to how it can be most effectively, efficiently or safely used. Simply because, in the natural operation of a business of this magnitude, fatalities will occur, distressing personal injuries will occur, is no reason for the arbitrary curtailing of the entire industry. This is exactly what we have permitted to be

brought about by the police officers who are charged with the regulation of this traffic.

In the matter of saving of human lives, I yield to no man. I maintain that you cannot measure human lives in dollars and cents; but I do claim and I think can prove that there is little or no relation between the speed limits which are promulgated and attempted spasmodically to be enforced and these accidents. On the other hand, I think it can be shown quite clearly, and it has been my observation over a large number of years, that the reverse of this is true. I have seen and had reported thousands of accidents. I do not remember one in which speed was a factor when some other form of reckless driving did not contribute. On the other hand, I have had reported hundreds of accidents when reckless driving was the important factor and when the element of speed did not enter into it.

Before we get too far into the discussion of speed limit, let us see, first, what the speed limit is; second, why it was enacted into the laws of every state, city and town; third, what effect it has had on the safety of persons using the highways; and, fourth, why it should be so religiously guarded.

Speed Limits the Idea of the Police Official

In the first place, the speed limits were originated and are now in fact an arbitrary statement of what some police official believes to be a safe speed. It was arbitrarily arrived at to represent the police mind's belief that a slower speed than had been theretofore used was desirable. No attempt was ever made to prove that a speed of 15 miles an hour in the built-up parts of cities and towns and of 20 miles an hour in the outlying sections and of 25 to 35 miles an hour in the open country were in fact safe speeds, were speeds at which fewer accidents were likely to happen than at higher speeds.

I am not finding a great deal of fault with the original enactment of the maximum allowable speeds. When they were enacted, the automobile was to some a source of pleasure—to most a source of nuisance. It played no part in the industrial, commercial or social lives of any community. If it were slowed up, it made no particular difference to any one. It caused no congestion and did not cause one vehicle to interfere with another. I am, however, finding fault with the fact that we have permitted without change these speed limits to be the guiding factor in the motor vehicle regulation, while we have developed the automobile from a nuisance to a necessity; while we have developed it from an instrument in the hands of a few to an instrument in the hands of virtually everybody; when the slowing up of one vehicle means the slowing up of a long line of vehicles, and when this is likely to produce congestion resulting in serious inconvenience and menace. The effect of this regulation has been to slow up the traffic until it is an admitted major governmental problem in every city and town in the United States. It has slowed up traffic until in addition to causing congestion in the cities and towns, it is causing congestion and unsafety on all of the main highways of the nation. If this is a fair statement of the cause and the effect of speed limit regulation, I think we are safe in saying that a change is needed.

If the change is so urgently needed, you naturally ask, why is it not made? The answer is as simple as the question itself. It is not made because there are two groups of people who want to retain them. First, the policemen; and by policemen I mean the entire police authorities of the nation from the commissioners in the big cities and of the state police force to the one-man police force of the little town. They are demanding its retention because it gives them a yard-stick by which they can be assured of convictions from arrests.

Second, it is retained because of numerous individuals and groups of the American public, who have become alarmed at the increase in number of fatal and serious accidents upon the highways and who are demanding some relief without any knowledge of how this relief may be obtained.

At the last Hoover Safety Conference in Washington it was stated that in street and highway accidents for the preceding year, 23,300 persons had been killed and 600,000 had suffered serious personal injuries; that the actual money loss from these accidents aggregated 600 millions of dollars, and that the economic loss due to inadequate use of the highway runs into the gigantic sum of two billions of dollars.

It is my belief that the Hoover Safety Conference has done a tremendous amount of good in focusing public attention upon the enormity of the street and highway accident problem. It, with the National Safety Council, has done all that has been done to bring about safety upon the highways. This is a rather broad statement, but I think a true one. It is, and it is intended to be, a criticism of the police authorities for their lack of vision and lack of intelligent handling of the highway transport matter and of the very closely allied subject of street and highway safety. It is a fair statement that until the Safety Council and the Hoover Conference began advocating a study of the causes of accidents no police organization had made any attempt to determine the causes, and it is further a fair statement that no police organization is very effectively or efficiently doing this today. We have thousands upon thousands of persons engaged in the regulation of one of the biggest industries in the country, none of which have given any intelligent thought as to the cause of the accidents—none of which have ever made a study to determine the causes of the accidents—yet are attempting day in and day out to apply a remedy. Obviously, the remedies are going to be highly, if not totally, unsatisfactory, because they are attempting to remedy something the cause of which they have not the slightest idea.

Observance of Speed Regulations a Dead Letter

I said a moment ago that the police used the maximum speed solely for the purpose of obtaining arrests and convictions. I think this is a fair statement, because it is my observation throughout many parts of the United States that no attempt is in fact made to require the public to travel at the prescribed maximum speeds. On the contrary, I believe that no man or woman ever operated an automobile in a city for a consecutive period of 30 minutes without many times violating the prescribed speed laws. I believe further that no experienced operator ever operated a car, save for the time a policeman was actually looking at him, at any given speed because it was the prescribed one. He operated his car at a speed which he believes to be safe, irrespective of the prescribed speed. If the police believed in the speed limits which they insist upon placing on the statute books, then they should believe in their enforcement for the safety of the public. The police even do not regard the speed limits seriously, except at the time that they want to make an arrest and be assured of conviction.

You might, obviously, ask why, if no person obeys the speed limits, I should favor their abolition. I think the fact that nobody obeys them may in itself be sufficient cause for their abandonment, but I think the effect is tremendously more far-reaching than this. The police mind is in education, training, temperament and tradition, a mind which runs on a single track. The mind of the traffic policeman seems to have a well defined groove in which it runs. He believes that all traffic should be made subservient to his will, but he is in no wise a servant of the people—that traffic shall be operated according to his

judgment and not according to any rules of safety or of satisfaction. It has never occurred to him that after he has performed his first duty, which is the interest of safety, that the second and perhaps equally important duty is expediting the movement of traffic at a given point. It has never occurred to him that it is not his duty to compel traffic to obey his arbitrary rules, but that he is placed there in order that flexibility rules may be given solely in the interest of the traveling public. Many times I have seen a traffic policeman stop a vehicle going in one direction when there was no traffic visible in the opposite direction, simply to show that he had the authority to do this. The whole frame of mind of these police seems to be that they are in complete control and that the more arbitrarily they render this control, the more satisfactory will be their services to their superiors. That they are acting in the interests of traffic to expedite traffic never has, and as the police forces are constituted, never will occur to them.

Arrest Too Often Is For a Minor Infraction

I have seen policemen, and I am sure many of you have seen policemen, overlook the most glaring cases of reckless driving upon the highways, but make arrests for some minor infraction of the arbitrary speed law, when no question of safety to himself or others had been raised. I make the statement as my belief (because there is no way to prove it) that not one arrest is made in each one thousand cases of reckless driving which come to the direct attention of the police unless there is an accident involved, or in other words, that reckless driving, unless an accident results therefrom, is never a matter in which the police show any interest, or is ever brought to the attention of the offenders, and this despite the fact that this reckless driving causes most of the accidents.

I favor the abolition of the speed limit because in doing so we will remove the groove in which the police mind runs. We will make it necessary for him to go out and look for the real menace to street and highway safety—reckless driving. There is no difficulty in making arrests or in securing convictions for exceeding the speed limit, because practically all motorists do exceed them many times a day. It may be, and I think is, far more difficult for the policeman to convict a man of reckless driving. However, if a speed of five miles an hour in excess of that allowed by law is not dangerous, and reckless driving, as such, is dangerous, isn't it essential that we concentrate the police mind on this question of reckless driving? Simply because it is more difficult to obtain convictions is no reason for abandoning this regulation.

If we assume, and I think we should for the sake of argument, that the maximum speeds were prescribed because they had something to do with safety on the highways, we must immediately be confronted with the fact that the same safe speed cannot be prescribed for all types and makes of vehicles. If we assume that 15 miles an hour in the built-up parts of cities and towns and 20 miles an hour in the outlying sections was a reasonable limit only five years ago, we are forced to the conclusion that it is an unreasonable one for many cars today. Take any standard make and model of automobile; it is much safer at any given speed today than it was five years ago; two wheel brakes have given away to four wheel brakes; small tires with small braking resistance to the road have given way to large tires with large braking resistance; high center of gravity, likely to overturn, has given way to low center of gravity. Many of the standard cars today can stop quicker, operate better at 30 miles an hour than the same make and model could have at 15 miles an hour only five years ago. The cars of one make are much easier to stop than cars of

another make, but the same make of cars of different types have different degrees of safety at different speeds, and, indeed, the same car in the hands of a more efficient or less efficient operator become more or less safe. It seems quite obvious, then, that we cannot prescribe maximum speed limit unless we prescribe it for the poorest type of car in the poorest mechanical condition in the hands of the poorest operator. Does anyone believe that the American public is going to operate their improved motor cars at the speed thought necessary only for the oldest and almost obsolete type of car in the poorest mechanical condition? As a matter of fact, it is a fair presumption that the speed limit was adopted as a guide to the distance at which an automobile will be able to stop. It has been suggested that, in lieu of minimum speeds, we require all automobiles to have the ability to stop within a definite limit. This seems to me to be a step in the direct direction. The ability of cars to stop depends upon their design and on their condition. The condition of the brakes is a tremendous factor in the safety of the automobile, and yet I know of no place in the country where police-controlled brake-inspection stations are established and maintained or where the police and the owners make any effort to find out whether or not their brakes operate efficiently.

Unfortunately, the vast majority of the public, who have made no great study of street and highway safety, have taken the police judgment for their judgment. It is but natural that they should. Few of them realize that the police have made no study and have not determined at all the causes of street and highway accidents.

The Greater Question Involves Safety

The operator of the motor vehicle has unconsciously or subconsciously developed to the point where he thinks as does the policeman. Because the policeman, in attempt to make arrests, only looks for the man violating the speed law, so does the motorist try to protect himself from what he considers most unreasonable arrest and conviction for these violations. In concentrating his efforts on protecting himself from arrest for speeding, he does, in fact, lose sight of the greater questions involving safety. Both of them, in concentrating their efforts on the question of speed, have done a great deal to divert attention from the question of reckless driving, and the motorist's mind has come to follow the groove of the police mind. If the only thing we could do by the abolition of this speed is to abolish the groove in which the police mind runs, it, in itself, would more than justify what anyone would consider the loss from the abolition of the maximum speeds.

A fair sample of how the public takes its cue from the police mind, regardless of how warped or wrong it may be, is shown by an address which Mr. John Hertz, of Chicago, made before the last Hoover Safety Conference. I am sure I need not tell you that Mr. Hertz is one of the great business men of America today. He has built up a great industry, dealing in motor transport, and he has at the same time overlooked no opportunity to help in matters of safety. He is one of the outstanding figures of America, who stands always by safety first, yet his misconception seems to go very far because he has taken the continuous cry of the police as a fact instead of thinking for himself. In speaking at the Safety Conference, he said in part as follows:

"The mad, unrestrained rush to get some place is only a delusion on the part of the driver and is the cause of most accidents. We recently proved that. In our city we made a test of the time it took to travel from the South Shore Country Club to the Congress Hotel—a distance of about eight miles—first at 20 miles an hour and then at 35 miles an hour. With

such precautions as were absolutely *necessary* for safety, the difference in time was only four minutes, as I recall. But the difference between 20 miles an hour and 35 miles an hour, *with respect to safety*, on a crowded boulevard, is past calculation."

In the same address he said:

"I spoke a moment ago of simplifying traffic regulations for the motorist. It was our privilege, in Chicago, to contribute the system of stop signals in use on Michigan Boulevard, for the reason that we thought it would be a good thing for the public and a good thing for the Yellow Cab Company and Yellow Drive It Yourself Company, in which we are interested. We had no idea how good this would prove to be. We learned, however, quite by chance from the superintendent of a large hospital that the accidents caused by motors and brought to the hospital for first aid, *had decreased 65 per cent* since the installation of the synchronized traffic lights on the boulevard. I confess to a thrill of great satisfaction in thinking about the number of accidents prevented, and the actual number of lives saved through this system. And I will be candid by telling you that it has saved us a lot of money."

Properly Regulated Traffic Is the Solution

What Mr. Hertz said he was going to prove was that the mad, unrestrained rush to get some place was the cause of most of the accidents. What he was going to show was that the difference between 20 miles an hour and 35 miles an hour with respect to safety on a crowded boulevard was past calculation.

Now, just what does Mr. Hertz prove? Not this at all! What he proves is that the *regulated* traffic may move a great deal faster than unregulated traffic and with a great deal more safety. What he proved was that by simultaneously effecting regulations and by increasing the speed on the boulevard from 20 miles an hour to 35 miles an hour (and I think, in many cases, 45 miles an hour) he decreased the number of accidents 65 per cent. I am sure Mr. Hertz does not mean to argue that traffic on the boulevard actually moved at anything like 20 miles an hour. If he did mean to say that, we all know that it does move from 35 to 45 miles an hour, but with orderly regulation we eliminate a tremendous number of accidents and save a tremendous number of lives. No motorists think that the regulations on the Chicago boulevard are unreasonable and they are accepted as solely in the interest of safety. Parked vehicles are eliminated from the travel way. Right-of-way is always maintained on the boulevard over other streets. Right and left turns are made from proper lanes and at proper times and high speeds are not only permitted but demanded, and by doing so we make them safer than before by 65 per cent.

Whether we want to or not, I think it is necessary to recognize the fact that the American public is not going to go slow. Indeed, it seems to me that we have gotten to the point where human life is the cheapest commodity of the world. Just remember that only a month ago nine persons, one of them a girl, set out from California to gamble their lives against a few dollars and the plaudits of a few people that they could hit a speck in the Pacific Ocean, 2,600 miles away. Five of the nine lost the gamble and disappeared and within a few days their names disappeared from the press. A week later, a fine, courageous fellow set out to fly to South America. I am told that his only equipment for the flight was a good fast aeroplane. He did not even have a map and of course he disappeared somewhere en route. Who in the room knows this brave fellow's name at this time? Only a week later three people set out from New York City to fly to Rome. For some reason they flew a few hundred

miles out and actually made no more ripple in our daily lives than they made in the Atlantic Ocean when their plane dropped.

I do not mean to illustrate from this that we are to go on taking toll of human life. I think we should not, and I think every preventable automobile accident should be prevented, but I do mean to illustrate that when we try to prevent accidents by making vehicles move at a speed which the vast majority of people believe is unreasonable, we are bound to have a failure from this; and failure from this, we have demonstrated, means failure from many other things which make for highway safety.

If the police would enforce the present maximum speed, if the public would be required to operate their motor cars at the present maximum speed at all times, there would be sufficient sentiment within one week to demand a change in these laws, because the public for the most part does not know of their existence, except in a most indirect way. Because the public knows that they were enacted for some other motorist and not for them, they have accepted them because they have disregarded them. In the disregarding of this law, they are very lavishly bringing up a disregard for all other motor vehicle laws, some of which are essential for safety upon the highways. This in itself, I think, is sufficient reason for their abandonment.

Present Right-Of-Way Rules May Be Absolute

The greatest single menace to the operation of motor cars is not a violation of the law, but compliance with them. I refer to the present obsolete right-of-way rule. I strongly urge the immediate abandonment of the present right-of-way requirements and substitute for them the boulevard system of rights of way. The main lanes of traffic in the country and in the city should be operated so as to make the maximum use of them consistent with safety. This cannot be done with the present right-of-way law, and it can be done with the boulevard system of right of way. I think it is wholly unreasonable to expect a man operating a car in the open county or in the city to always give the right of way to vehicles coming in from the right. In the country there are many cases where a driver has no way of knowing that there is a road approaching from the right. The boulevard system of right of way becomes a success only with adequate marking on all intersecting roads, advising vehicles that they must come to a full stop and with suitable control at the intersection of boulevards. It has been my observation that many more accidents are caused from failure to give right of way than from any other one thing in connection with motor vehicle operation.

Now, in conclusion, I would like to say that some way must be found to eliminate the drunken driver. All of our regulations, all of our laws; all of our cautions come to nothing with the man under the influence of liquor at the wheel of an automobile. Since everybody wants him eliminated, I will not take time to discuss the havoc he can bring to traffic. Suffice it to say that he must be eliminated.

There are really only a few rules necessary to greatly reduce the number of accidents occurring on the highways. Speed is not one of these. If the driver of an automobile felt that the road ahead of him was and would remain reasonably clear of obstructions, the fear of greater speed on his part would be greatly reduced. If he was sure that there would be no parked vehicles in the line of traffic, if he was sure that no vehicle would come out from an obscure side road at high speed, simply because it had the right of way, and if he were assured that the driver in front of him would only make a right or left hand turn from a right or left hand lane, he would not be afraid to drive at a reason-

able rate of speed, and he could do so with the maximum of safety. If we will do just these things and forget about speed, if we will remove the groove in which the police mind runs, and with it the motoring mind, we will immediately greatly reduce the number of accidents. We should certainly reduce them as greatly as they have been reduced on the boulevards of Chicago.

When we are reducing the number of accidents, we will be greatly increasing the use of these highways. It is essential that both of these things be done to prevent the breakdown of the highway transportation system of the nation. It is necessary that some change be made and made quickly, and the outstanding need seems to be the elimination of the ridiculous speed limits provided at the present time.

CHAIRMAN COLLADAY: The negative of the debate this morning will be taken up by Mr. Walter J. Mattison, Assistant City Attorney of Milwaukee, who is a firm believer in the fact that there should be a speed limit.

Should The Speed Limit Be Abolished?

The Negative Presentation

Walter J. Mattison, Assistant City Attorney of Milwaukee, Milwaukee, Wis.

I have been a driver on the roads of the United States, going from coast to coast. I have for the last ten years driven on the highways of Maryland and I don't blame my good friend, my opponent, for desiring to abolish the speed laws when you have roads such as they have in Maryland.

I don't quite agree with his view of the members of the police department and their methods of enforcing laws. As a newspaper man and as a lawyer in private practice, as a prosecuting attorney and as a man who has been very close to the police department for the last 20 years, I would like to say that in my opinion his conception of what the police officer is today is erroneous.

We have just finished a course of instruction in Milwaukee. We had a safe drivers' school and I wish I could take all my time telling you about it. All of our traffic officers attended that school. We had as many as 2,200 people present at a single session and we had an enrollment of 1,400 who attended five out of six lectures. In addition to that, we had a woman driver's school, and they inform me that the average attendance in which they actually discussed safety methods, was 1,100 for four sessions. The police department of the city of Milwaukee cooperated in every way, furnishing lecturers—think of it!—for the safe drivers' school, telling people how to drive along the roads in a safe and sane way.

I happened to be driving on one of our roads the other day and a police officer stopped an automobilist. I came up to him, I knew him, and listened in. The officer said, "You were going 40 miles an hour, and in view of the fact that the road is wet that wasn't a safe speed, but," he said, "there is one thing in your favor, you slacked up at street intersections. In other words," he said, "you are not a reckless driver, but you are a bad example on the road, because some of the other drivers on the road who are not capable of exercising the same judgment you are exercising, may take you as an example and create a hazard on the road."

Wasn't that a splendid way of handling what might be a difficult case? It shows that the police officer was there for the purpose of instructing the motorist and not there for the purpose of making arrests or arbitrarily making arrests. We in Wisconsin like to point out the fact that we get through Zion City to the north of us here, without even getting arrested. There is another example of law enforcement which is the kind of law enforcement that our friend from Maryland spoke about. If you go through Zion City and cities like that you are going to be arrested if you

exceed even by one mile the prescribed rate of speed. We have one of our best safety workers in Milwaukee right here in the room today, who went from the 20-mile an hour zone to the 15-mile an hour zone, coasted into it, and he didn't go more than four car lengths, when a police officer arrested him and went into court and testified that he was going 16-miles an hour in a 15-mile zone. That is the other extreme.

One city in Wisconsin got a brilliant idea. They had heard about all the antagonism that law enforcement had aroused in the hearts of those who toured the country. They conceived the idea of discharging their motorcycle policemen and selling their motorcycles. They did it and sat back to await the good will of the motoring public. Signs were placed on the entrance to the city saying, "This is a city of good will. Automobilists use your discretion," and what happened? Last month they bought a new motorcycle and hired a new motorcycle policeman. It is a fine thing to say that automobilists use judgment when they are using the roads, but the experience of Kewasum, Wisconsin, is that either an automobilist is incapable of exercising any discretion, or he is a careless driver and deliberately refuses to exercise any discretion.

I will admit that as an individual my sympathies are wholly with the side which is taken by our good friend from Maryland. It would be wonderful when I go up to my shack in Northern Wisconsin just 302 miles away from my house in Milwaukee, which now takes me 11 hours, when I comply with the laws, if I could put my car into 60 miles an hour when she purrs beautifully and go up there in Northern Wisconsin and make that trip in five or six hours. But I may be a safe driver, you may be a safe driver, I may be able to exercise an honest discretion—at least I kid myself into the belief that I can exercise my own discretion in observing traffic conditions—but how many automobile drivers on the road today do you think are capable of exercising real, honest judgment as to what constitutes a safe rate of speed under any given condition?

A Very Nice Young Lady in Milwaukee

I know a very nice young lady in Milwaukee, one of these dear girls who drive an automobile to the despair of the traffic officers. She drives across the lanes of traffic and when the police officer calls to her she thinks she is a good scout, she wants to be a good fellow, and she thinks the police officer is flirting with her and she waves back in the most friendly manner. Every police officer in Milwaukee happens to know this particular girl, because they have all had experience with her. They tell a story about her, but I don't think it is true, because I read it in a magazine before. They tell this story: One of the motorcycle policemen got her over to the curb, stopped her and bawled her out in the vernacular. She listened and said, 'Mr. Police Officer, I am very glad you stopped to talk to me. I have always wanted to know you. I have a luncheon engagement, so I have to go right away. Now that you have met me, every time you pass me I wish you would wave your hand at me, especially when I have friends in the car, because I want my friends to know that I am friendly with you.'

This police officer said she started up and went right ahead and he stood there absolutely dumbfounded; he didn't know what to do, so he didn't do anything.

I am wondering what this dear girl would say if we abolished speed limits in Wisconsin, and some police officer should stop her and tell her she was driving beyond the point of safety? I would be very much interested in her answer. I would also be interested in hearing the answer of a young man who drives a Ford delivery truck, these little business trucks that shoot in from nowhere and shoot out regardless of what the traffic conditions are. I would like to know what the reactions would be of the average moron that is behind the wheel, a person whose judgment is warped by the fact that his mental age is far below his real age.

I have some statistics in my pocket to prove what I am about to say. I read that

the average mental age of the American people is 14 years. That means there are a lot of people over 14 years of age mentally, but there are just as many people under 14 years mentally. Now a 14-year-old boy or girl may be unusually bright, and may be capable of exercising a discretion while sitting behind a great, big powerful machine called an automobile, which is capable of making many miles an hour. But would you vest the discretion in a boy of 14 years to drive an automobile just as fast as he thinks he ought to on the road, judging for himself whether it is a dangerous rate of speed or not?

I recall a very scientific gentleman, who has a reputation in this country. He came up to visit our health commissioner and after discussing a proposition in the most sane way you ever heard, told the commissioner about his new automobile which is capable of making 70 miles an hour.

"What are you going to do with an automobile going 70 miles an hour?" said the commissioner.

"I get into the center of the street and drive right along."

"But that's dangerous driving, isn't it? What are you going to do if somebody comes out from the side streets?"

"It don't make a bit of difference; they have got to get out of my way."

That man isn't insane enough to be in an insane asylum, but he is driving an automobile. You find a lot of people driving automobiles who shouldn't drive automobiles. If every man driving an automobile were capable of exercising perfect judgment, then I would say, "Abolish all speed laws and let the man exercise his judgment in driving an automobile." But men and women, too, are not all perfect when it comes to exercising judgment.

Are Automobilists Capable of Honest Judgment?

If every automobilist was capable of exercising an honest discretion, an honest judgment, many of those driving automobiles today would be off the road, because they would know themselves, their judgment would tell them that they were not safe on the road. This dear girl I was telling you about who thinks that traffic officers are mere decorations at street intersections, would stay off. The chronic window-shopper driver would park her car rather than shop as she drives along. A chronic gossip, before looking around to see how those in the rear seat take her story, would also park. The slow driver who is out for an airing would keep away from the main highways, and you could go along until everybody was off that highway with the exception of my good friend, my opponent, and myself, and then I might be scared stiff to think he might run into me.

Everybody who talks ought to be able to give you some concrete remedy, and I am going to try to force upon you an idea I have had in my mind for a good many years. In the first place, I want to say that this proposal, while ideal from the standpoint of all of us who like to drive our cars just as fast as we can (and I am no exception to all the rest), is unworkable because of the fact that all automobilists are not capable of exercising the right kind of discretion. That presents the most difficult feature—the actual enforcement of that law. You are substituting reckless driving for a definite limitation. Your police officer comes up, he is all alone in his motorcycle. He has to make out a case of reckless driving, and you know and I know that it is very difficult to make out a case of reckless driving; you have got to be able to testify when you get into court on the number of automobiles, the number of people, the relative position, the signals that were given, and many, many other things all coming under the general heading of carelessness, and that police officer is going to get up there, as a rule, all alone, and is going to testify that this man, in his opinion, under the circumstances, was guilty of reckless driving.

In the automobile there were three or four passengers. In their judgment their

driver was driving that car safely, taking into consideration all the other facts regarding the condition of the road. There is a preponderance of evidence right there against this man and it is going to be utterly impossible for a police officer to make an arrest, even though he is honestly of the opinion that the automobilist was guilty of reckless driving. It may very well be that that police officer, being a human being, is incapable of exercising a judicial discretion and it may be that he is wrong; that is very true. But, when a police officer takes a case into court and he loses it, he is immediately faced with a suit for false arrest and malicious prosecution. You probably read in the papers within the last couple of days of the case in Cleveland where a police officer arrested a couple who were spooning in the park. When they came into court it developed that they were man and wife and the case was dismissed. Yet that police officer now has a judgment against him of \$3,000. How many of us, how many of you rather, could afford to take a chance of having somebody get a \$3,000 judgment against you? I know very few police officers who can take the chance. Yet, you expect a police officer to go out and take care of that road, patrol that road, keep conditions safe, when he knows if he doesn't prove up his case he is liable to be arrested on a civil warrant, he is liable to have a judgment against him of \$3,000, \$4,000, \$5,000, or \$6,000, which is more than he earns in three or four years. He is not going to make an arrest, and the result will be you are going to have traffic conditions worse than they are today.

The Prima Facie Evidence of Reckless Driving

Then take the poor fellow who is in the road and who is actually injured. Probably his leg is gone, his arm is gone, some family has been deprived of its father or mother, the loss is great. In addition to proving all these facts I told you about which come in and constitute reckless driving, he is faced with the necessity of showing that the reckless act contributed and was the proximate cause of the injury, and right then and there you will face the situation where the fellow will be minus an arm or leg, his earning capacity cut way down, and yet he has no recourse because he can't prove up his case.

My remedy for the situation is this: You have talked about the Hoover Uniform Law. It has good rules. For instance, it says, "Twenty miles an hour in the business district where traffic is controlled, 15 miles an hour where it is not controlled." Then they have 20 miles an hour in the residential districts and 35 miles an hour under all other circumstances.

Now it may be that 20 miles an hour in some residential districts might be too slow; it might be that 40 miles an hour under some circumstances might be too slow. Our experience has taught us that sometimes 10 miles an hour is reckless driving. But if you adopt a law that establishes a definite limitation on speed, and then make speed in excess of that limitation prima facie evidence of reckless driving, then instead of forcing the police officer to prove up his case you place upon the man who is actually speeding the burden of proving that his rate of speed in excess of the legal limit was not under the circumstances reckless driving.

If you pass a law in that way you are going to get all the benefits which I can see can be obtained under your scheme, and at the same time, you are placing the burden on the driver who elects to go faster than the legal rate of speed; you are placing the burden upon him of proving that the speed in excess of the legal rate was not reckless driving. I believe in that way you can solve the question of traffic in our cities and in the country.

CHAIRMAN COLLADAY: Is there any discussion on the subject before we allow Mr. Mackall five minutes to respond?

MR. POWELL: I want to call your attention to one instance where a speed limit

has been removed successfully. During the spring of this year I happened to have quite a long trip abroad. When I was in Spain, driving out of Madrid, I observed the man driving my car had a peculiar method. He would drive like the very devil until he met another car and then he would slow down. Then he would step on it again until he met another car. I inquired into the reason why he was driving in that peculiar way. First, I asked him if there was a speed limit.

"No, there is no speed limit, we had so many accidents the Dictator took off the speed limit."

"Why do you slow down so much when you meet another car?"

"Well, if we have an accident both drivers go to jail for 72 hours incommunicado, on bread and water. Then they fish them out and determine which one is responsible for the accident, put him back and let the other fellow go."

MR. MACKALL: Mr. Chairman, I believe Mr. Mattison has made a much better argument for the elimination of the speed limit than I am capable of making; certainly, he made a very much better one than I made.

I'd like to take a minute to speak about his girl friend. I think Mr. Mattison put his finger on just what I am talking about in the policeman. There was a girl who drove recklessly, dodged corners and what not, for which not a word was said by the police of Milwaukee. I think there are many people like that. Also, if I believed what Mr. Mattison believes with reference to the mind of the operator, I would take the same position he does. I believe that the boy on the Ford delivery wagon drives today without any regard to the speed limit, and he would drive exactly as he does if all the speed limits were reduced. Indeed, I think it might be a good thing to abolish boys from delivery wagons, but I don't know how we are going to do that.

I hope what I said will not be construed as a condemnation of all of the humane acts of the police. I believe the police have administered first-aid treatment to save a human life not only in Milwaukee, but everywhere. However, I am talking about the policeman when it comes to regulation of traffic, he has to be taught that there is one dangerous thing, to-wit: Driving in excess of the legally prescribed rate of speed. There is your difficulty. That policeman other than in the regulation of traffic is a perfectly normal and sane man, but when it comes to enforcing the law he is not there.

We don't have to go to Spain to prove we can drive carefully, safely, and effectively without a speed limit. You need only go to the state of Connecticut. They have abolished the speed limit, and I assure you in my experience I have never seen better driving anywhere than in the state of Connecticut. I have never seen worse driving than we have in the state of Maryland, where we have definite, well-defined speed limits which nobody obeys. I do wish Mr. Mattison would take a minute or two to give some of the reasons why he believes that the speed is the controlling thing. Mr. Hertz's argument is by regulating the traffic on the boulevards of Chicago and going two and one-half times as fast as the prescribed limit we are able to eliminate accidents by 65 per cent. The answer to me is perfectly simple. If you will drive safely you will not have an accident.

I want to say in conclusion just what Mr. Mattison said: if you will make people drive safely you will not have accidents, and the way to make them drive safely is to concentrate their attention and the policemen's attention to the things which make for unsafety; to concentrate their attention and the public's attention to the things that cause accidents, and not have them and the policemen looking for the arbitrary speed limit which somebody has established and which nobody obeys.

ADJOURNMENT

*SIXTEENTH ANNUAL SAFETY CONGRESS
NATIONAL SAFETY COUNCIL*

Home Safety Session

Monday, September 26, 1927

MRS. WALTER H. BUHLIG, Chairman
President, Illinois Council of Parent-Teacher Associations,
Chicago, Ill.

The session of the Home Safety Section of the Sixteenth Annual Safety Congress was called to order at two-ten o'clock by the chairman, Mrs. Walter H. Buhlig, president of the Illinois Council of Parent-Teacher Association, Chicago, Illinois.

CHAIRMAN BUHLIG: When it comes to home safety, The Parent-Teacher Association is one that should and could promote home safety. We are not a woman's club, because we are sure that the word "parents" means dads as well as mothers, and we do have many men members of our organization.

Many of our policies and the direction of much of our work comes from the national organization, and Dr. A. B. Meredith is chairman of Safety for our national body. Then in Illinois we have a State Chairman of Safety, Mrs. Julius Floto, of Oak Park. We are hoping to have the associations throughout the state take part in the survey that is being promoted by the National Safety Council. Through the Parent-Teacher Associations and their meetings much information can be disseminated concerning home accidents, concerning the training of children to protect themselves on the street, on the playground, wherever they may be; and then there is the more positive side of getting the parents really interested in the recreational lives of their children in order that life may be saved by teaching them how to do things.

I am very pleased to introduce to you Mr. Joel D. Hunter, who is the general superintendent of the United Charities of Chicago, who will talk on what accidents mean to social agencies.

What Accidents Mean to the United Charities

Joel D. Hunter, General Superintendent, United Charities of Chicago,
Chicago, Ill.

Prevention is a word which is often used when social workers are gathered together. That same word is probably in much more common use in the select circles of the National Safety Council. However, it has not yet been possible to prevent all the evils in the world; some still exist. From these, many different forms of distress arise. It is a matter of vital concern to know whether or not the social, economic, health and other problems arising from existing evils are being adequately and properly met.

It is the purpose of this brief paper to give the record of the United Charities of Chicago on accidents other than industrial for the six months between January first and July first, 1927, and then to discuss this record from the standpoint of prevention and adequate relief. Most of the material which has been obtained for this paper was gathered by Professor Scott E. W. Bedford, research secretary of the United Charities.

Some weeks ago Mr. Sidney Williams requested that a paper be prepared on "What Accidents Mean to Social Agencies" or some similar subject. After consideration it seemed best to limit the discussion to the records of the one social organization with which the speaker is connected. A questionnaire was sent to the superintendents of the ten different districts of the United Charities asking them for information showing first, the amount of money spent in accident cases during the six months above mentioned. They were asked to state the amount of money spent on industrial accidents and the amount spent on non-industrial accidents. Second, they were requested to send in case stories showing unusual features in home accidents. The answers to this questionnaire were intensely interesting.

I think it is safe to say that the general public has no idea concerning the number of home accidents, how difficult it is to prevent them, how little guarantee there is of adequate medical service and how great the economic strain and mental turmoil that come to the families in which the accidents occur. From January 1 to July 1 the districts of the United Charities reported 217 families in which an accident was the main problem in the family. Of these 82 were industrial accidents and 135 of them were non-industrial.

Hazards Lie In Most Child Activities

So far as the industrial accidents are concerned it is only necessary to say that these came to the United Charities mainly for two reasons: First, for temporary relief pending the settlement of their claim for compensation; second, because compensation had been denied. In these 82 families \$2,707.89 was spent for relief. There were 135 other accidents. In these families \$8,012.98 was spent for relief. It is difficult to make absolute classification of these accidents, however, it was possible to classify some of them:

- 29 were accidents in the home.
- 9 were on the street.
- 28 were auto accidents.
- 12 were related to recreation.
- 5 were directly due to alcoholism.
- 2 were in school.

No one will dispute the desire of social workers and that of the National Safety Council to prevent such accidents. The difficulties arising in doing it seem almost insurmountable. The following brief stories show something of the variety of the things recorded and the amount of work needed in order to prevent even a part of them:

1. Albert fell from a railroad elevation while flying a kite. He was in the South Chicago Hospital for six days.
2. Walter fell while playing and injured his knee. Osteolysis developed and this child is still under medical care.
3. John lost an eye by being hit with a snowball.
4. Andrew cut his finger to the bone while cutting bread. His finger became infected and had to be amputated.

This last story hints that proper medical attention is not always given when injuries are obtained in home accidents. While there is no absolute guarantee of proper care when an employee is injured while at work, yet one can be reasonably sure that such care will be given. One can also be reasonably sure that in many,

many cases it would not be given when a child or adult is injured at home or while at play.

Another example of this is shown in the story of Amy, who was 11 years old and burned her fingers quite seriously while at home. Her mother treated the burns with home remedies, but they became infected. This child was later provided with proper medical care and the wounds were healed.

In endeavoring to prevent accidents such as this the family case workers of the United Charities, as they go into these homes, are constantly advising the parents and children concerning safety at home and at play. The Coroner of Cook County at one time carried on quite an extended campaign to prevent accidents in the home. One thing which he suggested to mothers was that when they were washing always to put cold water into the tub first and then the boiling water. If his suggestions were carried out in all cases such accidents as that which happened to Tommy, two years old, would not have occurred. Tommy was left alone in the kitchen while his aunt went into an adjoining room. He fell with his arms into a tub of scalding water. This child's burns were treated at the Children's Memorial Hospital and there was a thorough and complete recovery, but the accident never should have happened. There is no doubt that a thorough study needs to be made of all accidents occurring in the community other than industrial and that a continuous battle to prevent them needs to be waged. Every individual in the community ought to be interested in furthering the program to reduce the number of accidents which occur on the streets and in the playgrounds and homes in the community.

The Family Problem in Non-Industrial Accidents

What are the problems which arise in the families in which non-industrial accidents occur? How are they met?

First—*Provide medical attention.*

Whether or not this is received depends entirely upon members of the family. The public has no organized way in which it shows interest in this particular type of accident. Another example of the sort of treatment that is sometimes obtained is as follows:

Mrs. Bartholomew fell down the cellar steps on January 22, 1927, and broke her leg. She had a man living near-by fix it for her. This man was not a doctor. Mrs. Bartholomew now walks with quite a limp.

Second—*How is the economic loss made up?*

It goes without saying that in many of the families in which general accidents occur they are using their entire income. Any reduction in the family income means that credit must be obtained or that outside relief must be sought. Whether or not this relief is given depends upon the efficiency and the financial ability of the organizations in the community which give relief. That considerable amount of relief is needed in some cases is shown by the fact that the United Charities gave \$741.00 in six months to one family in which there was an accident and \$721.00 to another family. The total amount given in 135 families was \$8,012.98, an average of \$59.35 per family.

This is not an ideal situation. I presume that there are family welfare societies in most of the large cities of the country and that reasonably adequate relief is given in all families that suffer economically because of a general accident when those families get in touch with the workers of the family welfare societies. However, there must be many that pass unnoticed.

I do not know what can be done except the extension of accident insurance. Probably the best way to extend this is through group insurance. The United Charities is now making an extensive study of group insurance covering life, disability and retirement. I do not know what we are going to do when the study is completed. If we take out group insurance covering all the employees of the United Charities, if any one of them suffers from an accident, no matter what the accident may be,

that individual will receive certain benefits from the insurance company. This seems to me a more practical way of spreading the type of insurance that covers accidents than through individuals taking out separate policies. Professor Bedford has been making this study for a number of months. The information which he obtains will be published somewhere when his research is completed.

There are also some things in the figures which were obtained by the United Charities which ought to make us all hopeful about the future. In the 135 accident cases covered none of them was from asphyxiation by gas stoves nor were there any by electricity. It is true that many of the families with whom the United Charities deals do not have gas stoves and very little if any electrical equipment, yet both are present in a certain number of families. The fact that no accident was recorded from either gas or electricity shows that the danger of those is universally recognized and that many protective devices have been adopted in the manufacture of gas and electrical equipment.

The statistics gathered in the United Charities for six months show that six per cent of the relief given in that period went into families who came to the United Charities because of some accident other than industrial. The records show that certain types of accidents have been prevented and that some of the others need not have happened. It is also clear that there is room for much more preventive work in which every citizen of the community should be interested. It is evident that whatever steps are taken in carrying on a preventive campaign should also include the information showing the necessity for immediate and proper medical attention for every person suffering from any sort of accident. Cases can be quoted showing permanent partial disability because of inadequate medical care. Whether or not the family is in economic need because of accident, adequate relief depends largely upon the support which is given to the family welfare agency in the particular community. To improve that situation it is my impression that accident insurance should be extended and that the quickest and best way to develop that insurance is through group policies.

Developing a Community Program for Home Safety

Dr. Bernice Neuberger, President, Cleveland Federation of Women's Clubs

In developing a community program for home safety, public service groups of men and women become interdependent. There is not much difference between the reaction that comes through organization of women's groups and those in which there are men members. The success of organization, on a community basis, depends upon the guiding sense of the leader, who must be one who knows your city and whom your city knows.

In reviewing the history of The Cleveland Federation of Women's Clubs, the records showed a "Safety Campaign" written into its history, which occurred in 1913 and the memory of which will today raise a smile. It was the successful effort to shorten the length of women's hat pins. Whether the immediate incentive was the scratch of some club woman's cheek, or a similar disfigurement of the husband, is not recorded; however, through the commendable efforts of the Federation of Women's Clubs resulted the passage of a city ordinance that limited the length of hat pins, forbidding their extension beyond the hat. Cleveland newspapers gave columns of front page to the subject. The first woman's safety campaign was successful and far reaching. A special correspondent in Berlin even found it important to cable that the action of the Cleveland women had found a grateful echo in the German metropolis. where similar legislation had, as a result, been promoted. Rather amusing

today, nevertheless it was a successful endeavor proving woman's desire for safety reform.

A woman's greatest occupation will always be her home, and it is a vast and notable one. The character of the home many times depends upon the woman in that home; lack of interest leads to disintegration. The community cannot become better than the citizens who compose it, better homes are good investments for any city, therefore, efforts made by women to make the home safer will help materially in creating a safer atmosphere in the community.

The great need of a community program for home safety in Cleveland is indicated by the accurate statistical information secured from the Police Department. During the year 1926 in Cleveland there were 611 persons killed; 237 traffic accident fatalities, 174 industrial workers killed and about 190 home accident fatalities. Falls, burns, scalds, asphyxiation, suffocations, poisons, fire, explosions account for 96 percent of all home accident fatalities, and for a large proportion of the injuries. The most tragic fact about accidents in the home is that so many victims are children. Science tells us death should be the final chapter of the book of life, not an early one. The mother should be the "Safety Engineer" of the home and acquaint herself with the principles of accident prevention in her place of employment and thereby be prepared to teach her children safety precautions at an early age.

The Age of Reason

This is the age of reason. Whatever other criticism may be brought against this era it must be given credit for its commonsense and practical way in which it faces the problems of life. A careful analysis of the facts showed that there are almost as many fatal accidents in the home as on the streets or in our industrial establishments and convinced the Cleveland Safety Council that attention should be given to home accident prevention, just as men in industries, after careful study of ways to reduce the number of accidents in their establishments, decided upon the logical procedure of founding schools for safety instruction for their employees, because employers know that accidents to their men will mean an economic loss to their establishments. That being the case, is it not equally important that we should realize that accidents in the home mean weeks of suffering, total disability or death, in addition to an economic loss to the community? Accordingly, safety instruction should be given the home manager, for no longer should we be excused by saying, "It was an accident." Accidents are careless acts and the home manager should be held responsible. If the home is worth fighting for, it is worth working for.

In conducting a permanent educational campaign for home safety in a community, we must deal largely with women who in their groups gladly give knowledge to those who need it badly. Much careful thought was devoted to the development of a program for Home Safety in Cleveland when the Home Safety Division was organized one year ago; for it is of the utmost importance that every affiliated organization of this large body of women should lend its support in service to make for efficiency. To be assured loyal support those asked to serve as officers of the Home Safety Division were heads of influential organizations; thereby through the representative corps of officers more than 500 organizations gave their assistance in the biggest cooperative movement ever undertaken by women of our city, an organization of 60,000.

The actively participating organizations were as follows: The Cleveland Federation of Women's Clubs with 154 clubs. The Parent-Teachers Association—100 organizations. The Citizens Bureau, having contact with at least

250 foreign groups, which are essential in view of the fact that there are so many avoidable deaths caused by home accidents in foreign sections of the city. The Federated Churches, the Catholic Societies, the Jewish Councils, Welfare Agencies, Social settlement houses, visiting nurses, and many individual members assisted generously. This substantial method of organization found the Home Safety Division of the Cleveland Safety Council soundly established. Preliminary plans were outlined for the year.

Enumerating the important features of this community program: (1) Home Safety committees appointed in clubs. (2) The Cleveland Safety Council issued a series of six monthly bulletins on home safety instruction which were mailed to the 500 presidents of the affiliated clubs. (3) The bulletins were read by the chairmen of the Home Safety Committees at their club meetings, open discussions followed and records were kept. (4) Five radio messages were broadcast on home accident prevention. (5) Enthusiastic quarterly meetings were held at which addresses were given on preventable accidents in the home. (6) A Speaker's Bureau was formed in our Home Safety group. (7) Publicity was given to the cause, not an individual; newspapers will always give publicity to a cause which helps better conditions for the entire community. (8) A city survey was made to determine sections of the city where home accidents were most prevalent. (9) Accurate statistics were secured each month and these data were studied to properly gauge our efforts.

Community Program for Home Safety

I will dwell for an instant upon the character of our community program for Home Safety. Each month the safety council bulletins on home safety instruction were read and discussed by heads of the women's committee at the meetings of their clubs. A most favorable reaction was noted. Time does not permit a lengthy description nor detailed account of these bulletins, but on the cover page was a significant pen sketch, a self explanatory safety appeal, and it was thought that these bulletins communicated to the 60,000 women of greater Cleveland, members of this safety movement, an abundance of useful facts, with concrete illustrations presented in a very comprehensive manner, which aided materially to make the home secure. The lessons ranged from the social aspects of home accident prevention to the subject of home engineering and the necessary safety equipment; however, knowing that accidents would still occur, the final bulletin was "First Aid" of a non-professional nature. The instructors on our public playgrounds last summer used the First Aid Bulletin.

Five home safety messages were broadcast over radio station WTAM during the year; which meant that for the first time in Cleveland's history the measures of accident prevention in the home were broadcast on a big scale, reaching the homes of the rich and the poor, the cultured and the uncultured in the city and the country districts as well.

A very important activity of the Home Safety Committee was the arrangement of the quarterly home safety luncheon meetings to which cooperating organizations were asked to send delegates. Attractive programs were arranged and addresses on home accident prevention were given by prominent speakers to the 750 delegates from Clubs. Based upon experience, heads of organizations must be kept vitally interested and genuinely enthusiastic in order to carry out a successful program for home safety. These meetings did much to rouse the interest of the public to greater care of its homes. The association of the home and the school is one of the strongest factors for good in any community, this being the opinion of the superintendent of the Public Schools, in giving his support in the successful promotion of these meetings. A committee of 75 teachers, representing the Cleveland School

of Education, and principals of schools attended these meetings to secure information on various phases of the home accident prevention problem, for these women are teaching the youth of today, upon whom rests the future of our country.

The speaker's program included Mrs. James N. Downey, of Detroit, Dr. Gabriel Tucker, of Philadelphia, Charles E. Hill, of New York City, and officers of our local safety council. Mrs. Downey gave her appreciative audience many safety engineering aids in the home, urging the women to work faithfully for safety in the home, saying that women must bear the burden when accidents occur. After having heard the illustrated lecture on "Preventable Accidents to Children," by Dr. Gabriel Tucker, of the Chevalier Jackson Bronchoscopic Clinic of Philadelphia, many young mothers were so impressed that they thought it would be a miracle if their children managed to grow up. Charles E. Hill, vice-president of the National Safety Council, gave a splendid address on "Preventable Accidents in the Home" at the spring luncheon of the committee. Mr. Hill said that "of the total number of accidents last year a large percentage occurred in the home. This would be a distressing situation were there no cure, but there is a cure and the responsibility rests with the women's organizations, the schools and churches. Cleveland has made a good record in this direction," he added.

A speaker's bureau was formed within the Home Safety Division and speakers were supplied clubs upon request. We learned that men were interested in home safety, inasmuch as men's organizations asked for speakers. Men know that women alone cannot solve the problems of modern life in the home; this must come through civic agencies of both men and women.

Home Safety Work in Cleveland

A survey was made by the Cleveland Safety Council to determine the most important causes of home accidents in the order of their frequency, the sections of the city having the highest percentage of accidents, classes of homes, and also a study of the most effective methods of prevention. The foreign sections have a large proportion of accidents in the home. The effectual measure used to give out home safety knowledge was the Citizens Bureau which has contact with all of the foreign groups and publications in the city. Mindful that frequent safety warnings would not go unheeded in the classes of homes in which accidents occur, due to the carelessness of the mother, home safety instruction was given in the classes teaching the art of good housekeeping at the social settlement houses.

We are justly proud of the good we have accomplished, since the statistical report of the Health Commissioner proves that the Educational Campaign for home safety conducted in Cleveland has had effective results, there being an encouraging reduction in home accident fatalities the first half of 1927 as compared with the first half of the previous year.

Women have shown that they are willing to assume their responsibilities and have demonstrated their sterling qualities of service in doing their share of work in civic housekeeping, and hence developing a successful program for home safety in Cleveland.

E. R. FARRA (Manager, Grand Rapids Safety Council, Grand Rapids, Mich.): I should like to ask if the result of the survey showed that most of the accidents, especially fatal accidents, were in the poor homes, or did you find a reasonable percentage happening in the middle class or better class of homes?

DR. NEUBERGER: As I have stated, we thought a great number occurred in foreign sections. However, none of us are excused.

E. R. FARRA: We can get cooperation from any city department or we can

get cooperation from the organized women's clubs. The problem as I see it is how to get the unorganized women.

DR. NEUBERGER: You will get them through the social settlement houses in your classes teaching the art of good housekeeping. We have a number of them in Cleveland. The Citizens' Bureau has contact with all of the foreign papers and you will reach them through the foreign papers and through the social settlement house.

CHAIRMAN BUHLIG: Many of the Parent-Teacher Associations reach the type of home that the women's club doesn't.

MRS. JAMES N. DOWNEY (Detroit Police Department, Detroit, Mich.): We are reaching the foreign groups through the International Institute, the educational branch of the Y. W. C. A. We are giving a lesson in English to these foreign groups. Then for those who have not yet learned the English language, we have a pamphlet that has been printed in 12 foreign languages, and we reach the people in that way. Another way we are going to reach all the groups is through the Parent-Teachers Associations.

What Is The Home Accident Problem?

R. L. Forney, Statistician, National Safety Council, Chicago, Ill.

A problem, according to the dictionary, is a question for discussion and settlement; a matter of uncertainty requiring further light to determine the truth, especially when difficult or uncertain of solution. If uncertainty and difficulty of solution be the prime elements of a problem, the home accident problem is one in the truest sense of the word.

In view of the fact that we must know what a problem is before trying to solve it, I have been given the job of telling you what the home accident problem is. I interpret this assignment to mean that I should say something about why there is a problem, what causes the problem, the extent of the problem, and what individuals are involved in it; but, fortunately for me, I am not obligated to give you a solution. That task is left to others on our program.

If the problem of home accidents were mentioned to the proverbial visitor from Mars he would, undoubtedly, have a lot of questions to ask and we should have to reply by saying, "Yes, accidents do occur in our homes. In spite of the fact that we have in our homes no coal mines, no steel foundries, no large bodies of water, no streets full of rushing automobiles, no airplanes, and no machinery worthy of the name, yet we do have a lot of accidents there." He would probably be surprised to hear about these accidents but would answer us by saying that although some accidents may occur in homes, yet these are fortunately very few in number. And at that point we would have to get down to brass tacks and tell him that, according to the best information we have, more people are killed and injured every year in homes than by automobiles or in industry. We should have to tell him that the workman who is injured in his home is just as thoroughly and completely injured as though he had been hurt at the rolling mill; and, furthermore, that the same sort of an economic loss results when the housewife falls off the rocking chair and breaks an arm as when her husband suffers a similar injury at the plant. We should have to tell him that the pain and suffering resulting from home accidents is not any different from that resulting from automobile accidents, and that the dollars paid for hospital bills and those lost by being unable to work are just as good dollars when the injuries occur at home as when they occur some place else.

What, then, are the facts about home accidents? Or, in other words, what is the home accident problem? We know from records of the United States Census Bureau that there were, in 1925 about 90,000 deaths in the United States resulting from accidents. We know furthermore, that the figure for 1926 will be very nearly

the same. Some of these accidents occur in industry, some in public places and the remainder in homes. Most of you know that although the United States Census Bureau receives a record of all deaths from almost 90 per cent of the population of the United States, the reports of these accidental deaths are not classified in accordance with the three-fold classification which I have just mentioned. We believe, however, that from an accident prevention viewpoint, it is essential that we know the approximate number of deaths occurring in each of these three places—in home, in industry and in public. With that end in view, the National Safety Council, in cooperation with police and health departments and local safety councils, obtains information on accidents that are so classified. Certain insurance companies have also analyzed reports in this way. A careful study has been made by the National Safety Council staff, utilizing all available information, to determine the number of fatal accidents occurring in homes each year. In past years estimates of home fatalities have ranged from seventeen to nineteen or twenty thousand. We have studied these estimates, the new reports received by us for 1926, and other sources of information, have taken account of the valuable information contained in the reports of the United States Census Bureau, have also taken into account the probable number of public and industrial fatalities, and have come to the conclusion that all previous estimates of the number of home accidents have been too low. We believe after studying the available information, that there were not less than 24,000 fatalities as a result of home accidents in 1926. Our experience further indicates that there are about 200 non-fatal injuries for every fatal injury in the home so that there were probably four to five million such non-fatal injuries in 1926.

Classifying the Home Accident

In considering the home accident, two types of homes are involved—rural homes and city homes. This distinction is necessary because in studying the accident situation on farms we must decide what are really home accidents and what may be considered industrial accidents, in the sense that they occur during the course of employment. In other words, we must as further study of the subject proceeds, set a dividing line where, on the farm, industry stops and home begins. If the housewife is injured while tending a vegetable patch near the home, is the accident an industrial accident or a home accident? Should there be any distinction between an accident that occurs while the farmer is hitching up his horses to go to the fields, and when he is hitching them up to the carriage to drive to town? Such distinctions will have to be made as we go farther into a study of home accidents.

The figure of 24,000 which we have estimated for 1926 includes only those accidents on the farm which may be called home accidents in the sense that they are accidents that also occur in and about the home of the city dweller. I wish to emphasize, however, that this is something which should receive attention as more and better statistics of home accidents are compiled.

It is difficult, if not impossible, to estimate the amount of economic loss involved in these 24,000 deaths and 4,000,000 to 5,000,000 home injuries. We believe that there are as many fatalities and more non-fatal injuries in homes than in industry. The economic loss involved in industrial accidents has been estimated at more than one billion dollars. While the actual economic loss involved in home accidents is probably not as high as this, it seems almost certain that it is at least half as much or at least one-half billion dollars. From an economic point of view, therefore, the home accident problem is also a real problem.

What we want to do is to prevent the occurrence of these fatalities and other injuries, and thereby cut down the economic loss and the human suffering involved in them. But we can't get very far in the matter of prevention on this narrow

advanced age. We now see that the situation is just the reverse for burns and scalds, where there is such a heavy fatality rate among small children. Here again it is the obligation of mothers and others in the home to maintain careful watch of these small children. Many of these accidents are scalds, in which the child falls into a tub of hot water placed on the floor, or pulls over on his head a pan or basin of hot water left sitting too near the edge of the table or stove. Children are also burned to death as a result of playing with matches or firecrackers, or as a result of catching clothing on fire from gas stoves or other flames. The latter type of burn is also responsible for many deaths of adults in the home.

Suffocation is another important cause of death among children. Again using the figures of the United States Census Bureau, we find that about 950 children under five years of age meet death by suffocation every year. This number does not include gas asphyxiation. These 950 deaths are in children who swallow objects, who strangle on food, etc. Here again we have an obligation to keep the child from getting hurt. We can be quite sure that most of these deaths of children so young occur in the home.

Asphyxiation still remains an important cause of home fatalities. Perhaps we are learning to be more careful with gas stoves, but if so we are becoming more careless with our automobiles, with the result that the toll from carbon monoxide poisonings is increasing. In the city of Cleveland, during a fourteen month period, out of 35 home deaths, charged to poisoning of all kinds, 22 were of carbon monoxide gas. Most of these were the result of running automobiles in closed garages. This is one of the things which should receive particular emphasis in the next few months when the cold weather will cause the car owner to shut garage doors that should remain open.

Poisonings Take Heavy Death Toll of Children

Other poisonings than gas poisonings are also important. Let us look again at the figures for children under five years of age. I am using this age group because in it we can be quite sure that a large percentage of all deaths do occur in homes. Figures of the Census Bureau show that a thousand children under five years are killed each year by poisoning. The things responsible are poison food, poisonous animals, and of even greater importance, various poisonous chemicals kept around the house for medicinal or cleaning purposes. From a study of all the facts available we believe that deaths by poisoning constitute somewhat less than one-tenth of all accidental home deaths.

There are, of course, other causes of home fatalities which deserve mention. Among these are fire-arms, electricity, and drowning. These are things which have great inherent hazards and those responsible for home safety should be on guard against them.

I have already said that we do not know so much about non-fatal home injuries. The difficulty is that in most cases no one knows anything about the accident except the family itself and the attending physician, if there is one. In industry it is a different matter. In nearly all cases the employer is required to pay compensation to the employee who is injured and in general it is to his benefit to obtain reports of accidents. Through insurance companies and state governments we are enabled to get this information about the way in which industrial accidents occur. In the case of public accidents the accident occurs in a public place, and in many cities and states someone involved in the accident is required to report it to a city or state authority, or the police department is able to obtain a record of it. Here again these reports are available for our information and can be used in analyzing the causes of these kinds of accidents and in taking measures to prevent them.

In home accidents the situation is very much different. In fact I know of no plan whereby even approximately complete reports of non-fatal home injuries have been obtained in any locality. Our estimate, therefore, of the total number of such

injuries occurring in the United States must necessarily be a very rough one. The Travelers' Insurance Company has recently made available some very valuable information concerning home injuries on which claims were paid by the company. In this experience, for the year 1926, the ratio of fatal to non-fatal accidents is about two hundred to one. The non-fatal accidents show an average disability of seventeen days, so we can say that in general they were serious accidents. It seems conservative, therefore, to say that there were probably four million non-fatal home injuries in the United States last year.

We have been discussing the causes of fatal home injuries. When non-fatal injuries are included there is at least one other important cause which should be added, namely cuts and scratches. These accidents are extremely numerous about the home and cause much disability and of course much pain and suffering. These cuts and scratches are ordinarily minor in character, however, unless the wound is not properly treated an infection sets in.

What Is the Home Accident Problem?

I have already stated that it is extremely important to differentiate between the experience of cities and country sections in studying any kind of accidents. The National Safety Council, in various surveys, has obtained certain information about home accidents in cities. I have made a study of ten cities on which we had information and have found in some cities that home fatalities run as high as 47 per cent of all fatalities. In seven out of these ten cities more than 25 per cent of all accidental deaths occurred as the result of home accidents. In one or two cases the percentage runs as low as 19 per cent. I am pointing out these facts regarding cities simply to indicate that the problem in any individual city relative to home accidents may be much greater than for the country as a whole. In a city, for example, like Providence, Rhode Island, where during the last four and one-half years 46 per cent of all accidental deaths were in the home it seems that no further indication is needed as to where the very greatest accident prevention efforts should be made.

These observations that I have been making are leading up to what I would call the keynote of my talk, and that is that we are still pretty much in the dark as to exactly what the home accident problem is. To a great extent I have been unable to answer the question—What is the home accident problem? What I want to say, however, is that in my opinion there are still two phases of it. Our ultimate objective, of course, is to solve the problem, i.e. to keep the accidents from occurring. It is my contention, however, that this cannot be intelligently nor completely done until we have more facts. These facts must be about non-fatal injuries as well as fatalities. As I see it, the first thing to do is to get those facts. Furthermore that is your problem. There are agencies in your community whereby this information can be obtained, and will be obtained just as soon as the people there who are interested in safety realize the importance of it.

A Heavy Death and Injury Total

My conclusion is that the home accident problem is one of preventing 24,000 fatal accidents and over 4,000,000 non-fatal accidents annually. Its solution means saving the lives of possibly 7,000 or 8,000 children every year—our school children with their future ahead of them. It also means saving the lives of that many older people—the lives of our fathers and mothers who have passed the prime of life. And finally it is a problem that requires a great amount of further study regarding causes and circumstances so that this prevention work can be carried on more intelligently and therefore more effectively.

MRS. L. CASS BROWN (LaGrange, Ill.): I should like to ask the speaker if he considers the melodramatic way in which accidents are put in the papers, a help to this sort of work. We deplore it many times, but would you consider it a help?

MR. FORNEY: We can say on one hand that any method may be worth while to get the matter to the attention of the public. It may be worth while to put it in a melodramatic way if it will start people to thinking. For preventive purposes, I can easily see where a thing of that kind might be a detriment. It might call attention to something that occurred in a particular case which would divert attention from the more important causes and the things which should really be driven at by the person who is doing the educating. For example, as I have said, and as Mr. Hunter also said, electricity is not an outstanding important cause of home fatalities or of home accidents. We frequently see reports of fatalities in the home due to electricity. Electricity is something that has great inherent hazards, if you will allow me to use that term, but the falls or burns which do not seem inherently so dangerous are the things which need stressing in the home accident prevention program.

Parents Should Realize Home Accidents Are Avoidable

MRS. HARVEY C. JOHNSON (Alcott Parent-Teacher Association, Chicago): Don't you think that the reason you still have so many home accidents is because people don't think that home accidents are avoidable? The average parent thinks that an accident in the home is something that couldn't be helped. If one member of the family were run over by an automobile, it could be avoided. If a child fell from a chair, it was unavoidable. Don't you think your education has not been far-reaching enough to the home maker? There are mothers who are interested to see that their children are safe and to do the right things in their homes. They are not ignorant, they are not foreign mothers, but they are busy mothers and mothers at home that can't get out to meetings. It isn't every mother that can go to the meetings and learn these things. Don't you think there ought to be a drive to get into the home regardless of education and money and whether foreign speaking or Americans?

MR. FORNEY: I certainly do. One difficulty is this idea, that a man's home is his castle, and it is pretty hard to find out what goes on within the doors of a man's home. We still are very much in the dark about the way in which home accidents occur. We are beginning to find out pretty definitely that automobiles are dangerous, and we started finding out some time ago that punch presses and various other machines used in industry are dangerous, and consequently we are beginning to be careful of them. I think the reason home accidents continue to occur is because we have not made people realize that these things in the home are dangerous. We haven't made them realize that falls do cause accidents. We haven't made them realize that burns and scalds do cause deaths.

MRS. JULIUS FLORO (Illinois Council of P. T. A., Oak Park, Ill.): These survey forms were prepared by the National Safety Council for the use of the Parent-Teacher Associations in the United States.

I, as chairman for Illinois, am anxious to send out these surveys to every Parent-Teacher Association in Illinois, and we hope that we will get 100 per cent results. I feel that after these surveys go in a great deal of information will be obtained on how our home accidents are caused.

CHAIRMAN BUHLIG: Is there anything further before we go to the next speaker? If not, I am very glad to introduce to you Mrs. Bertha Winter Mahoney, Director, Home and School Safety, Erie Safety Council, Erie, Pennsylvania, who will talk on *As the Homekeeper Sees It*.

As The Home Keeper Sees It

Mrs. Bertha Winter Mahoney, Director, Home and School Safety, Erie Safety Council, Erie, Pa.

I am one of these professional women. I shall say I was one of the professional women who left the ranks of the teachers and entered into the unprofessional ranks of housekeepers. As soon as I became a housekeeper, I was overwhelmed by the innumerable things I was supposed to do perfectly well, and by instinct. I had no education for it. I had had a little training by imitation in my professional age, but I had no education as a housekeeper. Those were in the days, I shan't tell my age, when we didn't educate housewives for their duties.

Men and women today have realized that industrial accidents, as has been told you before, are always blamed on the employer. He is responsible for his employees, consequently we instituted a plan of safety education in industry, very detailed, very definite. Then we had traffic difficulties. The number of people increase, and differences in education made it necessary that we have traffic education. The best way to have that was to put it into the schools. We are doing that. We have very detailed systems of education in our schools and I am so glad, because those children coming up are going to be equipped for the thing that I wasn't.

I am an unskilled laborer. You have them in your shops, but they are not that way long. I am learning by the trial and error plan. Do you know what that is? If I try a certain thing one way and it works, all right, I do it again, but if it doesn't work, I try some other way. I try, make mistakes, and profit thereby. Don't you? Isn't that the only way you learn, you housekeepers? We weren't educated and still all this big home accident problem is put at our doors. It is at our doors, but are we responsible? Is it our fault? No, ladies, it isn't. I am going to defend you. I am a very staunch defender of my sex and I am going to talk to the heads of households (laughter), the men. I want you to be the head of the household, not only nominally, but actually. As a head of a household you are directly responsible for the accidents that occur in that household, aren't you? Not the housewife. You heads of households, have you done your level best to educate your home keeper? As an employer in your shop would say that you had functioned right if you hadn't told every one of the foremen under your control how to do the job safely? And still do you carry into your homes those lessons?

Let's take an inventory of our homes. Start right up at the attic and come down. How many hazards do you have in your home? All you men who are here this week talking on safety in the shops, safety on the streets and everywhere else, think about your homes. Have you eliminated all the hazards in your own household for your home keeper, or do you have a home keeper perhaps who is now struggling by the trial and error plan to eliminate the accidents for which she is responsible according to all of these talks that preceded me?

Let's take an inventory of some of these accident hazards. I wonder if you ladies ever had the necessity of going up and changing an electric light fuse when it blew out. Do you all know how to do it, or did you have to telephone the electric light company to send a man? Did you ever see the supercilious expression when he goes up to change the fuse? He thinks, "There you are; we have to do this for the women; they don't know how to do it." Whose fault is it? Why haven't you taught your home keepers how to do it? We don't have the mechanical knowledge; you have to do it for us. You are the heads; you are responsible.

Think about that electric washer that you have in your basement, one of the biggest hazards of today, not in the laboring class household, but in households like my own where you learn by the trial and error plan. You screw a little bit of a nut, if it works, all right, if it doesn't work call the repair man. Have you ever had that contingency to cope with? I think you ladies understand perfectly.

The man in the shop is the logical one to talk. He is taught a series of safety lessons in industry that are absolutely invaluable to carry into the home. There is one way to reach your foreign homes. Why not tell your foreign laborers to go home and tell their wives how to do some of the ordinary tasks? Isn't that a way of reaching the home that cannot possibly be reached by a club woman?

I speak from experience. I have tried to enter some of these foreign homes. They resent it. They resent advice from a woman who thinks she knows all about it, but they won't resent it from a person on their own level. The International Institute is very good, but how many homes does that reach? Very few in comparison with the millions of homes there are to reach. Reach them through your shops. I am going to plead to you men that you will go to your shop gangs, your shop lessons, and tell those men to carry home a definite series of safety lessons for the home.

Why not give those shop men as heads of households the series of leaflets on home safety, prepared by the National Safety Council? Isn't it worth while?

Ladies, you have a sewage system in your homes. Do you know much about it? Do you know where it goes? If you do, I am so glad; if you don't, find out. Isn't it one of the safety things of the town to have a very efficient sewage disposal system? You don't think anything about it. Perhaps if you investigate you might improve conditions that already exist. What about the drainage systems in your houses? Disease lurks in improper drainage systems and that is true in every home with improper drainage. Couldn't you ask the men in your shops what a drainage or sewage system is? Isn't it going to help you to have the homes of those men in pleasant, healthful condition, so that they are going to function more capably in your shops? A man can't work when he is worrying about his home.

The Mechanical Side of the Home

Then there is the gas outlet in your house. We all have gas, or electricity. I think now that the homes in the United States not equipped with one of those two powers are very, very few, perhaps only in the outlying rural districts, and still do you know what gas is? Do you know whether it is manufactured or natural? Do you know where it comes into your house? If you should have a fire in your kitchen would you know what to do first? Think, what would be the first thing you would do? You would jump and scream and perhaps send Johnnie for the nearest fire box, and by that time your kitchen would be aflame.

I wish every man would have a fire extinguisher in his home. How many homes do have one? Have you ever used one? Would you know what to do immediately, without thinking or reading the directions? I doubt if you would. Let's find out what to do. You might be called upon to use one. We never know, that is a home safety problem. Your gas outlet is important; you should know where to turn it off instead of waiting for the fireman to ask you.

Very soon in every household kiddies begin to come and you have a new baby, a dear, dear child, the apple of your eye. Are you guarding that child in your house? The previous speakers have told some of the hazards—you know the hazards that a little tiny child in your house has to work with. Are you guarding against them, are you eliminating them? You can't always take care of your every little detail for the tiny baby. You can't watch him every moment, but you can at least provide a suitable place for him to play or creep that is going to be safe for him. I don't have to say anything more about a mother and father setting a good example for a tiny baby. It is known in school circles that children begin to form habits at the age of six months and they observe what father and mother does at that age and by the time they are four or five years old the habits are so very firmly fixed it takes a very decided system of education in our schools to obliterate them. They come home and see mother and father doing exactly the thing of which the teacher

in school says, "Don't do that, Johnnie," or "That isn't the right thing to do." You do it; it is done. Can't you tell the men in the shops not to do that? Wouldn't it be worth while to carry that lesson into the home?

Sometimes children like to follow the trial and error plan also. They like to do everything they see being done. They are curious, they want to experience all sensations. A child will fall into an accident because his curiosity leads him to find out what this thing is or what the effect will be if he does the thing he was told not to do. We can't help that, it is natural. The only thing we can do is to try to put away that hazard so the child's curiosity won't lead him to it.

CHAIRMAN BUHLIG: We have Mr. J. I. Banash, Consulting Safety Engineer, Chicago, to open the discussion.

MR. BANASH: We can't make engineers out of our wives, but we have by her method a real authoritative approach to house and home safety. You can't work in a manufacturing plant today unless you are a safe worker because you are safety supervised and taught and you have to do it, but when you get home you are your own boss, or you think you are, and you can be safe or not, as you please. As far as yourself is concerned that isn't so bad, but there is on you responsibility for the rest of the group in that house.

I want to say something about the rural communities. A farm is practically a factory. That is one reason we have so many accidents on the farm, not only in the home of the farm but on the farm itself. Almost every form of industry is indulged in by the farmer and we can't be expert on all of them.

Another point to keep in mind in electrical matters in the home is to do things with one hand only and put the other hand in the pocket and you are not likely to be injured by changing a plug.

Household mechanics have progressed to a considerable degree in the last three or four years. Industry is paying particular attention to the markets which are opening up through the increased use of utilities in the home, and I must say that the manufacturers have done pretty well in their initial attempt in various kinds of machines, especially the safeguards that they can design into those machines, with the cooperation and assistance of safety organizations such as the Underwriters Laboratories. If you are going to buy a household refrigerator of the mechanical variety I wouldn't advise anyone to buy one, unless it is approved by the laboratories. You are not supposed to know about refrigeration; it is not your business; it is theirs. They are a group of engineers who have no other tasks to do.

In this territory we have more fires in households on Sunday morning from fuel oil burners than in all the rest of the week put together. Why? Father has time to fool with it. (Laughter.) It happens; I am quoting statistics. Those are some of the incidental things that you run into in studying this question of home safety. You are really safer in a factory than in your home or on the streets. I want to impress on you men that the safety whistle does not blow at five o'clock.

J. E. THOMPSON (Toledo Safety Council, Toledo, Ohio): We found last year there were 23 home fatalities in Toledo in the first four months, nineteen in the second four months, and at the beginning of school we started a campaign against the home fatalities. What we did was ask our schools to submit lists of home hazards. We gave \$100 in athletic equipment for prizes, to the first, second and third schools. What happened? We gave them a little better than three months to complete their list. We had a bank in Toledo print 50,000 copies of the prize-winning list and they were distributed by the Boy Scouts to the homes. This year we have had a 32 per cent reduction over last year in home fatalities.

ADJOURNMENT

Wednesday, October 5, 1927

Chicago's Pageant of Safety

This Pageant, which was to have closed the Congress program on Friday afternoon, September 30, was postponed until the following Wednesday on account of weather conditions. At that time some 75,000 persons, most of them school children, gathered in Soldiers' Field stadium at Grant Park, forming undoubtedly the largest gathering ever assembled for a safety demonstration. Represented among the actors in the Pageant and among spectators were every public, private and parochial school in Cook County, automobile clubs, civic, fraternal, social, religious and other organizations.

Particularly impressive was the opening parade of 6,000 boys and girls, headed by the Lindblom and Senn High Schools, R. O. T. C., with their bands.

One division of the parade which attracted considerable attention was the memorial procession of 389 children; representing the boys and girls who were victims of fatal accidents in Chicago last year. Many of the paraders wore striking costumes, and numerous floats portrayed the dangers that confront youngsters on their way to and from school, at play and at home. Warnings against the perils of fire, the grade crossing hazard, contagious diseases and lessons regarding the importance of the tooth-brush, the value planned recreation and other points were presented. Floats were also entered by the Pullman Company, the Chicago Motor Club, the Public Service Corporation of Northern Illinois, and the West Park Board. Among other contributions to the success of the event, the Chicago Motor Club financed the transportation of the school patrol boys to and from the stadium.

A humorous touch was given to the event by the antics of a pair of rustic jay-walkers. Safety patrol boys gave a demonstration of how they protect the lives of children at crossings.

Twenty drivers of the Yellow Cab Company took part in an interesting demonstration of skillful driving, maneuvering their vehicles with the precision of infantry on parade.

Gold medals were awarded to two young heroes, Sidney Goldberg and Robert Styber, the medals being presented by Si Mayer, president of the Automobile Club of Illinois. Goldberg resuscitated a baby who had almost been drowned in a bathtub, and Styber saved the life of a baby and her nurse in Jackson Park when the perambulator fell into the lake.

Brief addresses were made by Edward J. Kelly, president of the South Park Board, and J. Lewis Coath, president of the Board of Education. The addresses were delivered over the public address system.

To the children the most interesting and exciting event of the afternoon was a demonstration of the fire extinguishing and life saving work of the Chicago Fire Department. A frame building, constructed especially for the occasion, housed an alleged descendent of Mrs. O'Leary's legendary cow. Inside the house were combustibles planned to produce a great deal of smoke and little flame. After a thrilling rescue of the cow, fire fighting apparatus from the City Fire Department arrived at the stadium and dashed around the field to the burning building. In addition to extinguishing the blaze, the city fire fighters gave a demonstration of the use of the life net and resuscitation.
