NOTE

Volume III of these Transactions, containing the Public Safety and Home Safety Sessions, is being mailed automatically to certain members of the National Safety Council who are believed to be interested in the subject. Any other member of the Council may also receive a copy of this Volume III without charge by requesting it.

National Safety Council

108 East Ohio Street, Chicago

HONORARY MEMBERS

ASSOCIATION OF IRON AND STEEL ELECTRICAL ENGINEERS
ROBERT W. CAMPBELL

OFFICERS (1927-1928)

HOMER E. NIESZ, President,
E. W. BECK, Vice-President for Industrial Safety,
C. E. HILL, Vice-President for Local Councils,
MILLER MCCLINTOCK, Vice-President for Public Safety,
C. J. MOORE, Vice-President for Public Relations,
C. E. PETTIBONE, Vice-President for Finance,
HENRY A. RENINGER, Vice-President for Membership,
G. E. SANFORD, Vice-President for Engineering,
A. W. WHITNEY, Vice-President for Education,
DR. C.-E. A. WINSLOW, Vice-President for Health,
G. T. HELLMUTH, Treasurer,
W. H. CAMERON, Managing Director and Secretary,
C. B. AUEL, Past President,

EXECUTIVE COMMITTEE (1927-1928)

W. F. AUSTIN, W. E. Wood Company,
ERNEST W. BECK, United States Rubber Company,
T. G. BRABSTON, Birmingham Safety Council,
A. R. BUSH, Marine Section,
R. W. CAMPBELL, Past President,
E. R. COTT, Steam Railroad Section,
L. A. DE BLOIS, Past President,
M. A. DOW, Past President,
DR. LEONARD GREENBURG, Chemical Section,
JOHN B. GRIER, Woodworking Section,
JOHN V. HANNA, Kansas City Safety Council,
G. T. HELLMUTH, Chicago, North Shore & Milwaukee R. R. Company,
CHAS. E. HILL, New York Central Lines,
DANA E. JONES, Erie Safety Council,
GEORGE J. KELDAY, International Harvester Company,
R. MCA. KEOWN, ASSE-Engineering Section,
W. G. KING, Past President,
MILLER MCCLINTOCK, Erskine Bureau, Harvard University,
C. A. McDOWELL, Mining Section,
CHAS. J. MOORE, Longmeadow, Mass.
A. T. MOREY, Past President,
FRANK A. MORRISON, Detroit Industrial Safety Council,
HOMER E. NIESZ, Commonwealth Edison Company,

J. A. NORTHWOOD, Metals Section,
 GEORGE OPP, The Detroit Edison Company,
 L. R. PALMER, Past President,
 C. E. PETTIBONE, American Mutual Liability Insurance Company,
 W. B. PETTIBONE, Willard Storage Battery Company,
 C. E. REDFERN, Providence Safety Council,
 HENRY A. RENINGER, Lehigh Portland Cement Company,
 G. E. SANFORD, General Electric Company,
 C. B. SCOTT, Past President,
 ETHELBERT STEWART, Bureau of Labor Statistics,
 ARTHUR M. TODE, The Texas Company,
 C. P. TOLMAN, Past President,
 A. J. VAN BRUNT, Newark Safety Council,
 PAUL VAN CLEEF, Chicago Safety Council,
 DAVID VAN SCHAAK, Past President,
 H. M. WEBBER, Illinois Bell Telephone Company,
 S. E. WHITING, Liberty Mutual Insurance Company,
 A. W. WHITNEY, National Bureau of Casualty & Surety Underwriters,
 W. H. WINANS, Union Carbide and Carbon Corporation,
 DR. C.-E. A. WINSLOW, Yale Medical School,
 J. M. WOLTZ, The Youngstown Sheet & Tube Company,
 A. H. YOUNG, Past President.

DIRECTORS (1927-1928)

JOSEPH H. ALEXANDER, Cleveland Safety Council,
 C. B. AUEL, Past President,
 W. F. AUSTIN, W. E. Wood Company,
 EDWARD H. BAUER, Worcester Safety Council,
 DAVID C. BAYLESS, Denver Safety Council,
 E. W. BECK, United States Rubber Company,
 C. W. BERQUIST, Western Electric Company,
 DAVID S. BEYER, Liberty Mutual Insurance Company,
 E. F. BLANK, Jones & Laughlin Steel Company,
 W. R. BOYD, JR., American Petroleum Institute,
 T. G. BRABSTON, Birmingham Safety Council,
 A. D. BROWN, Safety Division, Syracuse Chamber of Commerce,
 S. C. BULL, Rahway Safety Council,
 A. C. BURNETT, Safety Council Bexar County,
 A. R. BUSH, Marine Section,
 IRVING T. BUSH, Bush Terminal Company,
 ANDREW S. BUTLER, Safety Bureau, Buffalo Chamber of Commerce,
 FRED R. CALDWELL, Eastbay Safety Council,
 R. W. CAMPBELL, Past President,
 WILLIAM CAMPBELL, Packers & Tanners Section,
 T. H. CARROW, Philadelphia Safety Council,
 J. ROBERT CLAIR, Taxicab & Fleet Owners Section,
 C. L. CLOSE, United States Steel Corporation,
 FRANK L. COCHRAN, Safety Bureau, Minneapolis Civic & Commerce Assn.,
 HOWARD COONLEY, Massachusetts Safety Council,
 E. R. COTT, Steam Railroad Section,
 WOOLSEY E. COUCH, Rome Safety Council,
 A. D. CUTHBERTSON, Flint Safety Council,
 L. A. DE BLOIS, National Bureau of Casualty & Surety Underwriters,
 WM. C. DICKERMAN, American Car & Foundry Company,

Officers and Directors

J. B. DOUGLAS, The United Gas Improvement Company,
MARCUS A. DOW, Past President,
SENATOR LOUIS A. DREXLER, Delaware Safety Council.
DR. LOUIS I. DUBLIN, Metropolitan Life Insurance Company,
FREDERIC W. EASTON, Blackstone Valley Safety Council,
J. LEE EDWARDS, Atlanta Safety Council,
W. H. ELAM, Nashville Safety Council.
M. A. ERSKINE, Louisville Safety Council,
E. E. EVANS, Toledo Safety Council,
H. P. FAHNESTOCK, Safety Division, St. Paul Association,
H. K. FERGUSON, The H. K. Ferguson Company,
R. L. FERGUSON, Employees' Publication Section,
F. W. FISHER, Rochester Gas & Electric Corporation,
GEORGE T. FONDA, Philadelphia, Pa.
ALEXANDER FORWARD, American Gas Association,
HON. CLARENCE R. GILMORE, Texas Council of Safety,
S. GEORGE GRAVES, Grand Rapids Safety Council,
DR. LEONARD GREENBURG, Chemical Section,
JOHN B. GRIER, Woodworking & Lumber Manufacturers' Section,
ISAIAH HALE, The Atchison, Topeka & Santa Fe Railway Company.
T. F. HALPIN, Cement Section.
JOHN V. HANNA, Kansas City Safety Council.
E. C. HARDING, Construction Section,
PROF. C. D. HARDY, Evanston Safety Council,
B. D. HASKINS, Chattanooga Safety Council,
F. A. HASSE, Food Section,
H. G. HATFIELD, Oklahoma City Safety Council.
G. T. HELLMUTH, Chicago, North Shore & Milwaukee R. R. Company,
J. W. HENNING, Power Press Section,
CHARLES E. HILL, New York Central Lines,
GEORGE HODGE, International Harvester Company,
F. L. HOFFMAN, Babson Institute, Inc.,
WILLIAM C. HUSSEY, Rochester Safety Council,
J. H. JENKINS, Dallas Safety Council,
DANA E. JONES, Erie Safety Council,
LESTER JONES, Wichita Falls Safety Council,
GEORGE J. KELDAY, International Harvester Company,
R. MCA. KEOWN, ASSE-Engineering Section,
IRA V. KEPNER, Pennsylvania Salt Manufacturing Company,
WALTER G. KING, Past President,
GEORGE W. KNAPP, JR., Baltimore Safety Council,
A. W. KOEHLER, Electric Railway Section,
CAPT. ROBERT E. LEE, St. Louis Safety Council,
R. M. LITTLE, New York Department of Education,
JAMES MADDEN, Paterson Safety Council,
A. G. MAGUIRE, Youngstown Safety Council,
H. T. MARTIN, Fisk Rubber Company,
FRANKLIN J. MAYER, Safety Division, Milwaukee Association of Commerce,
CHAS J. MOORE, Longmeadow, Mass.
ARTHUR T. MOREY, Past President,
FRANK A. MORRISON, Detroit Industrial Safety Council,
H. W. MOTT, Safety Division, Memphis Chamber of Commerce,
MILLER MCCLINTOCK, Erskine Bureau, Harvard University.
C. A. McDOWELL, Mining Section,
R. E. McEWEN, Employees' Benefit Association Section.

T. H. MCKENNEY, Illinois Steel Company,
 HOMER E. NIESZ, Commonwealth Edison Company,
 J. A. NORTHWOOD, Metals Section,
 JOHN A. OARTEL, Western Pennsylvania Safety Council,
 GEORGE OPP, The Detroit Edison Company,
 F. J. O'ROURKE, Hammond Safety Council,
 LEW R. PALMER, The Equitable Life Assurance Society,
 W. J. PEACOCK, Paper & Pulp Section,
 C. E. PETTIBONE, American Mutual Liability Insurance Company,
 W. B. PETTIBONE, Willard Storage Battery Company,
 GEORGE F. PRUSSING, Petroleum Section,
 EDWIN PUGSLEY, New Haven Safety Council,
 E. G. QUESNEL, Tri-City Safety Council,
 F. H. RANSOM, Oregon & Columbia Basin Division,
 C. E. REDFERN, Providence Safety Council,
 ROBERT J. RENDALL, Hudson County Safety Council,
 HENRY A. RENINGER, Lehigh Valley Safety Council,
 A. D. RISTEEN, The Travelers Insurance Company,
 JUDSON G. ROSEBUSH, Appleton, Wis.
 C. J. RUTLAND, Public Utilities Section,
 R. C. SALISBURY, Rubber Section,
 G. E. SANFORD, General Electric Company,
 CHARLES B. SCOTT, Bureau of Safety,
 I. M. SCOTT, Wheeling Safety Council,
 DR. L. A. SHOUDY, Bethlehem Steel Company,
 REV. H. J. SIMPSON, Bay City Safety Council,
 F. T. SINGLETON, Public Service Commission of Indiana,
 COL. JAMES SINKE, Director of Public Safety, City of Grand Rapids,
 MATTHEW S. SLOAN, Brooklyn Safety Council,
 D. C. SOUDER, Quarry Section,
 E. S. SPRING, Lehigh Valley Transit Company,
 ETHELBERG STEWART, Bureau of Labor Statistics,
 ROBBINS B. STOECKEL, Commissioner of Motor Vehicles, Hartford, Conn.
 LUCIUS S. STORRS, American Electric Railway Association,
 C. L. SWIM, Chamber of Commerce Safety Council, Tulsa, Okla.
 ARTHUR M. TODE, The Texas Company,
 C. P. TOLMAN, Past President,
 A. J. VAN BRUNT, Newark Safety Council,
 PAUL VAN CLEEF, Chicago Safety Council,
 DAVID VAN SCHAAK, Aetna Life Insurance Company,
 L. W. WALLACE, American Engineering Council,
 HARRY C. WASHBURN, Textile Section,
 A. L. WATSON, The Koppers Company,
 HARRY M. WEBBER, Illinois Bell Telephone Company,
 BERT N. WHEELER, Safety Bureau, Duluth Chamber of Commerce.
 S. E. WHITING, Liberty Mutual Insurance Company,
 A. W. WHITNEY, National Bureau of Casualty & Surety Underwriters,
 A. M. WILLIAMS, Automotive Section,
 DR. F. WILLSON, Reading-Berks County Safety Council,
 W. H. WINANS, Union Carbide and Carbon Corporation,
 PROF. C.-E. A. WINSLOW, Yale University,
 LEO D. WOEDTKE, Springfield Safety Council,
 J. M. WOLTZ, Youngstown Sheet & Tube Company,
 W. E. WOOD, Richmond Safety Council,
 ARTHUR H. YOUNG, Past President.

*SIXTEENTH ANNUAL SAFETY CONGRESS
NATIONAL SAFETY COUNCIL*

Annual Meeting of Members

Monday, September 26, 1927

WALTER G. KING, Chairman
President, National Safety Council

The Annual Meeting of the Members of the National Safety Council at the Sixteenth Annual Safety Congress, was called to order at 10 o'clock by the President, Walter G. King, American Optical Company.

PRESIDENT KING: The Sixteenth Annual Meeting of the National Safety Council will please come to order.

Our deliberations will be opened with prayer by the Reverend Rufus A. White, of Chicago.

REVEREND RUFUS A. WHITE: Almighty God, assembled in this great and important convention, we are moved to thank Thee for our great nation and express before Thee at the beginning of our deliberations our great love for it.

Today we are renewedly proud of its achievements, we are full of hope for its future. And here today by the grace of our heroic dead under American skies, by our youthful heroes who sleep today amidst the poppies of Flanders and where the white crosses are caressed by the French sunshine and moistened with the French rains that fall like tears from French skies, may we pledge ourselves anew to this great land of ours and bow with renewed adoration and determination before the beauty and significance of our great national banner.

We are impressed today, O God, deeply impressed by this great convention. We are appalled by the necessity of this gathering. We live in a most marvelous world; the beauty of it has been ever a challenge to human emotions, and the concealed mysteries and forces of it are a daily challenge to the human mind, and man has met this challenge. One after another he has unlocked the doors of light to concealed forces; and from the hidden resources of the world he has forged new weapons whereby other great achievements and victories might prevail in the struggle of man for predominance over the forces of the world, and for the establishment of greater and nobler civilization. But we are impressed today with the great and sometimes ghastly fact that achievements of this kind bring with them their disadvantage and that death sometimes follows in the footsteps of industrial and commercial success.

We are impressed with the fact that man with his genius and his determination has unleashed forces over which we now have no complete control. So it happens today that men from all over this great land of ours have gathered here that they may consult together as to how these great unleashed forces which bring with them tremendous advantages, and yet which scatter here and there death and wounds and despair, may be controlled and harnessed and made to serve without danger and disadvantage the interests of mankind.

Therefore, we ask of Thee, O God, that upon this gathering Thy great blessing may rest and that wisdom may be given unto those who are here assembled that they

may wisely and well work out the problem that has become one of the greatest problems of the United States, how to handle these unleashed forces without danger and destructiveness. So we pray that out of these deliberations may come not only a deepened purpose, but a larger and a wider vision as to how we shall lay our controlling hand upon the great forces that have been unlocked and sent abroad from the treasuries in this marvelous universe of ours, that the ways of men may pass in safety and in peace while they serve us and hasten us on to the larger civilization and to the peace of God. Amen.

PRESIDENT KING: The secretary having advised the chairman that a quorum of members is present in person or by proxy, the chair will be glad to entertain a motion to dispense with the calling of the roll.

(A motion was regularly made, seconded and carried, that the roll call be dispensed with.)

PRESIDENT KING: The address of welcome to this gathering will be made by Mr. William D. Saltiel, City Attorney of Chicago.

Address of Welcome to the Congress

William D. Saltiel, City Attorney of Chicago

The Corporation Counsel of the City of Chicago was asked to be here this morning and of course considered it a very great honor, but destiny and fate have otherwise decreed that Mr. Ettelson, the Corporation Counsel, at this hour is grief stricken at the bier of his brother. He has asked me to extend to you on behalf of the city of Chicago a very cordial, hearty welcome.

We are quite cognizant in Chicago of the work done by your Council. We know of its inspirational force. We know of its scientific contribution. Chicago, a city of 3,000,000 people, with a metropolitan area of 4,000,000 people, has great need of an organization like your own.

With our 5,000 miles of streets and alleys, with our hundreds of thousands of visitors who gather here each week, with the automobiles of our city and with huge industries, countless machines and the ramifications and complications of the new commercial era, we in Chicago are very much in need of organizations of your nature.

We believe we have done all that we can humanly and practically do toward the adoption of the plans which your men of genius have laid before our governmental agencies.

The mayor of Chicago, Mr. Thompson, long felt the need of emphasizing the safety of our people and has therefore given instructions to all departments of government, which have anything at all to do with the public in regard to safety, to consider that first of all government has an obligation to protect and to safeguard her people. If government does not do that it has failed. Our police department, too small and inadequate in view of the size of our city and our people, is doing all it can. We have only 1,000 men at one time walking the beats of our city, because we have not as yet been able to secure enough legislation to give us men for the protection of our homes. Our Department of Public Works, our Engineering Department, all of these have done all they can; and in our schools we have tried to emphasize through the Board of Education how very essential it is that these 550,000 children in our schools are given an education so that their little bodies will be protected, so that the nation tomorrow will have strong, able-bodied men and women. We have done all we can, ladies and gentlemen, but we must come to you who have given your lives, your talents, your energies in this highly specialized field.

I marvel at the tenacity of your endeavors. I compliment you upon the earnestness and the sincerity of your work. We know that it means sacrifice to be in work of your kind. We know that there is an ideal in the work that you men and

women are doing. We compliment you for the fact that you, perhaps more than in most other avenues of human endeavor, are working with a genuine desire to serve. So we are proud that you have come to Chicago.

Chicago is a city which is growing rapidly, and it is a city which deserves a very serious and a very concentrated consideration and study. While you are here we want you to see all of the city which you possibly can with the limited time that you have at hand—our growing avenues, our widening streets, our bridges, our new sky line, our new schools, all that we are doing to live up to what we consider the inspiring tradition of the greatest pioneers that ever came to any section of the country. We love Chicago and we love her more because you have come here; you have enriched us by this session, you have added tremendously to our happiness by coming here, rubbing elbows with our citizens, holding your deliberations here in our center.

We wish you Godspeed in your endeavors, and we hope that you will carry on, throughout the nation and to any part of the world from which you come, the happy gospel that Chicago is an American city, thoroughly American, alive to her responsibilities, the responsibilities she owes her citizens in safeguarding their lives and their happiness. We want you to go out and proclaim to all the world that here is a city of 3,000,000 harmonious people working together with unusual teamwork to make it a finer and a more splendid city so that America will become what fate has decreed she should become, the greatest nation at any period in the history of time.

PRESIDENT KING: Mr. Saltiel, I want to thank you on behalf of the National Safety Council. We are mighty glad you know so much about our work. The people of Chicago have done a great deal for our comfort and our pleasure, and I know you will all be glad to give a rising vote of thanks to Mr. Saltiel for his splendid welcome to us.

(A rising vote of thanks was extended to Mr. Saltiel.)

PRESIDENT KING: Our next speaker is a distinguished sociologist of New York City. There has been no important social or religious movement in the United States during the past twenty-five years in which Mr. Stelzle has not had a leading part. He was born on the Bowery of New York City. He had little early education. He suffered all of the privation in early life that are associated with life on the Bowery. He has been a worker in the printing industry and holds a certificate for high-class workmanship in the machinist's trade. He has been a Presbyterian minister, a newspaper editor, an author of many books, an organizer and lecturer of international reputation.

There is no man in the United States better qualified through thirty years of experience to talk to us this morning on practical, social and industrial problems. Mr. Stelzle is deeply interested in the problems shared by the National Safety Council with others, and he has been kind enough to give up his regular work to come to Chicago to address us on this occasion.

It gives me great pleasure to introduce to you our friend, Mr. Charles Stelzle, of New York City.

Life's Greatest Adventure

Charles Stelzle, New York City

You impress me as a crowd of hard-hitters. I don't believe there is a sissy in the audience. That's the kind of crowd I like to talk to, because I am sure there will be a comeback that will make things interesting, whether it will be here or whether you get back at me later in some other relationship.

My interest in the work of the National Safety Council goes back to many very real experiences. My father died of an occupational disease when I was

ten years old. That meant that I had to go to work when I was eleven, and I never went back to school, that is not to the day school. I went to night school for fifteen years. For twenty years I lived in the tenements on the East Side of New York City, where I faced all the problems of poverty that face any man there today. Then for eight years I was a machinist in the biggest shop in New York City, serving five years as an apprentice and three years as a journeyman, and there I learned something about the everyday problems of the average working man. I still have a very vivid recollection of the accidents of those days.

Then I became a preacher, pastor of working men's churches, where for eight more years I found in the homes of working men many of the difficulties and problems which face working men today.

Then for eight years I was at the head of the national industrial work of a great denomination, establishing its church and labor department.

For the last ten years, as a free lance in this country and in Europe, I have studied industrial problems in practically every industrial center in the United States and in many European cities. That orients me, sets me straight with you, I hope.

Placing Safety Upon a High Level

"Safety First" is the slogan of a coward, it means merely taking care of yourself, but I am glad to learn that the National Safety Council repudiates the narrow meaning which has often been given this phrase. In an important sense there is need for safety first campaigns, and you are going to talk about these campaigns this week. I shall not spend any time telling you what to do on your kind of a job; I don't know your job. But in your opening session I want to lift your thought to a higher level, or to a different level. I want to deal more particularly with the motives which are back of your plans and your campaigns. I should like to point out to you the high purpose which will make safety first mean not only your safety, but the other man's safety.

Accidents of any kind are costly; you know that. They increase the expense of production, and that means that they decrease profits. It also means they lower wages. Therefore, any working man who will not do his share in keeping down accidents is a distinct detriment to his fellow-workers as well as to his employer. An incompetent workman is also costly; whether his incompetency is due to carelessness or ignorance or drinking booze, doesn't matter. He increases the expense of production, he decreases profits, and he lowers wages, because the rates of wages for all men are largely determined by the standards set by the last man who came into the shop door. When low-grade workers predominate in a plant, the high-grade workman suffers, because he is compelled to overcome the handicap of the mass of inferior workmen whose incompetency create low standards in the factory.

What are you going to do with a man who won't play fair, who cares nothing for the rest of us, whose low ideals and indifference makes it hard for all of us? This is the problem that faces every executive. What is the answer? Just this: You have got to carry him along; and you will carry him by lifting the level of living and the standards of practice of all of us. You can't leave him behind because there are too many of him.

Do you remember that there were nearly 2,000,000 men tested psychologically in the war draft, and that of all these 70 per cent were rated as having the mentality of fourteen-year-old children, or less, and about one-third were rated as morons, which means that they were incapable of complete self-guidance? And remember this, gentlemen, not all the morons are in the wage-earning class. I have discovered them even among preachers.

The job which this National Safety Council has cut out for itself is going to

require the finest devotion that this world has ever known; and I say that advisedly, because the saving of human life is humanity's greatest adventure.

The other day the cables carried the story of the death of Professor Adrian Stokes in West Africa, just as he had discovered the causes of the transmission of yellow fever; but the fever got him first. I think of the supreme sacrifice of David Livingstone in the heart of the Dark Continent. I am reminded of Dr. Grenfell who today is at work among the fishermen of Labrador; of Sheldon Jackson, the missionary, who saved the Eskimos in Alaska from starvation through the introduction of a herd of reindeer; of Father Damien, who gave his life to the lepers. And then there is Lillian Wald, who 30 years ago went down to the tenements on New York's East Side as a visiting nurse and lived among those people, and who now directs 250 trained nurses in the greatest public nursing service in the world.

Then there is Jane Addams of Hull House, Chicago, recently voted the greatest woman in America because of her service to humanity. And John Elliott, the Cornell graduate who went directly into the heart of Hell's Kitchen in New York 30 years ago and is still there, running one of the finest social settlements in this country. And Graham Taylor, in Chicago Commons, where he has given his life to the solution of the human problems of his neighbors. And thousands of others who were not so well known, but who gave themselves freely as these I have mentioned.

The other day, in a New York hospital, a little girl, because of anemia, required the transfusion of blood—somebody else's blood. Her young brother 16 years old volunteered for the service. After the thing was all over, the boy stepped outside the room and sat in a chair and waited for the doctor. When the doctor came out he said to him, "Say, Doc, when do I croke?" We can find many such unconscious heroes in the tenements of our great cities.

An Old Record From an Ancient Writer

Just to show you that heroism is not a thing of recent days, but an old story, I want to read just a paragraph or two of an old record from an ancient writer. He has been talking about men and women who have made the supreme sacrifice, and then he goes on to say:

"And what more shall I say? For the time would fail me to tell of Gideon, and of Barak, and of Samson, and of Jephthe; of David also, and Samuel, and of the prophets:

"Who through faith subdued kingdoms, wrought righteousness, obtained promises, stopped the mouths of lions,

"Quenched the violence of fire, escaped the edge of the sword, out of weakness were made strong, waxed valiant in fight, turned to flight the armies of the aliens.

"They were stoned, they were sawn asunder, were tempted, were slain with the sword: they wandered about in sheepskins and goatskins; being destitute, afflicted, tormented;

"Of whom the world was not worthy: they wandered in deserts, and in mountains, and in dens and caves of the earth.

"And these all, having obtained a good report through faith, received not the promise:

"God having provided some better thing for us, that they without us should not be made perfect."

In other words, the jobs of these martyrs way back in history, the tasks of Father Damien and David Livingstone and all these men and women who come to your minds, will be incomplete unless you finish your job; without you their tasks will not be perfect.

Humanity has been blessed through the great adventures of these heroes of the past and the present.

Organized industry and industrial management have their chance to serve humanity. In the divine economy, its function is to work for the abundant life of mankind, as do medicine, education and religion. American industry leads the world today. This is the verdict of every other nation, through commissions which have been studying us—England, Germany, Australia, and other lands—and our supremacy in the industrial field is due mainly to our system of mass production.

I recall, when I was pastor of a little church on the East Side of New York among working men, frequently passing a little shoemaker's shop. This little hunchback German shoemaker would pick up the shoe upon which he had been working, and holding it up to me would say with great pride in his face and in his voice, "I made that shoe, every bit of it. I made that shoe! That's my shoe!"

Today every shoe passes through a hundred different hands because of the specialization of that industry. The other day I was in one of these shoe shops. I saw one room crowded with women, with young girls, mainly, each of them was running an electric machine, and each of them performing the minutest detail in the making of shoes. You know that story far better than I do.

Industry Has Narrowed the Worker's Life

Through scientific methods the length of life of the worker has been prolonged, but the scientific methods in industry have narrowed the lives of the workers. It is true that they are enjoying more of the benefits of invention and labor-saving machinery, but their daily tasks have become extremely monotonous. Mass production, I want to remind you, is not self-expression: it is self-repression, it is restriction, it is restraint. The minute specialization of the efficiency expert has made most mechanics mere machine tenders. Many of the workers have found relief in jazz. Now to many excellent people who believe that the long-meter Dixie is the tune that the angels sing, jazz is the gateway to hell. I don't believe that. I believe that jazz is merely a protest against monotony, it is an attempt at self-expression.

We cannot go backward in the course of industrial progress. We will never go back to the time when that shoemaker will finish an entire shoe; maybe in ten years from now 200 hands will be needed to make one shoe; but it is imperative that the lives of the workers who become part of the system of mass production must be enlarged, enriched, and each industry must work out its own program for itself.

Mark you this. Unless we do something in this direction we shall soon have what would be equal to a nation of serfs, without the craftsmanship which has so long been our honor and our pride.

But the worker pays a heavier price for our industrial supremacy than the mere giving up of variety in his work and pride in his craft. In spite of the increased length of life of the people as a whole, working men's death rates are still abnormally high, plainly on account of their occupations. The death rates of working men in America of middle age today are nearly 40 per cent above the death rates of men as a whole in the United States. Ten years ago the death rate was almost 60 per cent above the death rate of men as a whole. So progress has been made.

Dr. Louis I. Dublin, the statistician of the Metropolitan Life Insurance Company, has given us some interesting and important data on this matter. It will be recalled that four-fifths of the 5,000,000 men insured by the Metropolitan Life Insurance Company are industrial workers, so that Dr. Dublin has a good

basis for his facts. Dr. Dublin says that the most determining factor in the lives of men is their occupations. He tells us that the length of life of industrial workers is eight years shorter than that of non-industrial workers. To this must be added the loss through sickness.

You are familiar with the figures showing the loss of life through accidents. I need not repeat them, only to say that in New York state alone there are annually over 2,000 deaths among working men due to accidents. Roughly, death from accidents among workers is two and a half times as great as among non-industrial workers.

But Dr. Dublin points out that death from tuberculosis among industrial workers is even greater than it is from accidents. It shortens the average life of all workers by two years.

A chart prepared by Dr. Dublin's office shows the death rate from tuberculosis during one year. Up to about the age of 20 the death rate from tuberculosis among all classes of men is about the same. Then there comes a sharp break—an upward shoot, showing that the death rate among industrial workers between 45 and 54 is 210 per 100,000—twice as many deaths among working men on account of tuberculosis as there is among men as a whole.

Dr. Dublin shows that industrial employment is probably the most important single factor in the tuberculosis death rate, and that the problem of confronting tuberculosis is today largely concentrated in the industrial classes.

Quoting very briefly from a recent address given by Dr. Dublin, let me just give you this paragraph:

"The term 'industry' is here used in its broadest connotation to include the effects of the dusts inevitable in certain trades, excessive fatigue, bad posture, crowded workrooms, and other conditions of employment which made the worker more susceptible to deleterious home influences. These circumstances surround all workers, and not only those who are especially exposed to this disease.

"Pneumonia," he says, "is twice as high among industrial as among non-industrial workers, and may, therefore, be considered an added occupational hazard. Possibly the loss in life expectation resulting from this cause is as great as that from industrial accidents.

The Individual Worker a Valuable Asset

"In like manner," says Dr. Dublin, "the degenerative diseases, such as cerebral hemorrhage, Bright's disease, and organic heart disease show strikingly the effects of industrial exposure. The death rates are two and three times as high as in the non-industrial groups during the active working years of life. These high rates probably reflect the results of long-continued strenuous labor, of heat, of marked changes in temperature, and, in some instances, of specific occupational poisoning." And so I might go on:

Every working man may be said to be worth the equivalent of a \$10,000 mill. There are probably 10 million workers in manufacturing industries alone in this country. This means a total value of 100 billions of dollars, or about the equivalent of our national wealth in 1902; one-fourth of our total wealth today.

The value of a man, namely, \$10,000, was determined by the courts many years ago, but as the price of sheep has gone up since, I rather think we will have to boost the price of men a bit in order to equalize things. Actually the value in cash of the working men of America today probably is at least half the total national wealth of these United States. At any rate, these workers would about equal the value of all the products in manufactures today. Surely such valuable equipment is worthy of more attention than we seem to be

giving it. They come to us full-fledged, \$10,000 mills, for which we are paying not one sou marqué—and there are 10 million of them.

In spite of the reduction in death rates from almost every kind of disease, the percentage of women dying as the result of child-bearing remains almost stationary in the United States. To what extent is this due to their industrial experiences before marriage and during marriage itself? That question should give industrial leaders very great concern. The real curse of child labor is not in the fact that children are compelled to work. Even a child of eight may perform a certain routine of duties on the farm or in the home without serious injury. It is the continuous toil for long hours under unsanitary conditions without proper and sufficient food that stunts the body and the mind, so that when the child arrives at the years when it should be giving expression to its best self it is impossible for it to appreciate the best values of life, and the tragedy of it is that there comes no realization of that which is missing. I have heard many a brute of a man declare that going to work in a factory at a very early age never did him any harm—and everybody knew he was a brute but himself.

Safety Work a Great Adventure

This emphasizes the influence of welfare work, but it means the enlistment of men of the very highest type. Unfortunately (and I think I know what I am talking about), most of those who are engaged in welfare work today in our industrial plants are inferior mentally and socially. The situation demands that such work should take on the nature of a definite campaign, a crusade, a great adventure. It should reach out to the utmost ramification of the worker's life.

In the last analysis, this whole problem has to do chiefly with human elements. These stand out as a challenge to American industry today.

Some time ago I had an hour's talk with John D. Rockefeller, Jr., about industrial problems in America. He was far more generous in his estimate of things than I, as a former machinist, would have been. In the course of that conversation, Mr. Rockefeller said to me: "The most important man in industry today is not the production manager or the sales manager. The most important man in American industry today," he said in substance, "is the man who is in charge of creating right human relationships." Industrial relationships and safety campaigns are so largely dependent upon the state of the human mind. I was about to say that nothing else matters, for unless the state of mind is receptive and open and friendly, you may as well stop.

Human engineering is much more important than mechanical engineering in the progress of American industry. We are just awaking to the importance of this fact. If you fail to establish a brotherhood in industry, no efficiency plans or safety rules will accomplish very much.

You know how suspicious every working man is concerning anything that emerges from the office. When I was a young machinist in New York City and a notice came from behind the glass door that divided the shop from the office—how I hated everything back of that damned glass door, as I used to call it in those days. I hated everybody and everything that emanated from that great cavern, or whatever it was, that I never saw, which no working man ever saw during the years that he worked there. And how we hated the clerk that brought the notice, the fellow who wore a white collar when I wore a blue shirt! I would go up to the bulletin board where the notice had been posted and jab my fists into my overall pockets and say to myself, or to the chap looking at it with me, "I wonder what those blankety-blanks are trying to put over on us now?" The better the plan looked to us the more suspicious

we were of it. Thoroughly human. I was a typical machinist. Human relationships, the human mind, the attitude of the man in the shop—these are the things that count.

Take the question of unemployment. During that winter of 1914 in New York City when there were something like 400,000 men out of work, I served as Director of Relief and Emergency Measures for Mayor Mitchell's Committee on Unemployment. It was part of my job to relate the public and private agencies in New York City, and I worked at that job all winter down in the Municipal Building. I learned a lot about unemployment; I knew something about it before. But surely you must know that unemployment is a fearful tragedy in the working man's life.

The average working man fears being out of a job more than he fears going to hell. I learned that as a preacher, if I didn't know it as a machinist. And yet most managers regard it very lightly, merely firing or laying off so much equipment. The man who meets with an accident may have a pension, but the unemployed working man is doomed, doomed, I say, literally, to deterioration and often to destitution. We seem to be able to prepare for almost every other kind of catastrophe, but the cycles of unemployment leave us just as unprepared as though we had never experienced such a thing in industrial history.

No More Epidemics of Unemployment

I hope the day will come when an epidemic of unemployment will be just as unpardonable as an epidemic of the small-pox. But it is going to require a great adventure on somebody's part, an adventure that will save many lives and many industries.

Another challenge to America and American industry that will mean much to us will be a better understanding of our deeper social and economic problems. Most of us are afraid of them, we are afraid not only to talk about them, but we are afraid to think about them, and we become restless when anybody suggests that we look the facts in the face. I am not going to lead you through that path this morning, there isn't time for it. Only I want to say this, we cannot evade the fact that labor is not interested in our safety plans, because they have not been sufficiently democratized. "That is the boss's job," we are told by them, and frankly we have made it a boss's job.

I recently spent four months in Europe studying industrial problems. In England I attended a meeting of the British Trade Union Congress for a week. I know the American labor movement very well. I have attended possibly a dozen conventions of the American Federation of Labor. I know every labor leader of prominence in the United States, some of them intimately. I wrote for the labor press, 250 papers, for eight years, and never missed a week.

I am convinced, out of that knowledge and experience, that the growth of democracy is the outstanding fact in every country in the world, with one or two possible exceptions. All through the centuries the great masses of people have been winning in their struggle for democracy, first religious democracy, then political democracy, then educational democracy, then social democracy, then the democracy of the sexes, then racial democracy, and now we are frankly facing the problem of industrial democracy. I don't know what it is going to mean, and I have no cure for it. If I had, I would be a world beater.

Many of us are afraid of the restlessness in our country today because we don't get at the root of it. What causes restlessness among working men? Why can't you get your safety plans across with many working men? Restlessness is not caused by the labor agitator. He has not created it; it has created him. It existed long before he got on the job. Restlessness is caused

by public libraries, by art galleries, by universities, by big business through its big advertising campaigns, by the church, by every great movement in our country today which points out to the people higher ideals and greater possibilities, showing them the conditions, wretched, physical, mental and moral, under which they are living, and then showing them the possibilities of a life to be attained through study, through art, through religion, whatever it may be. Social unrest, let me say to you, is the legitimate outcome of the finest idealism the world has ever known, and when once that gets hold of you, you will approach your safety problem, your industrial problem, whatever it may be, from an entirely different angle. You will forget all about labor unions and sovietism and all the rest of it, and you will face the things right in your own town that have to do with the individual man. When you do that, you will make a tremendous stride forward in any plan or program that you may have in the industrial field.

If I had the time I should like to show the importance of character in this whole enterprise of welfare. I recall a little while ago in New York in one of the subways they placed some placards which read something like this: "We spent \$1,000,000 (or whatever it was) to make the subway safe. Now it is up to you." And they were perfectly right.

Here is a doctor who comes to his patient, diagnoses the case, prescribes for him, and at that point he may as well take his hat and coat and go home, because it is then up to the patient as to whether he will stop doing the thing which he knows he ought not to do or, whether he will do the things which he knows he ought to do. No doctor in creation can help that patient unless he has the character to see the thing through for himself.

Only a small percentage of accidents can be prevented by mechanical safeguards. The balance must come through the development of character.

So far as employers and managers are concerned, what is needed is a great leadership, a leadership that is big enough to frankly face the outstanding American problems.

Give Social Experiments a Fair Chance

I have spoken of social unrest. May I barely mention two other questions which everybody interested in safety must honestly answer. The first is prohibition. Whatever may be one's opinion regarding prohibition, there can be no doubt that this greatest social experiment—let me repeat that, this greatest social experiment in the history of the nations of the world—should be given a fair chance by industrial leaders in our American life, if only upon the economic basis. That we have made distinct economic gains under prohibition, no reasonable man will question. It has simply become a matter of the fair and just application of the principles of prohibition to all the people.

The second is our relationship to world peace. America must find a moral equivalent for war. I recently spent a month at Geneva, and every day I went to the International Labor Office to interview the heads of departments—men from all over the world, except America. I came back impressed with this fact, that this Labor Department of the League of Nations, whatever may be true of any other function of the League of Nations, is doing more to bring about world peace than any other single factor in all the world.

For after all, if you trace back history you will find that practically every war had an economic and industrial basis, and if you can solve the labor problems for this country and other countries, you will have solved practically every problem that tears men apart, in so far as economics are concerned.

America must find a moral equivalent for war. The destruction of human life through national conflicts has become unthinkable. Next to peace, I love a

good night. If we as a nation decline to become participants in leagues of nations, or whatever you choose to call them, we must—mark you this, gentlemen—lay at the feet of the nations of the world accomplished tasks in social, economic and political reforms as an equivalent for what they are trying to do by League of Nations, by World Court, or whatever else that body may be. We, as Americans, cannot avoid our responsibility as a nation in humanizing the affairs of the world. This week as you go to your conferences and your meetings, God speed you in the task of helping to bring about that condition where right relationships shall exist between man and man and between nation and nation.

PRESIDENT KING: We find it necessary to make a slight change in our program. Brigadier General Dalton is on our program for this afternoon. He is obliged to leave on a one o'clock train. I want to introduce you to him at this time.

Brigadier General Dalton has for many years rendered distinguished service to his country and has had a long and brilliant career in government service. He graduated from the Infantry and Cavalry School of Fort Leavenworth, Kansas, in 1895. He served the United States in France and was cited for gallantry in action. He has been a great soldier and is now continuing to serve our national government as the President of the United States Shipping Board, Merchant Fleet Corporation. He has come from Washington especially for this convention. General Dalton is an authority on the problem of "Safety on the High Seas," and it gives me great pleasure to introduce him to you.

Safety on the High Seas

**Brigadier General Albert C. Dalton, President, Merchant Fleet Corporation,
Washington, D. C.**

I am sincerely pleased to have the pleasure and privilege of addressing you during the meeting of the National Safety Council. With your indulgence, I will attempt to outline the accomplishments with respect to safety at sea of the largest steamship organization in the world today, the United States Shipping Board Merchant Fleet Corporation, which is operating approximately 300 passenger and freight vessels reaching many ports of the high seas.

"Safety at Sea" is a very broad term. Our efforts are directed toward accomplishing everything possible to fully safeguard the health and well-being of those aboard our ships.

An incident occurred on board one of the passenger vessels of our United States Lines which indicates our caution in this respect. A young lady asked a member of the deck crew where she might find the captain. He answered, "He's forward, Miss"; and she promptly explained, "That's all right. I am not afraid, I have been out with college boys."

"Safety at Sea" demands, first, a seaworthy vessel, staunch of hull, fully equipped and mechanically sound. Second, the vessel must be properly and sufficiently manned with efficient officers and seamen. Third, the lifeboat equipment must be in first-class operating condition and qualified seamen properly drilled in their respective duties in the handling, launching and navigating of such craft. Cargo must be properly and securely stowed in order that the vessel sails properly trimmed, and with sufficient freeboard and stability to withstand all weather conditions which may be encountered.

The loss of the "Cyclops" was due to the hasty method in which the ore that was dropped in her hold was stored. During the heavy sea it shifted and

the weight was so tremendous that we never heard of that gallant crew again. All the seafaring men know the great danger of that.

The transportation of grain is an excellent example of the care that must be shown in the handling and stowing of cargo in bulk. Grain is loaded under the immediate supervision of an inspector of the National Board of Marine Underwriters under rules that are necessarily complete and compulsory. Grain may become a most dangerous cargo, if it is loaded in bulk and not securely confined by grain-tight bulkheads, and shifting boards. Shifting during the voyage frequently means the loss of the vessel together with loss of life. Many of those present will recall the case of a foreign vessel loaded with a full cargo of grain which sank with all hands two days out of Boston in 1925—a loss which was the more pathetic as a large passenger ship was at the scene but on account of the terrific storm raging could do nothing to assist. Dangerous commodities are always afforded special stowage under deck if necessary, or on deck if advisable, so that they may be readily cast overboard if an emergency arises.

Covering a period of four years, that is, 1922, '23, '24 and '25, the world's maritime loss was 1,691,272 gross tons, and of this amount the American flag losses were 190,642 gross tons.

When you figure the cost per ton to build a vessel, not counting the valuable cargo that was on board these vessels, you can see what terrific losses marine disasters cause to our nation and to the world.

Passenger Service Wonderfully Safe

During the same period there were 1,247,864,106 passengers carried on passenger vessels flying the American flag operating in ocean, coastwise and inland water services, that are required by law to report the number of passengers carried to the United States Steamboat Inspection Service. Of this number 267 were lost, or in other words 4,672,974 passengers were safely carried for each passenger loss. Since the inception of our passenger service, viz., the United States Lines, there has never been a loss of life through casualty.

As you know, the United States Lines are operated directly by the United States Shipping Board. We don't take any particular pride in that accomplishment, but it only indicates to you the care which we try to give to this great problem.

To speak directly of our own passenger service, we have fitted these vessels with every practical device for the elimination of accidents. We now have equipment which is conducive to accurate navigation and protects the ship regardless of its position and the weather she may experience. This is a device used in the pilot house, which due to its being all bronze has been nicknamed by mariners "Metal Mike." "Metal Mike" actually takes the place of the old seadog who stood at the steering wheels. While we must continue to honor and admire such helmsmen as we have had in the past, "Metal Mike" actually keeps the vessel on her course more correctly. All that is necessary is to set the required course on the indicating dial and "Metal Mike" will follow that course regardless of weather conditions. The officer on watch merely observes from time to time if there is any deviation from the course as recorded by the device of which "Metal Mike" is the boss.

During the old sailing vessel days, and up until recently, the lead line has been used and remained to an extent the unchallenged means of learning ocean depth. With steam vessels the use of the lead line, of course, continues to give the depth sounding, but in most cases represents the depth of water at that moment past.

The new sounding device is continuous in its action, and measures the time necessary for an echo of a sounding impulse to return from the bottom of the

sea to the ship's hull. A powerful sound is mechanically produced by an apparatus attached to the ship's hull. This sound travels through the water in all directions at a velocity of 4800 feet per second. Between the time of the release of this sound and the return of its echo a special device accurately measures the time, which is calibrated by a dial for that purpose which shows the number of fathoms or feet between the bottom of the ship and ocean floor which the vessel is then passing over. The operation of this instrument is entirely automatic, the depth is indicated directly and is recorded instantaneously, so it is unnecessary for the navigator to make any calculation.

When a vessel is traveling a speed of 20 knots, which is approximately 23 nautical miles per hour, and it takes several minutes to make a sounding with a lead, remember that she is a couple of miles from the place at the time the word gets up to the pilot house. In the pilot house a little button is pressed and instantly you see the exact depth of the water under keel. That is going to prevent, I am certain, many accidents that occur by grounding, particularly in a fog.

Finding the Ship's Position in Fog

Another device which we are using on our passenger vessels, is especially valuable when the ship is lying-to or traveling through a thick fog. This instrument which is called a distance-finding machine is used to determine the ship's actual position in relation to other vessels or the shoreline. This method of determining the ship's position is based on the difference in velocity of radio waves and submarine sound waves. Radio waves travel with the velocity of light, therefore, the time required for such waves to be recorded at a distance of 50 miles is negligible. Submarine sound waves have a velocity of 4,800 feet per second and there is a measurable elapse of time necessary for such submarine sound waves to travel over a similar distance. To make distance measurements at sea, radio and submarine waves or sounds are produced simultaneously on a light vessel, while the vessel whose distance is to be determined carefully measures the time elapsing between the reception of the radio wave or sound, and the reception of the submarine sound, thus obtaining a basis for computing the actual distance between the ship at sea and the light vessel, or a signal station located on shore. For example, if ten seconds elapse between the arrival of the two sounds, the distance is eight nautical miles. You are no doubt aware that the United States Government, through the various radio stations of the Naval Communication Service, renders this service without charge to all government or merchant vessels upon request. During the month of May of this year, a total of 3,797 radio compass bearings were furnished Naval vessels, and 16,990 bearings were furnished merchant vessels, 42 radio bearings were also furnished to 9 aircraft. A grand total of 20,829 radio compass bearings were furnished during the month in the average time of 2.79 minutes each.

In the event of the failure of radio communication or in the contact with the vessel without this modern invention, we still have the International Code of Signals. The far-reaching effect of this system was demonstrated last May when a Shipping Board vessel, the "Aquarius," sighted a four-masted schooner flying the international distress signal at its spanker peak—the two flags, N-C, meaning "In distress—want immediate assistance." When our vessel approached the schooner it was found that she was the French vessel "Boree" and that her crew could understand very little English. The schooner was laden with iron scrap and china clay and was barely floating, having encountered a heavy storm which caused her to become water-logged. The "Aquarius" stood by while the grateful members of the crew of the "Boree" made

their way to the safety of our ship and the schooner was left to go to Davey Jones' locker without the sacrifice of lives.

The average passenger embarking for a voyage to foreign shores has reason to be satisfied with a comfortable stateroom, the excellent service and cuisine afforded by the modern vessels, but seldom realizes the existence of the many devices which have been installed to make his voyage safe. He may use the radio to maintain contact with his business affairs at home, but the radio means a great deal more when used for the saving of human life. The two thrilling rescues during the past two years by vessels of the United States Lines may well be taken as concrete examples. About noon on October 19, 1925, the SS. "President Harding" received an "SOS" call from the Italian Steamer "Ignazio Florio" and upon learning she was the closest ship "headed" for the distressed vessel through mountainous seas and through a 70-mile gale. The next day about nine a. m. when the "President Harding" should, according to calculation, have been at the reported position of the Italian steamer, radio compass bearings indicated that the distressed ship was still ahead. The radio operator of the "Ignazio Florio" was then instructed to transmit radio signals every five minutes which enabled the "President Harding" to take radio compass bearings on which full reliance was placed. The "Harding" continued to steam at full speed, and about 11:30 a. m. sighted the distressed vessel which had been steaming ahead during the entire time at exactly three degrees off the starboard bow of the rescuing steamer, as indicated by the radio compass.

I had the great pleasure of presenting to the captain of that vessel in London recently, the Distinguished Medal for gallantry on the high seas, awarded by the Italian government, presenting it in the presence of some of the most outstanding and representative shipping men of England. That is only an indication, however, not only of what our own American seamen can always be depended upon to do, but an indication of the bravery of all of the seafaring men, as a rule.

Efficiency of the Radio Compass

During the rescue of the British Steamer "Antinoe" by the SS "President Roosevelt" in February, 1926, the radio compass was used in picking up the distressed vessel when it was found that her given position was some 75 miles in error, and although sight was lost of the "Antinoe" she was later on located despite the fact that her radio equipment was not working, and through the use of the radio compass she was reached during a heavy snow squall and the rescue of her crew was accomplished.

Recently the American SS "Malolo," while on her trial trip, was rammed during a thick fog by the Norwegian SS. "Jacob Christensen," resulting in the "Malolo" broadcasting an appeal for help. This was answered by the American Tanker "Gulfland," which was 38 miles away. Her bearing was observed on the SS "Malolo" radio direction finder and she was given a course to steer. Radio messages were sent to New York requesting tugs, and to the Coast Guard Base at New London, Connecticut, requesting the assistance of their fast cutters. The trawler "Fisher" reported her position near by and was given a course to steer. The bearings of the Destroyer "Shaw" and the steamer "City of Pretoria" were also taken by the "Malolo," and these vessels were given true courses to steer that brought them to the "Malolo" through the fog.

Equipping our vessels with numerous safety devices and aids to navigation which have been developed during the past 20 years has required of the officers

and crews a technical knowledge of radio and electric mechanics in order to efficiently operate these instruments. To aid in the development of our personnel, we maintain libraries of technical books on everyone of our vessels, and in this manner make it possible for the humblest member of the crew to acquaint and educate himself with these marvels of latter day science and inventor's skill, and in the last analysis it is on the human element that the policy of "Safety at Sea" depends.

When the Alarm Signal is "S. O. S."

Receipt of the international distress signal known as SOS by all vessels within listening distance strikes terror to the hearts of all those on board and you can readily visualize the prompt action taken by such ships receiving this distress signal to do everything possible to render assistance and while the perfection of these individual devices is wonderful the coordination and results obtained from the use of both of them is really marvelous. During the foggy weather heavy rains or snowstorms at sea, visibility becomes limited and there is, of course, grave danger in navigating a vessel through such weather, without taking every conceivable precaution to learn the approach or proximity of other vessels and in turn warn them of your position, consequently the blowing of a whistle or ringing of a bell intermittently has been the method employed from time immemorial, but this system has its disadvantages because sound as created by fog horns or whistles is often distorted to such an extent by deflection and absorption that at times it becomes impossible to locate with the proper degree of certainty the direction from which it is coming. It has been found also that there are silent areas of considerable extent where such signals are inaudible, although such silent areas may be closer to the whistle or bell and ships at a greater distance than those within the silent area may receive such signals. Because of this uncertainty of sound signal there has been devised a light signal which discharges neon gas at a high electrical tension and tests have proven these lights visible at certain distance when other lights are completely obscured by fog.

I saw recently that there has been an invention which really sends an electric ray through dense darkness.

The International Marine Conference of 1889, held in London, codified the rules for the safety of life at sea and prescribed international requirements for the preventing of collision. In 1914 another International Marine Conference was held which modified and added certain provisions to the former Conference.

On October 4 of this year, there is to be held in Washington an International Radio Telegraph Conference which is to consider and amend the articles of the International Radio Telegraph Convention of 1920. At this meeting, consideration will be given to the revision of the International Code of Signals to bring it up to modern requirements as it has not been revised since 1889. At this forthcoming Conference, interested Government Departments, of which there are a number—The Weather Bureau of the Department of Agriculture, the Coast Guard of the Treasury Department, the Department of Commerce, the Department of State—are working in co-operation with the commercial telegraph and radio organizations throughout the country. Some forty-odd foreign nations are to be represented. The Shipping Board, as the Government instrumentality interested in merchant marine and passengers, is lending its utmost aid.

A terror of the seas which demands every precaution is the menace of the iceberg. There are several ways of determining the location of an iceberg. One of the most simple is to run into it while trying to maintain the ship's schedule. After so locating the berg, it will be found the ship is fast aground

on a ledge which is worn just below the surface by the action of the ocean current. The cooling breeze wafting gently downward from the neighborhood of the ship's topmast will assist in proving that an iceberg has been located. I am glad to state, however, that icebergs have not been located in this manner by any of our vessels. The temperature of the atmosphere and the sea are recorded on an iceberg-alarm device located in the pilot house. To determine the direction of the berg an under-water sounding device similar to that used for determining depth of water beneath the ship's bottom is used, which gives the true direction of the berg by the echo of this sound.

It is quite interesting that in going through the North Atlantic where formerly there was great menace of icebergs, you seldom find now any of our great passenger steamers slowing down in the least, even during foggy weather, due to the installation of this wonderful device.

The Ice Patrol in the North Atlantic

Following the epoch-making disaster of the "Titanic" the Government of the United States offered to maintain an ice patrol in the North Atlantic during those months when the icebergs threatened the vessels running between North America and Northern Europe. In accordance with this arrangement, each year two United States Coast Guard vessels are detailed for this work, relieving each other at intervals of two weeks. In the early spring the vessel on watch takes up a position several hundred miles off the coast of Newfoundland and when the bergs begin to come down from Greenland the southernmost berg is located and the vessel drifts south with the berg, sending out radio messages at frequent intervals warning all ships of the latitude and longitude of this southernmost berg. In accordance with standard instructions all passenger vessels keep to the south of the point indicated by the patrol. When the berg has finally dissolved in the warmer water the patrol vessel heads north until another berg is encountered when the patient watch is recommenced.

The word "Fire" at sea causes the greatest fear and anxiety to the officers and crew, particularly in the event it occurs on a passenger vessel. Discipline of the sea obligates every member of the crew to make any sacrifice to extinguish a fire without it becoming known to the passengers.

Modern cargo vessels are equipped with steam lines to all cargo space for the smothering of fire by merely opening a valve. Passenger vessels also have these facilities. In addition fireproof and watertight doors make it possible to completely isolate any particular compartment in which there may be a fire.

Story of the Dumb Congressman

I will tell this anecdote as indicating often times the layman is unfamiliar with very simple things. During a congressional investigation of the sinking of one of the great vessels, a Senator of the United States, who was a member of the investigating committee, asked the first officer of the vessel why, when the vessel began to sink, the passengers didn't get into the water-tight compartments? That is an actual fact and is in the congressional record, indicating why I am calling attention to these things, although I hope none of my audience will ever try to crawl into water-tight compartments or suggest it to their friends.

In all staterooms on a modern passenger vessel a small device usually hidden in the joiner work gives immediate notice of an increase of temperature over normal and this is recorded on the master device located in the pilot house on

the bridge of the vessel. The officer and such members of the crew assigned to the particular station are summoned by signals and the fire is being fought within a very brief time after its discovery.

The smoke detector system, which consists of numerous small pipes running from the various rooms, compartments and cargo holds to the detector signal board in the pilot house is also used on all well-equipped ships. By the use of a small electric motor air is continuously drawn through these pipes from all sections of the vessel and exhausted in front of a reflector lighted by a small electric light. Should smoke be exhausted it immediately becomes visible similar to a beam of light entering a dark room through a small crack.

There are other numerous hand-operated fire alarms of the familiar "break the glass and pull the hook" variety located in all parts of the ship which likewise report an alarm to the central station. All of these fire-indicating instruments are grouped in or near the pilot house and a constant watch day and night is maintained by men detailed for that particular purpose and who do not perform any other duty during the period of the watch. For the machinery spaces a smothering blanket of liquid chemical is instantly released from large storage tanks by merely opening a valve.

Adequate Life Boat Equipment

The necessity of abandonment of a vessel at sea today is remote but vessels are prepared for this contingency. The lifeboat equipment is required by law to be sufficient to accommodate all passengers and the ship's personnel. The motor launches of the passenger vessels are equipped with radio sending and receiving apparatus. All lifeboats have automatic or semi-automatic releasing devices as one of the most essential parts of the lifeboat equipment. You will no doubt well remember the "Titanic" disaster which claimed so many lives. At that time the releasing gear was not perfected as it is today, and lifeboat after lifeboat loaded to capacity with human lives, capsized or was dashed to pieces against the steel sides of the vessel before it could be released from the tackle and pulled to safety by its crew.

To meet the emergency of abandoning ship and fighting fire, there are held what are known as "fire," "abandon ship" and "boat drills." There must be for each lifeboat or raft a certified number of capable seamen supervised by an officer, all of whom have had sufficient seafaring experience to enable them to qualify as certified lifeboat men.

Before a vessel sails a muster list is prepared, approved, and posted at designated places throughout the ship, especially in the crews' quarters for the guidance of all persons concerned.

Life preservers are arranged for easy access in every stateroom in accordance with regulations of the United States Steamboat Inspection Service. Small life preservers are furnished and are easily accessible for the use of children.

In the endeavor to minimize accidents to the members of the crews of our ships, I have recently arranged a special contract with a firm of safety engineers whose duty it will be to promote industrial education and accident prevention. We have found that on our United States Lines steamers that three out of every five accidents to the crew were sustained through human rather than mechanical failure. These losses have not been confined to new employees but are common to the older and experienced seamen due to their disregard of existing hazards and their willingness to assume an unnecessary risk. This contract which we have recently entered into is an additional expense in our operating costs, but I believe it will impress our seamen with that care

and scrutiny of their duties which will lessen the foolhardy risks they might undertake and in turn protect their fellow workmen. Such an expenditure reflects not only in the morale and humanitarian aspect but also in economy in claim settlement.

Among the perils a Master encounters at sea, is one peculiar to the Far East where our vessels contend with an Oriental maritime superstition. The small junks in the Chinese and Philippine waters deliberately cross the bow of steam vessels under way and as a result it is not uncommon to run down these small craft. There is a prevailing belief among the Orientals that in crossing the bow of another vessel, the local devils pursuing their craft will be transferred to the other vessel. They believe that the closer this passing is accomplished, the more efficient the transfer of devils is made, but very often their calculations result in the loss of their craft and perhaps some lives. This, however, is a problem in "Safety at Sea" which inventors must leave to the missionaries.

Under this broad title "Safety at Sea," I desire to mention the United States Shipping Board policy regarding the employment of seamen for our vessels, as I feel it will interest you. All seamen are required to undergo a thorough physical examination prior to employment.

I heard mention made by the previous speaker of the great danger of tuberculosis. We give particular attention to that. All of our waiters are very carefully examined. If there is the least indication that a man has tuberculosis, he is not employed, as you can readily see the great danger that would come from this white plague in being passed on to others.

A Safeguard for Passengers Also

The safeguarding of the whole of our vessel personnel in this manner protects others aboard the ship including the passengers. At New York, Baltimore and New Orleans we have our own medical staff with the necessary facilities for making these thorough physical examinations; at the other ports such as Boston, Philadelphia, Norfolk, Savannah, Mobile, Galveston, San Francisco, Portland and Seattle, thorough physical examinations of seamen are made for us through the courtesy of the United States Public Health Service. During the fiscal year ending July, 1927, there were 68,636 placements made by our Sea Service Bureau of seamen physically competent to properly discharge their duties. The employment of this large number of seamen will also give you a definite idea of why a thorough physical examination of every seaman is required, if we are to protect the health of not only our entire vessel personnel, but of our passengers.

We are not entirely satisfied with these precautions. Every effort is made to maintain seamen's quarters aboard ship in perfect sanitary condition. The discipline maintained aboard our ships demands this and we have greatly benefited the seamen on American ships by having practically revolutionized their living conditions, giving them comfortable bunks, with clean mattresses, linen and blankets, excellent light and natural ventilation, supplemented by electric fans and artificial ventilation. The food served is of good quality, well prepared, and in sufficient quantities. All water used for drinking and cooking purposes aboard ship is very carefully safeguarded. Our policy may appeal to you as being expensive, but the avoidance of a few cases of injury or death suffered by a passenger, or a member of our ship's personnel, or loss or damage to cargo fully offsets the cost.

I wish to refer to the La Follette law, a law that was passed to guard the American seamen in American ships. You cannot expect the youth of America

who choose to go to the high seas to work under any less favorable conditions than their brothers who stay at home in the factories and are fully safeguarded. We find many private ship owners and operators who complain about that law. It requires them to go to large expense to provide suitable living conditions, well-ventilated quarters, clean and decent sleeping accommodations, good food, and all those things that a decent, respectable seaman should have, in my opinion.

America is raising the standard throughout the world today and is demanding more and more comfort and safety for the men who go on the high seas.

Great Improvements for the Seamen

If that question ever comes up to you in any way, just remember that it is only an endeavor to give to the men on the high seas the same reasonable, comfortable working conditions that you are giving to the men on shore, who are protected by state laws, by federal laws, by municipal laws, in the factories and in the work shops. We are doing that in the Merchant Fleet Corporation today. It would amaze you if you could go through some of the quarters that are provided in the United States Lines for the members of our crews, and then go through some of the quarters provided in some of our foreign competitors' boats. We shall continue that policy. It is not only human, but it is the one thing that America must do. America must take the lead in these matters, as we have taken the lead in nearly every other field of industrial effort to safeguard our people, the men who work with their hands.

Time after time passengers will ask "Why is it that we never pass any large steamers?" The answer is this: one of the first moves to prevent collision at sea was the establishing of definite lanes of travel for passenger vessels crossing North Atlantic. These lanes are laid out for different seasons of the year, and westbound vessels maintain their course approximately 60 miles to the north of eastbound vessels. In this manner there is small opportunity for passenger vessels to meet even in the densest fog. There is no law compelling cargo vessels to keep off these lanes, but by custom of the sea, cargo vessels keep clear of the passenger lanes except when necessity compels them to cut across due to their ports of call.

I said that I was going to crave your indulgence for a few minutes to present to you a problem that I feel is of very great importance. It is one of the problems that has particularly come to the fore since the so-called failure of the Geneva Conference. That is the question of whether or not this great country of America, this great United States, shall have and shall continue to maintain a Merchant Marine Fleet that shall meet the requirements of her foreign commerce and keep the American flag flying upon the high seas, upon all those trade routes that are essential. That is a great problem; it is a problem which you people in the great Middle West are as seriously concerned with as those on the Atlantic and the Pacific coasts. This is a great country; it has been very difficult to make the people of this country sea-minded. It is not their fault, of course.

As I told the representatives from the Seaboard the other day, you are only traveling around the rim of a great coconut; the real milk of the coconut lies in the heart of America. As our industries are being built up in this great Middle West, as the center of population moves westward, as we develop more and more a great world trade, the necessity for an overseas route to all the present markets and the great future potential markets of America becomes more and more an important matter, to this great Middle West, the great heart of America, to the farmer, to the manufacturer, to the exporter, to the miller.

and to the lumber men, who are all engaged either in agriculture or in industry.

It is a lamentable fact that the bulk of our foreign trade is today being carried in foreign flag vessels owned and operated by the very nations who are our industrial and agricultural competitors in the markets of the world. Of all the great travel in the North Atlantic, 70 per cent of which is by Americans, we have five vessels flying the American flag today, headed, as you know, by the great "Leviathan." These vessels compose the fleet known as the United States Lines, which is operated directly by the Merchant Fleet Corporation, with the managing office in New York. Just think of that! Seventy per cent of all the travel on the North Atlantic is American, and American dollars are paid into foreign ship coffers, and those ships are built, they are repaired, they are victualled, they are supplied in their home ports. All of these dollars go where? They do not turn back to America that supplied them, but go rolling to the trough of Europe.

Other Nations Have Renewed Competition

That is an economic question. It is an interesting fact in this connection to note that the ship is only the carrier of foreign trade. America has advanced industrially to such a point that we must have markets for our surplus products, if we are to maintain our future national commercial supremacy and prosperity.

In 1914 we had \$3,850,000,000 of foreign trade, and our exports exceeded our imports by \$477,000,000, a very comfortable balance, a balance that you see was about 12 per cent. In 1916 our foreign trade had reached the stupendous total of \$9,250,000,000, and our balance of trade was less than a half a million.

The other nations of the world, as they are coming back to their pre-war productivity, are opening up new markets. We have hundreds of millions of people in Africa and South America; remember, there are 90,000,000 south of the Rio Grande. There are 180,000,000 in Africa, 500,000,000 in China, 500,000,000 in India, and untold millions scattered through the great Malayan Peninsula. As they are rising gradually in the scale of civilization they are demanding more and more the products of the Caucasian race, more and more the products of American civilization. America today is better equipped to supply those by reason of her high industrial development and mass production, than any other nation in the world. But we cannot reach those markets and we cannot hold those markets unless we have the carrying trade. We must have the vessels to transport them. How can we reach a market of another nation producing the same article, reaching for the same market, controlling a merchant marine service fostered by her people and by her government, if we must look to those nations to transport our surplus products?

I want to tell you what we are doing. We are operating today nearly 300 passenger and cargo vessels, including a small fleet of tankers, on twenty-four trade routes leading to every market of the world, operated by the United States Shipping Board about which you have heard so much talk, and rarely have our foreign competitors and those who are interested in foreign flag lines given us any real credit for what we honestly and conscientiously are trying to do.

There has been a challenge that America, who leads the world today in every field of industrial mechanics, cannot build, cannot operate and cannot maintain merchant vessels upon the high seas in competition with those of other nations. Gentlemen, that is a challenge to the militant spirit of America, and that challenge, I feel, is not going unanswered. I have an abiding faith in the militant spirit of America, in that same militant spirit that has transformed the wilderness into a great and prosperous nation, to answer that question and to put the American flag upon the high seas in every place that she has a right to

have the flag, not to dominate the seas, not to have commercial supremacy of the seas, but to give her, with due regard to the rights of other nations, that place to which she is entitled as a great nation and a great people. We are going to do that, and during these days of hard pioneering effort that the Shipping Board is passing through, have a little indulgence and a little kindness in your criticism. Remember that all great pioneering efforts are full of mistakes. We have only been engaged in this activity for seven years as against the other nations for 100 to 300 years.

As an example of what we are able to accomplish, last year we reduced the expenses of the United States Lines, which lost \$645,000 the year previous, and turned it into \$370,000 profit, and I think that shows that Americans can hold their place on the high seas. They are afraid of America, these foreign nations; they are afraid of our little United States Lines because it indicates what America will do when she makes up her mind to do it in the way that America has always accomplished all great enterprises that were essential to the prosperity and security of her people.

In regard to the cargo vessels, we were losing \$13,780 a voyage, on an average. During the past year, with a larger fleet, we have reduced the average to \$9,000 per voyage. That is some accomplishment. It indicates what we can do. So have faith in the agency that is trying to do honestly and conscientiously the task that you have set for it. Whenever you have any criticism, send it in. We want to be criticized. Any system or administration that won't accept criticism is not worth living. But give us constructive help, some constructive thought, some constructive suggestions. Ask all of the men who are shipping to look about and see if the American flag vessels can't give them equal service. We can do that.

Our Nation's Welfare Depends Upon Us

I just ask you again to bear in mind that America's prosperity and future security depend upon this. We must dream dreams and see visions of what the next generations will demand and must have to maintain this country in the great place that she has a right to occupy among the nations of the world. We must give serious thought to this question of creating an American merchant marine. Don't let the question as to government ownership or operation and private operation defeat the great object. That has defeated it continuously, and that is a question as old as government itself. I personally am in favor of governmental aid in some form that will permit private enterprise to carry out this great national work, but until that is solved by the American people and by their representatives in Congress, we who are charged by law with this great task shall continue to carry it on as efficiently and economically as it is possible to do under all the handicaps that surround direct governmental operation.

Give this some thought. It is a matter that is coming up in the coming Congress. We must have modern, up-to-date ships. No man or group of men, no genius in shipping, can any more take the nine and ten-knot cargo vessels that we are now operating and compete with the fourteen to sixteen-knot modern Diesel vessels of our competitors than you can establish a stage-coach service drawn by horses, no matter how efficient it may be, and compete with the modern motor bus. Therefore, we must have some method (and that method must be provided by you), of building a modern, up-to-date merchant marine fleet that shall be commensurate with that greatness to which we are entitled in world commerce, that shall spell security to the future generation.

As I said before, I have an abiding faith in the American people that they have the good judgment, the militant spirit and the business acumen to accomplish this great result.

Annual Address of the President**Walter G. King, American Optical Co., New York City**

This is our Sixteenth Annual Congress and on behalf of the National Safety Council I extend a cordial and hearty welcome to everyone. We are glad you are here to renew friendship and acquaintance and we know the time spent at this conference will be fruitful and helpful to us in facing our daily problems in accident prevention.

The people of Chicago have done everything for our convenience and comfort and we desire to express the thanks of the National Safety Council to everyone who has worked to make this Congress a success.

On this, our sixteenth birthday, it is gratifying to report on behalf of our Executive Committee and officers a record of still further progress in the great National Safety Movement.

Another successful year has been added to the history of the National Safety Council with results accomplished that are real and important.

The National Safety Council now represents fifteen years of continuous history in loyal self-sacrificing service to its members, a history that stands for much in the life of our Council and the welfare of humanity.

To be a servant of the Nation is a privilege. It is our happiest occupation to serve the American people through the influence and activities of the National Safety Council. We are servants of the public, crusaders for the great cause of accident prevention and loyal members of an institution that has persevered faithfully in its efforts to conserve human life. Next to creating a life, the greatest thing is to save a life—there is nothing that can so well justify our citizenship as this gospel.

In reflecting upon the status of safety in America, we are impressed with the growth of the science of accident prevention. It has been truly said that as knowledge grows more extensive, it grows more intensive. Many of the safety principles discovered a decade ago are still recognized as dependable for both pioneer and development work, but our intensive knowledge is growing so rapidly that it is a serious question as to whether the National Safety Council and similar public institutions are not developing technical facts faster than the industries and the general public can absorb them. It is fair to state that if the knowledge obtainable from the present archives of the Council were carefully applied to the known accident hazards, that 95 percent of all kinds of accidents could be eliminated. As leaders, teachers and propagandists, our most serious task at the present time is to concentrate our efforts to impress upon the public mind the availability of this knowledge and the need for applying it.

We are keenly conscious of the fact that associations are judged by their achievements. The members of the National Safety Council can congratulate themselves that their years of wide efforts have created the most powerful and efficient safety organization in the world. This accomplishment has been due to many causes. First of all, to the loyalty to our humanitarian undertaking. The Council was conceived in the righteous thought that industry had social obligations and must conserve human life. Our thousand voluntary officers and committeemen have their own daily duties and many opportunities to serve their country, but their services to the National Safety Council is an expression of patriotism, the generous spirit of contributing toward the welfare of mankind; to save their fellow countrymen from premature death. Cecil Rhodes once said: "It is all very well to have a noble idea, but if you do not have enough money to make it effective, is the idea worth while?" The growth and effectiveness of the Council can also be measured in the terms of the business acumen of its members and responsible officers and committees. Business experience has been applied to the economical

administration of the Council affairs. It has always been realized by your selected officers that money, and more money, would be needed to carry out the aims and ideals of its founders. Membership dues have not been sufficient for our purposes. We have had to pave the way by charging for some forms of service, but your auditors have certified to you that every penny of income has been intelligently spent for promoting interest in safety. As the reports of the treasurer and managing director indicate, the Council is in an enviable financial condition; our reserve is sufficient for contingencies and we have a substantial income from many sources, but we must all work together to obtain more money to increase our effectiveness.

We point with pardonable pride to the work accomplished during the past year in the field of industrial safety. That a larger number of employers are making safety an integral part of their plant operations than ever before is revealed by the summarized accident records to the Council for 1926. These records increased approximately 50 per cent over 1925. The significance of this increase is understood more clearly when it is realized that the tabulation and analysis of records is one of the real fundamentals of success in accident prevention work.

If the cumulative experience of our reporting members is typical of American industry as a whole, then we know that the trend of industrial accidents is downwards. It is regrettable, however, that there is no one national agency to which all industrial accident records are reported. Such a reporting system would provide reliable statistics representing the experience of the entire country.

The appreciation of the Council is due to the American Petroleum Institute for its invaluable co-operation in assuming its share of the responsibility for the accidents that occur in the petroleum industry. It is only because of the generous financial assistance of the Institute that we are able to employ a full-time salaried safety engineer to "sell safety" to all petroleum companies. It is hoped that similar associations in other industries will follow the leadership of the American Petroleum Institute.

Credit for Sectional Officers and Committees

Our sectional officers and committee chairmen deserve unlimited credit for the efficient manner in which they have conducted their affairs. The Safe Practices Conference Committee has also merited our gratitude for the unselfish service which it has rendered in this essential branch of our work.

During the past year, regional safety conferences have been held in many leading industrial centers of the country. These, combined with the publicity in trade journals, newspapers, and other mediums are of inestimable value in presenting accident information and inspiration to industrial executives, many of whom could be reached in no other way.

Many books and pamphlets have been published from time to time making available vast funds of information concerning the principles and details of safety education and safeguarding activities. The past year, however, marks the beginning of a new epoch in the safety movement, for without in any way depreciating the values of education and safeguards, research has been given a well-deserved stimulus and scientific studies have been started to determine the fundamental causes of industrial accidents and diseases which should point the way to improvements in methods and processes that not only will minimize the accidents and diseases, but also have a favorable effect upon production.

Substantial progress has been made during the past year in the prevention of accidents outside of industry. It is a striking fact that while industrial machinery and factory methods existed for several generations before the birth of the industrial safety movement, the recent advent of the automobile on our streets and highways has been followed almost immediately by a popular demand for prevention of the accidents which have arisen from this new invention. Certainly the conscience of the American people is more alive today than ever before to the value

of human life and the necessity of conserving it. As we read in the newspapers, the daily record of public accidents, which in many parts of the country are still increasing, our hearts revolt at this continued slaughter. Approximately 2,000 children were killed in automobile accidents last year, fully 140,000 boys and girls were injured in the streets and highways by motor vehicles. Practically all of these youngsters were between five and fifteen years of age. The deplorable fact is that practically all of these accidents might have been prevented. We feel almost horrified at the ignorance or indifference which permits it. It is well that we, as leaders of the safety crusade, should be filled with this holy zeal. But we may also remember that it takes a good while to move 120,000,000 people and that seldom, if ever, in our history has any national need, short of war, aroused so quick a response as has been awakened by the need for safeguarding travel on our highways.

We must confess that if anyone expected the millennium to follow immediately upon the adjournment, eighteen months ago, of Secretary Hoover's second conference on Street and Highway Safety, he has been disappointed. The participants in that impressive gathering did not, as some perhaps expected, at once put into effect in every corner of the land all the remedial measures recommended by the conference. Of the state legislatures in session this year only one-quarter adopted any considerable part of the conference recommendations. Opposition appeared in unexpected quarters, but we must remember that all remedial legislation must travel a rough road. The results actually obtained, in motor-vehicle legislation for safety, were probably quite as great as might have been expected the first year. The efforts of our national and local councils and of our allies in this cause must go on unabated and with methods improved by what experience has taught us. After all, we put our trust in educational processes rather than in legislation; in voluntary co-operation rather than in coercion.

Cooperation for Safety in Aviation

Aviation, our most recently developed method of transportation, promises to eclipse all competitors for the expression of the spirit of our day and age—speed. It is earnestly to be desired that the same splendid qualities of engineering that made this wonderful accomplishment a fact will insure the greatest possible degree of safety in this new science. Proper governmental regulations should keep pace, protecting against unnecessary loss of life through careful licensing of pilots and their ships of the air. The National Safety Council stands pledged to cooperate in the development of a constructive policy for safety in aviation.

I want to call attention to the truly remarkable accomplishment of our Statistics Committee and the Statistical Bureau of our staff, secured by purely voluntary methods. Under their leadership, in less than three years, a uniform system of reporting the facts about automobile accidents has been adopted and put into use by cities and states covering over one-quarter of the population of the country. These jurisdictions, more than sixty in number, are making monthly reports to our national headquarters, possessing an accuracy and detail that were unknown in all but a few such jurisdictions three years ago. As a result we are rapidly building up, for the first time in the history of the world, a mass of accurate and valuable information about the real causes of accidents—*Why people get hurt*. With the recent enlargement of our Statistical Bureau, made possible through the contribution of Mr. John D. Rockefeller Jr., we are making every effort to live up to our responsibilities in this field by scientifically analyzing and interpreting the accident data thus secured for preventive purposes. Our statistical work furnishes a perfect example of what is the proper function of the National Safety Council which does not itself go out on the highways to collect accident reports, that being the proper function of the state and local governments; but works with the various officials, furnishing them the scientific assistance they desire, and helping them to coordinate their efforts for the common good.

An equally important contribution has been made by our engineers. In a community as in industry, preventive work must be based on a definite knowledge of the problem. The traffic problem has come upon our American communities over night and few, if any, of them have been prepared to handle it. Traffic signals, one-way streets, boulevard stops and similar measures are an aid to the safe and free movement of traffic when properly used, but when improperly used they are a tremendous nuisance and an unnecessary expense. Our larger cities have, as usual, been the first to recognize the need for engineering analysis of these problems and they can afford such service. The smaller cities realize in a general way their need for technical advice, but often they do not know where to get it and sometimes they cannot afford to pay for it. Within the past three years our engineers have assisted twenty-one cities in making scientific analysis of their traffic and safety problems through surveys directed by members of our staff, but utilizing to the fullest extent the participation of local officials and representative citizens. This is one of the most valuable services that the Council has been able to render to the American people.

Along with these community surveys we have continued to do our full share and more in working out engineering remedies for public accidents.

Education Division Doing Splendid Work

In the teaching and training of school children our Education Division has continued its splendid work. Through our school magazine *Safety Education*, field work, prompt correspondence with many cities, attendance at educational conventions and other means, the work of this division is undoubtedly getting results not only in the reduction of child accidents today, but in the rearing of a safer generation for tomorrow. For this accomplishment we again acknowledge our deep indebtedness for the generous financial support of the National Bureau of Casualty and Surety Underwriters.

The real application, the every day use, of all this service can only be brought about through the continuous efforts of local safety organizations in the larger cities at least. At the present time there are organized councils reaching a total population of 22,209,000, and we have considerably increased our efforts to organize community councils where fertile soil is found and more especially to assist those already in existence. Our staff is much better equipped than ever before to assist every local group to direct its efforts so as to achieve success and financial stability. For the year 1926 the local council cities reporting their accident records to us show a 7 percent better record in automobile fatalities than the other cities of the same general size and character. During the first part of 1927 the local council cities again showed a better record than the others.

It is gratifying to report that during the past year the prestige of the Council has been increased to a most encouraging extent. That the press of the nation has been impressed with the work of this institution is indicated by the fact that we have received more than 1,000 editorials mentioning the name of the Council. Thousands of articles inspired by the Council have appeared in daily papers from coast to coast. Thousands of pictures, presenting safety lessons have been published in daily newspapers. Hundreds of trade, technical and class periodicals have printed special safety features. Daily radio talks have been broadcast by more than eighty stations in various cities. Today the National Safety Council is recognized by editors throughout the world as the headquarters for accident prevention information. We also receive requests for data from publications in other countries. The leading press associations and news syndicates look to our organization for accurate facts. We have established a reputation for being more interested in spreading facts relating to the lowering of accident fatalities than in trying to procure publicity for ourselves, a policy that is respected by the press.

We have continued the most cordial relations with many other national and local bodies—the American Engineering Standards Committee, the American Association of Industrial Physicians and Surgeons, the various federal and state departments, the Safety Section of the American Railway Association, the insurance organizations, the national and local Chambers of Commerce, Associations of Motorists, engineering societies, the service clubs, and many others which are working continuously in some measure on the solution of the accident problem.

We members of the Council assemble only once a year for the valuable personal contacts and the values of our discussion, but the work of the Council must go on throughout the year, and I commend to you particularly the services rendered on your behalf by our national officers, Executive Committee, Directors, Headquarters Staff, and the many other committeemen whose faith and confidence you have established.

I am confident that the sessions of this Congress will be an inspiration to everyone of you to go back home and perform that kind of safety service which springs from the heart, that you will continue by your own personal efforts, by your day-by-day, hour-by-hour accident prevention work in your communities, a service which will result in great benefit to humanity during the coming year.

PRESIDENT KING: The Executive Committee having appointed three Inspectors of Election, the Chair will appoint these men also as tellers of this meeting. These gentlemen are: Fred M. Rosseland, Walter S. Smith, and D. K. Finley.

The next item on our program is the reading and disposal of the minutes of our last Annual Meeting. As the minutes have been printed, a motion will be in order to dispense with their reading.

ROBERT SCOTT (Atlantic Coast Line Ry.): I move we dispense with reading of the minutes.

(The motion was seconded and carried.)

PRESIDENT KING: The next item is the report of the Nominating Committee. Mr. J. E. Long, as chairman of that committee, will present the report.

Report of the Nominating Committee

Complying with your instructions, we, the Nominating Committee, appointed by you, with the approval of the Executive Committee and as provided for in Section 4 of Article VI of the By-Laws of the Council, and as further provided by Section 5 of Article VI of the By-Laws, present herewith the report of nominations for successors to the Directors whose terms of office expire at the annual meeting, September 26, 1927.

The following list has been approved by the Committee and is herewith submitted:

Nominated to succeed those Directors whose terms of office expire September 26, 1927:

Irving T. Bush, President, Bush Terminal Company, 100 Broadway, New York City.

William C. Dickerman, Vice-President in Charge of Operations, American Car & Foundry Company, 165 Broadway, New York City.

Alexander Forward, Secretary-Manager, American Gas Association, 342 Madison Avenue, New York City.

Dr. F. L. Hoffman, Dean of Advanced Department, Babson Institute, Inc., Wellesley Hills, Mass.

F. T. Singleton, Commissioner, Public Service Commission of Indiana, Indianapolis, Ind.

E. C. Spring, General Supervisor, Lehigh Valley Transit Company, 14th and Gordon Streets, Allentown, Pa.

Lucius S. Storrs, Managing Director, American Electric Railway Association, 293 Madison Avenue, New York City.

L. W. Wallace, Executive Secretary, American Engineering Council, 26 Jackson Place, Washington, D. C.

C. W. Berquist, Superintendent of Industrial Relations, Western Electric Company, Hawthorne, Chicago, Ill.

H. T. Martin, Manager, Health and Safety Department, Fisk Rubber Company, Chicopee Falls, Mass.

H. K. Ferguson, President, The H. K. Ferguson Company, 4900 Euclid Avenue, Cleveland, Ohio.

The names of the following Directors whose terms expire September 26, 1927, are submitted for re-election:

E. W. Beck, E. F. Blank, Dr. Louis I. Dublin, G. T. Fonda, I. V. Kepner, R. M. Little, Dr. L. A. Shoudy, Robbins B. Stoeckel, Prof. C. E. A. Winslow, and R. J. Young.

Very respectfully yours,

J. E. Lyng, Chairman.

PRESIDENT KING: A motion will be in order to accept the report of the Nominating Committee.

(A motion was regularly made, seconded and carried that the report of the Nominating Committee be accepted.)

PRESIDENT KING: Under the provision of our by-laws, a motion to close the nominations is in order.

MR. SCOTT: I move the nominations be closed.

(The motion was seconded and carried.)

PRESIDENT KING: As there have been legally nominated just enough men to take the place of those Directors whose terms expire and to fill the vacancies, the Chair suggests that in order to facilitate the transaction of our business, the Secretary be directed to cast one ballot for the candidates named for the terms for which they have been nominated.

(A motion was regularly made, seconded and carried that the Secretary cast one ballot for the nominees presented. The Secretary cast the ballot.)

PRESIDENT KING: The report of the tellers shows that 2,216 votes have been cast for the nominees, and none against. It therefore gives me pleasure to announce that these gentlemen have been unanimously elected Directors of the National Safety Council for the terms for which they have been nominated.

I should like to ask Mr. Charles B. Scott, Chairman of the Resolutions Committee, to report any resolution which in the judgment of that committee should be entertained by this conference.

CHARLES B. SCOTT, Bureau of Safety, Chicago: Mr. President, your Committee on Resolutions offers the following in memory of Judge Elbert H. Gary, honorary member of the National Safety Council.

Resolution in Memory of Judge Elbert H. Gary

"WHEREAS, In the death of Judge Elbert H. Gary, Chairman of the Board of the United States Steel Corporation, we have lost an honorary member of the National Safety Council, and

"WHEREAS, His loss not only is deeply felt by a multitude of friends and co-workers throughout this Council membership, but is shared by a grateful

nation, appreciative of his sympathy and powerful influence in furthering the pioneer safety work of his corporation, and

"WHEREAS, These distinguished services in the Safety Movement must have their continuing influence throughout the field of industry, in the betterment of working conditions, in the upbuilding of human happiness and in the saving of human lives, now therefore be it

"RESOLVED, By the officers, directors and members of the National Safety Council assembled in Annual Meeting, that we express by a silent rising vote our profound sorrow and regret at the passing of Judge Gary, and be it further

"RESOLVED, That a copy of this resolution be transmitted with our deep sympathy to Mrs. Elbert H. Gary and to the Board of Directors of the United States Steel Corporation."

I move you the adoption of this resolution.

(The motion was seconded and carried by a rising vote.)

MR. SCOTT: Mr. President, your Committee also offers two separate resolutions outlining the platform of the Council with reference to public safety and industrial safety, as follows:

Public Safety Resolution

WHEREAS, In the United States last year, some ninety thousand persons were killed and innumerable others were injured by accidents on the streets, highways and other public places, at home and in the industries, causing pain, sorrow, deprivation and an economic loss of billions of dollars, and

WHEREAS, A majority of these accidents could have been prevented as was demonstrated by the thousands which have been prevented through united efforts of those intent upon accident prevention, and

WHEREAS, Public officials and leaders of public opinion have become increasingly alarmed over the traffic accident problem in particular and have very properly determined that this wastage of life must stop, therefore be it:

RESOLVED: That the members of the National Safety Council and others greatly interested, assembled in Chicago at the Sixteenth Annual Safety Congress, pledge themselves to continue diligent and ever increasing efforts to prevent accidents and to further and make effective these efforts, recommend to the states and cities, the schools, civic organizations and all citizens, the following:

1. Adoption of the Standard Accident Reporting System in every state and city so that effective preventive measures may be based on accurate information.
2. A scientific, non-partisan study of the traffic situation in each city; the improvement of streets, revision of ordinances and regulations, and adoption of traffic control measures as shown necessary by such surveys.
3. Universal acceptance of the principle of uniformity in state and city traffic laws and regulations and in the design and use of signs, signals, and pavement markings, for both safety and convenience, and the generous co-operation of all interested officials and organizations to that end.
4. The licensing of all drivers, under state law, in such manner as will eliminate as far as possible the unfit and irresponsible.
5. The unstinted recognition by all users of the highways, both motorists and pedestrians, of the rights, the safety and the comfort of all other users.

6. The safety instruction and training of all school children and, to that end, the furnishing of necessary safety information and materials to all teachers.

7. The continued co-operation of newspapers and periodicals, as well as of all civic organizations, in giving the widest publicity to the consequences of accidents, to the specific means of avoiding accidents, and to the vital need for personal caution and law observance.

8. The impartial and certain enforcement of reasonable laws on that small minority of the population who cannot otherwise be brought to realize the rights of others.

9. The promotion and the co-ordination of all these measures through the formation, in each community, of a community safety council or committee, non-partisan, non-commercial, representing all groups and interests, mobilizing the forces of public opinion and supporting the public officials in the loyal and efficient performance of their duties.

Industrial Safety Resolution

WHEREAS, Some twenty-four thousand workers were killed and hundreds of thousands were injured in industry during 1926, causing pain, sorrow, destitution, interruption of orderly processes, slowing up of production and the economic loss of billions of dollars imposed upon employers and employees, and

WHEREAS, more than forty-three hundred employers, members of the National Safety Council, have demonstrated that most accidents can be prevented through organized prevention work, and

WHEREAS, it has been demonstrated, by members of the National Safety Council, that this achievement is possible in all fields of industrial endeavor, if all employers and employees will realize that accident prevention is a responsibility which should be shouldered by everyone, Therefore, be it

RESOLVED, that the members of the National Safety Council and others deeply concerned, assembled in Chicago, Illinois, at the Sixteenth Annual Safety Congress, urgently recommend the following:

1. That all employers make a survey of their respective establishments, both large and small, to ascertain the why, where and how of accidents and accident prevention.

2. That employers keep and analyze their accident records for the purpose of devising ways and means of preventing the recurrence of accidents.

3. That employers safeguard, in so far as possible, all mechanical equipment and revise manufacturing processes so as to eliminate these hazards.

4. That the personnel of all establishments be impressed with their individual need of safety and with the necessity of properly instructing their fellow-workers in Safe Practices.

5. That employers support efforts being made by community safety councils, the National Safety Council, federal, state and municipal officials and others, by conducting necessary organized accident prevention campaigns.

6. That employers encourage the inclusion of safety education in the courses of public, private and parochial schools and colleges.

7. That more colleges and universities incorporate Safety engineering in existing engineering courses.

RESOLVED: That those assembled at this Sixteenth Annual Safety Congress hereby express their gratitude to the many employers who have been conducting organized accident prevention plans in their establishments and supporting the public safety movement designed to protect the public, and acknowledge their indebtedness to the millions of employees and citizens generally and to other organizations, editors of newspapers, trade, technical and class periodicals and to radio stations, who have so whole-heartedly supported the safety movement.

I move you the adoption of those resolutions.

B. W. WHEELER (Duluth): I should like to suggest one little addition to the public safety resolution, if there is no objection. It should be numbered 6½, as follows:

"The unstinted education, by automobile clubs and commercial institutions, of all automobile drivers, and the same unstinted education of pedestrians by public officials, in careful, safe and courteous driving and walking on all public highways."

The President has just emphasized education and cooperation, and the education part of this public safety section has to do only with the school children, and adults should be educated as well.

MR. SCOTT: We offer the resolution with the amendment, Mr. Chairman, and I move the adoption of the resolutions.

(The motion was seconded and carried.)

MR. SCOTT: The Committee offers the following resolution in recognition of national organizations.

Resolution on Safety Recognition in National Organizations

"WHEREAS, The National Safety Council has, throughout its existence, greatly appreciated the opportunity of cooperating in a helpful way with many national departments and organizations having an interest in the safety movement, the list of which is too long to be here recited, and

"WHEREAS, There has recently been an increasingly marked and definite trend on the part of many influential engineering societies and commercial and industrial associations toward the inclusion of specific commitments in the interest of safety as an important part of their avowed purposes, and

"WHEREAS, The mutual helpfulness of these departments, societies and associations and the National Safety Council has distinctly advanced the solution of the safety problem, therefore be it

"RESOLVED, That we, in Congress assembled, do appreciate with great interest and with hearty commendation, the increasing determination to adopt safety activities as an essential part of the aims and purposes and as a part of the program of the national organizations, and pledge to all such our continued and increasing cooperation and support."

I move the adoption of that resolution, Mr. Chairman.

(The motion was seconded and carried.)

MR. SCOTT: The Committee on Resolutions offers the following resolution:

Resolution Concerning Aviation

"WHEREAS, Aviation has already become and promises to still further become a matter of extreme importance to our national welfare and calls for the highest order of federal, state, municipal, civic and individual cooperation, be it

"RESOLVED, That the National Safety Council urges the most intensive study and earnest cooperation of all of the aforesaid agencies, and pledges the fullest cooperation at its command to that end."

I move you this as a part of the last resolution presented and move its adoption.
(The motion was seconded and carried.)

MR. SCOTT: Your Committee also offers the following resolution:

Resolution of Thanks to the City of Chicago

"WHEREAS, The holding of this Sixteenth Annual Congress of the National Safety Council in the City of Chicago, Illinois, and the notably successful arrangements made for it are distinctly due to the sincere interest and support of the public officials, civic organizations and leading citizens of Chicago, and

"WHEREAS, The National Safety Council feels that the exceptional interest and ability which these agencies have shown in coping with the accident problem of Chicago is a demonstration of successful safety work which makes a most valuable contribution to the cause of safety, and desires to express its appreciation and to pay tribute to those responsible for this demonstration, therefore be it

"RESOLVED, That a vote of thanks be extended to the City of Chicago, its public officials, civic organizations, industries and leading citizens for the inspiration and help which their demonstration of the possibilities of successful accident control has given to the entire national safety problem, and be it further

"RESOLVED, That the National Safety Council extend to the City of Chicago, through its mayor, through the various sub-committees of the General Congress Committee, and the Chicago Safety Council, its thanks for and appreciation of the opportunity now afforded those attending this conference of observing the practical methods employed in furthering accident prevention and their results, and of the hospitality of a City and people deservedly and far-famed as hosts."

I move the adoption of that resolution.

(The motion was seconded and carried.)

MR. SCOTT: Now, Mr. President, it gives me pleasure to offer this final resolution:

Resolution of Appreciation to President Walter G. King

"WHEREAS, Walter G. King has served the National Safety Council as President during the past year, with marked ability, faithfulness and earnestness, and

"WHEREAS, Much of the credit is due him for the continuous success and expansion of the Council, therefore be it

"RESOLVED, That the Sixteenth Annual Safety Congress assembled at Chicago, Illinois, expresses to Mr. King, by a rising vote, its sincere appreciation of his services as President and of his helpful contribution to the cause of safety."

(The resolution was unanimously adopted.)

PRESIDENT KING: It would be useless, fellows, for me to tell you how much I appreciate that. It is wonderful. It is a great satisfaction to be associated with a group like this. I don't think there is a group like it on the face of the earth. I look forward, as you all do, to meeting these old friends, and seeing these familiar faces.

The expression you made in that resolution touched me very deeply. It is a tremendous reward for all I have tried to do in the work in which I believe so thoroughly. I thank you sincerely.

Is there any unfinished business to come before the Council? Is there any new business?

E. B. LEFFERTS (Automobile Club of Southern California, Los Angeles): We

in the Automobile Club have been very much disturbed by the increasing tendency that we find today in national advertising to emphasize speed in automobile operation. We may not agree as to whether speed is the main cause of accidents, but I think we will all agree it is a contributing factor. It is not in an unfriendly way that I bring this up, but I do believe it is something that should receive the attention of the National Safety Council as the outstanding safety organization in the United States, and that they should, through its Executive Committee, take this up with the motor manufacturers. If it is in order, I should like to make such a motion.

PRESIDENT KING: If you could make that as a part of the resolutions, I think we would all be in accord with it.

MR. LEFFERTS: If that is the proper way, I should like to bring it before the Resolutions Committee and let them draft it.

PRESIDENT KING: I think you all understand this. Do you make a motion to the effect that this be embodied in the resolutions?

MR. LEFFERTS: I make such a motion.

(The motion was seconded by several members and carried.)

PRESIDENT KING: If you will draft that, we will see it is included in the resolutions.

Annual Report of the Managing Director

W. H. Cameron, Managing Director, Chicago, Ill.

During the past fiscal year 693 new members have joined the National Safety Council. A comparison of the total membership for the past two years shows:

Membership July 31, 1927.....	4,359
Membership July 31, 1926.....	4,224

New Gain	135
----------------	-----

The net gain in membership revenue was \$14,144.34. The total annual dues now being paid by 4,359 members is \$252,026.13, or an average of \$57.81 per member. The solicitation of new memberships through the voluntary committees and other ways has been continued unabated.

The NATIONAL SAFETY NEWS has gained in circulation and importance. The quality has improved and the number of special features and articles has increased. The minimum number of pages has increased to 80 per issue. There has also been an increase in the number of extra copies ordered by members. The advertising has doubled. The circulation has been checked by the Audit Bureau of Circulation. The "Safety Exchange" and sectional articles have proved popular. The aim of the NATIONAL SAFETY NEWS is to provide practical information and to keep before safety workers the vision of the worthwhileness of their work.

The Safety Posters have been published regularly and have been steadily improved in quality. Four hundred and eighty posters have been prepared during the year. This includes eight 17x23 inch posters and thirty-two 9x12 inch posters each month. More time and money have been spent upon their preparation, and well-known artists have furnished illustrations. All posters have been made more attractive by the addition of a third color; the circulation has increased 25 per cent and the new varieties have emphasized the growing appreciation of safety posters as an educational medium to lessen accidents. A 34-page catalog of 252 selected posters was mailed to members January 1. A new service of seven sectional catalogs was inaugurated. Poster inserts for every package of posters were distributed on alternate months. Prizes were awarded to workers in contests for opinions on posters. The Council's street posters, distributed through community councils, have filled a need for con-

tinued education of the public in the safe use of the streets. The members and the sectional poster committees contributed generously to make this poster service possible.

The Safe Practices Pamphlets have appeared bi-monthly under the supervision of the Conference Committee of 75 safety engineers. Eighteen of the series have been revised and reprinted during the year. Six new pamphlets have been produced. This "Safety Encyclopedia" now includes 89 separate treatises on the fundamentals of safety engineering practices. One sectional Safe Practices pamphlet for the Quarry industry was produced during the year. New members are ordering complete sets of these pamphlets for reference purposes. Three hundred and thirty-six sets have been ordered by members during the fiscal year.

The Consultation Service has answered 6,266 requests for information. For the fiscal year ending July 31, 1927, there were 2,677 such inquiries. There is a marked increase year by year in the use of the facilities of the Library and Information Bureau. During the fiscal year 50,308 pieces of information were distributed in answer to 6,266 inquiries, including books, pamphlets, clippings, photographs, blueprints, posters and similar material. Forty-one thousand eight hundred and forty-one new pieces of material have been added to the Library files during the year. The largest number of exhibits was prepared for regional and national conferences than during any previous year. The information files have been systematically built up by the acquisition of up-to-date information on all phases of accident prevention, industrial health and hygiene, and allied problems.

Slides and the Safety Calendar

Films and Slides have been in demand by members in increasing quantities. Five new stereopticon machines have been purchased for use of members and the entire glass slide collection has been converted into film slides. There is a continued demand for the Council's films "Ask Daddy" and "Hindsight and Foresight." The Film Committee has prepared a scenario for another new film to be ready for exhibition at the 1927 Congress. The list of motion picture films was revised and reprinted during the year.

The Safety Calendar increases in popularity as a medium for reaching the worker and his family, school children and the general public. Six hundred and fifty thousand copies of the 1927 Calendar were distributed. The 1928 Calendar was ready for sale January 1, 1927, and an effort was made through salesmen to interest non-members in the distribution of this safety information. The information on the reverse sides of the 1928 Calendar sheets relates to fire prevention in the homes.

The 1926 Congress and Exhibit eclipsed every previous Safety Convention in attendance, number of speakers, exhibits and interest. The transactions of that Congress were published in three volumes with complete alphabetical index. The 1927 Congress program, now ready for mailing, will contain 72 pages.

National Safety Codes have continued to receive the careful attention of your committees and staff. Representatives of members of the Council are assisting in the formulation of 40 of the national standard codes. The Council is now sponsor, or joint-sponsor, for 15 codes. The Council continues to contribute toward the expenses of the American Engineering Standards Committee.

Editors of Employee Magazines have continued to receive a special service including original safety cartoons and accompanying stories. Other special material and assistance have been accorded members publishing plant magazines or contemplating the establishment of this type of publication. An attractive program has been prepared for the annual meeting of these editors at the Chicago Congress and the special feature in the NATIONAL SAFETY NEWS giving editorial advice to the publishers of employee magazines has been continued.

The Industrial Sections have been more active than ever. All of them have held Executive Committee meetings and have continued intensive service to the members within their groups. There has been an increase in the number of sections issuing monthly news-letters. Many of the sectional committees have conducted energetic membership campaigns and performed invaluable service to fellow-members by stimulating the furnishing of statistical data, material for posters and an interchange of safety experiences. There were 18 regional safety conferences during the year. Seventeen hundred plants contributed their accident records for 1926 and the tabulation has been printed in a pamphlet and distributed to the contributing members and others. The officers and committees of the sections held a mid-year conference in New York. The first salaried secretary for a section has been made possible through the generosity of the American Petroleum Institute. Another notable addition to the service has been the contribution by several sections of special articles published in the NATIONAL SAFETY NEWS.

The ASSE-Engineering Section has participated in the regional safety conferences, as well as the Fourth Pacific Coast Safety Conference. Five research committees have been at work. A new safety engineer was employed during the year to assist the technical committees with their research problems and the preparation of reports. The amalgamation of the American Society of Safety Engineers and the Engineering Section, which took place at the Louisville Congress, has proved the wisdom of cooperation and has continued the unity of effort and strength necessary to win respect for the safety cause.

General Sections: Nineteen industrial sections have been rendering service to the members during the year in addition to the health, education, engineering, public safety, plant publications and employees' benefit associations.

Work of the Public Safety Division

Public Safety: The Advisory Committee of the Public Safety Division has held three meetings during the year. The Council has continued to assist the National Conference on Street and Highway Safety to accomplish its purposes by stimulating legislation based on the Uniform Motor Vehicle Law. State conferences were organized and followed through for this purpose. Your staff recommended to the conference the preparation of uniform local ordinance and committees are now at work. Much of the Council's activities for safety on the streets and in the home has been directed toward the formation and upbuilding of community safety organizations. The staff of the Public Safety Division was materially increased during the year through the contribution of Mr. John D. Rockefeller, Jr. This extra money has made possible the publication of the monthly bulletin, *Public Safety*, distributed to 10,000 public officials, automobile clubs, chambers of commerce and others. Twenty-two community traffic surveys have been completed to date. The 1927 statistical report has been completed and distributed. The Statistical Manual for reporting street and highway accidents has been revised, reprinted and distributed. An increasing number of communities and states are reporting to the Council their public accident experience. Forms have been completed for reporting home accidents. The pamphlet "Safe Use of Gas in the Home" has been reprinted and distributed. Six Home Safety lessons were prepared and printed. The Dash Board Card service has been continued. Service has been given on several committees, including "Traffic Signs and Signals." Complete revision of material for the Boy Scouts' handbook was contributed. Special engineering studies were made on drowning accidents, on decentralization in cities, traffic courts and bureaus, and effect of parking restrictions. Other similar studies are in process. A special leaflet was printed and distributed through the General Federation of Women's Clubs. Special articles were contributed to many magazines, and conferences and meetings were attended.

The Education Division has made progress through the leadership of Mr. Albert W. Whitney and the generous support of the National Bureau of Casualty & Surety Underwriters. Through the school magazine, *Safety Education*, field work, constant correspondence with many cities, attendance at educational conventions and improved. A catalog of sample posters was printed. Cooperation has been continued other means, and especially through the services of the executive secretary and field representatives, the work has been advanced. A special survey was made of the safety teaching methods in Massachusetts. The school safety posters have been with other national bodies, such as the Playground and Recreation Association of America, the National Congress of Parents and Teachers, and numerous others. This Division was represented at the meeting of the National Education Association and other similar conferences of educational authorities.

Our Educational Publicity Service in the industrial and public safety fields has been considerably increased. Scores of news articles, special articles, seasonal safety lessons, photographs, charts and other propaganda have been used by hundreds of daily and weekly newspapers, magazines, trade, technical and class publications. Dispatches and feature stories have been cleared through the national news distributing agencies. Daily radio talks have been broadcasted through a special service sent to more than 80 radio stations in different cities at their request. Special material has been given to community councils and members for local publicity campaigns. Numerous periodicals have published editorials commending the Council's work. Our news release sheet service is now printed and sent to more than 1,600 newspapers and 500 trade, technical and class periodicals. The mat service is sent to 235 newspapers on request. A national poster contest has been inaugurated among cartoonists and money prizes offered.

Work Among the Community Councils

Community Councils: Our intimate contacts with the services to the community councils have been increased. There are now 60 affiliated local and state councils. These councils reach a population of 22,209,000. Twelve hundred volunteer committeemen are rendering service, the salaried staffs aggregate 110 people, and these councils are spending \$435,000 annually. The Council's service has been concentrated on existing councils but efforts are made to enlist the interest of other communities in local council activities. A new director of this division of the Council's service was employed during the year and another field representative added to the staff. The 10-volume loose-leaf encyclopedia, "Standard Practices for Community Safety Councils," has been kept up to date, and complete working standards have been developed for our field representatives, insuring a more coordinated method of approach in handling this work. The monthly News-Letter of specific information to community council officers, with enclosures, has been continued. Three field representatives have given all of their time to the organization of and service to state and local safety councils. A Summer Institute, lasting one week, was conducted for council managers and prospective managers. The quarterly conferences of managers were continued. A Speakers' Manual was prepared, printed and distributed during the year. Detailed standards for Inter-Fleet and Inter-Plant Accident Reporting Contests have been developed and are now being used by 17 councils. The service and experience of the National Safety Council and local councils on many recommended activities have been organized and prepared as memoranda.

External Relations: Friendly relations have been maintained with other institutions interested in safety, such as the American Red Cross, American Museum of Safety, Chamber of Commerce of the United States, Canadian Safety League, American Association of Industrial Physicians and Surgeons, the Safety Section of the American Railway Association, American Gas Association, the Safety Bureaus of the Insurance Companies, National Fire Protection Association, National

Education Association, Joseph A. Holmes Safety Association, International Association of Chiefs of Police, Playground and Recreation Association of America, National Child Welfare Association, American Automobile Association, National Automobile Chamber of Commerce, Associated General Contractors of America, International Labor Conference of the League of Nations, the State and Federal Government Departments, as well as the American Engineering Standards Committee and the National Bureau of Casualty & Surety Underwriters. The Council has maintained its policy of cooperation with these institutions and has looked for opportunities for closer contacts with those leading the safety movement in their respective spheres of influence. A great many safety exhibits have been furnished on request for trade association meetings and similar affairs.

General Activities: The Research Committee to study the health problem due to the use of spray guns has completed its work and the final report, with appendices, is now in the printer's hands; approximately \$10,000 has been spent on the field investigation and printing. One hundred thirty-one bulletin boards have been distributed among members. A new but simple bulletin board has been designed for new members. The distribution of the pamphlets "Make It Safe" and "Safety-Ize" has been continued into thousands of copies. Assistance has been given in the drafting of a Model State Safety Law for safety codes. A monthly News-Letter has been sent to members. A new service department has been organized during the year. The printing division has been augmented by the purchase of a second printing press. The Council is now printing all its posters, as well as miscellaneous printing jobs, on its own printing presses. A new cost accounting and bookkeeping system has been devised. A new magazine for workers has been planned. A domestic accident committee is studying the home accident problem. The entire offices of the Council have been re-arranged and furnished to accommodate the increasing business and staff of the Council. The foreign membership has increased and the Council has augmented its foreign service.

The Council Headquarters Staff

Staff: The real staff of the National Safety Council is the membership, a large number of whom have contributed to the National Safety News, the safety poster service, the Safe Practices pamphlets, the upbuilding and service of the sections, the Annual Congress, the film and slide collections, and all of the committees, both sectional and local. More than 1,000 persons now serve on these committees. The headquarters staff now numbers 80 persons. The leaders in this staff are:

William H. Cameron, Managing Director.
 Sidney J. Williams, Director, Public Safety Division.
 Julien H. Harvey, Director, Territorial Councils Division.
 W. Dean Keefer, Director, Industrial Safety Division.
 Willard L. Wheeler, Director, Business Division.
 Arnold A. Mowbray, Director, Public Information Division.
 Lee H. Gardiner, Director, Poster Division.
 Paul F. Stricker, Field Representative.
 Ernest W. Corn, Field Representative.
 Robert C. Haven, Field Representative.
 Carman T. Fish, Editor, NATIONAL SAFETY NEWS.
 Guy M. Briggs, Associate Editor, NATIONAL SAFETY NEWS.
 Stanley H. Kershaw, Safety Engineer, Industrial Safety Division.
 George E. Burns, Safety Engineer, Industrial Safety Division.
 Stewart J. Owen, Jr., Safety Engineer, Industrial Safety Division.
 Harry N. Blakeslee, Field Representative, Petroleum Section.
 Earl J. Reeder, Supervising Engineer, Public Safety Division.
 Bruce I. Whiting, Engineer, Public Safety Division.

Reuben L. Forney, Statistician, Public Safety Division.
 Carroll E. Robb, Statistician, Public Safety Division.
 Gordon L. Lewis, Advertising Manager.
 Richard H. Porter, Director, Service Extension Department.
 Herbert H. Greenwald, Accountant.
 George O. Lindquist, Director, Publication Service Division.
 Roy H. Olson, Director, Membership Service Department.
 Idabelle Stevenson, Executive Secretary, Education Division.
 Marian L. Telford, Field Secretary, Education Division.
 Florence Nelson, Editor, *Safety Education*, Education Division.
 Mary B. Day, Librarian.
 Mary M. Wells, Assistant Librarian.
 Myrtle H. Mollan, Chief Clerk.

Annual Report of the Treasurer

H. M. Webber, Vice-President and Treasurer, Chicago, Ill.

COMPARATIVE BALANCE SHEET—JULY 31, 1927 AND 1926

Assets				
	As at July 31, 1927	As at July 31, 1926	Increase	Decrease
Current Assets:				
Cash	\$ 27,562.40	\$ 13,954.26	\$13,608.14

Sectional Activity Expense, including Printing Bulletins.....	47,227.20
Education Expense from Contributions of National Bureau of Casualty and Surety Underwriters	24,000.00
Education Division—Sundry Disbursements	6,991.46
	<u>\$540,411.15</u>
Transfer to Prepaid Membership Dues Reserve.....	15,878.30
Transfer to Surplus	22,378.14
	<u>\$578,667.59</u>

H. M. WEBBER, Vice-President and Treasurer.

We have examined the above Comparative Balance Sheet of the National Safety Council as at July 31, 1927, and July 31, 1926, and the Statement of Revenues and Expenditures for the year ending July 31, 1927, and have compared them with the books and vouchers and have found them correct.

ARTHUR YOUNG COMPANY.

Chicago, Illinois, August 20, 1927.

Certified Public Accountants.

ADJOURNMENT.

*SIXTEENTH ANNUAL SAFETY CONGRESS
NATIONAL SAFETY COUNCIL*

General Session

Monday, September 26, 1927

COLONEL A. A. SPRAGUE, Chairman
Chairman of the Board, Sprague, Warner & Company, Chicago, Ill.

The General Session was called to order at two-twenty o'clock by President Walter G. King.

PRESIDENT KING: Our chairman this afternoon is a very distinguished Chicagoan. He has many accomplishments in both business and public life. His name is associated with many public enterprises. His civic interest is supreme. His business ability and leadership have very high respect in Chicago.

Colonel Sprague is a graduate of Harvard University. He is the leader and director of the Sprague, Warner & Company organization, a director in a number of large business enterprises, a trustee of the Chicago Field Museum of Natural History, the John Crerar Library, the Art Institute, the Children's Memorial Hospital, and Rush Medical College.

He served with distinction in the World War as Lieutenant-Colonel. He has been the Commissioner of Public Works in Chicago since 1923, and gives very liberally of his time to public enterprises.

It is indeed a very great honor to this convention to have Colonel Sprague sponsor it by accepting the directorship of this meeting. It gives me great pleasure to introduce him to you as your chairman for this afternoon.

(Col. A. A. Sprague took the Chair.)

CHAIRMAN SPRAGUE: I think for a person to venture to be chairman of a meeting with as little knowledge of the subject as I have would be regarded, usually, as a foolhardy adventure. However, as Commissioner of Public Works of the City of Chicago, which I no longer am, I became so interested in the necessity for safety education and safety campaigns that when I was asked to preside at this meeting, I accepted with considerable alacrity.

I understand there has been a change in the program in that General Dalton who was to have been the first speaker this afternoon had to leave town, so he spoke this morning. However, I think you will find that the paper you will hear which will be read by Past-President Lew Palmer, and which was prepared by Mr. Harry F. Guggenheim, will be of great interest to you. I think it is rather unnecessary, but it gives me great pleasure to introduce Mr. Palmer, who will read the paper of Mr. Guggenheim, President of the Daniel Guggenheim Fund for the Promotion of Aeronautics, New York City.

MR. PALMER: We have a telegram here that disappointed us. We received it from Mr. Guggenheim last evening.

"Regret exceedingly that illness prevents my going to Chicago. Deeply appreciate

compliment Council paid me and am disappointed at losing opportunity personally to cooperate with you in emphasizing need of safety.

"Harry F. Guggenheim."

We are not all airmen, or it would not be necessary, perhaps, to explain to you here today in detail who Mr. Guggenheim is. Every one directly associated with aviation is familiar with his past record, but it would be interesting to know here that he had several years' flying experience in France during the war. He is president of the Daniel Guggenheim Fund for the Promotion of Commercial Aeronautics.

As a member of the National Safety Council's Aviation Committee, I attended the dedication of the new research laboratory given by Daniel Guggenheim to the New York University, a gift of more than \$500,000.

We regret very much that Mr. Guggenheim is ill. Not knowing whether he would be able to be here in person, he arranged that Rear Admiral Cone was to take his place. The Rear Admiral is the Vice-President of this Fund. He advises that the Admiral has been called unexpectedly to Washington, so they have drafted me, as Vice-Chairman of your Aviation Committee, to read Mr. Guggenheim's paper.

Safety the First Essential for Progress in Air Transport

Harry F. Guggenheim, President, The Daniel Guggenheim Fund for the Promotion of Aeronautics, New York City.

Flying under properly organized conditions can be made as safe as any other form of modern transportation. People are beginning to realize this as they learn more about airplanes and airplane operation.

The past few months have witnessed a miraculous change in the public's attitude toward aviation. From a state of apathetic curiosity people throughout this country, and for that matter, throughout the world, have been transformed as if by the wave of a magic wand into enthusiastic worshippers of the "Flying Gods." The magician performing this miracle was a blond-haired youth of 25 who with faith absolute and courage sublime demonstrated by glorious effort that man can fly where he will.

The inspiration given by Charles A. Lindbergh marked the turning point in the American public's interest in aviation.

With this interest will come knowledge—and understanding by the public of flying and flying operations which is today the greatest need in America to assure permanent progress by sane and sound aeronautical development.

When Lindbergh successfully accomplished his flight hundreds of thousands said, "If he can fly from New York to Paris, I guess I can try a little hop some day."

Then came a summer of spectacular, and for the greater part, entirely useless flights—some good, some bad and some indifferent.

The net result has been perhaps greater confusion in the public mind about aviation than ever before, but there has been aroused a conviction on the part of the majority of people that aviation has "arrived" and they now want to understand the whys and wherefores of any disappointments.

Coincident with this inquiring mind, however, the public is developing an insistent demand for safety. There is no better illustration than the turn of public opinion against trans-oceanic flights which were causing so many tragedies. More people every year are using our aerial transport facilities, but we cannot expect great progress until we make our airplanes relatively as safe as our automobiles and our railroads.

This public skepticism is not disheartening—such a view is always to be expected. Sir Samuel Hoare quotes an old newspaper clipping of 1843, which, commenting on the railroads, said "the largest item in railway returns ~~is~~ ^{is} to be the list of

killed." The railroads proved they were safe and the traveler today has no worries when he steps abroad the fastest train.

In making the airplane safe we have to start almost at the bottom of the art of flying, since we must remember that aviation is yet an infant industry in many ways.

It seems obvious that a pilot would not overload his plane, yet a number of fatalities have been caused within the last few months merely because the plane was overloaded. We wouldn't think of putting the load of a five-ton truck on a roadster or of fitting such a truck with the motor of a roadster. Overloading an airplane results not only in structural strain but entails a flying condition that is abnormal and naturally dangerous.

It is often a simple and preventable error of this kind that causes a fatality. It cannot be charged against the airplane any more than can a death resulting from a careless pedestrian walking in front of a motor car be charged against the qualities of the automobile.

If we examine the hazards of flying we find they can all be traced to physical sources. Flying is nothing more than counteracting the law of gravity. Safety in flight, however, involves much more than the mechanics of the plane itself, but, unless we center our attack on some one problem we can only touch the surface. For this reason we are trying to solve the problem of the plane itself. In April the Daniel Guggenheim Safe Aircraft Competition, with prizes totaling \$150,000, was announced and entries are now being received.

This competition grew out of the realization that airplanes, to be aerodynamically safe, must land more slowly, roll only a short distance after landing, be able to glide steeply and in safety over obstacles surrounding a field, take-off quickly and on a steep path, remain in perfect control at the stall and in all other flight attitudes, and be inherently stable when, owing to weather conditions, the pilot cannot himself maintain an even keel.

The Airplane Structure Seldom Fails

The modern airplane is a light, but excellent structure and it is very rarely that we hear of a structural failure in the air. The air-cooled aviation engine is now a highly reliable mechanism. Careful installation of the power plant has eliminated fire hazard to a large extent. But while the airplane has made marvelous progress in speed, economy and load carrying since its early days, it is still lacking in safety from an aerodynamic point of view. Improvements in aerodynamic safety characteristics have in fact been sadly neglected by designers who have bent their energies largely to progress in performance.

When engine failure does occur in cross-country flying, safety depends on the availability of an emergency field. The emergency field may be broken up in surface and very small. The average airplane lands too fast and rolls too far in such terrain. Moreover, the field may be not only small, but surrounded with obstacles such as trees and wires. The only possible approach is then on a steep glide. But a steep glide on the airplane of today on landing frequently means disaster.

In getting out of the small field with a present-day airplane the converse of the above circumstances is found. The take-off run is too long, and the plane while climbing rapidly may not climb steeply enough to clear surrounding obstacles.

A frequent source of accident exists today when a plane is climbing rapidly and the engine suddenly fails. The plane may "stall" and the pilot lose control, the plane fall off on one wing, and go into the dreaded "spin."

In fog flying, the pilot no longer has the horizon to guide him. He is completely blind, and gusts of wind and disturbances may make his instruments no longer reliable. He may then be flying in the most extraordinary and dangerous altitudes without being aware of it, unless the plane is such that it is always stable, and will keep an even keel independent of the pilot's efforts.

Most of these problems have been solved individually in different planes and it is the purpose of the competition to coordinate them into one plane, which will be "safe airplane."

For instance, we can obviate to some degree the necessity of forced landings because of engine failure by fitting our planes with more than one motor, so that the plane can fly with one of them disabled. All planes carrying passengers should be multi-engined, which incidentally is one of the requirements for the passenger-carrying planes which will be bought under the equipment loan plan announced some time ago by the Fund.

Further progress is indicated by one of the remarkable aeronautical inventions of recent years which may have a marked effect in stimulating our efforts to obtain safety in flight. This aircraft, the Autogiro, invented by Senor de la Cerva, contrary to common belief, is not a helicopter. It cannot rise vertically and its revolving wings are not power driven, but in many respects it is just like an ordinary airplane. It has the usual engine-driven propeller to pull it through the air, the customary fuselage housing the engine and crew, the usual form of landing gear and tail surfaces to provide up and down and side steering. Its fundamental difference is that its lift is obtained from a sort of giant windmill with four blades. When once this windmill has been set in rotation and forward motion is attained, the windmill continues to rotate. In so doing, it provides an upward reaction or lift.

The Autogiro Is Safe and Stable

There are two great advantages to the Autogiro. With an ordinary fixed surface, the wings must meet the air rapidly in order to give sufficient lift. In the Autogiro the craft may be flying or gliding very slowly as a whole, yet the blades will be revolving fast and thereby providing all the lift necessary. Therefore, the Autogiro is an aircraft which can fly and land very slowly and never "stalls."

The second great advantage is found in the fact that the blades are not only free to revolve round the vertical shaft, but are also hinged at the inner end, so that they can adjust themselves in any required fashion without the windmill introducing any sideways tipping forces.

The Autogiro is therefore very safe and stable, and remarkably easy to fly. It has not yet demonstrated the efficiency and high speed of the airplane, but it has aerodynamic safety characteristics which every aircraft should embody.

Another example of fundamental progress in safety is Mr. Handley Page's slot and aileron control, which has gone a long way toward allowing complete control of a plane at low speeds. Captain G. T. Hill's tailless airplane is an important step in the direction of inherent stability.

Fundamental research work of this kind and experimental planes now in operation indicate a complete solution of the problem of aircraft safety not only is possible but may not be far distant.

However, even when we have found our "safe airplane," we still have other obstacles to overcome such as the nature of the terrain, clouds, darkness, wind, fog and sleet.

Most of these obstacles can be overcome by improvement of equipment and by organization and skill of operation. The more experienced a pilot becomes the better is he able to cope with the atmospheric conditions. There are still many things to be done to help the pilot, however, Commander Byrd's experience in his recent oceanic flight brought vividly to the attention of the world the necessity of finding safe ways of flying in fog, and more especially, of landing in a fog.

Concerted efforts are now being made by scientists to devise some way of solving this problem. Perhaps it will be some way of dissipating the fog, of penetrating it with light rays, or of perfecting instruments to guide the pilot in flight and in landing.

Closely associated is the subject of weather and other meteorological reports. Only recently we organized a committee of representatives of the Weather Bureau, the War, Navy and Commerce Departments and the Guggenheim Fund to co-ordinate research work in this field. Eventually we must have frequent and accurate weather reports from wide areas, available at all fields, and we must have a communication system to bring these reports as soon as possible to the pilot in flight.

The scope of these weather reports, incidentally, demonstrates just how large the field of aviation really is. Weather conditions in the United States must be reported in Canada. Storms along our coasts must be reported to Europe. Professor Hobbs of the University of Michigan is now in Greenland studying the effect of Arctic weather on Atlantic weather. When the day of regular trans-Atlantic flights arrives, there will doubtless be a regular Weather Bureau station in Greenland reporting by radio the inception of any storm that will make transit over the ocean dangerous or impossible. Aviation has wiped out boundaries and is international.

Absolute safety, of course, will call for a complete system of well equipped and maintained airports and airways, lighted when necessary and dotted with emergency landing fields. We can expect installation of this ground organization just as soon as the demand arises.

There Are Virgin Fields for Research

In the improvement of equipment there are several almost virgin fields for research, such as, for example, shock absorbing aircraft in which crashing will not entail injury to occupants of the plane, but in the long run we have made tremendous progress, greater, I believe, so far as the time element is concerned, than has been accomplished in any other field of transportation. The wonderful performance of the Air Mail Service is only an indication of the possibilities of commercial aircraft.

It is well to remember that we have been attacking this question of commercial aeronautics only for a few years. The war interrupted our commercial development and concentrated all attention on military planes, which must have speed and maneuverability rather than safety as primary requirements.

Government orders for military planes still form the backbone of the aeronautical industry, which is a costly business and cannot finance experiment in commercial fields to any great extent until there is a market for the product.

When we solve this problem of safety, however, people will want planes and by quantity production they will be in the reach of the same people who today own automobiles.

In conclusion, let me say that there have been, to my mind, surprisingly few aviation accidents in the United States during the past year in view of all of the circumstances. Hardly any of the accidents can be attributed to commercial development. Most all of them can be traced to stunt flights, reckless private flying, experimental flying and military and naval aviation. These latter services are obviously dangerous and accidents in them must be accepted as the price of preparedness for war.

Aviation development in the United States in the past eighteen months has been extraordinary. Only as recently as May, 1926, did the Federal Government officially recognize that such a thing as aircraft existed and at that time first passed legislation to foster and protect aviation. When at that time the Air Commerce Act was passed the public was little interested in aviation, and manufacturers, operators and pilots were fearful lest too much legislation might interfere with aviation development. At the present time the public is vitally interested in aviation and their views in regard to safety and development are of paramount importance. This is a healthy sign of progress and is a good omen for aviation.

The Bureau of Aeronautics in the Department of Commerce during the short time of its existence has made remarkable strides and has been of inestimable value

in aviation promotion. In the light of experience more legislation is undoubtedly needed at present to control flying and prevent accidents. Every aircraft and pilot flying in the United States should be licensed by the Department of Commerce which the present law does not require. In addition regulations providing against the overloading of aircraft are essential.

However, legislation will never be a panacea for accident prevention, or if it is, all progress will stop. In the last analysis such organizations as the National Safety Council, through its wide influence on public opinion, can be the greatest service to aviation safety and development.

A. T. MOREY, General Manager, Commonwealth Steel Co., Granite City, Ill.: I move you that the Congress express its regret at Mr. Guggenheim's absence, and appreciation of his paper that we have just heard read, and that our managing director convey that expression to Mr. Guggenheim, together with a copy of the resolution on aviation adopted this morning.

(The motion was seconded and carried unanimously.)

CHAIRMAN SPRAGUE: I think the foundation of the Guggenheim Fund for the increasing of knowledge and safety in aeronautics is a tremendously patriotic thing, and I believe it is going to be a very productive thing for this country.

It isn't alone on the Atlantic Coast that this work is being done. This summer I saw in Seattle, at the University of Washington, a large building for the study of aeronautics and all of the sciences that pertain to that, erected by a Washington family whose boy had been in the aviation service in the war. I wondered at that time what would have been the result if in the early days of railroading the railroads had been helped by this sort of study. I think Mr. Guggenheim is right when he says that it will mean a very immediate solution of many of the problems that now terrify the public.

Our next speaker came from Cleveland to address this meeting. He has an enviable record for public service. He has been a newspaper editor, a manager, a leader in many civic movements, a well-known advertising man, and an author of many books. He has a national reputation as an orator.

Mr. Rose is the President of the William G. Rose Company: he has been a trustee of the Welfare Fund of Cleveland, a vice-president of the Advertising Clubs of the World, the manager of the Cleveland Industrial Exposition, the Detroit Industrial Exposition, the Cleveland Art Exposition, and the Cleveland Electric Exposition. Mr. Rose has already addressed several of the largest meetings of the Community Council, and he was invited partly on the demands of the members of the National Safety Council who insisted on hearing his exposition of the quality of enthusiasm in safety work. It gives me great pleasure to introduce to you Mr. William Ganson Rose, of Cleveland, Ohio.

Putting Enthusiasm into Safety

William Ganson Rose, Cleveland, O.

It is indeed embarrassing to be asked to talk on the subject of enthusiasm to what (I am told) is the most enthusiastic gathering in the sixteen years of annual meetings of the National Safety Council. Yet I do not feel as much embarrassed as did the Cleveland politician who spoke a short time ago in one of our political campaigns in a colored church. The colored minister introduced him, and he said, "Breddern an' sisters, I want to present to you a good friend of de colored people of Cleveland. Dey ain't no better friend of the colored folks of Ohio dan our speaker tonight. Why, he don't know no color, he don't know no creed, he don't know no religion, he don't know nothin'."

Speaking of embarrassment, you can imagine how I felt this afternoon when I came into this hall and was handed a poster which told me how to prepare my

speech on Tuesday morning and give it on Thursday morning. But this safety device, like many others, has come too late, and I am going to pass it on to my good friend Statistician Cattell, of Philadelphia, believing that he can use it to advantage, as he delivers only 1,000 addresses a year.

"Safety!" That word has had a strong significance for me, ever since boyhood days when I fell off my first safety bicycle and punctured a floating rib with a safety pin. That was some time before my first scrape with a safety razor.

My subject is "Putting Enthusiasm into Safety." I can't tell this group anything new about enthusiasm; but I might remind you that Emerson said, "Nothing great was ever achieved without enthusiasm." Enthusiasm discovered America, it led to the Declaration of Independence, it made the United States the greatest nation in the world; and enthusiasm has been a dominant quality in all leaders of men—Alexander, Hannibal, Caesar, Napoleon, Washington, Lincoln, Sprague, King and Cameron.

Enthusiasm Is the Headlight of Progress

Enthusiasm is the headlight on the train of progress, and, by the way, enthusiasm is contagious. If the head of a house has ginger germs, the rest of the establishment catches enthusiasm. That is, they should become inoculated, and if they don't it is because they are immune. You know the kind of humanity that is immune to enthusiasm. They are human wet blankets, Job's comforters, and the rest of the cheer-up-the-worst-is-yet-to-come crowd.

Enthusiasm sells goods. You know that an enthusiastic salesman can sell horse liniment to a man who owns an automobile. An enthusiastic real estate dealer can sell a swamp to a man with inflammatory rheumatism. An enthusiastic builder can sell a fireproof building to a merchant who needs the insurance.

The problem of the National Safety Council is a selling problem. The theory of this organization's work is unchallenged. The plans devised by the many divisions of the Council are admirable. The program of this wonderful convention to be addressed by more than 300 speakers will be crowded with helpful recommendations; and yet the real success of the work will depend upon the enthusiasm of the American people in accepting the Council's great plan. It is a problem of selling, selling ourselves, selling every member of the association; and, through the schools and homes and factories, selling the American people. We all know what a difficult job it is to sell safety to a nation where the people love to take a chance.

I suggest that enthusiasm be made the keynote of this great convention, for without enthusiasm, no matter how good your plans, you cannot sell safety.

One of the best essays I ever read on selling was headed, "Don't sell things; sell effects." I am going to read just a few sentences from that: "Don't sell pianos; sell music and pleasant evenings. Don't sell automobiles; sell travel and the great out-of-doors. Don't sell books, sell the joys and profits of knowledge. Don't sell things, but sell ideals and effects and self-respect."

So in this great safety movement, don't sell safety, but sell the happiness of the people, sell the care of little children, sell the well-being of the other fellow, sell peace of mind and protection and the gratification that comes from doing the right thing.

It is difficult to sell a public where nearly everybody is thinking along several lines at the same time. This calls to mind the story of Arnold Bennett when he came to Chicago during his recent trip to America. They gave a large reception for him here in this city, and at the reception a very effusive young woman ran up and thanked him for his works and said, "Particularly I want to thank you, Mr. Bennett, for your wonderful article on concentration."

"That is fine," said Mr. Bennett. "I am pleased to learn that I have helped you. May I ask upon what you are concentrating?"

"Oh," said the effusive young woman, "upon lots and lots and lots of things." I am afraid that is the way most of the American people are concentrating today. If all the industrial institutions would only sell safety with the enthusiasm that happily marks thousands of companies, the total industrial fatalities would drop from the annual figure of 24,000, and the time lost through accidents would no longer be equivalent to 700,000 men continually disabled and off the pay roll. If we could only sell, with enthusiasm, the idea of safety first to parents and little folks, the awful toll of 21,000 nieces and nephews of Uncle Sam would not be taken, and 20,000 fatalities in American homes would be reduced to a comparatively small number.

If we could only sell to motorists the idea that it pays far better to stand up for safety than for our rights, automobile fatalities would drop far below that sickening figure of 25,000 a year. Putting enthusiasm for safety in the hearts of the American motorists would materially decrease that economic loss due to street highway accidents now totalling some \$700,000 a year. Of course, no observation of safety rules can be expected of the intoxicated driver, who is one of the greatest menaces on this earth. He is just as bad as an insane man, without the excuse. He is a potential murderer. Members of the National Safety Council, let's get rid of him!

When is a Pedestrian Safe?

It is a pity, but nowadays a man doesn't know when he is safe. Let's get a picture of the pedestrian of 1927 trying to cross the street here in Chicago at an intersection.

Chug-chug-chug-chug—an automobile is running toward him from the north. Pip-pip-pip—a motorcycle is coming at him from the east. Whirr—!—a fire engine is rushing at him from the west. Honk-honk-honk—a truck is coming up from the south. Brrrrrrr!—an airplane is falling down upon him. He stoops down, pulls up a manhole cover and jumps through—just in time to be run over by a subway train!

This is an appropriate time to recall the words of that distinguished jurist who recently passed away, Judge Elbert H. Gary, an honorary member of this Council, an industrial leader, humanitarian. You remember he said: "The question of safety calls for vigorous and aggressive action, and its results are expressed in most precious terms—human lives."

A leading merchant of Cleveland told me the other day that one of his chief functions is inspiring enthusiasm in his traveling salesman. "First, I give them all the information they need," he said, "and then I pump them full of enthusiasm. And when I think the spirit is beginning to die out, I call them home and then I pump again." Pump enthusiasm into a pessimist and you will have an optimist. Pump enthusiasm into a quitter and you will have a winner. Pump enthusiasm into yourself, and it will give you greater strength and courage and confidence.

The enthusiastic minister is the most persuasive—Henry Ward Beecher, Rabbi Wise, Cardinal Gibbons. The enthusiastic actor is the most inspirational—Irving, Mansfield, Bernhardt. The enthusiastic business man is the most successful—Carnegie, Schwab, Gary. It is the same in every line.

But going back of enthusiasm in business, what do we find? Enthusiasm in self! Here is something worthwhile. If you think you don't need enthusiasm as a social attainment, why, get it for purely selfish reasons. There's nothing like it for a cheer-up tonic. It quickens the brain, stirs the circulation, warms the cockles of your heart. Enthusiasm contributes to true happiness. Of course, there are different ideas concerning happiness, a fact that calls to mind the story of the Irishman with seven daughters. A friend was congratulating this head of such a large family, and he said to him, "Most people believe that the possession of wealth is happiness. But

tell me, which do you consider the happier—a man like yourself, the father of seven daughters, or a man with a million dollars?"

The Irishman thought for a few minutes and said, "Sure, I giss the fayther of seven daughters is the happier."

"I'm glad to hear you say so. What is your reason?"

"Well," said the Irishman, "the man with the million dollars always wants more."

It is different with boys. The Irishman, father of seven sons, was being congratulated. "Sure," he said, "and they're a fine lot o' boys. I niver had to raise me hand against one o' them excipt in self-defense."

Enthusiasm contributes to optimism, and optimism happily has been a dominant quality in this Council ever since it was created. The organization has always endeavored to make things better and has never used as a slogan, "It might be worse." That calls to mind the story that Cardinal Hayes of New York told me some time ago. He was illustrating a point in optimism. He told about an Irishman in New York who, no matter what adverse conditions might arise, would always draw a long breath and smile and say, "Well, thank God, it might be worse." That grew to be tiresome, and finally a priest told the Cardinal that he would cure Pat of this habit. So he met Pat on the street a few days afterward, and he said: "Pat, I had a dream last night. I dreamt that Judgment Day came and you were condemned to hell for all eternity."

The Irishman was taken back. He dropped his head for a moment; he couldn't speak. But finally he drew a long breath, looked up and smiled, and said, "Well, thank God, it might be worse."

"How could it be worse?" asked the priest.

"Well" said Pat, "your dream might come true."

The Optimist Who Lost a Ten-Dollar Bill

The chairman alluded to the fact that I am interested in advertising, and let me say that enthusiasm plays a large part in the advertising business. I happen to recall a story that I think of when I think of advertising, the story of the ten Chicago men, each of whom lost a ten-dollar bill. Nine of these men were pessimists and they said, "The money is gone. Well, let it go." But one of them was an optimist, so he advertised, and the next day eight men came to his office each bringing a ten-dollar bill. He gave to these men each a one-dollar bill for his honesty. The other two bills fell into the hands of thieves, who naturally kept the money. So, you see, the nine pessimists got nothing, the two thieves got ten dollars apiece, the eight honest men got a dollar, and the optimist got seventy-two dollars. The moral is, honesty may or may not be the best policy, but it certainly pays to advertise.

There is probably no other nation that has made as scientific a study of safety in many lines as our own nation. This is possibly largely due to the fact that we have so many unsafe inventions and institutions, but no sooner is an unsafe idea born than American brains start a safety device as a remedy.

I heard of one company that manufactured a hair tonic that caused dandruff, and then quickly put on the market a dandruff cure.

Enthusiasm, unhappily, leads to many fields that lead to accidents. Take golf as an example. I understand there are many golf players here at the convention, and some of them on the links this afternoon. You know, golf leads to accidents, even as played by our best citizens. I know that President King, according to the report that was given me this morning, is an ardent golf player, and he himself is guilty of leading to an accident on the links—that is, if I am properly informed. He inspired the poet, by this incident:

I shot a golf ball into the air
It fell to earth I knew not where;
For so swiftly it flew, the sight
Could not follow it in its flight.

I kicked my caddy into the air;
 He fell to earth, I didn't care;
 For nothing I know can make one rile
 Like a supercilious caddy's smile.

Soon, soon after, I found the ball.
 It hadn't moved from the tee at all;
 And the caddy was standing sardonically grim—
 I had kicked my opponent instead of him.

I am sorry to see Colonel Sprague smile because I understand that he was responsible for another accident. You know, he made a hole in one once. As I understand, it went something like this.

He teed the ball up in the hall
 And only swung in fun.
 The mirror has no glass at all,
 He made the hole in one.

By the way, speaking of golf, I am sure Dr. Haggard will be interested in the definition of golf given by a Cleveland socialist, who said, "Golf is an institution for needlessly prolonging the lives of worthless citizens."

Men need enthusiasm. Somebody has said that no opportunities will make a two-legged animal a man without enthusiasm.

A Big Job for the National Safety Council

I spoke, a few moments ago, about promoting the publicity of safety through the schools. I think that is one of the biggest jobs before this Council, because if the children of today are thoroughly informed about the real significance of safety, then the men of tomorrow will understand, and it will be an easy task, comparatively, from that time on. I notice that the children are to play a big part in the pageant on Friday. I hope you will all be there to witness it. There is one point where I think we ought to give attention to safety in connection with the children, too, and that is in the matter of prevarication. I remember only a few weeks ago in Cleveland there was a little boy who started as a story teller, became a prevaricator and finally a regular little liar. They did everything they could for him. Finally one day the teacher called him up before the whole school and said, "Willy, do you know what happened to Ananias and Sapphira?"

"Yes," said the little boy. "God struck them dead for lying, and I saw them carried into the drug store."

Cities need enthusiasm. In their case we call it civic pride. Remember that everybody can do something with enthusiasm for his own city. Some men can give their city a library, some a museum, some a hospital; some can't afford these things, but everybody can do something for his city. I heard this morning of an absolutely worthless vagabond who did the best he could do for Chicago; he moved to Detroit.

Speaking of civic enthusiasm, let me congratulate the committee in charge of arrangements for its consummate nerve in bringing the nation's seekers for safety to Chicago, city of gatherings, altruistic, evangelistic and pugilistic.

Nations need enthusiasm. Be thankful that we live in the nation that stands first in enthusiasm, and let's use that enthusiasm to keep our nation first in national safety. Enthusiasm wins battles in business or in war, and it can put to rout the whole army of pessimism, commanded by General Apathy, General Indifference and General Debility.

It wins battles on the football field. This is the football season and I am going to tell you a football story about the coach who went to the college president and said, "Young Brown has been dropped off the team. I don't know how important it is to you, but without Brown we can't win another game this season, and I believe with Brown as the center of our plays we will win every game on the schedule."

The coach went away and the president thought it over. He sent for the head of the chemistry department and said, "I understand young Brown failed in chemistry."

"Yes," said the head of the chemistry department. "He stood nothing in his last examination."

"I am sorry," said the president. "He is a fine young fellow and I should like to encourage him."

"Well," said the professor, "let's give him another examination."

A few days later the president learned that Brown was back on the football squad. He stopped the chemistry professor and said to him, "I understand that Brown passed his last chemistry examination."

"Yes," said the professor, "I knew you were interested in the boy, so I gave him another examination. I cut the passing mark to fifty, and I gave him two questions. The first question was, what is the color of blue vitriol, and he said yellow, and that was wrong. And the other question was, what is H_2O and he said, "I don't know," and that was right."

I want to leave with you this suggestion, that we make enthusiasm the keynote of this convention, and that we sell with enthusiasm the wonderful program that will be developed here this week.

On a recent trip through fifteen nations of Europe and the Near East, I was proud to find that there is universal admiration for those two great Americans, one of whom established the safety of this nation and the other who preserved the safety of this nation. I was over in Budapest on the Fourth of July, and much to my amazement I found an Independence Day celebration there in the great City Park at the foot of the monument erected to the memory of George Washington. After the ceremony, I translated the inscription on that monument. It is one of the finest things I ever heard of Washington. It says: "George Washington, not a king among men, but a man among kings."

Only a short time after that I was in London and went, on a rainy day, over to Westminster Abbey and wandered for hours among the British tombs of the great in all walks of life, and then I came out on the porch, and I noticed the rain had stopped and the sun was shining through a cloud, and I saw the figure of a man across the way looking over at the old Westminster Abbey. America is young. Her list of statesmen is small indeed compared with that of Britain, but the figure that stands there all alone in the most conspicuous spot in London is that of an American fully worthy of that signal honor—Abraham Lincoln.

When I returned to Cleveland I found that in my city Mr. W. G. Taylor, one of our veteran real estate men, owned the original photograph of what is either the first or second picture of Lincoln, and today I want to present to you, Mr. Chairman, this picture of the American who preserved the safety of the nation.

Officer Mulcahy Interrupts

CHAIRMAN SPRAGUE: I am sure, Mr. Rose, that the president gratefully receives this.

OFFICER MULCAHY (F. L. Madden, St. Paul, Minn.): I have enjoyed this talk about enthusiasm and this traffic situation, but us fellows who stand out on the corner trying to deal with these enthusiasts would like to hear something more practical about the situation. Ladies and gentlemen, if I had the amplifying horns in this great room on my corner I could increase my efficiency 50 per cent and I could

decrease my vocabulary the same amount. I beg your pardon for buttin' in, but you see it was this way. I'm glad to see so many people interested in safety, particularly in street traffic safety, because that is the thing that I am mainly interested in; and I have come to the conclusion, after much observation, that any man who don't take an interest in traffic safety ain't going to live very long to take an interest in anything else.

I have found, in my observations, that every guy that's got a brain in his head thinks he knows something about this question of safety. The trouble is that most of them think of it in terms of a great flow of motor trucks and automobiles and Fords and taxicabs and street cars and horses and buggies and the like o' that. In other words, they think of it somewhat in terms mechanical, and whether you know it or not, I'm here to tell you that there's nothing mechanical about traffic at all. It is intensely and entirely human.

Now as far as I've been able to observe, there's no automobile that ever did anything to anybody of its own accord. It's only when you take the mechanical perfection of the automobile and then add to it this human intelligence we brag so much about that you begin to have trouble. It always required a human being to steer that car into the grand panorama of painful accidents that traffic history presents to you.

It seems to me that if we give that matter any thought we will find that most of the difficulty lies in the individual. Every minor or fatal accident that I have ever seen—I don't care what the results may have been, I don't care how many people and much property damage figured in it finally—was caused by an individual, either one or two of them; and the sad part of it is that neither one of those guys wanted that accident. They probably never met before. It's safe to say they wasn't mad at nobody when they reached that spot; and I never met a guy yet—and I'm speaking now of the fellows I don't like as well as those I admire—that left home in the morning and included in his plans for the day an accident that would blast one of his fellow beings into another world. But you see, they accomplish the same results through their thoughtlessness or their carelessness, or what have you, as though they planned the thing, don't you see? It is all due to the cuckoo notion that they can handle a ninety-horse power buzz-wagon through traffic and still have their mind engaged on something else than what they are doing, all at one and the same time.

Just Supposin' You Lived Where Automobiles Ain't

One of the reasons for that situation is that the whole street traffic problem, as I understand it, has come along sort of gradual, and we take it in its present motley condition as part of the general scheme of things. If you stop and think, now, of the impression that you will get, supposin' you lived in some remote place where automobiles weren't in excess of the number of bath-tubs or the birth rate, and supposin' you were suddenly taken from that impossible place and planted in the middle of the Loop District in Chicago and you had never seen a situation before like is going on in these here streets. Can you visualize to yourself what your impression would be? If you don't know I can probably tell you. After the first panic had passed away and you still survived, you would come to this conclusion; you would say, "Begorra, 50 per cent of the population is ridin' crazily around on wheels and the other 50 per cent are pop-eyed from leapin' from place to place for safety."

We consider that we live in a civilized country. We get very red in the face when anybody says we are not. Yet according to these long-haired or heavy-browed guys that call themselves statisticians, (whether they are wrong or right I don't know or care), we killed off about 25,000 people last year in street accidents in the United States of America, the home of the free and the brave, and those

25,000 people all were dragged up to the back door of a morgue because of something they didn't intend to get into and had no argument with anybody about; nobody wanted it. Did you ever stop to think that if you went into a barbarous country or a country whose people we loftily look down upon as savages, if they found out that 25,000 people were being killed off in that country for no reason, they wouldn't even stay there? That means, if you are good at mathematics, that about once every 20 minutes in the United States of America some poor guy is gittin' bumped off through a street accident. If you have watched them drive the way I have, backin' out of allies and zippin' around corners, you would wonder why they wait 20 minutes to bump anybody off.

It ain't my idea at all that all of the responsibility for this situation should be pinned on this here car driver, you understand. We have that peculiar and perplexing being who, in my judgment, was put on earth to try the patience of traffic cops, known as the pedestrian. You can remember the time, and so can I, when walking was looked upon as a very beneficial and healthful exercise. Physicians used to prescribe it, particularly when they were up against it to know what else to prescribe. But if a physician should prescribe it today, you know what would happen: you would get suspicious of him, you would think he had surgical aspirations, or something of that kind.

When the Baby Walked It Was An Event

I can remember in my own lifetime, by golly! when the baby learned to walk it was an event in the family. We used to call the neighbors in to tell them about it, we used to wire to the relatives and write the news to them; and today if the little divvil at three years of age don't know the gearshift on at least five cars he's considered a backward child.

I appreciate, just the same as you do, we gotta have both of these guys in the world. There's the motor car driver. He has come to stay, at least as long as we let him live. There's the pedestrian. He has come to stay as long as the motor car driver don't interfere with him. But to the traffic cop, the guy that stands out on the corner, pedestrians all look alike to him. There may be great differences in these people, but we ain't got time to analyze them. We just put them in two general classes, one that are going to live their allotted span of life and those that won't. Both these people have rights under the law, and it is proper that they should have. The trouble is we make the mistake (and I'm talking now to people who are enthusiasts about presenting this safety idea) of stressing too much the idea that they have laws which govern the situation and also that they have rights of way and all that kind of stuff; and it is perfectly proper that those things should be there. Nobody wants them taken away.

But the thing you have got to stress, in my judgment, and that is what I do on my corner (I don't usually have a chance to talk to a gang like this, but I talk to them individually), is to tell them that this is nothing more nor less than an individual responsibility; and if you can't get that into their heads you are never going to cure the situation, because 999 guys can go along minding their own business and one guy can put a bomb under the whole gang of them. If you can make them understand that there is an individual responsibility to every guy who gets into the highway, whether he is on his own two feet or is driving a buzz-wagon, and he's got to observe that in order to be safe, we find that if a guy minds his own business and succeeds in getting past himself without causing any trouble, we don't know of any instance where he has dragged anybody else into trouble.

The only thing that I can see as a cure for this situation is to try to bring home to the individual the fact that he is the boss of this job; because, as a matter of fact, traffic is you and a lot of other people trying to get some place; and with the aid of a kind Providence and some traffic cops, sometimes you get there safely.

There is only one word more I would like to leave with you, because the most misunderstood institution in the world is the traffic cop. A traffic cop isn't out there for the sake of argument, at all; he isn't out there to interfere with any man's institutional rights, although that is a very hard thing to put over with most people. His purpose out there is to help you to get where you are going as quickly and as safely as possible. But I would like to say this, and I would like to put great stress on it, that when the argument once starts—you understand, once the argument begins—it is a historical fact that 999 times out of 1,000 the traffic cop wins.

CHAIRMAN SPRAGUE: The gentleman who has just spoken to you is Mr. F. L. Madden, business man of St. Paul. For nearly a year he has been giving weekly talks on traffic and safety under the name of "Officer Mulcahy," over Station WCCO, as well as speaking at numerous meetings of various organizations in that district. Our friends in St. Paul tell us that Officer Mulcahy in his talks has done much to educate the people in safety.

Our next speaker, Dr. William D. Haggard, of Nashville, Tenn., was the President of the American Medical Association in 1925, probably the highest honor any physician can hold in the world. Dr. Haggard has a medical inheritance. His father was the first president and one of the founders of the Southern Surgical Association. Dr. Haggard has held many important public positions, including membership on the advisory board of the division of surgery during the World War. He served as a major and lieutenant-colonel, saw service in France, and since then has devoted much of his time to the advancement of medical education. He is now Professor of Surgery in the Vanderbilt University at Nashville, Tennessee, and represents the South in our advancing medical science.

What Price Health

Dr. William D. Haggard, Professor of Surgery, Vanderbilt University Medical School, Nashville, Tenn.

I imagine that when you see a doctor get up you will say, "Now we will suffer." I am one of those who believed that my immediate predecessor on this platform was a traffic cop. I labored under the same delusion that the famous English actress did when, in rehearsing her play before Mr. Frohman he undertook to give her some general suggestions about the difference between the English stage and the American stage. In high dudgeon she walked down to the footlights and said, "Sir, I'll have you understand that I'm an artist."

Mr. Frohman said, "Madam, I'll keep your secret."

I don't know how you think a doctor can touch the question of safety and of fire prevention, but one of my surgical colleagues after leaving the operating room to see his patient, found the curtains very closely drawn in her room and asked the nurse why. She said, "Doctor, there's a fire across the street, and we thought if your patient came out from under the anesthetic and saw that fire she might not know whether or not your operation had been entirely successful."

What price health? I don't believe, among all the statisticians of the world, one can compute the wonderful gift and joy of vigorous health. We never appreciate it as much, however, as when we lose it, and then it is not to be computed by all the rubies and all the riches of the world.

It is said that the sick bill of the United States each year is a billion and a quarter dollars in lost wages; and that for hospitalization, medical care, nursing, etc., it is another billion and a quarter dollars. That means that every man, woman and child in this great nation loses \$22 a year for sickness. the

greater part of which is preventable. Can anybody compute the value of a little child's life? Can anybody estimate the stupendous service to humanity of the loving care of the devoted mother? And still the statisticians say that a child at birth economically is worth \$7,000.

I wonder if you ever stop to think how much we, as individuals and through our government, have expended upon us by our state and municipal authorities for the prevention of disease, for the throttling of contagions, and for general sanitation. A hundred cities in this country averaged a dollar per capita; they are the best cities in the country. The average is less than ten cents apiece for your life and mine that the taxes we pay go to defray.

I want to say something to you today that I hope you will take home with you. The best investment that any community can possibly have is an all-time, highly specialized, splendidly trained health officer, who looks after the general health of the community, who prevents epidemics, who takes care of the cleanliness, the water supply, the food supply, the milk supply.

The Volume of Preventable Diseases Is Astounding

Montreal, the beautiful, our neighbor, has just gone through a terrible epidemic of typhoid fever. It is supposed to have come from the pasteurized milk plant that really did not operate properly. As a consequence, there has been a terrible epidemic of typhoid fever in Montreal, so great that the slogan has been, "Don't go to Montreal." Did you business men ever stop to think what that means to a community, commercially and economically, when every tourist, every visitor, every business man, everybody who gets off a steamer, hears "Beware of Montreal?" So it could be said of any other city in this country.

The number of cases of preventable disease is perfectly astounding. Formerly, one little baby in every four died before it was a year of age. Thank God! now it is only seven out of a hundred; and I think the time is not far distant when only two out of a hundred will perish before they reach the first milestone.

Unfortunately, at the present time 30,000 young men and women die unnecessarily of disease in this country which costs an average of six billions of dollars. So I say that it behooves every one of us to do our entire and complete duty in putting over the public and private health program of this world.

I am very highly in accord with the splendid efforts that this magnificent Council, this national organization, is making for people in industry and in commerce throughout the country, but I want to appeal to you gentlemen to look more after the general health. You lose every five minutes only one man from an accident; but every six minutes one person dies of cancer alone; and think of all the other diseases. Cancer is a curable disease. Hitherto you have not realized that, perhaps, but cancer is always local, it is always in one spot, you can take it out like you can the rotten part of an apple. Cancer is like a coal of fire that rolls out on the hearth-rug. In the beginning anybody can stamp it out; after it is neglected and gets through the house, nobody can put the fire out, and that is all there ever was to the cancer problem.

Nearly half the people who are operated on for cancer of the breast are alive and well five, ten, fifteen years afterward. You don't hear of those. You only hear of those who die.

Some years ago I was in one of our largest cities; one of the surgeons was showing a group of colleagues some successful cases, as a matter of scientific interest. He presented a very distinguished looking gentleman from whom he had removed half of the tongue for cancer. The man answered his questions.

You could scarcely detect a lisp in his enunciation. After he left, I said, having noticed he was a man of great presence, "Who is this gentleman?"

The surgeon replied, "Why, he is the mayor of this city," and if I were to call his name everybody here would instantly recognize it, but no one knew that he had cancer. Such a murderous, such a horrible disease we shrink from. "Doctor, don't tell me if I have cancer," we hear every day. But it is the man who has the sharp tooth that rubs on the tongue who has cancer, it is the cigar smoker or cigarette smoker who has cancer on the lower lip, never on the upper lip. Woman never had it, although she is beginning to smoke more and more and will have it later. Cancer never occurs on a baby's skin; it always occurs on some place that receives great irritation, like the mouth, the alimentary canal, the stomach, the organ in the body most unmercifully handled. One man in every forty-five who is forty-five years of age will die of cancer of the stomach in spite of the fact that it can be removed with seven per cent mortality, and one-fourth would be alive and well after five years.

The progress of science has been very great. In the last fifty years the whole of medicine has changed, because the infectious diseases have all been unraveled. Think of the time when we had the terrible scourges in this country due to epidemics of scarlet fever, typhoid fever, cholera, small-pox. When the Panama Canal was first begun by the Frenchman, Ferdinand de Leseps, so many people died that they had to abandon it. Then the American surgeons in the Army found out that the mosquito infected with yellow fever could be inoculated against, and demonstrated this through the splendid sacrifice of Walter Reed, who gave his life to prove it. Then General Gorgas cleaned up the Panama Canal, and instead of a terrible charnel house, it became the cleanest place in the world. So Roosevelt and Goethals and these great Americans built the Panama Canal, but they could not do it without medical knowledge to protect the individual. There is no more yellow fever in the world today.

Typhoid Fever Is Now Under Control

Typhoid used to be such a horrible thing. We had a million men on the border before the war, with not a single case of typhoid fever. Sanitation, pure water, vaccination, were the answer. We had 4,000,000 men on the other side, with less than a hundred cases of typhoid. We would have had 268,000 cases if we had had the same conditions that existed during the Civil War. I mention this to show what tremendous strides have been made in medical protection for you and your loved ones.

Still the half has not been told. You can hardly recollect when some family circle has not been broken up by some lovely child dying with diphtheria. Now, with the use of antitoxin, it averages only nine per cent—on the first day one per cent, on the third day six per cent, after the fourth day thirteen per cent.

We can take every child as it comes to school and give it the Shick test and see whether or not it is immune. Many of us are. Perhaps those of us who have not had it were normally immune, but if the little child, yours and mine, is not immune, let's immunize him. Don't let him strangle to death with the products of infection and inflammation in his throat. I have seen the time when a surgeon going through a ward would see a child strangling with membranous croup, would pull out his knife and do a tracheotomy that the baby might breathe. That is a relic of the past. Heroic, wonderful, unnecessary.

The same is true of scarlet fever. We can immunize children against that.

So I want to say to this company that the medical profession also is interested in safety, your safety, but we want you to go a step further with us. We have

already added, in the last 50 years, a decade and one-half to the span of human life. In the sixteenth century man on the average lived to be 20 years of age. This gradually lengthened and now the average age in this country is 56 years. In New Zealand it is 65 years. Why not here? Why not in America? We have everything else the best. It is up to the citizenry of this country. The medical men have the knowledge and the willingness and the wisdom and the enthusiasm if you please, to put over this great national program of health, the prevention of disease and the alleviation of human sickness. But it is going to take intelligent cooperation of great bodies like yours to equalize and disseminate the knowledge that should be for all peoples all over the world.

We have already cut down in the last 12 years the death rate from tuberculosis nearly three-fourths, from diphtheria, from typhoid, and from these terrible scourges. The time must come in the next 50 years when we must add 20 more years to the span of human life, and, as Dr. Mayo said, the time ought to come within the century when we should live to be 100 years of age.

Infant Mortality Is Greatly Reduced

How are we going to do that? It used to be infant mortality was a dreadful thing. That is wiped out. Then these pests and scourges that I have told you about took dreadful toll. We don't have any more of that. Vaccination against typhoid and these other disease I have been telling you about has done away with it. But what are you and I going to die of? We have already passed the measles stage. We are going to die of the degenerative diseases of the heart, of the kidneys, of the blood vessels, of the brain. How can we prevent it? We can prevent it by the same safety devices that you use in your large industrial plants. You can do it for the men that are under you; but don't neglect yourself. Everybody believes every other man mortal but himself.

No business can exist without an annual audit. The balance sheet, the survey, accompany business. Do you ever have a thorough-going audit of your body and its functions? Do you know what your balance sheet would show? Do you have any idea of how your gearshift is working, and your batteries? You have your car tested. You won't neglect that. Every time I ride on a Pullman car, when we pull into the station I hear a man knocking on the wheels to see that everything is all right for that car to go to the next station. I think about the fellows in the other berths, 32 individuals, perhaps, and I wonder if anybody has ever tapped their wheels to see whether they are seaworthy or ready to go on with active life.

When we came to examine the flower of the youth of America for the draft, we found that one-third of them were defective. Some of the defects were small, errors of vision, bad tonsils, bad teeth, hernia, flat feet, things which could be cured, but many of them had heart disease. Why do you have heart disease? It is an infection. It gets in through your tonsils a great many times, rheumatic fever, and then attacks the heart. It is a wonderful engine, the heart, but it is subject to the same mechanical problems that you have to deal with. When it gets out of order you can't get to it to fix it, but you can prevent that trouble.

A man never thinks there is anything the matter with him. "If you doctors had to depend on me for a living you would starve to death," he throws out his chest and says. He gets a life insurance examination. There is a little albumin there, and he comes running hotfoot. "What in the world is the matter with me, doctor?"

"Why weren't you examined before this? Why did you have to be knocked

down by a life insurance agent before finding out what was the matter with you." Is your body, the temple of your soul, to be so neglected?

My plea to you for safety, gentlemen, is this: Have an annual physical health examination at least once a year on your birthday by your family doctor, head to toe. Let him examine everything about you, and if there is anything wrong, have him tell you what to do and what not to do, how to live.

The trouble we have with individuals is that they come too late. You don't think of sending for the fireman after the house has burned down. You wouldn't sit and look at a fire for a long, long time before you would ring up for the nearest fire department; but we do that habitually with our lives and our health.

I feel, gentlemen, that we are very close akin, the medical profession in its great efforts in your interests, and the splendid work you are doing in prevention. I want to call your attention to the analogy between your efforts and our professional endeavor.

I want to tell you that Oliver Wendell Holmes, the greatest writer whom you think of as the author of *The Autocrat of the Breakfast Table*, was a doctor, Professor of Anatomy in Harvard University, and he wrote these lines, which, I think, are applicable to the beautiful, the wonderful principles, the humanitarian aspects of this assemblage and what it is trying to do today for humanity.

As life's unending column pours,
Two marshalled hosts are seen,—
Two armies on the trampled shores
That death flows black between.

One marches to the drum-beat's roll,
The wide-mouthed clarion's bray,
And bears upon a crimson scroll,
"Our glory is to slay."

One moves in silence by the stream,
With sad, yet watchful eyes.
Calm as the patient planet's gleam
That walks the clouded skies.

Along its front no sabers shine,
No blood-red pennons wave;
Its banner bears the single line,
"Our duty is to save."

CHAIRMAN SPRAGUE: Some of the older members of the Council will remember our next speaker, because he took a prominent part in the 1916 Congress of this Council in Philadelphia. Edward James Cattell is known throughout the country as Philadelphia's grand old man and the city's greatest asset. He has earned this reputation through 25 years of service to the city government of Philadelphia, and during that time has worked under seven mayors. He has been a traveler all his life and has worked in many foreign countries. He has been an active and prominent member in a list of organizations that would take several minutes to read. He is a speaker of international fame and has probably made as many speeches in the United States during the past dozen years as any other single man in America, having the record of making more than 1,100 in twelve months.

Mr. Cattell has come from Philadelphia for the special purpose of addressing you.

Bigger Men, Broader Views, and Better Business

Dr. Edward James Cattell, Philadelphia, Pa.

I am so full of these remarkable addresses which it has been my privilege to listen to this afternoon that it is hard to think of what I want to say. Dr. Haggard's wonderful tribute to the work of the physician in saving life appeals to me tremendously. During my 28 years of service to our city we had an epidemic of typhoid that ran us up to some 14,000 cases, and I traveled to Minneapolis for the sole purpose of meeting a body of waterworks engineers. I wanted them to come to Philadelphia to stimulate public interest so we could raise a large loan to put in a new filtration plant. Other cities were also inviting them and offering them every temptation. When it came my turn to present a plea that they should come to Philadelphia, all I said was this:

"We have 380,000 homes. If you have ever been in a little home where death has wiped the color from the beautiful face of a loving mother, if you have seen those deepened lines in the face of a father when the light went out with the death of a little child, you know why I put my heart in my words when I say that the shadow hangs over 380,000 homes in my native city. If you will come to us we can lift that shadow. Will you come?"

And they came unanimously because they were men whose hearts were in the great work of saving life.

I feel in the same mood as I come today before you men who are doing one of the greatest works possible for a man to do, and that is to safeguard life. I have a right to say this because I have sampled it longer than anybody in the room. Honestly, I want to live to be 100 years old, renew the lease, and do my own repair work. There is no such thing as getting old when life gets better the longer you stay. The rustle of calico stirs me just as much now as it did 70 years ago.

I believe the prophet Jeremiah expressed a truth as true today as when he wrote it, when he said that a woman is only as old as she looks and a man is never old until he quits looking. I haven't quit.

I am delighted to be here today, but I am not going to talk along your scientific lines. Each one here knows more than I do on that subject. I am going to speak of the value of life, especially in this present day. Whatever my life is for length of years, God has been good to me. But on the scientific side, years ago I got my lesson in that. I was to speak on the tariff. I was young, inexperienced, ambitious. I had to take a train to the town where I was to speak. The train was an hour late. A man met me at the station and said, "Cattell, cut out the tariff speech. The meeting is on the second floor. We had to put up substitute speakers. They threw one of them out the window. The only way to save the day is to pretend you know Dr. Simmons. He's a prominent citizen, and if they think you know him you're all right."

I had never heard of Dr. Simmons, but I was young and up against it. When I went to the front of that turbulent audience, I said, "I came here, gentlemen, to talk about the tariff, but the moment I entered your town I thought of Dr. Simmons, and as I drove here every lighted window framed his kindly face. Under those splendid trees in your main avenue I re-enacted those talks that shaped the whole course of my life." They were with me. Then I went too far. I said, "If I were to forget Dr. Simmons I would be a brute. He brought me into the world."

"You darned idiot," my friend said, "he was a veterinary surgeon."

But I believe in life. I love it more every year I live. I have a grudge against the doctors, too. One of them is limiting me to 30 cigars a day, and it is hell. I am kept poor sending flowers to the graves of the men who tell me what to do to keep from getting sick.

But I think—and that is the thought that has been running through every speech today—that individual responsibility in using our God-given powers will help us to be safe. The Lord will do one-half the work, but it is the last half. We have to do our part first.

Years ago I wasted two solid hours, because I had read a learned book telling me to go to the ant and learn to be wise. I went out to the woods and watched an ant struggle for an hour and a half to get over a little bit of stone. He succeeded, but if he had used his head he would have walked around it in ten seconds.

We want to get into the minds of men and women that sense of personal responsibility not only for themselves, but for others. They are not the only persons on this earth. Emerson said a thing that is unforgettable: "We are strong by our relatedness, not our power of penetration." It is not how deeply my mind can go or imagination fly; it is, can I take the gifts which God has loaned me, and, linking them up with the gifts he has loaned to other people, lift the burden from the heart of the world. We are strong by pulling together and having an object in life.

Men Who Had No Excuse for Living

In the last twelve months, in the club where I live, I have seen a dozen men fade out of life because they had no excuse for living, no reason, no desire, over-introspection, thinking only of self.

I love music. A friend of mine said to me, a long while ago, "Go to the Symphony Friday afternoon and you will be in heaven." I did, and for ten minutes at least I was in heaven. I never heard such music in my life. Then the man on my right leaned over and began to talk about his liver to the man in front of him, and the man on the other side began to discuss his kidneys with the man next to him. I didn't hear any more music.

When I saw my friend later, he said, "How did you enjoy the Symphony concert?"

I said, "It wasn't a symphony concert, it was an organ recital."

Let's get away from this organ recital business. Think of the other fellow, not the man who has more, to envy, but the fellow who has less, to sympathize.

Don't jump too quickly to conclusions. I was driving along a country road in New Jersey one day, and I rounded a curve in the road and came upon an overturned load of hay which blocked my way. A man 65 or 70 years of age was in the road laboring to right the load. It was a very hot day, and I said to him, "My friend, come get in my car and cool off a bit and then we'll both get at it."

He looked me in the face and said without a smile, "I can't stop. Father wouldn't like it."

When I was afraid of my father it made a marked impression upon me in early life, but I wasn't 70 years old. I said nothing to him for a few moments, and finally I said, "Come and rest, and then I'll help you."

"No, father wouldn't like it."

I said, "Where is your father?"

"Under the hay." I thought the father was home on a cool porch and could wait. He was where he couldn't afford to wait.

In thinking of the other fellow, we can put our heads up against great problems with the prayer of my dear old friend Phillips Brooks, Bishop of Massachusetts when he died: "O God, do not give me tasks equal to my powers; give me powers equal to my tasks." Never let the fact that a problem is big frighten you. Ask for the power to solve it. By tying my arms to my body I do not save my muscle, I lose my arm. He who wrestles with me strengthens me. Big problems make big men. That is why I believe we are coming to the dawn of a very bright day, because in my memories that go back 65 years, just as vividly as I see the things that happen today

I see the things that have happened in that time, and I have seen a wonderful advance, oh, a marvelous advance in mankind. Superficially, we seem to be traveling in a circle. Closely observed, life to me is a spiral. We seem to repeat, but we are going higher and higher with each revolution and the world is getting better.

No boy today is half so bad as I used to be, and if I had my life to live over I would be a darned sight worse, there is no question about that. Let's be honest with ourselves. My grandfather was old enough back in the sixties when he died to have talked with Washington. He said, "You boys of this generation are ten times worse than we used to be." That has been going on and on. Each generation has a new way of showing and getting rid of its superfluous energy.

We have had good mothers, good fathers, and the world is getting better. Go back in your own minds. Some of you came from country districts, as I did, to a big city. You recall the time when you went home at Thanksgiving or Christmas and everybody was glad to see you. Then by and by when the excitement was over, dear old mother got you across the shadowy hall into the shadowy parlor and on bended knee, with her arm about you, she thanked God that her boy was home again.

You have gone back to the city. The day has come in the life of every man when he thought the fight was lost, opposing forces were stronger than he had estimated. Then a little miracle happened. The kind Father, if the mother had gone home to God, released that voice of the Choir Invisible and you felt that arm around you, you rallied, you won. What was it? Mother love, home influence. There are 26 million home circles under Old Glory. That is a pretty good anchor for the Ship of State. I am not a bit afraid of it. I have seen and written about every form of government that exists, and I have a greater belief in our government than ever before in my life.

The Smile of God Is Country-Wide

I have just come from an extensive trip, covering the Pacific Coast, and up into New England and down in the south, and I have never seen the smile of God more clearly showing on the face of this dear old earth than I see it now, from one end to the other.

We are realizing what you illustrate here in the concrete, that no man liveth to himself alone. We are coming to recognize the sovereignty of divine right is not an empty legal phrase, but the expression of the mightiest thought ever conceived in the mind of man. Each man touches with a quickening finger what the living God has given him, a work that nobody else can or will do.

Here our ruler is an agent and not an owner, as he is in Europe. I lived fourteen years of my life there, and the difference between Europe and America you can put in a phrase. There they labor under the lash of necessity, looking down; here we labor under the lure of opportunity, looking up. We are growing better and we are growing higher in this wonderful age. Oh, how I envy the younger people the mighty heritage of unused years, how I envy you men coming in daily contact with man. God's finest exemplar, here on this dear old earth.

Optimist? Of course, I'm an optimist! I hate a pessimist. He is nothing more than a blind man in a dark room looking for a black hat that ain't there. If he stays at it too long he gets like the man who swallowed an egg, afraid to move for fear of breaking it, afraid to keep still for fear of hatching it, he doesn't know what in hell to do.

Years ago a little fellow fell downstairs in the city hall opposite my office. I ran out and picked him up and said, "Hurt?"

"No, I was coming down anyway."

My philosophy of life is, if you can't get what you like, like what you've got. Its a good rule, even for married people. There's a whole lot in it.

Don't talk about luck. I'll back pluck against luck any day. Stop kicking. Every time you kick you lose a step. You've got to stop walking to get ready to kick; you lose two steps when you kick, and the other man is three steps ahead of you.

Love your town or leave it. That is what every American owes to his community. He will never succeed in the town he hates, and he is a detriment to other people. Get out into some other place. When you get away from it you will find the other place isn't half so bad. A darky said he loved to have the toothache because he felt so good when it quit hurting. We need contrasts. Don't be a fault-finder. People will measure you by what you create, not what you correct.

Keep the young people busy doing right and they haven't time to do wrong. Don't stress the wrong. My old mother used to say to me, "If you're going to New York you needn't look up the time table to Washington; it's the other direction; you're not going that way." Tell people what is the right thing to do, just as this learned doctor has told us today.

I got into trouble at a medical society meeting one time because I repeated an innocent remark made by a colored coachman. I went out and found him looking kind of blue. I asked him what was the matter. He said, "I'm going to lose my wife."

"What makes you think so?"

"The doctor says so, and he knows what he's giving her."

He didn't mean to accuse the doctor of homicide, it was just his awkward way of putting it. So many of our mistakes and frictions come from not understanding the other fellow.

But beyond and above all that we say, there come discouraging times. In our first canvass in Pennsylvania for good roads we had sixty-six counties against us, I think, and only one in our favor. In the last one there was only one against us and sixty-six with us. Keep working. I have watched you work for years. You are doing God's work.

The Immense Value of Laboring Men

I sat on the balcony of the Bellevue one night (I am fond of using my mind at figuring big problems without the use of paper), and I figured up that taking the wages of our great body of workers, you would have to take a sum twice, (and some say three times), the value of our total national wealth to equal the value that our laboring men are to this country. Economically you are doing great things.

In my conscious life, I have watched the growth of this country's wealth from seven billion dollars to 355 billions. That is a miracle that never has been paralleled in all history. In that period the population has only increased four and one-half times, and the wealth 55 times. In other words, I have lived through a period when the wealth in this one country has multiplied eleven times as fast as the number of people to divide it. That is the answer to any pessimistic thing you can bring forth.

Here is another little fact that fits in as the basis of my optimism. Before the war we had 174,000 people holding government bonds, and therefore a financial interest in the stability of our government. Today we have 18 million. We have 32 million people in America who hold securities and have something to lose if anything should happen to the stability of the government. Isn't it the part of folly to talk about three million who haven't, upsetting the 32 million who have?

In this age, in this country, where we are multiplying power, where we are cutting out the undesirables from abroad and so developing machinery that the

higher the type of work is done by those who remain, human life becomes more valuable and more necessary in our economic structure. And you, in doing that which preserves human life, are doing the greatest work in the line of patriotism that men or women can engage in.

It is terrible, when you love a city as I love Philadelphia, to see thoughtlessness and carelessness in our great industrial establishments bringing the shadow of an unforgettable and incurable sadness into a whole row of little homes. I have gone there to try to comfort them. Oh, I wish I could put into words the depth of my feeling and the honor I experience today in having this opportunity to look into your faces and say God help you, God give you power to broaden and deepen the influence of this mighty effort, this wonderful movement that is going to lift man nearer God and bring God nearer man and bring a little heaven down here on earth.

Luck Is No Longer a Belief of Men

I said I didn't believe in luck. We are getting that belief in luck out of the minds of men. Science is killing that old idea of luck. I had a friend who lived down in that old Democratic state of Alabama years ago. He had been in eight different kinds of business and had failed in each one and thought he was unlucky and born to continue that way until death. He made up his mind he would get out of the world and make room for a lucky man. But he had lost faith in everybody and everything, including himself. He had decided to buy a bottle of poison, but he said to himself, "Everything is adulterated these days; that won't work at the critical moment; I'll fail, I'll be ridiculous." So he bought a pistol. Then he thought, "They're making pistols out of anything in this day and age; that will break or won't go off; I'll fail, I'll look ridiculous." So he bought a rope to have three ways out. But in thinking it over his deep-rooted suspicion of everybody made him reach the conclusion that ropes were made of any old thing; that would break, he'd look awkward, he'd be ridiculous. So he got in a leaky boat on one of those little rivers down in the old Democratic state of Alabama. He drifted down until he came to a point where there was an overhanging branch, tied the rope around the limb, swallowed the poison, pulled the trigger and fired the pistol. The bullet struck a glancing blow and cut the rope, he fell into the river and swallowed so much water it was an antidote to the poison, was pulled out by a friend and elected to Congress on a Republican ticket.

Don't talk about luck. I don't believe in it, my friends.

Little things count. You may work and work and work and think that your work is lost, but it never is. No impulse comes from the human heart along lines which point Godward that is ever lost in this wonderful universe.

I met a friend on a trip in the West last year that I hadn't seen for thirty years. We had a wonderful talk, as you have with old friends, and he told me the saddest hour of his life was when he had to go home and tell his little wife that the bank, his bank, would have to fail on the morrow. Chicago wouldn't give him any more credit, Philadelphia wouldn't give him any more credit, there was nothing to do but fail. His wife said to him, "Tom, you go to bed and get a good night's sleep. I know you are troubled, but I have worked out a plan whereby I can save the bank."

He said, "I knew that little woman didn't talk unless she had something back of it." The next morning she went down to the bank, opened the box in the safe deposit vault, and handed him \$100,000 in currency. He said, "Kate, where in the world did you get that sum of money?"

She said, "Years ago when you married me, you said every time I kissed you it was worth a dollar. I made you pay it. I've saved it all up. Here it is."

He threw up his hands and said, "Oh, if I had only done all my kissing at home

I would have been a millionaire." You might take that home and think it over as a safety first principle.

Being an old bachelor I am a great expert on matrimony and the care of children.

There is only one trouble with this country; it lacks some of the old courage that has characterized it from the start and has been the secret of our great development.

To go back to that first Thanksgiving day in old New England, half the company dead, only seven or eight answering the roll call on the day before. What did they have? A day of fasting and prayer? No, a day of thanksgiving. We need that today. All over this country I have found—north, south, east, west—a little doubt, a fear of something, they know not what, coming from they know not where. I preach courage and a return to the old idea that one with God is a majority and that the solution will come if we jump into the problem.

I have cited that illustration in New England, and I have dared to say that I thought they got their inspiration for that wonderful bravery from that little incident recorded in the twenty-second verse, the eighteenth chapter of Deuteronomy. They were loading the Ark, and a little flea going up the gang-plank in front of an elephant turned around and said, "Who the hell are you shoving?"

Men Who Sacrificed on the Altar of Courage

Oh, my friends, you don't know how far a little courage will carry you. You seem to place that biblical quotation so quickly that I am tempted to give you one more. When I was over-praised in the introduction by your great, good chairman and I knew I would have to disappoint you, there flashed before me as a warning of what I should do, that I ought just to rest my reputation on his kindness and not speak. As a warning to me to keep still, there appeared before me in what seemed to be letters of fire, that wonderful eighth verse of the fourteenth chapter of Genesis where Jonah said to the whale, "This thing wouldn't have happened if you had kept your damned mouth shut." I can't keep mine shut. I have had to talk, and I have spoken from my heart to men who are doing what I (because I have long passed the three score and ten), haven't the physical power to do. I am doing all I can.

Saturday night I was at the ninth anniversary of the 314th Infantry in Harrisburg. There were a dozen men in the room on crutches, and there were plenty of armless sleeves. I have been with them at all their meetings—happy, brilliant, plain men, all kinds, but all united in a common love for a common country, this nation whose foundation is a God-fearing people.

I was with a man who had lost his only son. I looked at those men and remembered speaking at Gettysburg 50 years ago. There came the thought: In every crisis America rises to the great issue and shows the God in her.

I feel the radio is coming in now to help us solve two great problems. I know Russia, I have written about it, I have traveled through it. Eighty-five per cent of its people are illiterate. You couldn't reach them by the written word, but the radio will go to them; they have honor and honesty down in their peasantry, and they will respond. The radio, that brings you within three-tenths of a second of every human being, is going to teach China, with her immense resources, how other people live. A new buying demand is going to be created, greater than the restored supplying power of Europe and America. There will be even brighter and better things than that.

I was speaking to a body of men in New York a couple of years ago at the Commodore. There were 2,000 men in front of me and 20 million out in the darkness. I happened to remember in the middle of my talk that it was the anniversary of the greatest sorrow that ever came into my life 40 years ago when the mother I idolized went home to the God she had tried to serve. I couldn't help

speaking of her work in the hospital, in the orphan asylum, with the poor and the needy. It had no business in the speech. I felt, the next day, that I had failed.

A week later the president of the American Telephone & Telegraph Company sent me a little letter saying: "Cattell, I am enclosing a letter that I wish had been sent to me." It was only a short letter from a woman who had made a splendid fight and failed. She was in a little farming town in the southwest. Her husband had been ill for a long time; he had had an accident in his employment. When he recovered, his courage was gone and the little funds exhausted. Her nerve broke, she said, and on the last page she wrote, "I provided myself with a little powder that would bring me what I thought would be the oblivion I wanted, the end of it all. I was on my way to my little bedroom to find that forgetfulness of life, and I passed through our little dining room and kitchen combined. Force of habit made me tune in on the little radio set we have. Dr. Cattell was speaking of his mother who was gone. I remembered my own mother with the Master. I am alive this morning because of the message which came to me out of the darkness and led me to light."

Friends, when the call comes for me, that little lantern is all I can offer as the fruit of my life, and I won't require anything more.

You are doing great work, you have got back of you the power of the universe, you cannot fail. God be with you until we meet again, here, or where accidents never happen, old friends are found, and heartaches cease.

CHAIRMAN SPRAGUE: We still have one other remarkable feature for this appreciative audience, and I will give only a word in introduction. Your program calls this number "The Intruder" and the characters are to be represented by Mr. Ernest Domfield and Miss Mona Smith, of Chicago. Let us pass into that atmosphere of solemnity and realized responsibility for the misfortunes of others, which this powerful little playlet demands.

"The Intruder"

A PLAYLET

(Bell tolls, GRIM REAPER appears in midst of audience, unannounced.)

REAPER: Welcome to our annual conclave. (Bell.)
 Hear the constant tolling of our bell.
 What pleasant thought its monody compels. (Bell.)
 Hear the groaning of the bell,
 Tolling the doom of the millions—
 Aye, and will forever toll. (Bell.)
 Ye have crowned me king,
 Autocrat of all I survey.
 My abject slaves . . . All
 Blindly stumbling towards my dark abyss.
 Your mothers, brothers, aye, you yourselves,
 Soon must come to my realm.
 Nor wealth, nor glory,
 Can stay thy doom.
 The flower-decked grave, the tearful eye,
 But dimly veil my omnipotence. (Bell.)
 (Exultingly) Ring out ye bells,
 And let every stroke proclaim to the world

Its ignorance. (*Bell.*)
 Ring out ye bells, and let every reverberation
 Flaunt back to the boastful world
 Its shame of tolerance. (*Bell.*)
 And let your melodious dirge o'erthrow its chaotic
 Jangling, false ambitions, delays,—
 Aye, its sins. (*Reaper exits.*) (*Bell.*)

REAPER: (*Enters with report*): Hold! A report I wish to render.
 From the blood-soaked fields of Europe:
 We gleaned nine million deaths
 And many million serious injuries. (*Bell.*)
 Is it not glorious? Now an important amendment
 The woman in industry. (*Pause.*)
 No one discerns my sinister grasp, hovering over her.
 To clutch at will, dragging her down to thralldom. (*Subdued laugh.*)
 (*Bell.*)

Harken, to our never-ceasing pacans. (*Bell.*)
 Welcome, thrice welcome, this year of 1918.
 The past industrial harvest has indeed been a glorious one—
 The toilers, the children, aye; the mothers of children.
 Our New York conclave last year was naught in comparison
 There and then you boastfully recited the record of how
 You had deprived me of my harvest;
 There and then, flushed with pride, you made glowing
 Speeches extolling what you had accomplished.
 Humiliated was I, but silent.
 There and then you proclaimed the many toilers
 Who had escaped my scythe:
 The toilers whom you had armed to combat my prowess.
 Chagrined was I, to be apparently so thwarted
 By mere mortal men,
 But this year, here and now, I COME INTO MY OWN.
 Last year you confidently spoke of what you proposed to do,
 And in the meantime, stealthily, I reaped the grand harvest
 OF SIXTY THOUSAND DEATHS AND ONE AND ONE-HALF
 MILLION ACCIDENTS

Think of it! Go on, lay your plans,
 Still unheeding that "the best laid schemes of mice and men
 Gang aft a-gley." (*Subdued laugh.*) (*Bell.*)
 And now I must bid you adieu.
 Next year will I come e'en with a greater report. Adieu.
 All is most propitious,
 Our subtle pitfalls are now well laid,
 Naught can thwart me.
 Mortal man is impotent,
 His antique laws, decaying and weak,
 And e'en the Great Jehovah on high is powerless,
 And weeps for his children. (*Subdued laugh.*)
 The world is doomed,
 Who, who can stop me now?

SPIRIT: (*Appears*) I will.

REAPER: You, who are you?

SPIRIT: My name? At creation's dawn the simple herdsmen called me Brotherly
 Love,

Through the dark ages, the martyr's blood e'en was shed that
I might live, and smilingly with their last breath they whispered the hope
of the oppressed, Christianity.
Here and now it matters little, my name.

REAPER: Words, words, empty words. Your name?

SPIRIT: I am the personification of Love, Truth and Justice!

REAPER: Disciple of evil, your name.

SPIRIT: (*Throws off mantle*) UNIVERSAL SAFETY! And with today's setting sun, we swear to baffle you, Grim Reaper.

REAPER: And with tomorrow's rising sun,
Ye are all one day nearer to your graves.
My dark chasm is built and paved with such good intentions.

SPIRIT: They were. But henceforth we shall *live* our belief.
THINK IT. BREATHE IT. TEACH IT. So that after us the good work will go on.

REAPER: You will surely FAIL.

SPIRIT: In the bright lexicon of UNIVERSAL SAFETY, THERE IS NO SUCH WORD AS FAIL.

REAPER: Bombast—why, with these my ministers, my dupes, my helpers, will I—

SPIRIT: These? What have they done for you, Grim Reaper?

REAPER: Not what they HAVE done, but what they have NOT done.

SPIRIT: The sins of omission.

REAPER: Aye, the sins of omission.

SPIRIT: Forty-five thousand of God's creatures—

REAPER: One and one-half million and forty-five thousand! I struck them down.
Now they wander aimlessly in my dark cavern.
The blooming bud, the full-bloom flower,
The sere and yellow,
I gather them all.

SPIRIT: Nay, we saved one and one-half million. These were not struck down.
These were but accidents.

REAPER: Accidents! (*Laughs*) The blind! The maimed! The lost and crippled limb! The shattered nerve! The emaciated countenance! The palsied hand! The distorted mind! Living deaths. *I claim them all.*
With boots if whether a gear, a shaft, molten metal, a deadly wire, an open switch, mistakes,—

THEY ALL FILL GRAVES.

The tears of the widow and orphan attest my imperialism.

SPIRIT: Nay, new aid is pledged here.
And our hopes now blossom anew.

REAPER: Your aids will fail anew.
My true and tried destroyers are invincible—
CARELESSNESS, THOUGHTLESSNESS, RECKLESSNESS, IGNORANCE!

SPIRIT: And I have but one aid—UNIVERSAL SAFETY. And as the most acceptable service to God is doing good to man, I call on you, my helpers here and now, to place your left hand over your heart—so—and with hand uplifted—so—repeat after me:

"Our Father who art in heaven,
Vouchsafe and preserve us,
That we may promulgate to mankind
Thy message of universal safety;
That we may safeguard and protect
Our mothers, brothers, children,
From untimely death, accident, and disease.
Give us life and strength to preserve mankind,
Created in Thy image and likeness,
Unto all generations.
For ours is the happiness,
And Thine is the glory."

Nay, nay, keep thine hands uplifted. See, Death, defeated, sneaks away.
Nay, hands still uplifted, promise never to forget thy vow, keeping it like
unto a frontlet between thine eyes. See, see, stalks away the Grim Reaper,
dejected, baffled. Thus we vanquish untimely *death* and win the *victory*.
Thus, you shall save the world.

And now march on to happiness and victory. (*Exit.*)

ADJOURNMENT

*SIXTEENTH ANNUAL SAFETY CONGRESS
NATIONAL SAFETY COUNCIL*

Annual Banquet

Wednesday, September 28, 1927

WALTER G. KING, Presiding Officer
President, National Safety Council

LAWRENCE McDANIEL, Toastmaster
Attorney at Law, St. Louis, Mo.

The Annual Banquet of the Sixteenth Annual Safety Congress was held at 6:15 o'clock in the Grand Ballroom of the Stevens Hotel, Mr. Walter King, president, National Safety Council, presiding.

PRESIDENT KING: We have a few announcements to make at this time. We have received a letter from the National Safety First Association of London:

"The National Safety First Association of Great Britain unite with your Counsel in wishing continued success to efforts of your Congress toward eliminating waste of life and limb in avoidable accidents."

The American Gas Association extends best wishes for a successful Safety Congress. They say, "It has been and is a pleasure to work with the National Safety Council."

"The Directors of the Province of Quebec Safety Association, in session assembled, wish to extend their sincerest wishes for a most successful convention and assurance of their wholehearted support for the success and extension of the accident prevention movement."

"The Southern California Society of Safety Engineers extends greetings to delegates attending the National Safety Congress. With sincere wishes for a successful meeting we extend heartiest invitation to all who attend for the Pacific Coast Conference and Fifth Annual First Aid Meeting in Los Angeles, October 24-25."

At this time it is customary to announce the newly elected officers for the coming year. The following is a list of the elected Executive Committeemen at Large.

Elected Executive Committeemen at Large

Ernest W. Beck, United States Rubber Co. New York City
Frank Austin, W. E. Wood Company, Detroit, Mich.
Harry M. Webber, Illinois Bell Telephone Co., Chicago, Ill.
Arthur M. Tode, The Texas Company, New York City
S. E. Whiting, Liberty Mutual Insurance Co., Boston, Mass.
W. H. Winans, Union Carbon and Carbide Corp., New York City
George Opp, Detroit Edison Company, Detroit, Mich.

W. B. Pettibone, Willard Storage Battery Co., Cleveland, Ohio
 Chas. J. Moore, Retired, Springfield, Mass.
 Henry A. Reninger, Lehigh Portland Cement Co., Allentown, Pa.
 C. E. Hills, New York Central Lines, New York City
 C.-E. A. Winslow, Yale University, New Haven, Conn.
 Miller McClintock, Erskine Bureau, Harvard University, Cambridge, Mass.
 George E. Sanford, General Electric Company, Schenectady, N. Y.
 A. W. Whitney, National Bureau of Casualty & Surety Underwriters, New York City
 C. E. Pettibone, American Mutual Liability Ins. Co., Boston, Mass.
 G. T. Hellmuth, Chicago North Shore & Milwaukee Rwy. Co., Chicago, Ill.
 Homer E. Niesz, Commonwealth Edison Company, Chicago, Ill.
 George Kelday, International Harvester Company, Chicago, Ill.
 Ethelbert Stewart, United States Bureau Labor Statistics, Washington, D. C.
 J. M. Woltz, Youngstown Sheet & Tube Co., Youngstown, O.

The following is the list of the elected Executive Committeemen, Community Council Representatives.

Elected Executive Committeemen—Community Council Representatives

A. J. Van Brunt, Representing Newark Safety Council
 Frank A. Morrison, Representing Detroit Industrial Safety Council
 Paul Van Cleef, Representing Chicago Safety Council
 T. G. Brabston, Representing Birmingham Safety Council
 John V. Hanna, Representing Kansas City Safety Council
 Dana E. Jones, Representing Erie Safety Council
 R. F. Redfern, Representing Providence Safety Council

The following is the list of elected Executive Committeemen, Sectional Representatives:

Elected Executive Committeemen Sectional Representatives

R. McA. Keown, Representing ASSE-Engineering Section
 Leonard Greenberg, Representing Chemical Section
 A. R. Bush, Representing Marine Section
 J. A. Northwood, Representing Metal Section
 C. A. McDowell, Representing Mining Section
 John B. Grier, Representing Woodworking Section
 E. R. Cott, Representing Steam Railroad Section

The following is a list of executive officers who have been chosen to serve you and I will kindly ask that as their names are read, if they are present, they will rise so we will know who they are:

Executive Officers

E. W. Beck, Vice-President for Industrial Safety
C. E. Hill, Vice-President for Local Councils
Miller McClintock, Vice-President for Public Safety
C. J. Moore, Vice-President for Public Relations
C. E. Pettibone, Vice-President for Finance
H. A. Reninger, Vice-President for Membership
G. E. Sanford, Vice-President for Engineering
A. W. Whitney, Vice-President for Education
Prof. C.-E. A. Winslow, Vice-President for Health
G. T. Hellmuth, Treasurer

Now, friends, the great question about the next announcement has caused a great deal of anxiety among the prominent families in Chicago as to whether this man would be elected for another term. We have tried him out and he is all right. The man we have selected for our managing director, to me, is the finest man I have ever known. I have never seen such patience, such kindness, such willingness to serve, and after getting together and discussing this thing at some length we finally agreed for this coming year we would try out again our good friend, W. H. Cameron, of Chicago.

(The audience arose and applauded.)

PRESIDENT KING: The man who has been chosen as our new president is loved and respected by all of us who know him. He was born in Ohio, the home of Presidents, and educated in an institution of learning in Ohio. He moved to Chicago, his present home, becoming associated with the Edison Company, starting in the construction ranks of this great company, filling the positions of assistant construction superintendent, superintendent, assistant to the president, manager of the Cosmopolitan Electric Company and, finally, his present position of trust and responsibility, manager of Industrial Relations of the Commonwealth Edison Company of Chicago. He is past-president of the Chicago Engineers' Club, a member of the American Institute of Electrical Engineers, of the National Electric Light Association and the Chicago Athletic Club. Our new president is fundamentally a big executive, schooled in the exact science of engineering. He has been our vice-president in charge of finance, and has rendered invaluable service at all times giving freely of his time and his energy.

It is indeed a privilege and an honor for me to introduce our new president, our co-worker and my very dear friend, Homer E. Niesz, of Chicago.

(The audience arose and applauded.)

Acceptance of Presidency of National Safety Council

Homer E. Niesz, Manager Industrial Relations, Commonwealth Edison Company, Chicago, Ill.

I would, indeed, be less than human if I did not feel a sense of deep appreciation of the honor of being elected president of this wonderful organization.

I would be lacking in sentiment did I not thrill through my whole being from the glowing tribute your president has given me and the enthusiastic reception accorded me at your hands on this occasion.

To be the executive head of the National Safety Council is not only an honor but an opportunity and an obligation. This opportunity and the attendant obligation can be met with confidence because of the splendid cooperation of the Directors, the Executive Committee and the officers of the Council—men who

devote their time and energy, their brains and their hearts to this great work which is humanitarian as well as economic in its nature.

Your elected representatives are prepared to assume the duties delegated to them by the membership, which is at the same time the inspiration and the medium of accomplishment of the purposes of the Council.

The work of the Council through its various Sections, and Division and Local Councils includes the promotion of safety at work and at play, on the streets and highways, in the schools and in the homes—in short—universal safety.

The scope of its activities is as wide and as encompassing as human life whose protection and preservation constitute its high objective.

The men and women attending this convention and the thousands of others engaged in safety work all over this land are the most enthusiastic, the most willing, and the most devoted body of workers to be found anywhere and their fidelity and heart interest approximate consecration to the cause.

With this splendid support, we who are to lead and guide the destinies of the Council for the ensuing year can be encouraged to take up the burden and carry on with a feeling of confidence that we are constantly progressing toward our final goal—the elimination of accidents and the attainment of safety, prolonged life and happiness for all mankind.

PAST PRESIDENT KING: My time is short. This year has seemed a very short one to me. It has gone quickly, but I can assure you, ladies and gentlemen, I have been conscious all through this entire year, every day, of the wonderful honor it is to represent this magnificent body, a wonderful experience, and it has been the happiest year, I think, of my life.

Now, I am stepping down, but I am not stepping out; I am with you, always will be with you.

There is a questionnaire before you and we are going to try to find the answer tonight. "Consider the Toastmaster. Why is a Toastmaster?" I understood I was expected to introduce this gentleman to you. He slipped in quietly this afternoon. I don't know his background and couldn't find out anything about him, but I heard some one call him "Larry," and in looking him over I made up my mind he was a regular fellow. I think we are going to be very greatly entertained tonight by the toastmaster who has been selected to take charge of this meeting, and it is my pleasure to introduce to you Lawrence A. McDaniel, of St. Louis, Missouri.

Toastmaster McDaniel Takes the Helm

TOASTMASTER MCDANIEL: I want to see if I can't make you hear without the use of the "mike" as they call it. I don't like the echo that comes back. It makes me think of an echo that my friend Cameron found out in Colorado last summer. A guide took him to a mountain pass, where a wonderful echo could be heard, and Cameron, at the direction of his guide, yelled into the hills, "Hello," and the echo came back "Hello." Cameron yelled, "Are you there?" and the echo came back, "Are you there?" Cameron yelled, "Come down and have a drink," and the echo came back, "I will be right down."

I will tell you why the president knows nothing of my background. When I got in this afternoon I couldn't find the committee in charge of this meeting. So finally I saw a waiter with a tray. Upon that tray was soda water and ginger ale. I followed that tray. The committee was in session.

Now I don't know who the author of this book is. He wants to know why is a toastmaster. Why, ladies and gentlemen, the toastmaster is the spice of the meal. He is no good, whoever wrote this book. I say to him, as did the minister of the gospel who had trouble with his flock, and they asked for his resignation; while

the quarrel was pending the Governor of his state appointed him the chaplain of the penitentiary. He accepted and announced he would preach his farewell sermon and he took for his text these words: "I go to prepare a place for you that where I am ye may be also."

Now the duty of the toastmaster is to say a few kind words to the audience and a few kind words about those who will entertain you and address you. I think of the man who went into a dining room in this hotel this morning and said to the waitress, "For breakfast give me two soft boiled eggs, a cup of coffee and a few kind words." In due time she brought the eggs and the coffee. He looked at them and said to her, "Now give me a few kind words."

She looked around and then leaned over his shoulder and whispered, "Don't eat the eggs."

I am going to play safe. I am like a Scotch friend whom I took out to the dog races the other night. Do any of you have dog races in your communities, where greyhounds chase an electric rabbit? My Scotch friend watched the first race without betting. Then as the time drew near to place bets on the second race he approached the window of the ticket seller and said, "Give me ten dollars on the rabbit to win."

"Now, Just One More," Says the Toastmaster

Now just one more. A Jewish gentleman sent his boy to college. Now, you understand the dog race I know. He heard that in college his boy wasn't behaving himself. He was doing many of the wild things that he shouldn't do. So his father thought if he could just bring his religion back to him once more he would straighten up and behave himself. So he wired him, "Dear Ikey: The passover starts tomorrow." And in a little while he got a telegram back: "Dear Papa: Put ten into winner for me."

Now, ladies and gentlemen, I am going to introduce the first thing on the program. Many of us are radio fans. We get out of the air the voice, the music, the speech. The radio is a wonderful thing. You set here and listen to me, and if you don't like it courtesy demands that you stay and listen to it anyway. If I were talking over the radio and you didn't like it, by that (*indicating a turn*) it is gone. Sam 'n' Henry are known to all of us who listen over the radio. They speak, they act over WGN, the Chicago Tribune Station. They are in business here in Chicago. They are in the transferring and drayage business here in Chicago, and their horse, Grandpa, is the chief asset of that business. We are not going to have them in person; we are going to have them over the radio. Our first selection is by way of the air, not hot air that you get from this table, but out of the ether, Sam 'n' Henry of WGN, the Chicago Tribune.

(The broadcast of Sam 'n' Henry was then heard.)

TOASTMASTER McDANIEL: Two telegrams of compliment have come in, one that I can't be heard in San Francisco and the other in New York, so I will use this. It makes me think of the wonderful society wedding in New York, a church decorated with orchids and beautiful flowers. As the bride came tripping down the aisle, it seemed that all the loveliness, all the sweetness in the world had been rolled up in this one beautiful creature. As she came down the aisle there were the usual Ah's and Oh's and so on, and as she got about half way down, this beautiful, lovely creature, who seemed to be almost sprouting wings, tripped over a lily pot that stood in the aisle, and in a voice which could be heard all over the church, she said, "Ain't that a hell of a place to put a lily pot!"

The next on the program is the International Harvester Company Choral Club. The International Harvester Company has been a pioneer in safety. They have ever supported the safety movement; they have given the best, and this wonderful choral club is recruited from the office of this company in Chicago. We will now hear this wonderful choral club.

(Several selections were sung by the International Harvester Company's Choral Club, amid general applause.)

TOASTMASTER McDANIEL: Mr. DeYoung, will you please stand while I introduce you as the director of this wonderful choral club?

Now we know why the music center of the world is moving westward to Chicago.

The next on the program is a young man who comes to us from that mighty center of industry, the largest city in the smallest state in the Union, Providence, Rhode Island. This young man is the president of the Safety Council of his school, known as the Junior Safety Council. He was born in the shadow of that little church where Roger Williams first sowed the seed of religious freedom. He comes to us as a sample of what the youth of this nation are now doing in the interest of safety. With a great deal of pleasure I present to this magnificent audience, Mr. Prendergast, from Providence, Rhode Island, who will now address you.

Your Job and My Job

James Prendergast, President, Junior Safety Council, Oxford Street Grammar School, Providence, R. I.

I am certainly getting a great kick out of being here tonight, and a part of it is being allowed to say a few words to you about the safety of all the boys and girls of this country.

Providence, Rhode Island, is certainly a long way from Chicago but we have the same safety problems there that you have here. We have over 80,000 school children in Providence who are in danger of some kind or other all the time, and we are doing all we can to keep them from getting crippled or killed so that they will grow up and be able to have the good times every one should have.

It is a much harder job to do this than it was a few years ago, pretty much on account of the automobile which is now used so much. There is no doubt that the automobile is going to stick around because it is so useful, but it has given you and me a new job—the job of keeping ourselves and others out of its way.

When you stop to think that nearly 7,000 children under fifteen years of age have been killed in automobile accidents during the past year and hundreds of thousands of others badly hurt, you can begin to realize the size of our job. I say "our" because, big or little, old or young, we can each do something that will help the situation—in fact we must do it if these deaths and injuries are to be stopped.

While your job is the same as mine, I feel that each of us has different things to do. What is *your* job, as we children see it? First, to set a good example; and second, to give your support to safety work. I wonder if you men and women realize how much the boys and girls look to you for ideas and help in all that we do. I don't think you appreciate how much we want to grow up like father and mother or you would be more careful in what you do and say—particularly when we are around to see or hear.

Take this matter of automobile accidents, for instance. We learn at school that about 75 per cent of these injuries are caused by persons crossing the street in the middle of the block and nearly 70 per cent of them are children. It may be fairly safe for you to cross in this way because you are better able to judge how fast the car is coming than we are. We in Providence, are being taught that the corner is the place to cross and this idea is being spread through the Junior Safety Councils that are organized in all of the schools. If we were not allowed to play in the streets we would also avoid many of the accidents. But seeing our elders cross the streets any place and using them for their play at times, does not help us to heed these

warnings and look out for the dangers that exist, and all this makes it harder to sell "Safety" to all of the children. If we are going to do as you say, you must "practice what you preach."

Another thing—if you just have to break traffic rules when you are driving, don't do it while your boy or girl is in the seat beside you. He knows the rules even though he can't drive. He knows the makes of all the cars and can tell you a lot about the machinery, and when you do these little things it makes it all the harder for us to really get safety over to him.

Your second duty is to support the organizations that are teaching safe practices to people on the streets, in the homes or at work. It takes money to carry on work of this kind successfully and it is up to you, especially those who have children, to see that the work is not hampered by the lack of funds. The need for this work is easily seen, and it has become a duty, as well as a privilege to help even in only a small way in providing the necessary means to enable such organizations to "carry on." The safety movement is still young but the need for it cannot be questioned and no citizen can escape his part of the job.

For our part, our job is to follow the teaching and example of our elders with whom we come in contact, and in so far as we are able show our playmates and companions that safety is a serious matter. And then, too, it is up to us older boys to set an example for the little folks who need the most protection. We are pledged to do that for them just as we want you to do it for all of us children. This is all we can do until we have reached the time when we are ourselves in your shoes, and then I am sure our experience will make us want to shoulder our part of the job so that the information may be passed on to others who are as yet unborn.

It does seem too bad that the present generation cannot indulge as freely in the games our parents played without running the risk of getting hurt, but such is the case. It is true that we can still play the same games, but in the face of things as they are, we must choose the time and place so that the dangers can be overcome. Our slogan at home is, "Use the playgrounds for your games," and I wish that slogan could be impressed on every child under fifteen years of age in the country today. This, coupled with the desire to live and work and play the safe way rather than the unsafe, or "take a chance," way is the answer to the child accident problem of today.

As I have said, all our work is done through the Junior Safety Councils and with the aid of the schools. Do you have Junior Safety Councils in your city? If not, you should take an active interest in getting them started. I could talk to you for a long time about the work of the Junior Safety Council, but time will not permit. However, I would like to recite the pledge of the Junior Safety Council which every one of you could well afford to use as your safety motto. Here is the

Pledge of the Junior Safety Council

I will work for the safety of others as I would want them to work for my safety.

I will try to be careful, all the time, everywhere.

I will not take unnecessary chances of getting hurt and will warn others against doing so.

I will do MY PART to help reduce the number of accidents this year.

All this I will do for the sake of humanity and the honor of my school.

I am just a boy, nothing more, but I want to live and enjoy life just as every other boy and girl in this country wants to do the same thing. You were all children yourselves at one time and many of you have children of your own; and I know you wish these things for us just as strongly as do we. And so I appeal to you to go back to your different cities and do even more than you are now doing to make life safe and happy for the children of America.

TOASTMASTER McDANIEL: Jim, we thank you for this wonderful, inspiring address. The rest of us wish we could do as well.

Did you ever meet a man and immediately like him?

Did you ever meet a man whose first words to you marked him as a man you would like to have as a friend? I had that experience today with the next speaker, the distinguished president of the University of Chicago. I wondered why it was I thought of the insane asylum where they had had so much trouble with superintendents, and finally the Governor appointed a new superintendent and he seemed to get along fine where others failed. One day, in talking to some of the inmates, one of them said to him, "Do you know, you are the best superintendent we have ever had at this institution?"

Out of curiosity he said to the patient, "why do you think that I am the best superintendent you have ever had?"

The patient said, "Well, I guess it is because you are so much like the rest of us."

Dr. Max Mason, president of the University of Chicago, who was born in Madison, Wisconsin, where nature painted one of the most beautiful spots on the face of the earth, is a graduate of that wonderful University of Wisconsin. Going from there to Europe he completed his studies. Coming back to the United States he filled many places of honor in eastern higher educational institutions. During the great World War he served his country in many ways. He was the inventor and the perfecter of an instrument to locate submarines. That instrument is now used by all the navies of the world and is known as Mason's Hydrophoto. (Is that right?) It is near enough, he says. It doesn't make any difference between friends.

It is a credit to Chicago that in 1925 the University of Chicago called him to that great institution, and with a great deal of pleasure I present our distinguished guest, who is the next speaker, Dr. Max Mason, president of the University of Chicago.

The Highest Common Factors

Max Mason, President, University of Chicago, Chicago, ILL.

If the time were not so short I should deem it my duty to start an argument with the toastmaster as to the validity of the facts which have been presented, but I thank him more for his generosity than I appreciate his judicial mindedness.

I find that I am down for the topic of highest common factors. I know that I chose that. It was at a distant date, however. I have tried to reconstruct the reason for choosing it. As I look at this audience and appreciate the work that you are doing and the temper in which you are doing it, I am convinced that I made a more or less rational choice of a subject, as I will try to show you.

In the first place, it was a familiar subject. I started from mathematics and physics in my work and I like to take a run before I jump into the unknown of public speaker; so the highest common factor gives me a sort of familiar feeling to begin with. You remember in school what it meant. Probably you took your work home and asked father or mother how to find the highest common factor of certain numbers. It was always more or less dramatic to me. You take a series of numbers that apparently have no relationship to one another, take 42, 70, 91, 105. If we threw them down on the table you wouldn't think anything common belonged to all the numbers. Study them a little and you find there is a factor running through all; in this particular instance the number seven is the factor common to all of them, a trivial example of the emergence of unity out of a set of different things; and that is the sort of theme I want to speak to you about.

The broader type of the highest common factors, the sort of thing that the scientists do, that they find out of a vast array of disconnected facts, is that common thread by which they become understandable, by which the orderliness of nature is

shown, by which we may use those facts, and in a way attempt to give you the feeling I now have, that one of the most pronounced influences of our generation, and of the past two or three, has been the emergence of common factors in our knowledge and particularly in our daily life.

It takes me back as well to the teaching days, and I have a favorite anecdote. It actually happened to me, so perhaps you will pardon it since it illustrates the state of mind and the state of preparation in which I appear before you this evening. I taught physics at the University of Wisconsin, and one time a student came back, a man who had graduated from our department several years before. He was always noted for his frankness rather than for his tact, and when he appeared at the laboratory I found he had not changed any since he left us. He visited with me until five minutes before the hour at which I was to lecture. I then had to excuse myself saying that I had to look over some notes before I lectured at eleven o'clock, and this student said, by way of apology, "I am sorry that I kept you so long. I should have known that if you didn't look over your notes you wouldn't be able to give your lecture." After he said that it didn't seem very gracious to him, so he corrected it by saying, "Of course I don't mean that. Why, I took your courses for years here and I know that you often lecture without any preparation at all."

Great and Simple Unities Emerging in Life

We are very familiar with the phrase that life is becoming complex. I should like to enter into controversy (start an argument, as we have learned to say this evening), on that subject. While the individual facts that we must know are perhaps becoming greater, it seems to me that the trend of science and the trend of human life is decidedly in the opposite direction. In place of an unreasoning complexity which seems to be appearing, great and simple unities are emerging. Life in its broader aspects and science in its broader aspects, instead of becoming more complex, are vastly more simple, vastly more understandable, vastly more rational, vastly more nearly a unit. That is to say, the highest common factors of knowledge of endeavor are emerging rapidly.

Take the science I am most familiar with, physics. Who would have dreamed a thousand years ago of the unity of the falling stone on the earth, the tidal effects on the globe, the rotation of the planets in their orbits, the motion of all the planets on the celestial sphere, the briny star, the laws governing the motion of all the stars, of all the planets, of all the heavenly bodies in this universe? Who would have believed that they are all united, that there is a simple concrete unit, an orderliness, coming out of those motions, by which anybody can understand, can predict them?

Superstition has been removed in regard to their motions, and the understandable, simple orderliness of nature has emerged by virtue of the scientific study of the motion of heavenly bodies. Indeed the whole science of physics has become vastly more simplified, for we have learned that all the physical behavior of matter can be accounted for by the hypothesis of the Electra, a constitution of matter, and each sound electric magnetism is an evidence of the same sort of thing, not unrelated phenomenon, not unrelated qualities of matter, but all to be explained, to be understood on the great hypothesis of the electric constitution of matter.

Physics has come to a marvelous simplicity, and chemistry has come to a marvelous simplicity. All of the elements, although different structures, different problems, are understandable; their combinations understandable, their chemical problems, their physical problems a simplicity that is understandable, and all the nature of matter and the interaction of matter that would have been incredible 100 years ago. A great unity is emerging from the scientist's study of the law of nature, physics, chemistry, biology, or what not.

No more do we seek oracles, no more do we give incantations, no more do we

trust in superstitions, but our mind is clear and our mind is free to believe in simplicity, to believe in orderliness and to find new truth; we are relieved from our fear of finding truth.

It is for this that universities exist. It is for this that we train men to work quietly, silently, through their lives, unselfishly, to push forward the boundaries of knowledge, that more highest common factors may emerge, that more unities may appear. For that we graduate our doctors of philosophy. I wonder how much the average man appreciates the doctor of philosophy. I think perhaps the attitude of many of us is something like that of the servant girl who evolved an epigram quite unexpectedly to herself as well as to others a short time ago. A friend of mine who was a physicist—by the way, this reminds me of the response of an old lady when she was introduced to Professor Pickelson. She said, "What strong words you are using these days. We used to call them sody water clerks."

Not the Right Kind of a Doctor

This friend of mine, Trowbridge, was down on the Maine Coast for the summer and was known as Dr. Trowbridge. He was a doctor of philosophy. People there didn't know him or what kind of a doctor he was, but they called him Dr. Trowbridge. One evening an excited man rushed to the door of his house. The maid came to the door. He said, "Is Dr. Trowbridge in?"

"No, sir," the maid replied.

"I must find him right off. Where can I find him?"

"I don't know where he went."

"I must get the doctor, my wife is very sick."

The maid said, "Dr. Trowbridge wouldn't do your wife any good."

"What is the matter? Isn't he a doctor?"

That stumped her. She knew they called him Dr. Thowbridge, but she said this on the spur of the moment, "Yes, he is a doctor, but he ain't the kind of a doctor that does anybody any good."

That, I think, is the average opinion of many people. I want to put in a plea for these doctors of philosophy, for these people who work silently in quiet places, devoted and unselfishly, that new truth may emerge, that we may understand the laws of nature and the behavior of men; that they may find more of the highest common factors that govern the universe and that govern man.

More important than all of the scientific discoveries in their application, seems to me to be the temper of mind that the success of science has produced in all of us. We are really living scientific lives. We are determining our actions in the scientific manner. Science is a long word. It means nothing but common sense. It means nothing but the orderliness and the discovery of orderliness. It means really fact-finding and generalizing, but today that is the word of the day. Even the boy on the street has the scientific temper. He wants to find out how it works and why it works and discover the laws.

We constantly hear that many of the problems of life are to be solved by education, and to my mind it means the inculcation of this scientific temper of mind. It is simplicity itself. It means, first, that you can conceive of life as a set of interesting problems, that you rejoice at the problems. It means the removal of the attitude. It means that difficulties present problems and that a problem gives the greatest source of happiness that there is for mankind, for it gives him a chance to test himself, and of reward as he solves the problem; so that life is a set of problems, it seems to me, problems to be solved happily, and solved in what manner? By the manner that we have learned only in the last 300 years, by finding the facts of the situation, by forming a judicially minded conclusion from those facts and then by acting on the facts. It is so simple that you wonder at my stating those things about fact-finding, honest conclusions and action; and yet when we say that this or that

or the other evil of today is to be cured by education, don't we mean that this or that or the other evil is to be cured by applying that technique of living? If we are training our boys and girls to that method of thinking and that way of living we can look forward with equanimity to the future—honest fact-finding, impersonal judicially minded conclusions from the facts and action, and that is the scientific temper.

In colleges, in universities, in life, in business, in industry, the greatest problem of all is the problem of teaching these highest common factors of successful performance.

I said I thought in the last generation or two, we had seen emerge many simplicities, many things which in point of fact appear as compromises but in reality are the units emerging from two opposed tendencies. We see a unity emerging from the scholarship and daily life. It was only a short time ago that scholarship was looked upon as a decoration for life. Scholarship was encouraged, and in many cases was pursued, I really believe, largely to furnish a mental sitting room in which one could retire from active life. One became educated away from tangible performance. One became educated away from the stress and turmoil, the rough and ready fight for existence, and in education was seen a relief and a vacation from the sordid reality of the work. That heaven, that temper, has changed. Education, learning, scholarship has been taken out of its cloister and put to the service of man in the daily life of the worker, and out of daily life and the attitude of the scholar has emerged that unity of scholarly life that is our ambition for today.

When There is a Real "Kick" in Business

Industry and philanthropy. "Business is business" was the old phrase. Now, to quote the words of my eminent colleague, Mr. Prendergast, a man gets a real kick out of business when he combines it with philanthropy. He gets a real kick out of philanthropy when it is businesslike and tangible. He is not a church member on Sundays and a schemer and cheat on six days of the week. He has got a unity of life which combines his performance with his expression.

Business and scholarship have become the great unit. Business is no longer rough and ready. It no longer sneers at attitude. It no longer sneers at a reasonable expert. I will admit that some experts go pretty far. It reminds me of the last definition I heard of an expert which applies the limit process familiar to those of you who remember your Euclidean geometry. This man said to me, "When a man starts to learn a lot about very little, he learns more and more about less and less until he finally reaches the limit and learns everything about nothing."

But business no longer sneers at the scholar, business employs the scholar and business is scholarly. The scholar no longer sneers at business, no longer sneers at business methods, and scholarship has become business life, and in fact our business life is emerging into the scholar business.

It gives me the greatest happiness to greet this Congress, one which has evolved a remarkable unit, a remarkable highest common factor, an activity in which your enthusiasm is self-evident of responsibility. I know your enthusiasm for the work is as intense today as it was when you were starting the pioneer enterprise; and no wonder, for you have evolved this rational unity. You have found this great highest common factor, an organization which is businesslike and concerns itself with business as well as with every activity which is scholarly, which promotes research, which studies to the bottom of problems, problems demanding (as they will demand still more from decade to decade) an understanding of the physical laws of chemical behavior of human psychology. Business, scientific research and high idealism, humanitarianism of the highest type.

Can you ask for a finer unity? Can you ask for anything more typical of America today, in which idealism and practicality are merged for the benefit of the

future? The word of America is tomorrow. You are working for it, we are working for it in our colleges and universities, and we stand shoulder to shoulder with you in the daily life of performance, with a longer perspective in looking still further ahead, that our children may live happier, more useful, more understanding lives, and that tomorrow may be better than today. And so we proceed in the belief that we are but beginning the greatest social experiment the world has ever known, this experiment of the intellect, of the heart, of the soul, in which we work with tangibility, with the practicality and inventiveness that are American, with the heart and sympathy that is American and with the skilful hands that are American.

I have spoken of natural science, of the contribution of the scientist to the temper of mind in producing among all of us that which today is as ordinary, as usual as air, the water we drink, the scientific technique of living: but the natural scientist now has shown the way to another group of students, to those who are studying social science, studying man and his work. You are social scientists, practically applied social scientists. You are making the world safer, better and happier, and men are studying the very mentality of themselves and of human beings, to the end that without prejudice and without superstition we may gradually, hopefully and clear-mindedly build for the future with courage.

The Council a Forerunner of Tomorrow

And so I greet the Council as a part of today and as a forerunner of tomorrow. I feel that we all should be optimists, happy and hopeful. Civilization in this world never before saw such a combination of the work of the head and the heart and the hand, of the emergence of that great unity of the intellect and the heart, of the intellectual with sentiment, abandoning sentimentality without an intellectual basis, abandoning the cold intellectuality without the guiding spirit and the warm blood of the heart and the soul. From that union, intellect directed with sentiment, and with heart, we are building our knowledge of man and we are directing our events, we are participating in the great adventure, in the evolution of a civilization of a society, even of a race. We are educators, every one of us, whether we will or no, for our influence is felt on every younger person with whom we come in contact; and so we look forward with happiness to the future that lies before man as he applies with deference, with sympathy and with sentiment, the scientific spirit of finding facts and acting on them. Man is but well started on his journey, the great end of all these marvelous evolutionary processes that have existed on the planet; he has started evolving this civilization and we are all co-workers.

It is as though we were in a vast and dim cathedral. We sense its beauty, but we know not the details; and we stumble on an organ, the organ of intelligence. Our clumsy fingers until now have only stirred that organ to produce a few shy notes, but the sweetness of these notes is so piercing that we tremble in ecstasy at the thought of the glorious harmonies that are to come.

TOASTMASTER McDANIEL: Turn backward, turn backward, O time in thy flight; make me a boy again and let me go to Dr. Mason's university.

The next feature on the program comes from St. Louis. You know, I read today of a missing millionaire who had been found in St. Louis last evening. Coming from St. Louis, as I do, I didn't appreciate part of that story in the Tribune this morning because, according to the Tribune, the lost millionaire said in his interview that he came to Chicago to see the fight, that he wanted a nice, quiet place to rest and he went down to St. Louis.

The next on the program is Safety Sam and the Careful Twins. They are going to arrive by airplane. Down in St. Louis we have a habit, if we want to go to Chicago, if we want to go to New York, or to Paris, we just fly over.

They have finished their broadcasting over KMOX, the voice of St. Louis, and

will be here shortly. Safety Sam and the Careful Twins broadcast six nights a week over KMOX. They have organized a children's safety club. That club now has over 400,000 members. Almost as many members as belong to the Democratic party. Each one of the members of this safety club has received a button, a pledge card, and a copy of a verse of song which they sing each night as the program is broadcast. They are going to come up here tonight in the "Spirit of St. Louis." As you know, Colonel Lindbergh was besieged by many who would have him write a testimonial that might be used in advertising some product. He has only written one testimonial and I will give it to you. He writes: "On my flight to Paris I used the Atlantic Ocean exclusively and found it satisfactory."

As you note from the program, Safety Sam is Mr. Girard C. Varnum, manager of the St. Louis Safety Council. Handy Andy is Mr. William F. Yorger, also associated with him in the management of the St. Louis Safety Council, and Ready Eddie is H. J. Brammeier, also associated with Mr. Varnum in the management of the St. Louis Safety Council. We will be quiet just a moment and see if we can hear the hum of the "Spirit of St. Louis." Ah! They have landed on the roof of the Hotel Stevens. They will be here in just a moment, as soon as they can come from the eighty-fourth floor.

Safety Sam and the Careful Twins—Handy Andy and Ready Eddy

Broadcast During the Banquet Session, Hotel Stevens, Chicago

SAFETY SAM: Good evening, my little friends; and here is your old friend, Safety Sam, not in old St. Louis as he generally is, but up in a sister city, Chicago. We have had a very pleasant trip, the Careful Twins and I, up here tonight to the Hotel Stevens, and I only wish you could be standing where I am, looking out upon this great audience of smiling safety enthusiasts. Oh, how I wish everyone in this hall this evening could do something that even I can't do, and that is, look into the hundreds of thousands of homes where all of you boys and girls are sitting before your radio. Some of you may be standing up; some of you may even be lying down in front of the grate fire listening. I wish we could see how many of you have your safety pledge hanging near your radio where you can get it and read it often to be sure you know all that it contains. Truly, radio is next to safety, one of the greatest things of the world.

It has been a long time since Handy Andy, Ready Eddy and myself appeared on a single program and had a nice, friendly chat with our club members. We are going to make affairs of this kind more frequent in the future, and as the days go by I am getting more and more jealous of the opportunity that is so often extended to the Careful Twins to have an evening's fun with many of the boys and girls of our club. I think I am going to make them load me in the old aeroplane with them and bring me along every once in a while, and then I wouldn't be surprised but what I am going to get a little particular myself, and I am going to fly off and leave them so I can have the chance of talking to you all by myself.

However, both Handy and Ready Eddie told me as we came over here tonight, that they had some very important things they wanted to say to our club members, so I am going to introduce them to you again tonight, just as I did on September 13, 1926, when we had our first program and when you heard all of our voices for the first time. First I am going to introduce Handy Andy. I should not have said introduce, I am going to say to you boys and girls: "Here's our old friend, Handy Andy who has something to say. Alright Handy.

HANDY ANDY: Hello, boys and girls! How are all of my little friends this evening? Safety Sam was just telling you about the wonderful gathering of men and women who are here solely because of their interest in the safety of all of you

boys and girls, our mothers and fathers, and all of your friends; and maybe you don't think Safety Sam, Ready Eddy and myself are proud of all of you because of the wonderful work you have been doing to prevent accidents not only to yourselves, but also to your many friends. We are especially proud of all of the boys and girls in St. Louis. During the month of July a number of our club members who reside in St. Louis carried on their own program. From information they had received from Safety Sam they learned that a large number of boys and girls are killed each year during the months of August and September by automobiles. Resolving that such would not be the case this year, they exerted every bit of energy they had to make the other cities in the United States sit up and take notice of what they could do when they really tried. As a result not a boy or girl has been killed in St. Louis by an automobile since July.

I am sure you will agree with me that this is sufficient reason to make us proud of these boys and girls. It is this kind of spirit among all of our members that has made our club the biggest and best safety club in the world. Many of our members in other cities are doing just as good safety work, only along other lines.

From time to time I am going to pick different cities and tell you just what the boys and girls are doing to prevent accidents. Don't fail to tune in every evening at ten minutes to six because your city may be next.

How Accidents Are Caused in the Schools

SAFETY SAM: Now, I know you are all interested in what Handy had to say and I really think you will be surprised if you will do what Handy has told you and listen in and see when your city will be recognized because of some of the nice work you boys and girls may be doing.

And now I am going to present Ready Eddy and let him talk to you for a few minutes. Alright Ready.

READY EDDY: Good evening, children! It is somewhat of an innovation to speak to you boys and girls from the Banquet of the Sixteenth Annual Safety Congress. There is certainly an atmosphere of safety throughout this entire banquet room. I just wish everyone of you boys and girls could have an opportunity to be here with us this week. It is certainly wonderful.

I was very much surprised the other day when I received a report of accidents that occurred in the public schools of one of our large cities during one year. No doubt this report is typical of the schools throughout the entire country. Little did I realize that so many accidents happen while you children are at school. Just think, over 500 accidents happened in the grade schools of one city. Many of them were of a minor nature, but still fifty-five were of a more serious nature, such as dislocations, broken bones, fractures and injuries to the eye. Of the total number, almost one-half of the accidents were caused by falls, from tripping, slipping, losing balance, either by being thrown or pushed down. Next in line were injuries caused by flying or falling objects, such as baseball bats, baseballs, rocks and sticks.

Rough play came in for its share of accidents. By that I mean wrestling, boxing, and kicking one another. I want the boys to listen to this. More than twice as many boys as girls met with accidents. That does not speak very well for the boys, but we realize that the boys play a little harder than girls and their games are usually more strenuous, so it is up to you boys to be twice as careful as girls.

The greatest number of accidents of this total occurred during the month of October, and a large percentage of them happened during the noon hour. The school-day part of our life covers a very few years, but it is the happiest period of our life, in which a great growth in body and mind must take place. If you boys and girls are to learn the lessons and make yourselves ready to use the knowledge in the years that follow, you must keep well and strong and build up a vigorous body while you are growing up. So let us not have any accidents. We should all

rn that there is only one way to do things and that is the right way, and the
ht way is the safe way.

Throughout the country there are many junior safety councils organized in the
ools and they are wonderful organizations. One of the junior safety council
dges is as follows: "I will work for the safety of others as I would want
m to work for my safety. I will try to be careful all the time, everywhere.
will not take unnecessary chances of getting hurt and will warn others against
ng so. I will do my part to reduce the number of accidents this year. All of
s I will do for the sake of humanity and for the honor of my school."

Even though there may not be a junior safety council in your school I am going
ask you to learn and observe that pledge.

SAFETY SAM: I think that junior safety council pledge Ready Eddy gave you
s very good although I don't really believe it is as good as the pledge of our own
b. Now before we sing our safety song I am going to ask each of you to take
r pledge in hand and read each one of them with me. Here we go!

1. I will not take chances—it does not pay. 2. I will not steal rides on auto-
biles, trucks or street cars. 3. I will play on the sidewalks or in a playground,
not in the streets. 4. I will cross the street at crossings only and will not
o into the street between automobiles parked at the curb. 5. I will care-
ly look both ways before crossing a street. 6. I will not play with firearms.
I will not play with matches. 8. I will not touch a dangling wire; it may be
ive wire. 9. I will not take medicine out of a bottle without a label; it may
poison. 10. I will stay in shallow water until I have learned how to swim.

I will stay away from stoves and will not play with gas. 12. I will not play
window sills or porch railings.

Now our time is just about up and we are going to sing our safety song, and
ope each of you will sing just as loud as you can. I am going to ask the audi-
e here this evening in this great banquet hall to sing the second verse and chorus
a me and with you, so when I raise my hand to the audience I hope you will
consult your banquet program where the words of the song will be found, and
; with me the second verse and chorus. Now let's see how loud we can sing.

Oh, the children that live in Safety Town
Are healthy, happy and wise,
And all because they heed advice
About the dangers to their lives.

Oh, we are going to play no more, no more
About the streets and highways,
And all because we are members of
The Careful Children's Club.

Oh, we never run across the street,
We walk and take our time;
We always cross at the street corners
Or where there are white lines.

Oh, we are going to play no more, no more
Upon streets and highways,
And all because we are members of
The Careful Children's Club.

Good night kiddies, and remember our slogan, "One Thought for Safety Is
th a Thousand Regrets."

Ladies and Gentlemen, just one more little word. When we asked to put on this program for you this evening we decided it ought to be done two ways, that one of us should be here in order that you might see the microphone work being done and the others could be concealed from view so that you could put yourselves in the place of the child sitting at home listening, so I am now going to take pleasure in introducing Handy Andy and Ready Eddie who will step out and wave.

TOASTMASTER MCDANIEL: Ladies and gentlemen, can you realize what a wonderful work this has been to reach 400,000 children with this message of safety every night over the radio? They know they reach 400,000 because they have sent in their names and addresses; probably twice that many are reached every evening as shown by this practical demonstration by Safety Sam assisted by Handy Andy and Ready Eddie. It has been wonderful.

Now we come down to the last speaker on the program. I think of the father and husband who had died. It was in a rural community where no secrets are kept from anyone and the nice old lady in the neighborhood said to the little daughter, "Mary, what were you father's last words?"

Mary said, "Pa had no last words; ma was with him."

The Ladies Take a Great Interest in Safety

It is a wonderful thing, the interest the ladies take in this work of the organization. I think of the negro who heard the word monotony and didn't know what it meant and he couldn't find out what it meant so he could use it. He thought it would be a wonderful word to use, so he sought out the negro preacher and asked him what the word monotony meant. The preacher said, "I will have to illustrate it to you. It is like this. If a man had three wives at one time, that would be polygamy. If a man had two wives, that would be bigamy. If a man had one wife at one time, that would be monotony."

Now, this next speaker is an old friend of the National Safety Council. Almost since the day of its inception he has served it well. For five years he was a member of the Executive Committee. I am referring now to the man whose picture appears upon the program; underneath the word "Program," as if he were the whole program, Mr. Forster's picture appears. He hails from Philadelphia, the city of brotherly love. First in rugs and linoleum, first in peace and last in the National League. Mr. Forster is so many things and has so many accomplishments I must read some of them. He was educated as a mechanical engineer and is by selection a preacher of accident prevention. He is connected with Brown, Crosby & Company of Philadelphia, prominent insurance brokers, and professionally interested in interrelated subjects of fire prevention, accident prevention and industrial relation. As managing editor of the Crosby Fisk Forster Hand Book of Fire Protection, Mr. Forster has presented the subject of fire prevention and accident prevention in a manner that is proving valuable to the insurance fraternity, the safety movement and industrial plants generally.

Now, I forgot to announce Dr. Mason's subject, but I want to announce Mr. Forster's subject because he is the nightcap of this meeting. He is going to send us away full of pep. I heard the boy from Providence say he got a kick out of something, and I heard the distinguished President of the University of Chicago say he got a kick out of something. I guess it is all right to say that I got a kick out of something. I have two distinguished presidents to go by. The distinguished President of the United States is one president who has had more stories told about him than anyone else. It was related of President Coolidge that he went to church one Sunday morning and Mrs. Coolidge did not accompany him. When he returned to the White House Mrs. Coolidge said, "What was the text?"

The President said in his short, brief way, "Sin."

Mrs. Coolidge then asked, "What did he say about it?"

The President in his careful way said, "He seemed to be against it."

Now, you know I sat up here tonight between Mr. Forster and Dr. Mason and rarely have I enjoyed a dinner as I did between those two distinguished gentlemen. I did manage to eat while listening to them, one on either side, but it is a great thing to know Mr. Forster. I know that he is going to give us a wonderful address.

Safety—A Source of Inspiration and a Test of Courage

H. Walter Forster, Brown, Crosby & Company, Philadelphia, Pa.

From the frequency with which it has been my privilege to appear before you at National Safety Congresses, I think I could more appropriately address you as, "My most endurable audience." This is the largest dinner in the history of the safety movement, but, in spite of your cordial greeting, I do not think for one fleeting moment that this great turnout of safety men and women has been appreciably affected by my being scheduled to speak. No, not for a moment! You know me too well. You came to be among your friends, to eat some of this good Hotel Stevens food, to be entertained, and to listen with as good grace as possible to the toastmaster and to the speakers, without whom no dinner seems to be complete.

I think I speak for the assembled multitude when I say that the toastmaster has been not half bad. He has a winning personality, he is mentally alert, he keeps things moving, and his stories were decidedly fresher than generally is the case. Even his introduction of me was not nearly as bad as one that lingers painfully in my memory. The peroration of that introduction was, "And our next speaker has the proud distinction of being claimed by two cities: Chicago claims he belongs to Philadelphia, and Philadelphia that he belongs to Chicago."

The entertainment has been of a high order. I would hesitate to put to a vote the question of whether the next number should be another safety sketch or the remarks I am scheduled to make.

From the rapt interest with which you have followed the addresses of the school boy from the East and the university president from the Central West and from your tumultuous applause, I can also diagnose the speeches up to the present time as great successes.

It is exalted company in which I find myself tonight. If it were not for my enthusiasm at the opportunity to speak to this record-breaking audience, I probably would feel like the Philadelphian who, after careful preparation and with great trepidation, launched his maiden dinner speech with the words, "William Penn is dead, Benjamin Franklin is dead, Washington is dead, Lincoln is dead, Roosevelt is dead, and I don't feel any too well myself." No, I am feeling very fit, and I accepted the invitation to be here tonight gladly and by wire; and, in order to show our Managing Director that I had not forgotten whence came his forebears, I sent it collect. Now, I am trusting in your natural courtesy, your hope that my talk will not be as bad as you fear, and that the gavel of our vigorous toastmaster will enable me to deliver the remarks I have painstakingly. I hope not painfully, prepared.

By the way, are the amplifiers working well; can you folks in the rear of the room and in the balcony hear me clearly? I want to avoid the experience of the after dinner speaker whose voice did not carry any too well, and who was interrupted by a cry of "Louder," followed by "We can't hear you back here." A man half way back turned around and said, "Be quiet, you lucky cuss."

We come to these Congresses to bear witness to the importance of accident prevention, and to strengthen our faith for the fight we must make during the

year to come, for safety, in spite of its unquestioned importance and possibilities, is not achieved by passive measures. We come to renew and to broaden our friendships, to contribute our experiences and ideas, to learn the answers to our specific problems, to absorb good ideas that we can apply, and so completely to gird ourselves with faith and courage that nothing can deflect us from the goal toward which we strive. Even today, when safety has been so widely endorsed and so generally practiced the safety man often finds himself carrying so large a proportion of the safety burden that he very properly could assume the attitude of the Texas ranger. A riot broke out and spread rapidly in a small town west of San Antonio. Some of the responsible citizens telephoned to the headquarters of the Texas Rangers for help. They were assured help would go west on Train No. 9. When the train pulled in, these anxious, responsible citizens were at the depot to meet it. Only a single long, lean, tanned Ranger swung off the front platform of the smoker. He greeted the anxious committee with "Where's the trouble, gents?" The spokesman answered, "Are you all they sent?" "Why?" said the ranger, "Is there more than one riot?"

Safety Men Succeed in Spite of Trials and Troubles

There is no doubt that renewed courage is one great advantage of attendance at these Congresses, and this renewed courage comes to a considerable extent from finding that the difficulties, disappointments, discouragements that you have suffered are not unique; that virtually every successful safety man has experienced them in the past and does today, that the wonderful records of individual plants, of groups of plants, and now even of industries as a whole, are achieved in spite of 57 different varieties of trials and troubles. And, further, that in spite of the support of management and men, the responsibility for getting results and of keeping and increasing these results devolves largely upon the man who has safety in charge. We know he gets results only by working through the organization, but we also know that ideas, stimulus and courage radiate largely from him if he is putting his heart and soul into the job, and knows exactly what he desires to achieve. Not like the two men who went hunting together and had to share one gun. One stammered; the other had St. Vitus dance. The stammerer took the gun first. As they walked along, his companion spied a rabbit. Pointing with trembling arm, he cried, "Shoot!" The stammerer shot and missed. It was now the turn of him who was afflicted with St. Vitus dance. He took the gun. The two walked further along the woodland road. Suddenly the stammerer saw a squirrel up a tree. He cried out, "Sh-sh-sh-sh-shoot!" His companion pointed the gun upward, but described wobbling circles with the muzzle. Finally he fired; the squirrel dropped to the ground. "I hit him!" cried the nimrod. "Wh-wh-why, shouldn't y-y-you," stammered his friend. "Y-y-you aimed all over the t-t-tree."

No strong man fears difficulties. He does not go out looking for them, but when they come, he takes them on courageously and intelligently. I have often repeated a phrase that I heard years ago apropos of the troubles that go with the higher-up jobs, namely, "if it were not for the troubles, the office boy could have my job." A more artistic way of putting it was found by the poet who wrote, "The game fish swims up stream."

True courage can only come from believing that what we support is fine and truly worth while. No man could fight year after year for a cause of which this was not true. If a stranger from Mars, let us say, ignorant of the merits of accident prevention, could know that this group of men and women for fifteen years, in ever increasing numbers, had poured their strength, faith, and hopes into the safety movement, he would need no further endorsement of the excel-

of our cause. And he might not be so very surprised to learn that at the organizing meeting in New York in 1913, there were 300 persons present, and that the money then pledged totaled \$1,400 per year; that at this Congress the attendance is over 5,000, and that the annual income of the National Safety Council and of the local organizations that function with its cooperation is well over \$1,000,000. And he could readily believe that as a result of all the outpouring of manpower and money marvelous results have been achieved; that tens of thousands live today who otherwise would have come to an untimely end; that hundreds of thousands have escaped serious injury; that literally millions of minor accidents have been prevented.

Some day a great poet will catch the full significance of what safety has done for humanity and will write a poem as beautiful, as inspiring, as universally appealing as Lt. Col. McCrae's "In Flanders Fields." But instead of singing—

"We are the dead: short days ago
We lived, felt dawn, saw sunset glow,
Loved and were loved, and now we lie
In Flanders' Fields."—

he will sing of the lives that have been preserved by a fight as worthy as the one in which they died, of the joy in their hearts instead of the happiness that was theirs and of the services they can render instead of the sacrifices they made.

Such a poem will be written in words quite different from those complained of by the woman in front of whose house some linemen were working. She wrote to headquarters to protest against some excessively profane language she had overheard. The superintendent of construction wrote to the foreman, one Michael Mulcahy, for an immediate written report on what had transpired. He answered that he saw no reasons for any complaint, because the facts were as follows: Patrick Sweeney was on top of the pole, working with a pot of hot solder. Accidentally, a lot of it dropped down his, Mike's, back, and he had called up, "Pat, me darlin', ye must be more careful."

The Bond That Unites Men in Friendship

Thank God, there is a lighter side to safety; it is not all a matter of inspiration, and courage, and fervor. It also has a most valuable by-product in the creation of many warm friendships, not only among safety men, which these progressers so excellently further, but also in the plants. A safety man frequently knows the organization better than any other man in the plant. He reports to headquarters; he works through it clear down to the humblest laborer whose understanding of English is largely limited to the kind of language of which Mike Mulcahy was so unjustly accused. He knows these men; and, while he has his troubles with a lot of them in the course of a year, there is not one of them, providing the safety man is able, industrious and fair, who does not respect him. A large proportion will admire him, and many will be sincerely fond of him. The respect and friendship of men are a delight, and excellent barometers of the real worth of a man. When you live with a job year after year and you are esteemed as a man and a preacher of a worth-while cause, you have achieved a position that is enviable; remember that when you feel discouraged.

Closely coupled with friendship in the safety movement is generosity. Not only generosity in time and energy and brain power on the specific job, but helping any other safetyman who can benefit by what has been achieved. I

never heard of a real safetyman who was selfish; he gives with both hands and asks no direct return. Not like the Scotchman who gave one of his close friends a homing pigeon as a wedding present. This Scotchman must have lived next door to the one who introduced the style of holding weddings in back yards, so that the chickens could pick up the rice; and he must have been a relative of the one who beat a Jewish friend one up at golf by counting against the Jew the sunstroke he had suffered on the eleventh hole.

We laugh at jokes at the expense of Scotch thrift, but the National Safety Council owes the Scotch a great debt of gratitude. Our first president in those two trying years was a Campbell; three Robertsons served us well in those early hard years; other Scots have sat in the councils of the mighty, and "Willy" Cameron is Scotch. Every virtue of the race—physical fitness, fine mentality, indomitable courage, boundless energy, have been lavished by him in our cause. And we never would have \$175,000 in bonds and other cash assets if our managing director were not 100 per cent Scotch when any one wants a National Safety Council dollar for anything but most efficient service. We have had almost a dozen effective presidents, scores of valuable directors and executive committee members, hundreds of other real workers in the safety vineyard, but head and shoulders above us all in furthering safety in America stands our capable, indefatigable, modest, beloved Will Cameron. Mr. Toastmaster, may I suggest that you ask the managing director to rise and at least bow to 3,000 of his friends.

Often when I have thought of the safety movement, the word "crusade" has come to me. The Crusaders, fired by the zeal of their leaders, put away mundane things, girded themselves for a long march and a hard fight, organized themselves for effective cooperation, and went forth to win or die. And is not that exactly what the safety movement requires of us today?

We have needed and we always will need leaders fired by zeal for our cause. There must be the bugle call to arms, the prayer for strength, the heartening of those whose conviction is not complete.

We also must put away mundane things to a very considerable degree. Fortunately, there is a wordly side to safety; the fact that safety could be shown to be good business has enabled us to advance the cause far more rapidly than would otherwise have been possible. But successful safety work never has been and never will be based primarily on a cold blooded and calculating attitude. The splendor of the cause and the possibilities of the movement have been and must continue to be our prime motivating forces.

Gird for a Long March and a Hard Fight

We, too, must gird ourselves for a long march and a hard fight. We must prepare ourselves for our work and keep prepared. Zeal alone does not get results. We need an astonishingly wide preparation if we are to meet successfully the management, human, engineering, and legal problems by which we will be confronted, and, once prepared, we need the courage of which I have spoken to hearten us for the fight for the results that we can see ahead.

We also must organize ourselves for effective cooperation by departments, by individual plants, by groups of plants, even by industries, and we have in our National Safety Council that source of stimulus and of organized planning which the Crusader had in the Holy See in Rome.

We, too, need faith to win or die; not in the sense of leaving our bones to whiten on alien sands, but in that we make a fight as brave, as inspired, as thoughtless of selfish ends, as did the mail clad knights who went forth to fight the Saracen. Chesterton has wonderfully summarized the spirit of the Crusaders

in his great ballad "Lepanto." He has Mohammed, who in Paradise hears the war-drums of the Crusaders threatening his land, say of the selflessness of the Crusader, "It is he whose loss is laughter if he counts the wager worth."

And, finally, to complete the analogy: what device has symbolized his cause to the religious crusader of by-gone centuries and to the safety crusader of the twentieth? The banner with the cross! The red and white in the one case to symbolize the blood of Christ and the purity of the cause; the green and white in the other to symbolize the sacredness of life and the spirit of him who champions the cause.

While the religious crusades of almost a thousand years ago and the safety crusade of today have certain common characteristics, let us consider for a moment the ends sought in these two great movements. Godfrey, Barbarossa, Richard the Lion Hearted, and other great leaders and their myriads of followers, sought to wrest from the infidel Turk the church of the Holy Sepulchre in Jerusalem. To achieve this end, six major crusades were undertaken, two of them temporarily successful. How great was the loss of life and the expenditure of treasure no one knows, but they were so great that they crippled and almost beggared kingdoms.

And how worth while really was the end that they finally achieved? What real good was gained with the capture of Jerusalem, lost again in a relatively few years? It gave Christendom a great central interest and no doubt furthered the principles and the spread of Christianity, but a dispassionate analyst would gravely question if the end justified the cost.

Human Benefit Is the Victory Sought

The safety movement, on the other hand, seeks not a victory empty of direct human benefit and achieved only with great loss of life and waste of treasure, but safeguarding life without physical danger to him who furthers that safety, protecting property that men have gained by the sweat of their brows, making two blades of grass grow where one grew before, and following every sound teaching in whatever religion it may be found that bears on the sacredness of life and the responsibilities which all possess, whether they sit in the high places or beg alms by the wayside.

Perhaps the contrast in the worth-whileness of the ancient and modern crusades can best be emphasized when we consider the children's crusades of then and now. The former sacrificed childish lives in great numbers upon the altar of a mistaken ideal. Imagine the feelings of the Master who had said, "Suffer little children to come unto me, for of such is the kingdom of Heaven," when he saw this horrible sacrifice, and supposedly in His name.

The safety movement, on the other hand, has organized myriads of children in every corner of this great land for an end gloriously different; to save instead of to sacrifice life; to protect instead of to maim; to apply Christian principles instead of to follow a false ideal; to inculcate a sense of the sacredness of human life and of the responsibility each has for the other. Surely in this phase of accident prevention, probably more than in any other, we can feel the happiness, the uplift that comes from doing the Master's work.

We here tonight are a mature group of men and women. Perhaps it would have been more gallant and politic for me to omit the word "women" from a sentence featuring maturity. I hope my failure to play safe will not result in any painful after effects to me. I do not want to have to break any world's speed records across the waste lands of Grant Park tonight, the sort of speed made by the husband of the woman who told him one evening that the cook was leaving because he had talked to her on the phone that day in a manner

more abusive than she had ever heard in her life, and who answered, "My God, was that the cook; I thought all the time it was you."

But the point I wish to make is that with maturity comes an understanding of what is really worth while in this complex, difficult, adventurous, interesting existence we lead. Most of us clearly see the ways of the false gods, and we are not appreciably attracted by things that are not basically worth while. We know that true happiness comes from work which is useful and from making progress in that work; that the strong man is willing to carry load and glad of his ability to do so; that successfully meeting stress and strain is proof of real capacity; that the respect of many and the love of a few is a crowning glory of a lifetime of work.

If you analyze work in the field of accident prevention in the light of this specification of how to serve mankind, build character, and achieve happiness, you will find (in fact, you already know), that there are few fields of labor in which are found such satisfaction, such happiness, such inspiration. To the devoted worker in the safety vineyard will come at times some of the uplift that caused Elijah twenty-six centuries ago to sing, "They shall mount up with wings as eagles; they shall run and not be weary; they shall walk and not faint."

TOASTMASTER McDANIEL: Walter, we thank you.

MR. FORSTER: Larry, I thank you.

TOASTMASTER McDANIEL: This mutual admiration society will soon be adjourned now, but before I turn the meeting back to the president, I want to tell you what a wonderful privilege it is to be here and to meet those interested in this great work. You know the greatest thing in the world is to meet your fellow man and know him and love him and associate with him and be with him and learn from him and teach him; and after reciting this little poem, I turn the meeting back to the president.

It is the human touch in the world that counts,
The touch of your hand and mine.
It means far more to the fainting heart
Than shelter and bread and wine.

For shelter is gone when the night is o'er,
And bread lasts only a day;
But the clasp of the hand and the sound of the voice
Go on and on alway.

PAST PRESIDENT KING: We have had a wonderful evening. We stand adjourned.

ADJOURNMENT.

**SIXTEENTH ANNUAL SAFETY CONGRESS
NATIONAL SAFETY COUNCIL**

Safety In the Small Plant

Thursday, September 29, 1927

JOHN ROACH, Chairman
Deputy Commissioner, Department of Labor, State of
New Jersey, Trenton, N. J.

The session devoted to safety in the small plant was called to order at two-fifteen o'clock by the chairman, John Roach, Deputy Commissioner, Department of Labor, State of New Jersey, Trenton, New Jersey.

CHAIRMAN ROACH: I think the meeting we have this afternoon is one of the most important that will have been held at this Congress of the National Safety Council. I remember at the Detroit meeting with what splendid interest and unusual enthusiasm the delegates assembled in a large room and spent three very intensive hours in the discussion of operating problems that affect the small plant.

I know, when we use the term "a small plant," that we are dealing in very general language and using a term that is not entirely pleasing to the statistical mind which likes to label and tag things in a codified and orderly manner, and various examples have been presented at several conferences on the small plant as to just how large a plant should be to come within that classification.

I don't know that this point has ever been definitely settled by any authorized statistical authority, but I have been informed that probably 75 per cent of the productive energy of the people of our country is employed in plants that number nowhere under 300 persons. That's a very general statement and cannot be supported by statistical data, but the impression is very strong that this large percentage of all America's industries is employed in the smaller group of plants, where it is more difficult, infinitely more difficult, to promote intelligent safety education than is in the very much larger group.

I sometimes wonder what would happen to the safety movement that has made such splendid history for America's industrial progress if the large employing groups, the public utilities, the rail and water transportation, and the large industrial corporations should separate, disband and leave the organized safety movement to go on without their splendid assistance and cooperation.

I am afraid we would have hard sledding and a difficult time to promote the educational program that has focused the entire attention of the world on America's chief in its moral obligation to operate the industries of our country safely.

I concede that the state has an important obligation in this matter of providing industry with intelligent operating rules, and that this obligation on the part of the state can never be discharged by merely enforcing the mandates of the law, and forgetting that example, precept and patience are sometimes a trinity that will accomplish much good when the policeman's club has been found ineffective.

If the state provides sound engineering rules of conduct and procedure that are available through the American Engineering Standards Committee, and the employer

in the small plant participates in the organized safety movement in his locality, and then the employees in this great group of small plants are encouraged to conduct themselves during the course of their employment in accordance with sound engineering practice. I am sure the fearful toll of accidents, death and suffering that has been recorded during all the years, will lessen appreciably from time to time.

We have many important papers to be read this afternoon. I will, therefore, call at once on Mr. W. H. Weitknecht, superintendent, Lehigh Portland Cement Company, Mitchell, Indiana.

Why Should the Small Plant Be Interested in Safety?

W. H. Weitknecht, Superintendent, Lehigh Portland Cement Company, Mitchell, Ind.

I am very glad, Mr. Chairman, that your remarks are such a fitting introduction to what I hope to say. What I shall say comes from the result of experience and the deductions I shall try to make are based on that experience and on observation.

I do not know how many executives of small plants are before me. I hope that many of you are either in charge of small plants, are the safety directors of small plants, or represent safety committees in small plants. And by small plants, I mean that plant which has not the opportunity, does not command the means of employing a full time safety man, but must depend upon the work that is done within the organization by the management cooperating with the safety committees of the plant.

In the first place, what constitutes real safety? You have heard much about the two principal factors or elements in accident prevention—the mechanical element, consisting of safe places, tools, equipment and safety appliances, and that indefinite, inconstant human element that has to do with the mental attitudes and the mental aptitudes of the workmen.

I wonder whether you have come to the same conclusion that I have, that there frequently appears to be too definite a distinction made between these two factors. I want to try to correlate them to show their relation one to the other in attacking that problem from the angle of responsibility.

It is readily conceded, I think, that the matter of the mechanical equipment, of safe mechanical equipment, is largely if not wholly a matter of the ownership and operating management. They owe it to the workmen to furnish that. Does their responsibility largely cease when they have a well equipped plant, safe in all its mechanical equipment and appliances? Is it now to be turned over to the workman, and personal injuries resulting from so-called accidents henceforth to be the result of carelessness or bad practices on the part of workmen?

Is not the management responsible for the supervision of the practices and performance of employees? Quite as much as it is responsible for purchasing the proper equipment and safeguarding it? Is not the foremanship throughout the plant the responsible expression of the ownership and management? Is it not true that many of the personal injuries resulting from industrial accidents arise out of bad practices that are permitted, if not engaged in, by the foreman himself? Is it not true that the employee is frequently not adapted to the employment that is offered him? Is it not true that either inadequate or frequently incompetent instructions are given to the employee? Is it not likewise true that the very foremen, who are the expression of management, are guilty of practices either as a result of carelessness or incompetence that is imitated by their workmen? Am I placing too large a responsibility on the management when I draw attention to these facts?

What are the responsibilities of workmen? There are natural deficiencies and delinquencies among properly instructed workmen which cannot reasonably be fore-

men by a competent supervising management. For those the workmen are largely responsible; but they are comparatively few in a well managed, well supervised plant.

Safe practices and safe places constitute the sum and substance of real safety, or both of which management is largely responsible. In proof of that I wish to cite the work that was done by the various cement plants (mostly member companies of the Portland Cement Association) when first the work of accident prevention was suggested to the industry—the placing of safeguards on mechanical equipment, the determining of safe places throughout every department of the mills and quarries, without any corresponding advantage or progress in the matter of accident prevention.

Accident investigation gave us the clue and in nearly every instance it could be said not only that the workman should reasonably have foreseen the condition that resulted in his injury or near injury, but that the supervising management, the foremanship in that department, should likewise have foreseen it and prevented it.

After we began to place individual responsibility, personal and mechanical, on the foreman of every department, we commenced to reduce personal injury accidents, and we have continued to proceed along those lines by assuming the responsibility for practices and performances ourselves, the result was that soon a cement plant operated throughout a calendar year with but very few hours of lost time per hundred thousand man-hours employed. That was followed the next year by a perfect record, where a cement plant operating with (I think) 150 employees continued throughout the calendar year without a single lost time accident in an industry prominently known and conceded to be rather hazardous. The succeeding year two plants went through the entire year without a single lost time accident, each plant having more than 100 employees. That was followed by two plants, one of which employing over 500 men, operating throughout the entire calendar year of 1926 without a single lost time accident. Proceeding on that theory, that the management must assume the responsibility for much of the practices, and trying to discharge that responsibility by careful supervision, what will you say when I inform you that to date in 1927 there are 23 cement plants in the United States and Canada, each employing from 100 to over 700 men, which have not had a single lost time accident.

A Fine Safety Record Is Anticipated

According to the way they are running now, we hope that at least 20 of those cement plants will complete the calendar year of 1927 without a single lost time accident. That is an accomplishment which is the result of what? The assumption by the management that it cannot pass the responsibility, pass the buck, in other words, down to the rank and file for careless practices, that it must give the working organization careful, safe practice habits, and that those must be developed only under careful supervision.

Does the matter of accident prevention assume a somewhat different aspect to you as managers of small plants, now that I have told you what the results are from following that line of thought? Are you willing to go home and put into practice the best efforts at supervision and management that you can think of, in order to discharge that responsibility for the personal injuries that occur in your plants, including the fatalities? If you can get that point, if you can take that home with you, if you will practice that, you will have made a real start in real accident prevention.

What has been done in a hazardous industry like the cement industry can be done in any other industry if you will attack the problem with the same spirit and with the same understanding.

That's the phase of it that affects the industry itself, the plant itself, in the pre-

vention of accidents. The economic side, the directly economic side I shall just barely touch on because there is much dispute with reference to it.

What do you think these cement plants will do when they find that they can run year after year, as they are going to, with just minor lapses so far as their compensation or liability are concerned? They are going as far as it is possible for them to go in states where they are permitted to carry their own insurance, and the best risks which the insurance companies have will drop out. What will be the natural result? As this scheme of accident prevention gains momentum, the industries that do real accident prevention work will drop out as customers of insurance companies and become self insurers.

What is going to happen in the matter of workmen's compensation and liability rates to those who remain as the customers of the insurance companies? Double, treble, quadruple—I shall not attempt to indicate the manifold increases that you may expect and that are bound to happen. If you do not want to be among that class of industry which pays a prohibitive compensation or accident liability premium, you had better begin on the matter of real accident prevention.

There is a far more important reason why the small plant should be interested in safety, for real safety properly inculcated will express itself in habit. No individual can be a safe man in an industrial plant at his employment, and set the garment of safety aside when he leaves the property of the employer. It becomes a matter of habit with him just as much as it does to get up in the morning at five o'clock and before the alarm rings which he has set the night before. All of you have had that experience, I presume, setting an alarm to get up at a certain hour in the morning, and following that practice for several months, only to find that in a very short time you will awaken before the alarm goes off. You do it as a matter of habit, governed by the subconscious mind. That is a problem for psychologists to answer. You will shift the gear on your automobile after you become familiar with the operation of it, without thinking in detail what you are doing. You apply the brake automatically as occasion arises. Your actions are governed unconsciously. You cannot do two things consciously at the same time, but still you can do a number of things at the same time, while your mind is consciously employed at something else. That is the development of habit.

Permanent Safety Habits May Be Formed

So will habit operate in connection with the development of safety in a plant; it will continue to operate after the man has left the plant. He sees a dangerous condition, he recognizes the danger and he does not rest until either he has remedied it or has called the attention of someone whose business it is to remedy it.

That is another thing you want to tell your employees. If they want to be real safety men, they must follow that line of action, for if they don't, if they consider a hazard not a part of their business because it is outside their plant, they will again be like you when you hear that alarm go off several times in succession and do not get up. It will be but a very short time until you will not hear the alarm. You will have destroyed that unconscious government; so with the development of habit and its subsequent destruction. That's what I consider the sum and substance of real accident prevention work.

How does that apply in the community? Are we facing any community problems, especially in the smaller community, in the smaller cities? I heard something this morning that the Safety Commissioner of New York City said eleven years ago in discussing traffic problems of the larger cities. He made the statement that some particular point in traffic regulation did not apply to smaller cities since cities of 250,000 population had no traffic problem. Think of it, eleven years ago cities of 250,000 population did not have a traffic problem—and you know that was largely true.

Is there any need for the development of safe practice habits in industry? Is there any need that safety habits shall be so developed that they will express themselves in the community at large? My belief is that the matter of public safety can be accomplished in no way more quickly and effectively than if we can enlist the active support in accident prevention work of every small industry throughout the United States and Canada.

If it is true, as the chairman has said, that the majority of workmen in industry are employed in plants of 300 men or less, what more important work can the management of such small industries do than to start active, effective accident prevention work in their plants? It will have a far greater effect, will be more far reaching, than the best accident prevention work that is done in large industries.

Take in connection with this fact, the figures from the workmen's compensation bureau, that some industries have proportionately more accidents. Insurance companies now consider them much greater risks than the larger industries employing many hundreds or many thousands of men. Is that due to the fact that there are larger hazards in the smaller industry? No. The reverse is really true. There are greater hazards in the larger industries, but the reason we have less personal injury accidents in the larger industries is because effective accident prevention work is being done.

Safety Influence Will Extend Beyond the Plant

In my opinion the obligation rests upon the management of small industries to help the safety movement by inculcating safe habits among their employees. The big thing that you, as managers of the small industries, can do is to start preventive measures, and if an ounce of prevention was ever worth a pound of cure, it certainly is in preventing personal injury accidents, and no place will be as productive of good results, no soil so fertile, than right in your own small plant. It will relate itself to the schools; the children in the home will be taught by the father. That instruction will come as a result of the instruction he receives in his plant. Many a boy and girl going to school will be saved as the indirect result of your accident prevention work in your industry. Many a boy and girl, yes, many a man and woman, will obey the traffic regulations because they have been taught that it is the wise and the right thing to do. They are in a mental attitude to obey. They don't want to run past the red light. They have been taught the reasonable thing to do and they have acquired that habit, for we are all creatures of habit, and as we perform in our daily life in one way or another, so we perform in moments when we think less about ourselves or about anybody else. We are governed by the law of habit, which is a development of the governing function of the subconscious mind.

How many of you have been mentally preoccupied when you came to a traffic light and have run past it without noticing that the red was turned against you? Mental preoccupation. That's one of the things you must guard against. You weren't controlled by any unconscious governing body within you. Your mind was active on something else and you ran past it. You hadn't formed the proper safe practice habit with reference to stopping at those signals.

If you can in a measure agree with me that the work of accident prevention in the small plant can thus be related to public safety in your community, who is there to deny the great possibility for good? Who is there who will not say that the effort is not worth while?

CHAIRMAN ROACH: I am sure we are greatly indebted to Mr. Weitknecht for the very interesting discussion he has given us.

The next paper will be read by Mr. John Shaw, assistant to general manager, Hercules Powder Company, Wilmington, Delaware.

Safety a Personal Responsibility in a Small Plant

John A. Shaw, Assistant to General Manager, Hercules Powder Company, Wilmington, Del.

By "Personal Responsibility," I understand that the manager does safety work in a small plant, instead of delegating the work to a safety engineer, as in a large plant.

First of all, what is a small plant? I should say it is one in which the manager or his immediate assistant has, at all times, intimate contact with every worker. Such a plant may run from 25 to 200 men. I do not believe the manager can enjoy or maintain close contact with the workers in a plant running over 200 men. A great deal depends upon the manager himself, and in these days of multi-unit corporations where much office work is required, some managers find it hard to maintain close contact with 200 men. Some managers like to think they have this contact and pride themselves on knowing all about the workers, but such managers are fooling only themselves.

The good manager will not be so fooled, and when he realizes that the size of his plant or his other duties prevent him from keeping personal contact with each of his men, he will make sure that all his foremen know his ideas on safety, and he will hold them responsible for carrying out the company's safety policy.

Whether a plant is large or small, the personal responsibility of the management is the same but the methods of conducting safety work differs. In the large plant the safety work is delegated by the manager to a safety engineer who may conduct a department and even have a corps of assistants or a safety committee, depending on the size of the pay roll. In this case, the manager is personally responsible for the safety engineer and his work. He must aid, counsel and direct his safety engineer who, in turn, is personally responsible for the safety movement and the spirit of safety throughout the plant.

In the small plant where it is uneconomical to employ a safety engineer, the plant manager must take the direct personal responsibility for safety. On his daily rounds he has an eye out for unsafe practices and improper equipment. He discusses hazards and ways of eliminating them, directly with his foremen and even the workers. Safety is the one activity which permits this without danger of disorganizing the foremen and the workers. Every foreman who has the right safety spirit understands that the boss is not interfering with orders, but is trying to protect the workers and plant from accidents and interrupted employment. The wise manager in a small plant seizes the opportunity which safety offers to get into close touch with his men. Often, the "safety approach" results in the development of better ideas for greater production, better quality and improved methods and machinery, as it develops friendship and confidence between the manager and the workers. Thus safety is a common ground on which both sides may meet. By direct responsibility for safety the manager of a small plant has a very much better opportunity to put his safety ideas across, than in a large plant.

Whether the responsibility is direct or otherwise the manager must be absolutely convinced that safety is sound and economic as well as humanitarian. He must interweave safety throughout his factory methods so that the best way is also the safest way to do a thing. There is no need of setting up a separate line of procedure or thought for safety. It must be considered and weighed with its degree of importance in every job analysis. A true conception of its importance depends upon the knowledge, experience and consideration of the manager, and his sense of personal responsibility.

Of course there are great differences in individuals, and some managers personally put over very much better safety programs than others, but then again some are better managers than others. Frequently one may observe the successful manager at work. He is known for his ability to obtain good production, low costs and high quality of product. Go further and you will find that his employees like him. Investigate his safety records and you will find low frequency and severity resulting from personal injuries.

Safety is no longer a side line activity in industrial management. The large plant manager recognizes this and organizes accordingly. The small plant manager may not recognize this because one occasional accident may be forgotten. However, his one accident may give him a higher frequency than 10 accidents in the large plant. Thus in the small plant a true sense of proportion may not be appreciated, while in the large plant the manager sees 10 accidents on his report, and is more readily impressed. When the manager of the small plant grasps the meaning of this he holds himself directly responsible for the safety movement in his plant. If he is sympathetic and enjoys associating with his workers, he has no difficulty in making the desired contact. On the other hand, he may not have the proper knack for this, but he may accomplish very good results by appointing a small competent safety committee whose members represent the various departments in the plant. When working through a safety committee he is still personally responsible for the safety policy and the inspiration of his committeemen.

Management Influence Is Far-Reaching

So far no mention has been made of the personal responsibility of every individual working in the plant. The personal responsibility of the individual grows with the development of the safety spirit and the safety spirit must come from the management. Therefore, if the manager holds himself responsible for safety in his plant it will not be long before we find this personal responsibility extending well down the line. The personal responsibility of every worker is the same in the big plant as in the small plant.

In our experience where we have plants running from 20 to 400 men, we are obtaining best results where the managers look upon safety as a personal responsibility. The small plant manager works through direct contact and the large plant manager accomplishes his results through a safety engineer and a safety committee. One of our small plants engaged in the manufacture of high explosives employs on an average of 65 men. That plant has had one lost time accident in the past 1,000 days and no accident at all so far this year. It is also interesting to note that this plant has practically no labor turnover in spite of seasonal attractions for labor in the neighborhood and large mining operations near by. We consider the close friendly contact which the small plant manager is able to hold with his men gives us an ideal condition for fostering safety.

CHAIRMAN ROACH: I wonder, would anybody like to discuss these last two very interesting papers? They have opened up avenues of thought that perhaps might lead to some worthwhile discussion, because it does seem as though we have to do something to stir up the small plant manager.

The next paper will be a paper that was to be read by Mr. L. M. Challis, employment manager, Copeland Products, Inc., Detroit, but Mr. Challis is not present and his paper will be read by Mr. J. C. Graham. I might add that Mr. Graham is an industrial safety engineer from Detroit.

Safety Committees—A Necessity or a Nuisance

L. M. Challis, Employment Manager, Copeland Products, Inc., Detroit, Mich.

In reading over my topic a second time, it may readily be thought that the subject is more or less open to controversy. Personally, I have suspected that a division of opinion on the part of those present has been expected and that the topic was therefore assigned to a little fellow, on the assumption that if the discussion grew too heated, a little fellow would be able to run much faster than a big fellow.

Nevertheless, I am prepared to affirm my belief that safety committees are a real necessity in modern industry. In our own plant, the Copeland Products, at Detroit, the safety committee is a vital factor in accident prevention.

The personnel of our safety committee is made up of the factory manager, the superintendent, the master mechanic, the inspection superintendent, each departmental foreman in the factory (nine in number), the company surgeon and myself as employment manager—the factory manager serving as chairman and myself as secretary. The committee meets at regular intervals, twice a month, and has special meetings at such other times as conditions may warrant. Our plant is of medium size and as previously mentioned, each departmental foreman is a member of our safety committee. We feel his presence on the safety committee bears a wholesome significance to his job. Some one at the safety congress in Louisville two years ago very wisely remarked that "the Foreman is the backbone of industry." And so he probably is. He is the point of direct contact between management and men, in transmitting to the employees whatever policies the management desires. As has been stated often, he is to industry what the sergeant is to the army.

In the greater majority of shops and factories, production is the dominant factor, and the man primarily responsible to the management for production is the foreman. Hence, it is quite natural that he should be an important factor in accident prevention. His presence on the safety committee, therefore, is equally as important to the management as his presence at a production meeting.

Today, the safety of employees is undeniably tied into production, just as much as is low manufacturing costs or the accurate planning and scheduling of materials. A successful foreman, therefore, will take advantage of his membership on the safety committee, as he represents, in our opinion, the crux of the whole safety procedures and practices. Safety thus becomes an integral part of his job in putting over the plant safety program, as given to him through the safety committee. The foreman, as an individual, bears a very important relation to the success of any safety committee, as he represents, in our opinion, the crux of the whole activity, and it is for this reason that a brief analysis of his position has been treated.

Modern methods of wage payment, such as group bonus, gang work and piece work, enhance greatly the importance of production and likewise create a natural need for a definite safety program, administered through well organized effort. The safety committee, in our opinion, is the logical solution to this situation.

Plant safety problems involve three essential features: education, engineering, and safeguarding.

However, we are of the belief that these elements will fall short of their objective, unless they are sponsored by an active, enthusiastic safety committee.

Assuming that the management is convinced of the value and need of accident prevention work, safety committees should have for their purpose the following functions:

1. To be a channel through which a frank discussion of safety policies and practices may be had.
2. To make periodical inspections of the factory and then to submit definite recommendations. (Incidentally, it might be a wise plan to have a member of the

safety committee, preferably a foreman, make an individual inspection, occasionally, of a department other than his own; to detect the possible existence of hazards. Sometimes, even a conscientious, responsible foreman overlooks conditions in his own department that may constitute a hazard, because of his intimacy with them.)

3. To review thoroughly the elements which contributed to an accident and make the necessary recommendations to eliminate a recurrence. Constant education and instruction, together with proper disciplinary measures are the only weapons available. (Cause classification forms, submitted by the foreman in whose department the accident occurred are valuable in this phase of committee work.)

4. To invite and receive suggestions from employees regarding unsafe operations and practices they may observe.

5. To improve the spirit of cooperation and willingness between employees and management.

6. To make the safety plans, as developed in their committee meetings, virtually a part of the operating policies on their own particular job.

The attitude of department heads toward accident prevention work will be reflected by employees, just as accurately as their attitude toward production is reflected. If the manager of the plant treats safety problems lightly, his "key" men will treat them lightly. If, on the other hand, he regards safety as an important feature of the plant's operating policy, his foreman will reflect his attitude and will see that employees under their supervision are educated to observe fundamental precautions necessary to plant safety . . . Hence the need for the existence of the safety committee, beginning its work at the top and working downward to the employees.

The Safety Committee Helps the New Employee

The new employee has long been regarded in industry as a bad accident risk. However, in a plant in which there is a well organized safety committee, a new employee does not present as great a safety problem as his presence would in a plant without a safety committee. The employment manager uses to advantage the lessons learned in safety committee meetings, after making a safety analysis of the particular operation for which a new employee is needed, together with the caliber of employee best suited. The prospective employee's attention is directed to a safety sign occupying a prominent place in the employment office, stressing the need of men being careful to avoid injury to themselves and others, if they desire employment. The new employee is given a letter addressed to him personally, from the factory manager (who is chairman of the safety committee), inviting his interest in accident prevention and admonishing him to work safely—this letter being given to him at a time when he is most impressionable. This safety element is also a product of our safety committee. He is then taken from the employment office to his foreman (likewise a member of the safety committee) who introduces the new employee to his job; he points out carefully the hazards that may exist on the operation if not done properly, and satisfies himself that the new employee understands the instructions. If the foreman may happen to be absent from the department at the time, these matters are handled by the assistant foreman. The foreman later checks up on the new employee's absorption of the safety work, as well as on his progress with the other phases of the job.

When production is rapidly increased or new construction is to be hurried along, these conditions carry with them a hasty distribution of new employees into the organization, and if these new employees have been previously working on jobs where safety has not been implanted in them, their very presence constitutes a menace to the well-being of the plant safety program. This type of man has the impression that he has been given employment to tide over a busy season, and for divers reasons he is not prone to exert himself, either in holding up his end of

the job, or in shouting from the four corners of the plant his firm belief in the principles of safety. The interest of this type is not always in his present job. So these men, commonly called "floaters" (and for some strange reason do we have them in Detroit, as in other places), bring out the need of very good judgment and tact on the part of the foreman.

Here, we feel, is a real need for the foreman's touch with such an organization as a safety committee. On the one hand, he realizes that when the first let-down in business comes along, this particular type will be the first to be laid off. On the other hand, he realizes that if any of them get hurt in the meantime, it means broken safety records and payment of considerable compensation money. Unfortunately, as compensation adjusters have found out, some of these gentlemen would not object to a subsistence on compensation payments. Is the influence emanating from the safety committee a necessity or a nuisance, here? We believe it is an urgent necessity.

The chairman of our safety committee (factory manager) holds department heads responsible for accidents and their cost, the same as they are held responsible for scrap in a production meeting. If a foreman is interested in his job, he is interested in cutting down the expenses connected with his department. His connection with the safety committee gives him excellent reasons, at close range, for adopting this attitude. Departmental competition is strongly urged and its effects, we find, are very beneficial to the safety movement.

And so we all must continue to visualize what we are doing that we may sustain the interest in the work. Some of the points in our experience have been given and we feel pleased with the progress being made by our safety committee. We fully appreciate, however, that the job is never finished, and we must "carry on," always going forward and never for a minute losing faith in what we know to be a work well worth all the energy and effort that we can put into it.

Endorsement of the Safety Committee Idea

MR. GRAHAM: Mr. Challis has, in connection with his paper, submitted a letter from William Robert Wilson, who is president and chairman of the Board of the Copeland Products Company and likewise president and chairman of the Board of the Murray Body Corporation, and is also the president of the Detroit Industrial Safety Council on whose staff I am employed. Mr. Wilson's letter follows:

"My Dear Mr. Challis:

"In line with your paper for the annual congress of the National Safety Council in Chicago, I would like to record endorsement, as president of the Detroit Industrial Safety Council, of the Safety Committee idea.

"The Safety Committee idea, as used in the factory at Copeland Products, Inc., here will appeal to all executives who have found that the cooperation of intelligent men is superior to individualism in industry, and that with intelligent cooperative men ideas have an adherent leadership superior to the methods of the big stick. As safety has to be built into the minds of men before it can bring results, there seems no logical argument against the cooperative methods for the development of the safety conviction.

Sincerely yours,

Wm. Robert Wilson."

CHAIRMAN ROACH: Gentlemen, I am sure some very important and very worthwhile points were brought out in the paper read by Mr. Graham. If there is no discussion, we will have a paper read by Mr. E. J. Kreh of the Pittsburgh Railways Company. This paper was written by Mr. H. O. Allison of the Beaver Valley Traction Company, New Brighton, Pennsylvania, who cannot be present.

Interesting the Man on the Job in Safety

**H. O. Allison, Commercial Manager, Beaver Valley Traction Company,
Beaver Valley Motor Coach Company, New Brighton, Pa.**

To interest the "Man of the Job" in safety you must first learn what will interest him.

You must know your man; you must know what, and why, you want to interest him. Knowing these two things, you proceed with the full realization that you are dealing with other human beings imbued with all the elements of the human, leveled only by age, intelligence, experience and environment.

Set yourself apart from the official aspects of your position. Carefully consider what interests you. Then determine if that which interests you will interest the man or the group of workers you wish to interest. Do not make the error of deciding "it should interest them" instead of determining if they will be interested. When I want to interest a man I transfer some of the responsibility to him. This can be done in the plant. Why not call in a group and let them decide on innovations and have each one assume his share of the responsibility?

Man is interested most in those things for which he becomes responsible, and his interest lags as monotony and familiarity creep in, therefore, you have two things to guard against—monotony and familiarity.

In interesting the man on the job it is essential that you know what causes accidents and then apply the known prevention by the removal of the cause.

So let me proceed with some causes and we find:

Lack of proper care.

Inattentiveness.

Lack of instruction.

Lack of proper instruction.

Lack of determining man's qualifications.

Man misrepresents his qualifications.

Defective material.

Ignorance of the danger.

Lack of interest.

Familiarity with the job.

Lack of warning devices.

Momentary lapse of attention.

Excitement.

Poor judgment: (a), as to speed; (b), as to distance; (c), as to equipment; (d), as to danger.

Fatigue.

Dissipation.

Curiosity.

Taking a chance: (a), necessary, chances; (b), for economy—of time, of labor, of material.

Unnecessary chances.

These general causes may be classified and the remedy shown as follows:

Cause—Lack of Instruction.

Remedy—

1. Instruction by

(a), foreman; (b), older hand; (c), safety committee.

2. Bulletins:

(a), change frequently; (b), calling attention to results rather than causes.

3. Marking real danger points.

4. Instruction is not completed until man can do the job by himself or under proper supervision.

Cause—Defective Equipment.

Remedy—

1. Proper inspection.
2. Investigation to determine the cause.

Cause—Necessary changes.

Remedy—

1. Instruction as to how to meet emergency to eliminate danger as far as possible.
2. Equipment to meet emergencies.

Cause—Changes for Economy: (a), time; (b), material; (c), labor; (d), equipment.

Remedy—

1. Equipment to meet emergencies.

Cause—Ignorance: (a), unforeseen; (b), man ignorant of the usual practices of the job.

Remedy—

1. Anticipate as far as possible the danger.
2. Investigate as to real causes.
3. Educational: (a), publicity pertaining to accident; (b), instruction by foreman.
4. Slogan—in case of doubt—Stop.

Cause—Poor Judgment on the Job.

Remedy—

1. Put older men on the job.
2. Change of job.

Causes—Temporary.

Excitement—

Dissipation.

Curiosity—

Lack of Interest.

Remedies.

1. Instruction to meet irregularities.
1. Curiosity will cure itself.
2. Instruction.

Working Conditions—

1. Attention to windows and ventilators already installed.
2. Recommendations for improvements.
3. Rearranging lights.
4. Instruction.
5. Provide special equipment to protect against exposure.

Monotony of work—

1. Change of job if possible.
- a. Degree of developed intelligence.

Short working force.

Improperly nourished—

1. Suggestions to company physician.

Personal trouble—

1. Advise if opportunity presents itself.

Momentary Lapse of Attention—

1. Change of work.
2. Warning devices.

- a. Emotions.
 - b. Outside distractions.
- Fatigue.
 Taking a chance.
 Outside Troubles—(a), domestic; (b), financial.
 Scared of His Job—
1. Advise him, to give him assurance.
 2. Encouragement.

Causes—Permanent	Remedy
Nervous Disposition	1. Change of job
Lack of Interest	
Taking a Chance	1. Change his job
Familiarity with the Job	1. Change his job
Laziness	Discharge
Indifference	Discharge

The following causes of fatigue analyzed would be classified under the head of apparent carelessness, and most under the head of real carelessness:

Causes	Remedies
Too long work period without rest intervals	1. Taken care of in regular run of the work. 2. Avoid overtime if possible.
Poor equipment and tools.	1. Inspection of tools. 2. Maintenance of tools and equipment. 3. Considering complaints.
Physical disability	1. Lay off to recover. 2. Distribution of heavy work to meet the disability. 3. Change of jobs.
No incentive	1. Recommendation.
Dissipation	1. Personal advice. 2. Change of job.

Diverse Things Will Interest Diverse Minds

Some one has said: "To know safety is an act or condition of the workman's mind, not of the tellers. The worker's senses, rather than his common sense, must be appealed to. A safe and familiar line of thought must be used to the point of departure for new ideas; even prejudices must be taken into account. The type of mind that "rocks the boat" for amusement, and "did not know it was loaded," is not easily kept to any one line of thought; the attention wearies easily and can be engaged by concrete moving objects rather than with distant and abstract ones. Pictures, action, drama, thoughts of family, sex instinct, sports, classes of information—those are the fundamental sources of interest.

Not all men can be moved by the same cause.

John T. Ryan, vice-president and general manager of the Mine Safety Appliance Company, Pittsburgh, carries great weight with the men of his plant when he brings before them the fact that his company is manufacturing products which have to do with lives, and those of other men who risk their lives in the use of the product. To carry this home to them every one of the men employed either in the manufacture or the assembly of their devices

must occasionally wear the equipment themselves. Each employee is subject to call at any time to put on the equipment which he or a fellow workman has assembled and use it in a poisonous atmosphere.

This applies particularly to mine explosions, for, in the event of any mine disaster, Mr. Ryan takes these men to the scene of the disaster and they are in charge of the equipment on the outside and some of them have to wear it inside the mine.

This is a vivid demonstration of the necessity of careful workmanship. It is an appeal to the worker to have his product the best possible in order that the life of a fellow worker may be protected. When you consider that a good portion of accidents are caused from the neglect of another than the one injured you will grasp the force of Mr. Ryan's argument to his employees.

The Globe Wire Company of Sharpsburgh, Pa., is a small plant, employing from 40 to 50 men. The principal reason for the safety thought on this plant is that the superintendent himself is a safety enthusiast. This is as it should be and in turn enthuses the other men.

Personal contact does count and where employees are few it becomes possible.

Horrible examples alone will not create safety. Very few men can be scared into keeping their fingers out of the buzz saw.

Safety Work in Pennsylvania

In Pennsylvania there is more safety to the square foot than in any other state in the Union. My authority for that statement is none other than John A. Oartel, President of the Western Pennsylvania Safety Council—an organization which has done more to make Pennsylvania safe than any other in Pennsylvania. Safety starts at Pittsburgh, is fed by the Beaver Valley, my home section, and the National Safety Council.

My first experience in safety was in the start of the prevention of accidents, both public and employee, on an electric railway back in 1909, and I have been at it more or less regularly since that time. Just then our genial colleague and official of this organization, W. H. Boyce, was the pater par excellence. We worked together and formulated some 125 hazards together with the preventive measures. That railway was the first to have a safety engineer, the first to advertise in the newspapers for the purpose of preventing public accidents, and the work has continued regularly and consistently all these years and will continue for ages to come. As to results, the claims cost for public accidents dropped from 8 per cent of the gross receipts to 1.49 per cent and today the smallest part of a fraction of a cent per car mile is sufficient to pay all such costs. Employee accidents are nil. In competition with all other concerns in a No Accident Month last June, we stood 100 per cent perfect. The major accident this year has been my own fall at a company Field Meet at Schenley Oval, Pittsburgh, and the fracture of a few ribs—painful but lesson like. This speech was written during the days of recovery but while the stitch in the side was still making itself felt—I know that it “hurts to get hurt.”

We conducted a county-wide No Accident Month, June, 1925, and the results were:

Deaths in June, 1925, 13; in June, 1924, 42. The decrease was 69 per cent; lives saved, 29.

Drowned in June, 1925, 0; in June, 1924, 6. Lives saved, 6.

Street railway accidents (all classes included) decreased 44.8 per cent.

Public accidents (street railway) in which other vehicles were concerned, decreased 44.2 per cent.

To do that we had to interest the man on the job and the man in the street.

We did by talks in the factories, daily articles in the newspapers, a safety parade, the first and only one we have ever had, and a prevailing of the thought "No Accident."

In one of our campaigns we divided our force into ten teams, each with a pilot, and loaded them into aeroplanes and started them to the North Pole. Commander Byrd was making the real trip at the same time. A day without an accident let the plane advance, an accident set it back one day. Both employee and public accidents counted. Three planes reached the pole. Two were within two days, three within three days, and two were five days away. The record was shown daily on a large painting of the territory being traveled by the Byrd plane. Interest was created.

Again we organized the property into military formations for the prevention of accidents.

Those so unfortunate as to have an accident were court martialed to the guard house. We had a guard house and miniature figures were labeled with the name of the employee and placed therein as recommended by the court.

The "Man on the Job" is a man just like you. Stilted phrases, or a better than thou attitude will not get safety across. You may live and act it, but so do preachers, priests and rabbis, and still there are backsliders.

So, interest yourself in what interests them and you cover 90 per cent of the problem. As you do that and when you do that, you will get safety across and have but the 10 per cent to contend with—and that's a cinch, for engineers have solved it.

CHAIRMAN ROACH: That was a very interesting and tremendously important paper, despite the discovery that there was so much accident prevention service in Pennsylvania. Some of us will agree to that, and so it is pleasing to have our friend speak well of his own home town.

We will next have a paper read by Mr. P. W. Armstrong, assistant manager, Mississippi Valley Structural Steel Company, Melrose Park, Illinois.

Care of Injured in Small Plant

P. W. Armstrong, Assistant Manager, Mississippi Valley Structural Steel Company, Melrose Park, Ill.

One of the hardest things in the care of injured and safety work in the small plant is to determine how much you can afford to spend to accomplish the most good and obtain a fair return on the money spent. When you are limited to the amount a plant with a yearly average of 100 employees can afford to spend, a good deal of thought is necessary to get the most out of every dollar.

Plants with a payroll for a thousand or more employees can afford their doctors, nurses, dentists and plant hospitals. We all know these are to be desired and accomplish a great deal, but since they are out of the question for the small plant something else must be substituted, or some part of it used.

I've often thought that in some neighborhoods a number of small plants might combine and have these things in common, and I believe this has been done. However, unless the plants are somewhat similar it is hard to proportion the cost of maintaining it, due to the unequal benefits received by the different plants.

I'm going to attempt to describe a plan worked out over a number of years in a small plant providing for care and treatment of plant injuries and accidents. It has been in operation for a number of years and proves what can be done with a little thought and by taking advantage of services offered by our

National Safety Council. It is giving excellent results with practically no extra cost. A good deal of credit should be given to the company doctor who assisted in working out the plan.

This plant averages about 135 men, made up of laborers, semi-skilled and skilled workmen. No non-speaking English or women are employed. It is operated in a state which has no compensation insurance act until last January, and because of the activities of damage suit lawyers minor accidents and injuries had to be handled very carefully.

Several years ago the St. Louis chapter of the National Safety Council started giving once a year a nine-lesson course in first aid work. This was given by men trained in mine rescue station work. Each man was given personal instruction and practice in dressing, bandaging and emergency first aid work. At the conclusion of the course each man was given an examination and if he passed was awarded a diploma. The holders of the diplomas are required each year to take an examination to keep their diplomas. The only difficulty came from these nine-week doctors who complained of the small number of patients, which limited them in showing off their knowledge and skill to their fellow workmen.

This plant had a Safety Committee headed by a permanent safety man. He held an inspector's position and was ideal, since his duties took him to all parts of the plant. They also had in the shop office a first aid room. This room was in charge of the payroll clerk. He also was ideal in that he was familiar with the name, work and employment records of each man.

To this school they sent their safety man and their payroll clerk to prepare themselves to take care of the minor injuries, to prevent infection and for emergency treatment of cases requiring a doctor.

Taking Care of the Minor Injuries

Due to the natural hazards in this plant a large number of their injuries consisted of scratches, slight cuts and bruises, and with infection from rust always a possibility. The foreman and the safety man on their trips about the plant saw to it that all injuries, no matter how slight, were given first aid treatment.

As soon as a man came in his injury, if minor, was treated and dressed, and a record made of it in a daybook, under that date, giving the injury, who dressed it, and the treatment given. If the injury was serious only emergency dressing was applied until the doctor arrived. After the injury was dressed a report was made out and also a record made of it in a day book under that date, giving the injury, by whom dressed, and the treatment given. They never make out injury reports until everything has been done to make the man as comfortable as possible. By means of this day book a record of all injuries, dressings, redressings and discharges for each day was kept with the record of who attended the injured and the treatment given.

The doctor stopped at the plant each day provided he had any injuries that required dressings. At that time he looked over the records of the day book entered since his last visit. If the injuries appeared to be only minor and no infection reported, he checked the treatment only. If he decided after reading the report in the day book and talking to the man who dressed the injury that he should inspect the injury, the man was asked to come to the office. Each man was called in separately and his injury inspected and dressed.

They try to have only two men out of the plant at one time, one in the dressing room and one waiting. If it has been a serious case, after the injury has healed the doctor may instruct the first aid man to change the dressings as required, but in all cases the doctor examines the injury before final discharge. None of the injuries requiring treatment only from the first aid man are reported on

accident forms. About six first aid treatments are given daily, while only about three injuries a week require the doctor's care, all of which means a substantial saving in doctor bills.

They also believe in a liberal use of X-ray photographs and in all cases of bad mashes have pictures taken to insure a correct treatment. The plant doctor has this equipment in his office. They also believe in keeping in touch with the man whose injury keeps him away more than a week, and make it the duty of the shop superintendent or assistant manager to call on these men at least once a week. Much suffering and many misunderstandings can be prevented by such visits.

All employees are at liberty to come in and see the doctor by obtaining permission from the foreman, should they be dissatisfied with the dressing or treatment of the first aid man. Quite frequently the visit is not an injury case but a bad headache, toothache, sore throat or cold. The doctor gives these men treatment sufficient to last the balance of the day with the advice if they are not better by night that they should see their family doctor. The doctor does not charge for this service and the company furnishes the medicine free. They find this well worth while since in most cases it keeps the man at work and may head off several days' illness and loss of time.

Some Typical Records of Injuries

Let me read the records of injuries for three days in succession as shown by the day book as an illustration of the treatments and the detail manner in which it works.

November 5th:

Harry Heron—Thumb, left hand, redressed. Mercurochrome and bandaged by G. A. C. Injured Nov. 4th.

Esty Bennett—Thumb and knuckle of index finger, right hand, skinned. Accident not reported until became infected. Mercurochrome and borsceptic ointment applied and bandaged by G. A. C.

J. F. Masmic—Cut on back of left hand. Mercuro compresses and bandaged by G. A. C.

Joe Dargie—Cut index finger of right hand. Mercuro compresses and bandaged by G. A. C.

November 6th:

Esty Bennett—Thumb and knuckle, index finger, right hand, redressed. Mercurochrome and bandaged by G. A. C.

Joe Dargie—Redressed finger. Mercurochrome and bandaged by G. A. C. Injured Nov. 5.

Harry Heron—Redressed thumb, left hand. Mercurochrome and bandaged by G. A. C. Injured Nov. 4th.

Ray Hunt—Redressed index finger, right hand. Borsceptic ointment and bandaged by G. A. C. Doctor's bandage came off. Injured Nov. 4th.

J. D. Kyle—Foreign matter in right eye. Washed with boric acid solution. Doctor called.

November 8th:

Ray Hunt—Redressed index finger, right hand. Borsceptic ointment and bandaged by G. A. C. Injured Nov. 4th.

Harry Heron—Redressed thumb, left hand, clean bandage by G. A. C. Injury Nov. 4th.

Ernest Owens—index finger right hand mashed. Borseptic Ointment and bandaged by G. A. C.

A. M. Wallis—Bruised wrist, left arm. Borseptic ointment and bandaged by G. A. C.

John Snow—Burn and blister on second finger, left hand. Unguentine and bandaged by G. A. C.

That, I believe, gives you a good idea of what the first aid man does in caring for minor injuries and the saving in doctor bills. At the same time it gives a greater protection to each man, as it isn't possible or practical to call a doctor for each of these minor injuries. The whole scheme certainly helps do away with infection, as every injury is inspected and dressed daily.

To my mind, that is one of the main differences in the way most small plants run their injuries. If a fellow out in the shop hurts his finger, mashes it or something, if he is pretty well sold on safety, he goes to the place in the shop where there is some iodine and a fellow puts a rag on his finger and he comes back. Maybe that's the right treatment and maybe it isn't. It is a haphazard way in which no record is kept; nothing is heard about this man and no method is followed to look him up to see what happens to his finger after the first treatment; while the records in this book give a complete history and a check.

Treatment for the Worker's Injuries

With the aid of the doctor the following drugs were assembled and always kept on hand and the following treatments were standardized to cover injuries common to their plant and is the result of experiment and experience.

For all cuts they used listerine to wash the flesh around the cut. If the flesh is covered with grease or oil, gasoline is used to remove the grease or oil. Deep cuts are washed with chlormine and tablets dissolved in warm water and then bandaged. Slight cuts are painted with 2 per cent solution of mercurochrome or a mercuro compress applied.

For mashes and bruises where the skin is not broken, borsceptic ointment; where skin is broken, chlormine and tablets dissolved in water and poured over wound.

For burns, unguentine with gauze dressing, where skin is red and blistered. If skin has been broken picric acid solution with gauze dressing.

For foreign objects in eye use boracic acid solution with eye cup. If not relieved call doctor.

For fainting—Aromatic spirits of ammonia.

For heat prostration—Spirits of ammonia and epsom salts.

For bleeding from deep cuts, two feet of gauze and a stick for twister.

One and two-inch bandages and adhesive tape, gauze, cotton and woolen applications are kept on hand.

Their first aid room is about 10x8 and is equipped with the following articles: portable stretcher, folding emergency chair, blankets, table wash pans, towels, waste can, scissors and pair crutches.

As I said before, I know of no better or less expensive manner of taking care of injuries. The injuries have been systematized and the treatments standardized as far as possible. Systematic precautions have been taken to prevent infection. Systematic medical treatment is provided. Thought has been given to plan and carry it out. Personal touch with the injuries is maintained. All of this is done with an expense, exclusive of doctor bills, for less than \$100 per year for medical supplies. The only other expense is the time spent by the payroll clerk and inspector away from their regular duties.

I believe the principles outlined can be successfully applied to any small plant and obtain excellent results.

CHAIRMAN ROACH: What is the size of the plant?

MR. ARMSTRONG: One hundred and thirty-five men.

CHAIRMAN ROACH: That was a very interesting paper and a very worthwhile paper presented by Mr. Armstrong. I wonder if anybody present would like to ask questions or carry on a discussion?

JOHN S. SHAW (Hercules Powder Co., Wilmington, Del.): I don't wish to discount the speaker because I think his paper was excellent, but I have just three little suggestions.

The joint hospital affair, that is, the cooperative affair with another plant, sharing a doctor, sharing a hospital between two plants; we do that in two of our states, in New Jersey and Michigan, and it works out all right. It is a cooperative affair and we have a way of proportioning our share of the debt.

At another small plant where the hospital in the nearby town takes care of our injured folk, we pay their regular bills, their regular rates and at the end of the year donate to that hospital a like amount. If our annual hospital bill has been, say, \$350, at the end of the year we also donate another \$350.

This is an incentive to the local hospital to take good care of our men. That's where you have a small plant and can't keep your own hospital.

As to the first aid squadron who are itching for somebody to be injured so that they will apply their skill, I would suggest a few drills. Get somebody to act as the subject. Just have a few drills.

Personally, three years as Scoutmaster taught me a good deal that I apply even today, and the scouts get their drills that way. Some of these scouts are now men and you will find every once in a while in your plant men who have been thoroughly drilled in first aid measures and they will carry on, they will organize these drills for you. They like to have those drills.

Infections Call for Expert Attention

The third note is cases of infection. I would not trust them to the layman. If a man comes in three days after he has received a laceration, while it may be all right to put a compress or antiseptic or sterile dressing on that wound, that man should be taken immediately to the doctor. Don't monkey with infections because they are very often disastrous. I presume, though that the last speaker's plant does this.

CHAIRMAN ROACH: Would anybody else like to discuss the paper?

S. LANGNER (U. S. Fidelity & Guaranty Co., Chicago, Ill.): My work takes me in close contact with a large number of small plants and I often find that there is an objection to dictating to the employee who should give him medical attention.

I think it is important that the employee be impressed with rehabilitation starting with the initial medical treatment, and it is important that he get expert and specialized treatment for his injury. There is no doubt that a specialist in industrial accidents is far superior to the general practitioner in handling compensation cases.

Another point I think could be brought out is the importance of posting the men with the name of the doctor who is to take care of the injuries which occur in that plant.

There are plants I go through that have fine safety organizations and much work is done in accident prevention, but there is not enough stress put on this point of immediate medical attention and proper medical attention. I think that ought to be brought out in connection with caring for the injured employee.

MARK D. MOORE (Worden-Allen Co., Milwaukee, Wis.): I would like to ask the gentleman with the day book what their policy is in regard to particles in the eye, whether it is their policy to send the man to a specialist?

MR. ARMSTRONG: The only treatment we give an eye is an eye glass solution of boric acid. If that doesn't bring relief, the doctor is called. No one is allowed to gouge around. If it can't be washed out with an eye glass, the doctor takes care of it.

CHAIRMAN ROACH: I take it that your first aid department is not going to indulge in surgical practices. That isn't the purpose of first aid. It seems to me all those things should be taken care of by an expert skilled in that particular line of work.

If an eye suffers an injury, certainly treatment should be given by a skilled surgeon. I think we all agree to that. The main point under consideration, however, as brought out by Mr. Langner, is to impress on management; supervisors and workmen the necessity for skilled surgical treatment in case of injury; and that applies to minor injuries as well as those of major importance, because we have evidence enough now in the records to show that a very slight wound may become a matter of major importance through neglect, or if the physical condition of the worker is of a certain character.

I think many fatalities have resulted from neglecting to take care of minor cuts as soon as they occurred.

Effectiveness of the Safety Organization

MR. LANGNER: I would like to add that in most of our plants, those plants handling meat, lumber or scrap iron, we try to incorporate a rule that any injury which draws blood should be attended by a physician before that man returns to work the next day.

JOHN S. SHAW (Hercules Powder Co., Wilmington, Del.): I would like to ask this gentleman here why they pick on the payroll man for the simple reason that he is acquainted with the individuals who are employed in that particular plant. Why is it that this particular man was chosen? Was it because he had some previous experience in safety work?

MR. ARMSTRONG: There wasn't any particular reason. He was a man that was available and was interested in that work. He had done some work. He was available in the office. You know, some fellows like to do it and other fellows do not. He was interested and therefore we let him do it.

A. W. BRADFIELD (Industrial Works, Bay City, Mich.): Several years ago we inaugurated at our plant a first aid room in charge of a registered nurse. I might say that that nurse does remove particles from the men's eyes and it has been entirely satisfactory. We haven't had a lost eye in four years. Previous to that we had ten lost eyes in one year.

W. H. WEITKNECHT (Lehigh Portland Cement Co., Mitchell, Ind.): What was the occasion for the loss of eyes?

MR. BRADFIELD: That was preceding our work with the safety organization.

CHAIRMAN ROACH: That shows the effectiveness of a safety organization.

MR. BRADFIELD: I might add in the year 1916 we had more accidents in one day than we have had in the entire period for 1927, and I might also tell you that one of the most important features, I believe, that was ever inaugurated at the Industrial Works plant was that at the close of 1926 we received a form from the National Safety Council asking that we furnish our experience in accident prevention work. Later on we got a report showing our position in our division. I immediately conveyed that report to the foremen and the executive organization, told them of our position and asked them to try to do all possible to hold their line straight, and it was possible we might land in a leading position. We were not very far down. There was an immediate response and everybody seemed to be working. The mental attitude created was phenomenal.

I might say that last week we had our first lost time accident since the middle of last May and it was very minor.

We have the proper mental attitude that is pretty hard to beat and the result is

that we have gone from last May up until last week without any lost time accidents for the entire plant.

PETER DE MALT (Robert Gaylord, Inc., St. Louis): What do you do when a man refuses to return to work on the following day? We had a case of merely a pinched finger, no fracture of any kind, and he elected not to come back, so we were obliged to charge it as a lost time accident.

The reason I asked is this. A plant of 150 men was charged with 152 injuries. That was rather unusual. Some people charge their lost time accidents in different ways. That is why I asked that.

DR. LUCIAN W. CHANEY (U. S. Department of Labor, Washington, D. C.): There is a definition which is quite standard for lost time accidents; anything which causes disability beyond the day in which the accident occurs, is a lost time accident. At any rate it is the most widely used definition of lost time accidents that is applied anywhere.

CHARLES SWEGER (Mattheissen & Hegeler Zinc Co., La Salle, Ill.): If a doctor discharges a man and says he should go to work the next day and the man doesn't come, would you count that a lost time accident?

CHAIRMAN ROACH: Let Dr. Chaney answer that.

DR. LUCIAN W. CHANEY (U. S. Department of Labor, Washington, D. C.): It seems to me that depends entirely on the surgeon. If he decides that the man ought to come back to work and the fellow does not do so, it ought not to be considered as a lost time case. In my own practice the surgeon specifies that the man should come back. What the man thinks about it doesn't cut any figure in the statistics.

Discussion of the Lost Time Accident

MARK D. MOORE (Worden-Allen Co., Milwaukee, Wis.): In connection with this, in deciding just what is or what is not a lost time accident, we run quite a number of no accident contests in our plant and naturally under those conditions the foremen are trying to keep their accidents down and that's exactly what we want to get at. But there are instances where it depends largely on the individual. One fellow will crush the entire tip of his finger and probably through personal circumstances or home conditions or his own personal pride will stay on the job; and some other fellow who gets a minor scratch will stay home two weeks.

Where you have a doctor whose opinion can be relied upon, he will say he is perfectly able to work, and the foreman will want the charge taken off the board; and we usually do it because it isn't fair in the preventive contest for a foreman to have to stand for an accident where the surgeon claims it ought not to be a lost time accident.

Of course, there are times when a fellow stays on the job when he has a perfect right to stay home.

MR. LANGNER: We had occasion in one of our plants where a man left the job and came back a week or ten days later and said he had strained his back and had not reported it until that time.

The foreman maintained he was not responsible for that accident and shouldn't be charged with it, so in order to take care of future circumstances, we decided to discuss those things at a foreman's meeting and then let the safety committee decide whether a department should be charged with an accident like that.

MR. WEITKNECHT: Those disputed cases of lost time can probably be solved best by the visiting committee, probably from the department of employment. We have had occasions like that in which the men thought they should not resume work after the physician said they were perfectly able to return.

We didn't want to exercise force because of the report of the surgeon and yet those were cases that had to be solved, and we devised this scheme. We appoint a visiting committee, preferably from the department in which those men are em-

ployed, who go to see the man at his home; go to see whether or not he is able to come to work; and those fellows have a good deal of influence. Each man respects the feeling of his fellow-worker. We found that the most effective thing.

MISS MARIE L. MENCHAN (Ohio Brass Co., Mansfield, Ohio): This problem is very interesting, because we have not only iron but brass foundries and therefore we have a lot of sprained backs in our plant. On lost time cases the doctor must pass on the man coming back, but our men are paid for lost time whether they lose a day or a week, when it is an injury. We pay them two-thirds of their wages, the same as the state compensation pays them, in the second week.

We have 1,500 people in our plant. We usually have nurses and an extra girl in the dispensary, and so on eye cases the nurses are permitted to remove the foreign bodies, if possible. If it is a burned eye they give first aid treatment and then immediately consult a specialist. We permit the men to use their own eye specialists and their own family doctors. We never instruct a man in connection with his family doctor.

Mr. Olsen is our family manager. He is a very human type and he has laid out the entire plan of our dispensary and our personnel, and we find we maintain a wonderful mental attitude with all our people.

I imagine we have an average of 95 people coming to the dispensary daily. We not only take care of injuries but we attempt to keep our people well. We feel a well man can do better work than a sick man. We have three beds and we have a doctor part time each day.

Treating the Employee on the Level

If a man is injured, say, for instance, getting his back injured (we have tried to get our men when they feel they have sprained their backs in carrying metal to report to the foreman), he comes to the dispensary. We have a car to take him home and then the nurse calls on him the next day to see that he is having his family doctor.

We feel by expecting our men to do the right thing, but putting them on a high standard, they would be sort of ashamed to put anything over on the company.

The other thing I would like to discuss a little further is in regard to what was brought up in putting a man's name in the guardhouse. The more I see of people the more I think we should treat our people on a high standard; and don't think the average factory man doesn't believe in that sort of thing. I saw it worked out in one of our steel plants. I saw some very serious cases follow because a man was in the habit of protecting the record for his department, and I also found that foremen would try to see that things were taken care of on the side, so as to keep the record from being spoiled. I think that might be all right for running a race, but when we get into health and accident prevention I think we have to be extremely careful.

MR. LANGNER: I think the fact of putting a man in the guardhouse and so forth is all right. I think the objections can be overcome when the men are impressed with the seriousness of the result of an injury that is neglected. No doubt it is important they should be impressed with the necessity for immediate attention.

I think the objectionable features of races and so forth can be overcome if the men are properly instructed on the seriousness of neglecting accidents.

PETER DE MALT (Robert Gaylord, Inc., St. Louis): I would like to ask this gentleman about back sprains. Is it possible for a man to strain his back with a lift of material to his arms, providing that man is in good physical condition? Is it possible to strain muscles in his back through a lift of material by the muscles of his arm?

DR. LUCIAN W. CHANEY: There is nothing more puzzling to the medical profession concerning compensation than those cases of back strain. They are exceedingly difficult to determine.

It is possible for a man to strain his back simply pulling at his arm. I have done it myself. There isn't any doubt about the result, but there are a good many cases which are certainly close to the border line, and just how to get at them is a puzzle which any physician who has to deal with cases of that kind dislikes. He would rather have almost anything else to deal with because it is so difficult to decide whether the man is really injured or not.

It is possible for him to be injured. I haven't the slightest doubt about that. There are a good many cases in which he isn't injured at all, perhaps he only thinks he is; but personally, I wouldn't like to be charged with the responsibility of deciding.

DR. W. T. CARSTARPHEIN (Speer Manufacturing Co): I want to say one word. I have been very much interested in all these discussions because they all come so close to us, and as we found out in our meetings, there are so many angles to all of these questions that we have to use a great deal of common sense in comparing them one with another because our experiences are so varied.

I hadn't intended to say anything, but when you brought up this back question I couldn't refrain from saying a word. It may be of some help.

Three Types of Back Sprain

I don't know how many physicians there are in this audience. They may take issue with me, but I find that there are three types of so-called back injuries or back sprains. One is the true type that has to be treated. The probabilities of complications are present, but we only find them occasionally.

There is another group, and I am about to say a large percentage of that is not true back injury, yet the man is injured. He is entitled to consideration. I have done a little researching and I employ a good many doctors in our various plants, and we have come to this method of procedure.

When a man comes in and tells you he has turned a muscle and is not able to do any more work, the first thing we do with that man is to make a thorough examination of his mouth; and you will find in a great many instances that he has septic tonsils, chronic tonsils or else decayed teeth, and he has a pain which has been instituted by the sudden and direct muscular movement he has made on the machine.

It is pretty hard to drive that into the man's head. Sometimes he can't understand how the defects in the mouth end in the back, but it holds true all the same that this is the defect, and you can pass that on to your industrial physician for what it is worth.

The other group is purely imaginary. I had a big fellow some time ago in one of our plants. He was out a month, I think. Injury belts had been bought for him. He had gone through the compensation courts. The award had been paid for so much disability.

I happened to be downtown one day and I saw him come out of the Five and Ten Cent Store and mount a bicycle in the athletic way the boys do; he jumped up and started off. Prior to that time I had always seen him on crutches. I sent for him and he came to my office, and I said, "I saw you mounting your wheel last night at eight o'clock in front of the Five and Ten on Main street. It is all up." He laughed and said, "It is."

There is one other thing I would like to say which is a constructive thing. I have listened with very much interest relative to the first aid and its paraphernalia and its bearing on the small plant. I think a great deal of good could be accomplished if we could standardize, somehow (although I don't know how we can do it), our practice in first aid rooms. I offer this merely as a suggestion.

I had a plant some time ago, a steel plant. The treasurer came to me and said, "Here we are, losing \$25,000 a year on infection losses," and he wanted to know what could be done.

Well, the practice in the first aid department was not standardized, and the standardization, as I mapped it out for that particular plant, soon reduced the number of infections and the results were quickly noted in greatly lowered costs. Where the cost peak for such infections had been \$20,000 in the past eight years, the cost has only been \$500 per year. That is the actual statistical result in that particular matter of infection. I think if we could standardize our practice in the first aid room, culling from here and there the best things, we could save millions of dollars.

ADJOURNMENT

**SIXTEENTH ANNUAL SAFETY CONGRESS
NATIONAL SAFETY COUNCIL**

Industrial Safety Supervisors in Small Communities

Friday, September 30, 1927

**CHARLES B. SCOTT, Chairman
General Manager, Bureau of Safety, Chicago, Ill.**

The special session for Industrial Safety Supervisors in Small Communities was called to order at ten o'clock by the chairman, Charles B. Scott, general manager, Bureau of Safety, Chicago, Ill.

CHAIRMAN SCOTT: The work of any Industrial Safety Supervisor is definitely tied in with community interest and community activities in safety. The community needs the safety supervisor and his influence and he must have the interest and cooperation of his community. In industry our greatest problem is to build up a thoughtful, careful personnel within the plant and who must be selected from the citizenship of the community. Civic and home influences are the most powerful forces in the development of men and the channels through which men may be developed. Selfish aloofness by the industrial safety supervisor from these factors in our industrial interests is not good citizenship and is certainly not good business. That broad minded appreciation of our safety problem which encompasses the education of the child, the home influence and civic responsibilities and opportunities must characterize the successful safety supervisor whatever the type of his industrial operations and in every community, large or small. Thus, this meeting becomes an important one for we are to be told how these mutual interests may be advanced.

The speakers who have given their time and efforts to the subjects to be presented desire and deserve that you should follow each with snappy and pertinent discussions and for this reason we will not allow our program to lag. If there is not a prompt response to the invitations for discussion I shall take the liberty of calling upon many of you for your views. Our congresses give us a wonderful opportunity for expressing our own views as well as learning the views and opinions of others.

I shall now proceed with the program and we will hear from Mr. Frank Pollock of the Oliver Iron Mining Co., Eveleth, Minn.

The Safety Engineer As a Community Factor

Frank Pollock, Oliver Iron Mining Company, Eveleth, Minn.

Eveleth, my home town, is located on the famous Mesaba Iron Range in Northern Minnesota, sixty miles north by paved highway from Duluth which is situated at the end of the western finger of Lake Superior. Eveleth is a

city of 9,000, modern in all respects, with paved streets, sewer, water, fine public buildings; including the schools, which would do justice to a town many times its size.

Mining iron ore is the only industry. The Oliver Iron Mining Company for which I have the honor to be district safety engineer, employs close to 2,000 men, our company being the only large employer of labor. The city is next in line with 250 employees and the schools following third with 165 on the payroll. As the population of this town has a diversity of nationalities it may be interesting to know that only 32 per cent of our men are Americans, 31 per cent Jugo Slovenians, 16 per cent Finns, 8 per cent Italians, 3 per cent Scandinavians and 10 per cent others. It is evident that since the majority of the male population is employed by the mining company, there must be a very close bond between the miners and the homes in our city and everything that goes on around the works is of interest to the workers' families.

After four years of endeavor to "Safety-ize" a mining town we are convinced that any work done with this end in view is favorably reflected in the attitude of the employees toward the Safety idea in their work.

Aroused by the Deaths of Children

Five years ago when appointed to my present position the safety work was confined entirely to our own organization, with one exception: that of showing safety movies which were witnessed by our miners and the children of the community in one of our public halls. These pictures are still being shown once every two weeks to audiences of 500 or more children, two reels of safety and three of comedy making up the program.

A few public accidents occurred at this time which included the drowning of a boy who had trespassed upon mining property by swimming in a pond formed by a depression made in the earth when the ore was removed from below. The second kiddie was killed by an auto while he was observing the municipal Christmas Tree, which was placed in a hazardous position in the center of Main Street. Then two children were injured by playing with blasting caps which they had obtained from a road job close by. These accidents caused quite a discussion by our district safety committee which felt that something outside of their organization should be done to spread the safety idea throughout our community. A few of the committee, being members of the local Chamber of Commerce, turned to that organization for advice. They decided to form a safety committee as part of their regular program of work, making the writer chairman; the other members being the superintendent of schools, chief of fire department, chief of police, county mine inspector and two other men holding responsible positions in the community.

Local safety conditions were given consideration at the committee meetings and the most serious were brought up before the chamber for discussion. We feel, in handling this matter through a civic organization, with the prestige of a live Chamber of Commerce, that any safety suggestions broadcast over its signature is considered more seriously by the community than if otherwise handled.

In describing the work done in Eveleth through the efforts of the Chambers of Commerce safety committee, only the high spots can be touched. This can be done by citing the safety activities in our city under the following heads:

1. CIVIC—which includes schools and any municipal work.
2. ORGANIZATIONS—including clubs and associations; and lastly,
3. INDUSTRIAL—which takes in the Oliver Iron Mining Company, Minnesota Power and Light, Northwestern Bell Telephone Company, newspapers, garages, railroads, etc.

Realizing that 20,000 or more children are accidentally killed each year throughout the United States and that this total could be cut down materially through safety education, the local school board, when asked, approved of the safety program being carried on throughout the schools. The superintendent and supervisors of the different departments formed its first safety committee and appointed the head of the manual training department as its safety director. Membership was taken in the National Safety Council and a representative of their educational department was sent here to organize Junior Safety Councils. This was done three years ago and I will try to outline a few of the activities which are being carried on in our schools today.

Details of Eveleth School Training

Children, when they enter the kindergarten, are taught during the first month, how to cross a street correctly. In the primary grades safety slogans and poems are learned, while the pupils in the intermediate grades work mathematical problems which deal with accidents. Safety plays are presented. In the junior and senior high schools the Safety Council carries on the work. Safety bulletin boards have been installed in every room and National Safety Council posters are exhibited. In some of the rooms one student each day is made responsible for newspaper clippings covering some accident occurring the day before. This is first read to the class and then posted on the board. The art department students draw safety posters, the best of which are reduced to report card size, printed in the school printing department and issued each month with report cards. All students, before they graduate from the junior high school must be able to swim. Swimming instructions are given once a week to all pupils from the fifth grade up. They also receive training in life saving, prone pressure method of resuscitation, etc., during this course. In the home nursing department the girls receive training in first aid and home safety. During the summer months six playground instructors are employed. These playgrounds tend to keep children off the streets. Supervised play tends to lower accidents among children.

A thorough inspection was made of the manual training departments by this committee which resulted in all machines being properly guarded. During Fire Prevention Week, the schools are inspected by the local firemen who give talks to pupils on how to prevent fires in their homes, etc.

In the auto mechanics classes, students of 16 years or older receive special training in auto driving. You will say that boys and girls of that age are not supposed to drive a car! That is true, but, how often do we see them driving cars. Isn't it better to teach these boys and girls at an age when they are eager to learn and drill into them the safety principles which make for safety? Isn't it better to have them taught in this way than that they should be later compelled to learn the mechanical operation and the road rules out on the road? We believe this is a step in the right direction.

All accidents, both trivial and lost time, are reported by the student's teacher to the superintendent within 24 hours after its occurrence. These cards are kept on file by the safety director who classifies them as to *home* or *school* accidents and to their nature. It may be interesting to note that in 1925-26 term there were 32 lost time accidents while in 1926-27 only 5. These resulted in 224 lost school days.

We have observed that boys graduated from our local schools who have entered the company employ in the last year or so, are much easier to educate in safety lines of mining than those who come from elsewhere. It has also been noted that we are having few accidents with these young men.

Through the efforts of this committee an ordinance was drawn up and passed by the City Council forbidding all fireworks except those handled by municipal authorities on the Fourth. This law has been in force for two years and it is a noteworthy fact that there were no accidents from fireworks during that time.

With the assistance of the City Attorney a traffic ordinance which covers our arterial highways, bus regulations and liability insurance for taxi cabs was drawn up and passed.

The city joined the National Safety Council and has inaugurated a safety movement among its employees which number about 250. Men requiring goggles in their work are supplied with them by the city. Red flags and lanterns are used at sewer and water works excavations when such work is in progress.

At our public bathing beach, two life savers are in constant attendance during the summer months. Areas have been fenced off in shallow water for the younger children, who cannot swim.

The fire department puts on a Fire Prevention Week each year, making inspection of all the public buildings and the schools. The police department is active in trying to cut down the traffic accidents in the city.

Organization

Our safety movies have been used by the two local luncheon clubs on a number of occasions. Some of our company and Chamber of Commerce safety committee members belong to each of these organizations which helps to give a safety aspect to things that they carry on for the community good.

At our Parents and Teachers Association meeting, school and home safety has been broadcast through the medium of speakers and motion pictures. We feel that the wives of our miners through this organization can be made to realize what an accident to their bread winners means to them and their families, and a lot of good work is done through this association when followed up.

The Boy and Girl Scout organizations in Eveleth are well organized, there being a full time paid executive at the head of each. Scouts are given merit badges for first aid, life saving and public safety. The company first aid man has charge of giving part of the first aid course to all our scouts. The American Red Cross expert visits our camps and gives advanced training in life saving, while the chairman of our company safety committee also is chairman of the merit badge examination committee. The writer has been chairman of the scout camp committee for a number of years. Work in subjects such as life saving, canoeing by American Red Cross instructor and woodcraft are carried on. As the motto of this organization is "BE PREPARED" we believe that more of the boys and girls of our country should be given a chance to attend summer camps thus preparing themselves for any emergency that may present itself in their daily life.

Industrial

As a majority of the men in our city work for the Oliver Iron Mining Company, naturally anything that affects these men affects the community. It might be interesting to know that the early methods of promoting safety among our employees proved unsuccessful because of lack of interest in the movement by both the management and men. Safety meetings were held on the men's own time and broken safety devices were left to go unrepaired.

Five years ago our company began its intensive safety campaign. Safety meetings are now held on company time and machines with faulty safety devices are shut down until repairs are made. Educational methods have been introduced throughout the works in order to train our men how to work safely. Safety bulletins covering mine and home accidents are issued each month with the pay check. Our new employees receive their first instructions in safety from the employment supervisor, which is followed up by the foreman on the job. Every employee receives a pair of goggles and is instructed in their use. We have five motion picture theatres in the district where all our men have a chance, at least once a month, to see a safety movie. At our monthly workmen safety meetings, accidents in the home, on the highway, as well as those at the works are discussed. Our company nurse visits the homes of our employees and stresses safety in the home, and also teaches

Example of the School Safety Poster

the essentials of first aid to mothers. The progress in mine safety might best be illustrated by records of the Eveleth District of the Oliver Iron Mining Company which shows 477 lost time accidents in 1920 as against 28 during 1926. This means that 449 homes in our city remained happy last year, which goes a long way to make a better community and more prosperity.

The Minnesota Power & Light Company, realizing that the commodity they handle possesses swift death dealing possibilities to both employees and consumers, joined the National Safety Council and perfected its own safety organization a little over two years ago. After doing so, they employed the mining company's first aid instructor who taught their men the essentials of first aid and the prone pressure system of resuscitation. We have noted their men pulling tacks out of posts which have held advertising cards which they

considered a hazard to men climbing same. They have also put on a service man who spends the greater part of his time visiting the homes of people, showing them how to use special electrical equipment and repairing the cords on these machines when necessary. Men are sent through the city schools periodically, calling the children's attention to the danger of playing with live wires, etc. The city police department cooperates with the organization by reporting any hazardous condition of the power lines they may observe.

By using safe methods in their work and spreading the general idea of safety throughout the community, this company feels that they will occupy a higher place in the minds of the general public.

Our two weekly newspapers have been of great assistance in broadcasting the safety idea throughout our community. Such subjects as fire prevention,

home safety, state and city traffic regulations, have always been given special consideration by these editors. They have always been boosters of safety, and through their editorial columns are active in bringing unsafe practices before the public.

An inspection was made of the buildings housing public garages and filling stations and a number of improvements in ventilation which would intend to reduce the carbon monoxide hazard were recommended. Notices were posted at all filling stations requesting car drivers to shut off motors when being supplied with gasoline, thus reducing the fire hazard. Posters which have been sent out by insurance companies and National Safety Council on the much discussed carbon monoxide hazard are always passed on to the garages. We feel that much can be done in warning the traveling public by posting these bulletins and through live wire gas station or garage attendants.

The two railroads which haul ore out of our city and the telephone company are members of the National Safety Council and maintain active safety organizations.

It is needless to say, with all these safety activities going on in a small community, that some favorable results should be attained. In this country of lakes children go to swim where there is no supervision. We note there have been no fatalities among them in the last two years, which proves that swimming is an essential in any educational system. Our traffic ordinance has been in operation now for two years. During that time there has not been a fatality in our city limits caused by an automobile. We know of any number of cases of men in our employ telling us of safety ideas which the children have brought home from the schools. All of which proves to us that the time and cooperation spent in securing the above warrants the expense that our company has gone to in Eveleth in order to make our community free from accidents.

Details of the Prize Garden Contest

CHAIRMAN SCOTT: Mr. Pollock, you have given us a very interesting and profitable discussion on this subject.

Before we begin the discussion, are there any questions which anyone desires to ask Mr. Pollock? What is population of Eveleth?

MR. POLLOCK: About nine thousand.

F. C. MILLER (Power, Fuel & Iron Co.): I should like to ask about your prizes for gardens, and can the same party compete year after year, or are they eliminated after they win the first prize?

MR. POLLOCK: They can keep right along. We don't take the employees, but we take the park superintendents of two or three of our large cities and they visit my house, or my neighbor's house and decide at the end of their trip who should get the prizes. We classify as to locations and as to company-owned houses, or what we call "squatters." You can't buy land up in our country, you have to "squat," and that costs you one dollar per month.

Two squatters got the first prize this year of ten dollars apiece. They were in two different locations. We give ten, eight, five and three dollars—that is, four prizes, in each location for company-owned houses or squatters.

MR. MILLER: Our company gives four prizes in each of our four or five attempts, but we have found it necessary to eliminate a prize winner for this reason. It is so outstanding that that individual could just continue to take the first prize each year for evermore. So, as an incentive to new competition, we keep eliminating for a period of five years. That gives the other party a chance for the prize.

MR. POLLOCK: We don't. If a person has ambition enough to compete for first prize year in and year out, we give it to him.

CHAIRMAN SCOTT: We will allow five minutes for further discussion.

I. GORDON (Bureau of Safety, Chicago, Ill.): I want to ask Mr. Pollock in regard to the films. I believe you said you show safety films and comedy films. Who pays for these films, your company?

MR. POLLOCK: The company pays for these films. We get our safety films from the National Safety Council. The mining companies do not charge us for any films and the films we get from the National Safety Council are very reasonable, probably cost us about twelve dollars a week for them and we figure it is worth while.

CHAIRMAN SCOTT: Mr. Arkills, will you please discuss this paper for a few minutes?

M. E. ARKILLS (The Waterfront Employers of Seattle, Seattle, Wash.): I have had very little experience in small towns on safety, but if I were to be a judge of this paper, I would say that the safety man is pretty near the whole thing

in this little town. At any rate, there is no doubt but what the safety idea, put over as he has put it over, has done a great deal for the health and happiness of that community, and he has occupied a tremendously important place. The work he has done there should be an inspiration to every man, even in a large town, to put over some of the same activities that he has put over. I doubt if very many of us are utilizing the means that are right at our front door to carry on some of the activities he is doing.

I have talked before but one school and I think that probably spoiled my chance of talking before another; nevertheless, I am sure a great deal of good could be done through the schools, even in the larger cities, if it were properly approached.

CHAIRMAN SCOTT: Now, we have with us Miss Lee of Birmingham, Ala., who has a number of connections with the National Light Association, and is very active in the work of that institution. I ask Miss Lee to discuss this presentation.

MISS ELIZABETH S. LEE (Alabama Power Co., Birmingham, Ala.): I try to put in almost twelve months of the year working for my company, on my every day job, and between times I get in work on the Women's Committee of Public Relations and work on the Educational Section and on the Accident Prevention Section, so I don't have much time left except to sleep a little.

I was very much interested in Mr. Pollock's talk this morning and there was one part I was thinking of especially, that is the contacts with the Parent-Teacher Association, which probably gets in contact with most of the home makers of the community. I don't know just how far they extend in the majority of cities, but it seems to me that would be a wonderful contact for furtherance of this work to get in touch with groups such as women of the utility companies, the electric light, power and the gas companies, and in the manufacturing companies. That would give the women in the home more expert knowledge than I think they obtain from a few people going out from schools or safety councils or others in talking to these groups and in mingling with these groups of women and getting them interested. That is, because you would have numbers of women who are experts in their own line talking to these groups of people. It seems to me it would be a wonderful contact there if that could be brought about, and especially where women are using electricity in the home. I believe women would probably pay more attention to other women because they have their same point of view in teaching them any hazards in connection with electricity or gas, or whatever it is. Not with the idea of scaring them, but we want to present it to them in a constructive, positive manner, because we are going to use these things in modern life and they should know how to use them properly instead of improperly.

CHAIRMAN SCOTT: The next subject is "Cooperation With Representatives of Other Local Companies" and is to be presented by Mr. H. Henry of the Mansfield Sheet & Tin Plate Co., Mansfield, Ohio. I take pleasure in introducing Mr. Henry.

Cooperation with Representatives of Other Local Companies

H. H. Henry, Mansfield Sheet & Tin Plate Company, Mansfield, Ohio

Safety, both industrial and general community safety, as well as many other activities of interest to employers and employees alike, in Mansfield, Ohio, have received excellent stimulus through the cooperation of the Manufacturers Club, in the past nine years, under the able leadership of Wellington T. Leonard, now Member of the Industrial Commission of Ohio.

Industrial safety received his enthusiastic attention and cooperation as early as 1921. I might say here that our Manufacturers' Club is not a manufacturers' club in the strict meaning of the word. While financed by the manufacturers

It is a club where the employees of our community have felt free to consult and seek aid along any and all lines; and I believe it has built up an enviable reputation for the success of its work among the employees as well as in those matters of interest to the employers of our community.

Among the activities of the club, in the past ten years, have been the establishing of an employment office, industrial publicity bureau, industrial surveys, relief campaigns, civilian rehabilitation committee, vocational training in our schools, etc., and Mansfield has now in its schools a vocational training equipment and personnel much better than in many larger cities in our state. Mr. Leonard, because of his extensive experience in newspaper work and exceptional knowledge of human nature, because intensively interested in the safety movement, primarily, I believe because of its human appeal and the opportunity it afforded him to give support to a movement that would eliminate to a large extent pain, suffering and financial loss in the families of injured workmen.

Mr. Leonard's enthusiasm was contagious and he never failed to have a large representation from practically all industries, large and small in the community whenever a meeting was called to consider any phase of the safety movement.

Stimulating Interest in Greater Safety

Realizing that there was little knowledge of the Ohio Workmen's Compensation Law, and little attention paid to the then existing safety codes, Mr. Leonard in 1920 invited T. P. Kearns, chief of the Division of Workshops and Factory Inspection, of the Ohio Industrial Commission, to address a joint meeting of the employment managers and superintendents. Mr. Kearns explained the act and the compulsory feature relative to the obligation of the employer to safeguard his workmen in accordance with the various codes. He also agreed at this time to send a number of inspectors into our community and make a more intensive survey. Codes were distributed to all the plants.

Interest having been stimulated the question of rates, reserves and merit rating system under the Compensation Act next received attention; and Emil E. Watson, actuary of the Industrial Commission, was invited to address a meeting of managers, superintendents, and employment managers. A second meeting was held a few months later and further information along the actuarial line discussed by P. F. Casey, now chairman of our Industrial Commission.

About a year later the state inspectors and safety engineers, because of the enthusiastic reception accorded them thought that Mansfield should have an "Industrial Safety Education week." The Manufacturers' Club sponsored this week. Talks were given in all the plants, the newspapers gave the work a large amount of publicity and many of the retail stores carried safety displays of guards and posters.

The Mansfield Sheet & Tin Plate Company, being the largest employer of labor in our community, employing approximately 1,800 men, has equipment consisting of four open hearths, bar mill, seven tin and 12 sheet mills, and having inherently the most hazardous conditions, became interested in safety in 1921, and I was appointed safety director at that time, after several years' experience in the Youngstown district. A constructive program of engineering revision, education and enforcement was entered upon. A large force of guardmakers was immediately put to work guarding the numerous hazards, under the leadership of a very able guardmaker foreman. Our plant has been described as a museum of safeguards by several inspectors and safety engineers. Being the pioneers in safety work in our community, representatives of other plants were invited to inspect our safety, hospital and compensation departments. Our management also very heartily endorsed our efforts to spread the safety idea and movement to other industries and the schools. Effort was also

made by our company to gain new members for the National Safety Council and encourage them to send representatives to the annual Congresses.

The efforts of the Manufacturers' Club in sponsoring the safety movement in Mansfield and the success attained became known outside our community and our local club was instrumental in spreading the cause of safety and stimulating interest among the members of the Central Ohio Manufacturers' Club, and many safety talks and discussions were given before this association as well as plant inspections and talks at individual plants affiliated with this organization. In 1923 when effort was made to strengthen the Workmen's Compensation Law of Ohio and the amendments were receiving much discussion among employers and employees, representatives of our club and industries were looked to for information and leadership and many talks were given not only in the industries in our section of the state but in granges, schools and service clubs and trade associations.

The State, having accepted the offer of the National Congress to establish Civilian Rehabilitation, Richland County, in which Mansfield is located, lost no time in appointing a committee to carry on this work of rehabilitating the civilian cripples injured in industry. This committee was selected from recommendations made by the Manufacturers' Club and the writer was made its chairman.

Getting the Foremen Interested

In 1924 a City Foremen's Club was organized, largely through the efforts of our Manufacturers' Club and the cause of safety was further enhanced through the opportunity this organization gave of bringing the safety idea to the foremen of our industries. Many prominent men throughout the country have addressed our foremen's club, including Past President Auel of the National Safety Council.

The Mansfield Sheet & Tin Plate Company sent a delegation of 25 foremen and superintendents to the National Safety Congress at Cleveland in October, 1925. After their return it was realized that the third thing necessary to attain a good accident record must be enforcement. Engineering revision and education had received much time and thought, still accidents especially non-mechanical, were very high. Due to the combined efforts of management and men lost time accidents immediately dropped. The average lost time accidents per month in 1925 had been 28; in 1926 they were cut to 6½, a decrease of 69 per cent over 1925 and 79 per cent over 1924; and frequency dropped from 118 to 19.6. A number of records were established, among which were a decrease of 97 per cent in days lost due to permanent partial disabilities, and premiums were decreased 20 per cent over 1925 rates.

This very favorable experience by our company undoubtedly served to increase the interest of other companies in our community and safety departments were established among five other large companies; and nine new members were added to the National Safety Council in Mansfield and surrounding territory.

The interest and activity in the cause of safety on the part of the Manufacturers' Club culminated in May, 1927, in our club sponsoring, with the cooperation of the Department of Safety and Hygiene of the Industrial Commission of Ohio and our Chamber of Commerce of Mansfield, a Community Safety Education Week in Mansfield. Excellent cooperation was had from all organizations, City and County officials, Chamber of Commerce, Schools, Women's Club, Boy Scouts, public utility companies, mercantile organizations, etc. Many safety men of national prominence were brought to Mansfield and a very extensive program carried out in safety education. An accident survey, both indus-

ial and public had been made over the previous year by the department of business research of Ohio Wesleyan University and much publicity given to the results obtained which showed that in a city of approximately 40,000 population 29 deaths had occurred, of which 11 were in industry. In addition there were 4,355 industrial accidents, involving 96,803 days lost; 580 of the industrial accidents resulted in over seven days being lost. There were 14 traffic deaths.

Safety meetings were held in all the industrial plants, schools and churches, before all service clubs, women's organizations, parent-teachers' clubs, etc. Other meetings were held of mercantile, construction, city and county employees, railroads, public utility companies, playgrounds, commercial vehicles; and the safety message was broadcast two evenings from our local broadcasting station. Streets were painted with safety slogans and safety zones marked off. Placards were liberally placed on telegraph poles, in windows of stores and in the homes as well, so that one could not go far without having the gospel of safety brought to their attention.

I believe our cooperation with representatives of other local companies, through our local Manufacturers' Club, has resulted in a substantial decrease in accidents in our community and the saving of life and limb, as well as increasing the economic wealth and happiness of the members of our community. We have at least awakened our community, through safety education, to realize its responsibility in accident prevention and to appreciate the advantages that can be attained through a concerted and well organized effort to make the community safety conscious. Safety is not only an industrial problem but a public and community problem as well. The principles involved in the eliminating of public accidents are precisely the same as those involved in the elimination of industrial and home accidents; we must first locate the accident causes and then devise ways and means of eliminating or minimizing these causes. If the effort to build up the habit of reasonable carefulness as opposed to life-destroying habits of carelessness is to be successful, it cannot rest with one week's intensive effort, but must be carried on systematically throughout the year. The long recognized obligation of the employer to provide the safest possible conditions of work must be spread to every individual of the community in order that human life may be safeguarded at all times. Until the time comes when we realize that no one is safe unless every man, woman and child habitually practices carefulness—not until that time will our task be done.

Community and Plant Have the Same Interests

CHAIRMAN SCOTT: Mr. Henry, we thank you. Mr. Fred S. Armstrong of the Central Illinois Public Service Company, Springfield, Ill., will tell us what he thinks about the cooperation of safety directors in small communities with those of other companies.

MR. ARMSTRONG: Mr. Chairman, I am not capable of talking to you about accidents in industrial plants because I have never had any experience in that work. The company with which I am associated is a server of utility products, gas and electricity, etc., in which we are scattered over some 340 communities in the southern part of Illinois.

We believe that whatever is for the good of any single community that we serve is for our good and we are thorough believers in safety. So strongly do we believe in that, that during the past three years we have talked safety to over 160,000 school children in our properties.

We have taught them resuscitation and artificial respiration and as a direct result of that work in the schools there have been three who have been resuscitated from death by the abilities of their companions through the knowledge that they gained from our instructions. If nothing else has been done in the safety work in those

communities except those three lives being saved, the work has been paid for. Those lives were as precious to the families of which they were members as are the lives of the members of our own families; and whenever we lose track of the fact that human life is the most precious thing there is in this world, our safety work will be a failure.

MR. HENRY: What I wanted to add was the influence we have had regarding the safety council of Mansfield which resulted in five plants putting in safety and compensation departments. Three of our larger plants have this examination and we have a representation at this congress of about 15 from our community where, I believe, three years ago, there were only two or three. I think from that possibly you can get the idea of how we have spread the influence of the council and the membership through our community.

CHAIRMAN SCOTT: I wish we had more time for discussion. The next subject, I am sure, will be of interest to all of us. This will be given by Mr. Irvin J. Ott, Worden-Allen Co., Milwaukee, Wis. Mr. Ott.

Combining Safety with Recreation

Irvin Ott, Worden-Allen Company, Milwaukee, Wis.

Assuming it is true that a man's mind continues to turn over impressions even as he sleeps, a very significant fact is brought to our attention. In every 24 hours there is a period of 16 hours when your employee is not under your direct influence and control, but is, I contend, during that period, in a state of mental and physical relaxation that makes him much more highly susceptible to properly introduced influence than when at work.

It behooves us, then, to cast about for ways and means of utilizing this valuable period, so as to best accomplish our accident prevention aims.

A wise man recently said about the fair sex, "You think it is cute to have her slip her hand into your pocket—until after you marry her." Still, how else is she to get hold of our safety propaganda for home broadcasting, if we continue to hand same out to Tony at the shop, who absent-mindedly chucks it in his pocket, to be forgotten?

There are two mighty big reasons why. First, we should create safety propaganda for relaxation periods; and, second, Tony's wife should see it. In the first place, harking back to my original contention, which I think important enough to repeat, we want to reach our employee after he has gotten home from work, because it is logical to assume that during relaxation he can best be influenced. Influenced by whom or what? That's where Tony's wife comes in. The proverbial feminine tongue is still, I believe, the best means of speech repetition, so why not assure ourselves that Mrs. Tony is going to help us out?

To this end permit me to tell you about the plan our firm and several others I know of, practice. At regular periods, a notice is gotten out, bearing on safety, which contains either complimentary remarks about a satisfactory no-accident record; or if the reverse is true, a general synopsis of a poor accident record, and further notations that the recipient and his family have our sincere wishes for their welfare. These are mailed to the home, and of course the wife and family have an opportunity to discuss same; the wife discussing it, no doubt, far, far into the night, as Briggs, the cartoonist, would have it; and of course, bearing out my original contention that it is possible with proper methods to push this recreation safety so as to have it function 16 hours out of 24.

This all helps but it isn't everything that can be done. We all know the value of safety posters. Did you ever stop to realize what it would mean to

place one in your employee's home? The National Safety Council has made such a thing possible in the creation of their annual Safety Calendar. For several years, we have used this and as a means of promoting safety discussion in the home, in my opinion, its value is inestimable. Our welfare department, when visiting the employees' homes, finds the calendars hanging in prominent positions in the house; and what more can we ask than to have such an ambassador functioning for us right in the homes?

In passing, another thought occurs to me. This home accident prevention work, without a doubt, will tend to lessen domestic accidents, also, creating for us a much more contented and efficient employee, than the man whom family misfortunes often turn into an accident hazard or, at least, an absentee.

There is still a period of recreation that does not concern the home. During the noon hour and other rest periods and also during the early evening in some localities, a portion of the employees are prone to indulge in athletics of one kind or another.

It has been found necessary in our locality to give this matter our attention. Our employees, during football season, endeavored to play the game in their everyday overalls. After watching the gory results, we insisted on their playing a compromise game which consisted of tagging the man who had the ball, instead of tackling him. The system worked out fine and since then, we have had no bad results.

We have consistently discouraged the use of hard baseballs for recreation purposes at our plant, supplying the regulation playground ball, and it has worked out favorably, to the extent our plant is now in a soft ball league, formed with other companies who had the same safety ideas.

In this connection, the hazard from too small a space to play forms a problem for the safety man. The necessity of having to field the hit balls on railroad or street car tracks, or even on the street or road forms a stumbling and traffic hazard worth consideration. A wire mesh fence with conveniently spaced gates, generally solves this problem, as it deters the thoughtless runner, who, after a ball is knocked over the fence, merely goes through a convenient gate, retrieves the ball and play is resumed.

You might question the necessity for all this, as having little more than a humanitarian motive back of it, so to show its financial value I quote from our own Wisconsin Industrial Commission's report dated July 10, 1927, which has this paragraph of warning:

Compensation Liability During Noon Hour or Other Intermission

"It has been repeatedly held by courts and by this commission that any employee is within the protection of the Workmen's Compensation Act if injured during the noon hour or other intermission because of a hazard created by the industry. The employee need not be at the time of the accident performing actual services for his employer. Being rightfully on the premises in the capacity of a servant at the noon hour or other intermission and conducting himself in a manner reasonably to be contemplated by the employer, he is entitled to protection against a hazard of the plant or premises the same as if actually performing services. He is at such time, in contemplation of law, to be taken as in the performance of service growing out of and incidental to his employment."

This I believe speaks for itself.

So far, I have confined my remarks to the very selfish problem of recreation safety as applied to our employees. We are all supposed to be safety men from small communities, where it, no doubt, becomes our lot to interest ourselves in the matter of civic recreation safety also.

This brings to my mind the appalling number of juvenile accidents yearly and the extreme necessity for interesting ourselves in this connection.

In the United States it is a matter of record some 4,000 children are killed and some 250,000 seriously injured each year. In the city of Chicago, in 1925, 171 children under 16 were killed and 520 seriously injured through traffic accidents, bearing out the dire necessity for more safe play spaces and properly supervised ones.

We men from the small communities might endeavor to close our eyes to this and say that the small community does not have the traffic hazard to contend with. I would like to point out that in quantity of vehicles, the small community may not suffer as to accidents, but the rate of vehicle speed is generally greater than in our larger towns, hence the necessity for keeping children off the street.

The Playground and Recreation Association of America has provided a great deal of information on the subject of child recreation safety, and I would strongly recommend any one interested in this branch of our work to get in touch with it.

Promoting Safety Through Recreation

Recently the association published what they considered were the effective ways a local safety executive could best promote safety through recreation.

It asked for your cooperation with local recreation authorities, or in the absence of such, with local Chambers of Commerce, churches, etc., in securing more playgrounds, play streets (streets blocked off from traffic during play hours), more bathing beaches or pools and more picnic grounds.

They asked that you urge the fencing of all playgrounds.

To help work out plans for properly supervised coasting and skating places, was another plea.

To bring to the attention of playground directors new traffic games or other plays that teach safety, was also urged.

The concentration of our attention on this matter of child safety has in my opinion two big benefits. First, whatever the children are led to do along the lines of promoting safety will exert an influence in the home, for youngsters are sure to talk about such things, so that not only the child, but the whole family indirectly come under our influence.

Then, secondly, we are instilling safety into our future employees, making our job a much easier one, when the time comes for us, as the employer, to personally direct their welfare.

And after all, that is our big task and primary object, the education of employees and future employees, to develop their thinking along lines of safety, eliminating thereby our chief cause of accidents today—thoughtlessness.

Let us bear in mind that safety, in view of the facts just mentioned, can be considered a 24 hour per day responsibility with us, for all ages and sexes; and accordingly I would respectfully commend your future thoughts and deeds in this connection to a consideration of it as such.

CHAIRMAN SCOTT: Mr. Ott, we thank you very much, ~~Milwaukee~~ always brings a lot of information. Mr. Gordon, will you discuss that subject from your point of view?

I. GORDON (Bureau of Safety, Chicago): First, I think this a good hint to safety supervisors, that the employee is on duty at noon hour, at a time when we would naturally suppose, if he got hurt playing ball the company would not be responsible for the accident. I think that is something we might think about and consider.

I was impressed with Mr. Ott's remarks in carrying the safety work into the homes through the school children. It has been my pleasure and privilege to talk

to a large number of school children and I know there are many hazards in the school that, perhaps, the teacher doesn't consider a hazard, and I think it the safety man's duty to point those out at the time he talks to school children. This will emphasize the hazards that confront the children while at play and when their minds are busy with play and not hazards.

School teachers should give some thought to the things that the children are doing while at play. Who has not seen eight or ten boys in a group make a pile of jagged stones and then about 50 or 100 feet away another group of boys pile up another pile of stones, and engage in throwing these stones at one another for fun. The boys do not realize the possibility of a very serious accident. At the time a boy may be picking up a stone, he is not looking, of course, and there may be a stone coming toward him just as he faces the other group of boys, and it may result in the loss of any eye, or other serious injury.

The teachers should see that the play apparatus is inspected frequently for defects, and whenever there are dangerous defects forbid their use until repairs have been made.

Now as to climbing. I doubt very much if the teachers realize the danger of boys "following the leader," as we used to play in school by daring each other and doing some very dangerous stunts. For instance, the boy who climbs ten or fifteen feet high on a wall, a shed, or a roof, and the boy on the ground looks up at him and says, "I dare you to jump off." You have challenged the bravery of that little fellow, and without thinking he looks down and says, "I don't take a dare from nobody." Not very good English, but that is the way they put it, and after he jumps, expecting, of course, that the other boy will run up and commend him for his bravery, his only reward may be a broken leg.

I try to get the children to realize that the boy who dared won't praise. The chances are he will go up to the injured one and say, "I thought you had more sense than to jump off of a high place like that." Now, if we can get boys to realize that it is just as brave to say, "No," to a thing that is wrong, as it is to say "Yes" to a thing that is right, I think you have taught them a safety lesson.

The little fellow who has been dared should realize the danger of doing the thing that he has been dared to do and should say to the fellow who dared him, "What do you think I am, a dumb-bell? If I should jump off of this high place I might have a bad injury. I would suffer and not you." Oh, there is a wonderful avenue for teaching the children the safety lesson in their play or at their play.

CHAIRMAN SCOTT: The next and final topic on the program is tied in very closely with the subjects which have just preceded it. This paper will be given by Mr. C. Ziolkowski, of the U. S. Gypsum Company, Chicago.

Selling Safety to the Worker Through Community Activities

C. Ziolkowski, United States Gypsum Company, Chicago, Ill.

The remarks made by the first speaker here about the fact that some of our speakers are from Chicago, Youngstown, Mansfield, etc., and that they might have little connection with work in small communities, may have been somewhat misleading. I am sure most of them have had experience in small communities. In my talk, which I will make as brief as I can, I will deal a little more in abstract than in definite detail with community activities. What I have in mind is communities where plants are located with an employment roll of probably two or three hundred, usually companies engaged in the process of mining or pouring, where you have to locate your town around your natural deposit, wherever it is found, and build the town. A town

of that type usually has 600 or 700 inhabitants and the safety man there is not only a safety man but a personnel man and a community man, all put together.

I am sorry, as the chairman remarked here at the beginning, that the number of men who attended this meeting is small, because I believe that the safety supervisor in a community of as small a nature as I am mentioning, has a job that is peculiarly his own. He may not represent numerically as many employees as some of our supervisors or big railroads or other industries; but you will find a great many more plants scattered about the country in communities of say from five hundred to one thousand, or possibly two thousand. Therefore, I think if they met together they could find a lot of problems that are common to them to be discussed.

Your safety supervisor in the real small communities that I mentioned is primarily employed, of course, to prevent and keep down accidents in the plant and at the outset, the work takes up practically all of his time so that the community work is not given very much, if any, attention and probably in some instances, he doesn't even consider the community angle of it at all because he may feel that "I am hired to take care of the safety of the plant and beyond that, if I have time, all right, I will do it."

I believe, however, a safety supervisor who is really, in the true meaning of the word, a safety supervisor, is interested even beyond the plant. They should be, at least. He should be imbued with the spirit that moves our accident-prevention work sufficiently to get out of his sphere of the plant gates in his work and influence that he can exert. It will mean, of course, sometimes, in most instances, extra work, sometimes after working hours, but that goes along with what I explained about the feeling that he should have towards safety. A few extra hours of work shouldn't make such a tremendous difference.

I also believe work in a community of that size (I speak of from 2,000 to 3,000), is greater than in the larger community. He has more personal contact, and, as far as direct contact is concerned, he can do more in the hours spent in the work than possibly your men can in the larger cities and it should be an incentive for him to do it.

Carrying Safety Influence Outside the Plant

Now, I shall go briefly over the reasons why I think he should go into community work to help along his plant safety work. I am speaking from the angle that the work is not being done. I mean, he is not taking interest in community work and I am trying to show why he ought to, both from a humanitarian interest and probably a slightly selfish interest.

The papers prepared before me have all shown things that have been done and they were marvelous. I think, especially about the Minnesota Mining Company, which was excellent, and it gives us an idea how far you can develop community activity. Of course, all of us are not fortunate enough to be with companies of that size and that have the financial means to do all that Mr. Pollock stated he was able to do up in Minnesota.

Fundamentally, I think one of the main reasons for a safety supervisor (or the company he represents) interesting himself in community safety is one that has been mentioned before, and that is to carry the safety influence beyond the company property.

The employees quite often consider the interest the company takes in safety as somewhat of a selfish proposition. They say, "Well, they save a lot of money by getting us to work safe," sometimes forgetting the benefits they derive from being safe and saving their families from hardship. I believe you can confute that argument quite strongly because you can point very distinctly to who will be benefited by taking active interest in community safety. Through this the employee will understand, and rightfully so, that the spirit which moves the safety work at the plant is

ader than the plant alone. It goes into the community and into the lives of the ves, brothers, sisters and children, not only during working hours but after working urs, also.

The influence the family has on the employee is going to produce results, I think, t are greater than you could possibly produce at the plant. You use discipline at : plant, as well as education and some other ways. But when the family talks to : father or brother about being careful when he is at work, he knows that they only ve an idealistic, unselfish idea. He is much more likely to listen to them than to : one at the plant, because he knows at the plant he is not among people who are ated to him and it is an industrial and commercial proposition. I think the family luence is far greater.

Another thing it does, is to interest the family in accident prevention as far as the mediate family is concerned, the children, mothers and sisters, in their homes and the streets, and it spreads that gospel of safety in the community. It also gives : plant an opportunity to outline to the families the real motives behind the indus- al safety movement. It tends to quiet any false rumors about what is happening in : plant and gives a right picture of the conditions as they really are and gives the l reasons for safety work at the plant.

A Vital Interest Lies in the Community

Also, I think one of the biggest reasons for taking interest in community safety that it shows the company's interest in general, not only in safety as it stretches pond the plant gates, but it goes beyond them into the communiy and they really : vitally interested in how the community, as a whole, fares.

Of course, there is no question about this in a community where the company owns : land surrounding the plant and rents the houses to the employees; but the ques- n might come up where you have several industries and there is not the spirit of t one corporation. In communities where you have more than one industry, it will d to bring a closer cooperation between these industries in safety work; whereas : tendency so often is that each one works on his own hook and there isn't very ch contact or exchange of experiences in the safety work. When you create this ion of ideas and let down the barriers of reserve or coolness, whatever it may be, : have taken a very definite step in helping not only your own records at the plant, : the safety record of other plants also.

Now, I think one of the biggest reasons (I left it for the last), why you should e an interest is the effect that it will have upon inducing other companies to take : safety work and in that way lighten the burden of your individual plant when v men are employed. I am a strong believer in the idea that eventually every nt in the United States, and in the world, will have safety work developed to such legree that when you get a new man you will not have to go through all the ele- ntaries of showing him first aid, or what he should do in the case of an accident. y you had a fellow come from the Jones Company and you asked him what he uld do if he cut his finger, and he said: "We put some chewing tobacco on the and go right on with our work." That makes it difficult. You are starting at the tom.

But if you could get all your industries, especially in the small communities (where : people live for years and seldom change), vitally interested in safety work and hing it, you will come to a day when, regardless of who comes to your employ- nt office, you are certain that he knows the fundamentals of safety and understands at it is all about. All you have to do is impart to him any additional rules which : required because of the different operation, which are mere details, and you have ttered the burdens considerably.

Now, in starting a program of this kind in a community that hasn't had it, the n of finances, of course, is always a very touching one. I have found in the small

community work that you would like to do a lot of things until you get to the point of what it costs, and then the thing dies down. That is where I believe the ingenuity of the safety supervisor comes in. He can devise means. I have a hobby of my own, my personal way. I usually like to arrange entertainment with local talent. You know how in small localities you have opportunities such as you don't have in large towns. Anything with local talent goes over big; and the funds you need aren't always so great that you can't raise them through such means as athletics, or other things—sometimes in which you can get your community interested to attend and raise money that way to start it. Small communities, the term itself means a lot. You will have to adjust the plan to your community, as to organization.

Now, I would say, wherever a community can, it should organize a local council. You can do the work through your Rotary Clubs, Manufacturers' Associations, etc., but if you specialize on safety and organize a local council, I would say your job is going to be better done than if you place it with some organization which will consider safety as only part of its program. However, I know that some communities will be so small that you won't be able to do that. In such cases, you will have to use whatever clubs or organizations you have and get them interested to such an extent that they will take part and push the safety program.

One of the things they did was to arrange a safety week or month. Arrange to have all the plants in a safety campaign at the same time; and not only advertise them and give them publicity in the plant grounds, but give it publicity outside and by placing your plant signs on wagons and store windows, so the whole community becomes conscious that there is a special effort being made in the community; and I am sure it will result in a very effective way on the accidents in the community, too.

A Big Safety Opportunity in the Schools

Your school, of course, is a very vital medium as mentioned here. There are quite a few things which are a repetition. If you are furnishing the posters that the National Safety Council make up especially for schools, or any literature that you have on public safety, make it so that the schools can get them. An essay contest. I am sort of a bug on that, because it has been worked successfully in several of our plants. We have a safety community campaign, and at the time the campaign is on, we get in touch with the principal of the school and tell him about our plans and get his cooperation to such an extent that he announces an essay contest. Perhaps the subject will be "Why Should My Father or Brother Be Safe in Working in a Plant?" Then prizes are awarded to the best essays which are written; some in the first few grades and then up through the higher grades. It was really surprising what a response we got and quite often we knew the paper was dictated by the father or brother because the wording was similar to that of the plant; but it got them to sit down to the table at home, whether the father dictated the paper or not.

Another excellent way we have of getting safety through the home to the child is the use of our picnic. I felt rather guilty about that. A picnic is supposed to be a free for all pleasure, but we didn't let them go by without having some safety stunt after the races were over which would bring safety to their minds even while they attended the picnic. In our campaigns we have a safety show or rally, where movies are shown, and, of course, I presume most of you do this. You are missing a good bit if you don't attend and invite the family to attend this rally so they know what is happening in the plant.

Then, of course, there is your first aid contest. You organize your first aid teams, have a contest and make it public so that the families can attend and benefit, if possible, by the training that the contestants receive.

Then, there is your visiting nurse, if you are large enough to be able to keep a visiting nurse at the plant. I think she is a vital factor. You can utilize her services considerably in the plants and in the homes when she visits them.

Then, you have larger communities where you want traffic laws. I think whatever you organize, the Rotary Association should take a very active interest in demanding that these laws be adhered to for the safety of the inhabitants of that town, providing crossing signs for the community and around the schools. Then, if you have a plant publication of any kind, a very vital meeting is a community factor. I find in many instances, though, even though the plant publication is issued, it doesn't reach the home. Of course, there are several ways you can overcome that, even by mailing it to them at their homes. Or, sometimes, the fault is at the plant, so that the people at home who look into it are not interested. If you put all the material in it about the plant and nothing about home gossip, you are not going to get their interest.

I think it is a good idea, once in a while, to take a Sunday, or Saturday afternoon, and invite the workmen to bring their wives or their relatives with them to visit the plant. It gives the family an actual picture of what is happening at the plant. They hear so much at second hand that sometimes the attitude that the home relatives have regarding what is being done at the plant is not fair to the company.

Of course, if you have a newspaper in the larger communities, naturally you are going to use that for publicity and most of our contests are arranged in the plant itself. Or, if you represent a company that have several units and it is an inter-unit contest, I think in the small communities it is a wise stunt to arrange an inter-plant contest in that particular community. It may be two or three towns, or it may be in one town; but regardless what business you are in, get together, because that will bring out the civic and community spirit in the accident-prevention work.

That, for individual items, is about the list as I have prepared it, and, I say it is very difficult to say definitely for another man's town what he should do to get started on community safety, because it all depends on your local conditions. I have tried to speak in an abstract way so that you can pick what applies to your particular place, and you probably will think of a thousand other things that I haven't here. But one thing is certain, and that is, you are missing a big and helpful thing if you are not taking some active part in the community safety work. You can't shut yourself away in your plant, because the home influence is so great; if you don't get its cooperation you are not getting the full effect of your work at the plant.

It is very much like the farmer and his wife who went to the town to buy a box of dynamite. They sat in the buggy and there was a box of dynamite directly underneath the seat. The wife said, "I am not going to sit right over that box of dynamite, put it right back into the rear of the buggy." And so they rode home. You can't get away from it. If you try, like the ostrich, to put your head in the sand, and stay in the plant without doing anything in a community way, you can't do it; because it is going to affect you just the same, whether you think so or not.

So get out and get into it. It may mean a little more effort, and, as I said, a little more work, but I am sure when the final results are tabulated, a good percentage of your accident reduction can be attributed to the time you have spent in work in the interest of the community safety.

A Helpful Experience in Canada

CHAIRMAN SCOTT: Mr. Ziolkowski, that was a very fine talk. We appreciate it. Will Mr. Willis MacLachlan of Toronto, Ontario, please discuss this subject just presented?

WILLIS MACLACHLAN (Toronto, Canada): I didn't expect to discuss this paper. I am very much interested in it and enjoyed it very much, but there is possibly one type of small community that I know something of, and that is the small community of 200 or 300 people, up to say five thousand, in which the public utility have one man in a town, or it may have half a dozen. It may come up to twenty or thirty and that would be your limit of the number of employees.

Now, what can they do or what can you do in community safety to interest your employee more in accident-prevention in the plant? One scheme we used is the idea that you will learn something better yourself by teaching somebody else to do it; and we wanted to have the men particularly well trained in resuscitation from electrical shock because of the very apparent hazard of the industry.

I wrote to the local centers of the Boy Scouts, I wrote to the Scout Leaders, also, and told them the name of the line foreman or the man in that town who could teach the boys resuscitation. I also wrote to the man in the utility. Now, I don't think very many of the men in the utility went to the Boy Scouts, but I do know the youngsters came around to the plant and asked to have the man go.

I will give you one instance, in the town of Galt, Ontario, perhaps of about 3,000 or 4,000 inhabitants with about 20 or 30 employees in the public utility. They came around to the line foreman and asked him to come down to the meeting of the Boy Scouts and give them a talk on resuscitation. He tried to stall them off, but it wasn't possible. So he went down and he took a lineman along with him, and he taught them what he could on resuscitation. Then they began to ask him a lot of questions he couldn't answer. He said he would come back after he got the answers, and he did go back and tell them. That was the latter part of the winter. Along in August, a youngster was out swimming in the river. Two of the Boy Scouts happened to be along with the crowd and the boy in the middle of the river went down. These youngsters went out, got him out of the water, got him over to the bank. He was not breathing. They started in with resuscitation and brought him back. They received the hero medal for their work.

I wonder who values that medal most, the boy or the line foreman? I have talked to the line foreman and I know. I just suggest these things to you as examples from my own work of the training of resuscitation. There are various things that you want your men to learn. Why not get them to teach somebody else in your community, even though you don't have a community entirely composed of your own employees. Even in a small community where you may have only a few men, why not get them actively interested in the problem?

Round Table Discussion on the Subject

CHAIRMAN SCOTT: We will devote the remaining ten minutes allowed for this session to an informal round table discussion of any questions you may desire touching upon the general subject.

EUGENE T. LEES (Playground and Recreation Association of America, Chicago, Ill): In our own gang they call me the "Convention Hound of the Playground and Recreation Association." I get around to so many conventions.

I was very much interested in the several papers which I heard that touched this question of recreation. They were very illuminating and they showed that the light is gleaming around the country in reference to the possibilities that play of the right kind and recreation of the right kind, can have in this field of safety.

I just want to touch upon two or three points. Mr. Ott, in his able paper, mentioned that there were possibly 4,000 children killed annually from accidents. Unfortunately, we have to declare the number is very much higher. Last year we are told it was upwards of 7,000 in the United States.

Any of you who have seen my little exhibit downstairs, saw in the center of it on the background the sign "Save the Children" and then the figure "26,000 children killed in traffic accidents in the last eight years." Those are the official figures of the National Safety Council and the Metropolitan Company.

Now, you ought to have picked up, if you didn't, one of the little pamphlets, that were referred to by Mr. Ott, which were prepared jointly by the Council and our association. I had hundreds of those and the supply is gone, but you can get it by writing to our association in New York or to the National Safety Council in Chicago.

It is the last word on the subject of utilizing public safe playgrounds, as a safety measure.

Now, I will say this. We have to conceive of the possibilities of rightly directed play for the child as a life builder, as a builder of bodies, as a builder of nerve reserves, that will carry far as a safety protection for the child. In this age of strenuous living, in this age of dangers on every hand, we certainly need more and more of that thing—the building of bodies and nerve reserves in the children of America so that they can go through with their objectives in life.

Secondly, I am thinking of the special needs of workers today as never before. Probably in factory industries, the dominant thing is the universal use of automatic machines. But the man on the job doesn't get any exercise worth speaking of; he doesn't get any great satisfaction from doing the thing that he is doing, pushing a little lever automatically several thousand times a day. Now he has to get something off the job if he is going to continue as an efficient worker; if he, indeed, wants to go on with any kind of work, he has got to be revived and balanced up in his off hours, in that leisure that is being more and more provided today in the industrial field. He has got to be built up in order to be a safe worker on the job on each of the next days through the working year.

Safety Recreation for the Man Off the Job

One could discuss that for hours, of course. I am just touching the high lights.

The third point is this: The history of interest of employers in industry in the field of recreation will show that in the earlier days in America, the employer with any interest at all in that line, thought of putting up recreation facilities in the plant, possibly around the plant for his workers. The tendency in our experience, and from our observation from year to year, is that that is changing greatly. He is not lessening his interest in the possibilities of recreation as a protective measure from every point of view during the noon hour, and, therefore, providing facilities on the ground of the plant, but he is also (and this is the new tendency), taking that keen interest that was recommended to him, you will recollect, in the community's provision of recreation.

The man off the job has a whole lot of time. What is he going to do with it? The pleasure time problem, we are told by great authorities, is one of our great problems today. It depends partly on his own attitude, but it depends more largely on what the community is offering him in the way of a luring temptation in the way of recreation and there is a great field for employers in their various communities.

IRVIN OTT (Worden-Allen Co., Milwaukee, Wis.): I just want to say a word in defense of my address. I think the records will show, that while I quoted the number of children that had been killed and seriously injured in traffic accidents in the city of Chicago, when I quoted the national records, which I obtained from the National Safety Council, I mentioned that those were the children who were killed and seriously injured during play, not necessarily the total injured through traffic. I believe the records will show that.

GEORGE P. NEVITT (Paine Lumber Co., Oshkosh, Wis.): I just want to mention one point in defense of my being here. I am an industrial worker in the Paine Lumber Company and I think there is one point these men are missing in reference to industries. The National Safety Council tells us that 25 per cent of their accidents could be prevented by guarding and other devices in the plant. That means that 75 per cent of them are accidents that cannot be prevented except by creating an atmosphere and impressing the man with safety.

Now, that can be done just as effectively, if not more effectively, at home than it can be around the plant. Twenty-five per cent of our absences from the plant, approximately (I am not accurate on that figure), are through accidents at home. Now, that gives us a large field to work in and I feel that the outside safety propa-

ganda is really the most important and I feel is the only salvation for industrial safety.

That accounts for my being here because I put more importance on this field than I do on the purely industrial safety.

CHAIRMAN SCOTT: May we have a word from Mr. George Opp of Detroit? He is the dynamo of safety for the electrical industry.

GEORGE OPP: When I saw this item on the program this morning, immediately I questioned, "Why small communities?" or "big communities," because the same things apply in the larger communities that apply to the smaller.

In substantiation of that, let me say that through the directorship of C. E. Brauer, Commissioner of Recreation of Detroit, during the past summer, due to the intensive work carried on by that city, there has been but one fatal accident to a child in the vicinity of a playground, either on its way to or from that playground. If you stop to realize what that means you get the picture when you get the comparison that during the four months of school, earlier in the year, that figure was 16. You get the picture of what can be done through recreation facilities and planned recreation during the children's play period of the summertime.

CHAIRMAN SCOTT: I want to thank you for your interested attention and these speakers for giving such real contributions. I now declare the meeting adjourned.

ADJOURNMENT.

**SIXTEENTH ANNUAL SAFETY CONGRESS
NATIONAL SAFETY COUNCIL**

Group Plant Safety Supervisors Session

Tuesday, September 27, 1927

LEWIS A. DEBLOIS, Chairman

National Bureau of Casualty & Surety Underwriters, New York City

The meeting convened at two-fifteen o'clock, Mr. Lewis A. DeBlois, National Bureau of Casualty & Surety Underwriters, New York City, chairman, presiding.

CHAIRMAN DEBLOIS: I am not going to take any of your time discussing the subject myself. We have four papers on the program, each one dealing with a different phase of the problem. Our speakers are all experienced men, experts in their line.

Our first paper bears the title, "How to Organize for Safety." It is to be given by Mr. Harvey Ellerd of Armour & Company. Mr. Ellerd has been with Armour & Company since 1903. He is now assistant vice president and assistant director of personnel. Before that he was assistant manager at Kansas City, and prior to that was in charge of industrial relations here in Chicago.

It gives me great pleasure to introduce Mr. Ellerd.

How to Organize for Safety

Harvey G. Ellerd, Department of Personnel, Armour & Company, Chicago, Ill.

There is one very nice thing about this subject and that is that further original thought on it is scarcely possible. Volumes have been written about it and every enthusiast for safety has at some time or other prepared a paper or delivered a speech about it. This naturally has saved me a lot of brain fag, as I see no necessity for attempting to puzzle out new ideas on a subject that has been so exhaustively exposed.

Another very nice thing about this paper is that your committee has definitely limited its length. I say that it is a nice thing from the standpoint of the audience, but I have found it most difficult to try to condense into 30 minutes material that would take many hours to peruse.

As I went through the great quantity of material that was handed to me on this subject it seemed to me that there were just as many varieties and styles of safety organization as there are of women's dress. However, as far as covering the subject is concerned, modern safety organization plans go much further than the present trend in women's clothing. Beginning with very small and rather feeble attempts at organization for the promotion of safety work, we now find elaborate, complete, detailed methods of organizing that apparently are getting very splendid results.

It goes without saying, that the very purpose of organizing for safety is to stimulate in the worker the practice of thoughtfulness while at his work, thoughtfulness for his own and his fellow worker's safety.

You safety experts know, and you have had it proven to you by statistics at every one of these safety conferences, that mere mechanical safeguarding does not prevent all the accidents; in fact, I have read recently from some authoritative source the statement that the possibilities of accident prevention work through mechanical safeguarding are actually limited to about 25 or 30 per cent of the total number of accidents. The rest are caused by thoughtlessness on somebody's part, either the injured man or his associates, and the question immediately arises how can we stimulate his thinking to the point where safety is an ever present idea.

I have long felt that the term "Safety First" was not well chosen because I do not believe that in the mind of the man at work safety is the first thought or consideration. I have to confess that it is not with me when I am trying to accomplish anything. I believe that it is merely one of the considerations that we should have in mind in the doing of any job. If I want to get a certain piece of work done, my primary thought is to do it in the quickest and best way consistent with the accomplishment that I am trying to achieve; and then my inclination is to add the qualification that of course I want to do it with safety to myself and others. But I do not believe any of us start out on any business or work on the premise that safety is our first consideration. Therefore, I think it has been a mistake with many of us in the past to try to get the workman to consider safety as the first and most important consideration of his job. In doing this, we have actually cheapened the idea of safety. Our whole objective should be to get him to do his work and constantly keep safety in mind simply as one of the primary requisites of his job. The best method of doing this and of inculcating in him the safety habit as a regular part of his procedure seems to be through organization.

The Best Idea in Safety Organization

Many years ago, some smart safety man said: "Let's put the workmen on a committee that will make inspections of the place of work, and by the very act of doing this they will be thinking about safety; and when they are seen by their fellow workers they will be reminded that the Safety Committee is trying to find out ways of preventing accidents." This is probably the best idea that ever has been put forward for the promotion of safety, and while it is fresh and new and carried along by the enthusiasm of somebody in the management who is thoroughly sold on it, it goes forward with a great impetus. Unfortunately, however, the plant gets unusually busy and the workers are needed on their own regular jobs every minute of the time, and the management says that temporarily we will have to suspend our safety organization and safety committee work, and pretty soon the suspension becomes a regular order of business. I think if we are frank with each other, we will all admit that we have seen this sort of performance time and again.

Then along comes a serious accident or some evangelist on safety hits the plant again, then activities are resumed. I suppose this cycle will always be at work in industrial establishments, but it does seem too bad that so valuable a thing as safety organization, especially as represented through safety committees, cannot be established on a permanent basis.

One of the most substantial and most material evidences of the financial value of safety organization work is that insurance companies who handle Workmen's Compensation and Liability insurance allow substantial credits for a safety organization that is conducted along standard lines, and by standards they mean regular inspections, regular meetings, regular reports of such meet-

ings, and the definite evidence of activity on the part of safety organization. The discount allowed by these insurance companies from their manual rates proves conclusively that from a mathematical computation of experience, those plants which are organized along standard lines for safety will have a better experience and a lower loss ratio than those which are not so organized.

The safety committee in itself was one of the earliest and most successful attempts at organization. Through its efforts the message of safety is brought to employees through meetings. This is a very effective means in educating a worker for his and his fellow worker's safety.

We have had reports come into our office of serious accidents, and in discussing them we have asked our foremen and superintendents what can be done to prevent an accident of that sort; and it is surprising how many times the answer that you get is, "It is simply a matter of education." Then having this very simple answer, it should be a very easy matter to go out and educate. We have so often heard it said, that when you once know what the trouble is, it is comparatively easy to correct it; but don't let anyone tell you that it is easy to educate—it is the most vexing, most exasperating proposition in the world, to try to get people to use their heads to avoid hurting themselves. It should be a human instinct to avoid injury, but sometimes we are inclined to believe that people will go out of their way to put themselves in danger. Of course, this is exaggerated, but at any rate, they are guilty of moments of thoughtlessness and an injury is apt to result.

The Bulletin Board-Is Indispensable

The meeting with employees carries the spoken word to their ears. This is its place and its effect but we have to go further, and the next step is to appeal to the worker for thoughtfulness through what he sees.

The bulletin board, with its attention-arresting, sometimes terrifying, pictures and cartoons is exceedingly effective, and I do not believe that any of us would be without them. The constant reiteration of these self evident truths, illustrated with horrible examples or with pictures that appeal to the self interest of the individual are bound to be productive of some results. To what extent they are effective will never be known, but they are a factor in the general problem of organizing for safety.

Another means of working this out is the plant newspaper, and I want to say that we have the greatest confidence in the message that we are continually putting over to our people through our plant newspapers. The great advantage of the paper, which, in our own particular case at Armour and Company, is issued every second week, is that it goes into the home and the message of safety is carried back to the worker from the members of his family. I feel that it is made more impressive in that way.

Another effective means of making the worker think for safety is the safety campaign or the no-accident campaign. These are run in countless ways. In our company, we have now established a practice of running a two weeks "No-Accident" campaign during the early spring and a similar campaign during the late fall. You may be interested in some of the details of this arrangement and in some of its results.

As many of you are aware, the plants of Armour and Company operate under a plan of Employee Representation. Employees elect, from among their own numbers by secret ballot, men to represent them. The management appoints representatives. These men meet and deal with all problems of mutual interest. They settle such subjects as hours of labor, rates of pay, working conditions, health and sanitation, waste elimination and accident prevention, and all other matters that have to do with the relationship between the rank and file of the workers and the management.

One of the major activities of the Armour Plan of Employee Representation is safety and accident prevention. In each plant, there is a committee appointed to handle this work. It is composed of equal numbers of elected representatives and appointed representatives. In Chicago, our largest plant, the committee is at present made up as follows:

An hourly paid mechanic, who is an elected representative who has shown a special interest in safeguards and in the general subject of safety.

A highly skilled butcher, who is a veteran in the service of the company, and who is an enthusiast for safety.

These two men were selected for this committee by the entire group of elected representatives. They have every qualification for doing effective safety work. The two management members on the committee are the safety inspector of the plant and one of the department superintendents. I merely cite the personnel of this committee as a sample of our type of committeemen. This safety committee, and likewise the safety committees in other plants, make regular plant inspections; examine all accident reports, attempt to ascertain the real cause of the accident and to prevent its recurrence. These committees meet once a week for these purposes. Their reports are sent to the general superintendent of the plant, who puts into execution their recommendations. If he finds them impractical he gives the committee his reasons, whereupon an effort is made to meet the situation in some more practical way. A report of all the activities of the safety committee is made at the regular monthly meeting of the Conference Board, which comprises all the representatives.

No-Accident Campaigns Two Weeks Long

The semi-annual "No-Accident" campaigns are conducted under the auspices of the safety committee and with the cooperation of the entire group of elected and appointed representatives. Our "No-Accident" campaigns are now conducted for a period of two weeks. Each plant is in competition for first place in the campaign. We take into consideration only the frequency of accidents in relation to the number of people employed. There might be some question raised that severity should also be included, but after experimenting in various ways, we have come to the conclusion that any accident requiring the attention of our doctor is potentially a lost time accident and therefore should be charged against the plant in which it occurs.

From time to time, we have used various means of arousing the interest of the employees in the "No-Accident" campaign. The one which was recently concluded may be of interest to you. On the Saturday before the campaign started, a button was distributed to each employee. This button had on it the message "Let's work safely," also a picture of an Armour Star Ham. It also carried a serial number. As these buttons were passed out to the employees each name was recorded on a slip with the number. On the day that the campaign opened the safety committee in a secret session drew out of a box 25 numbers, each of which would win an Armour Star Ham under a certain condition. This condition was that the holder of that number must be wearing his button conspicuously displayed on his working clothes every day during the "No-Accident" campaign. This fact is ascertained by some member of the safety committee going around the department to see whether or not he has on his button. Of course, the person whose number has been drawn does not know it until after the campaign is over, and in this way, all have an incentive to wear their buttons at least during the campaign.

This is simply a bally-hoo stunt to have an item of continued interest at all times during the campaign. When a member of the safety committee is going through a department, each employee wonders whether he is the lucky one and he makes a great effort to see that the safety committee member sees the

button. At the end of the time the numbers who have continuously worn their buttons during the campaign are awarded hams, and the names of those who had been drawn out in the beginning but who failed to wear their buttons are published and there is a great deal of fun over this fact.

Of course, this particular thing has nothing to do with safety, but it gets a lot of people talking about the "No-Accident" campaign and about the safety prizes as they are called.

Each noon, during the two weeks, a meeting is held at a different point in the plant. To draw the crowd, entertainment of various sorts is provided. It is all voluntary entertainment put on by employees, and it is of every variety, bagpipes, whistling, cornets, Charleston dancing, real Indians doing their dance, singing, banjo playing, in fact, nearly everything in the entertainment line, and some of it is very good.

This idea is simply carrying out the old medicine show principle of drawing a crowd and selling them something. After the entertainment has gone far enough to have the crowd interested, some member of the safety committee makes a five minute talk on the subject of safety.

Foremen and Department Executives Have a Club

We believe that this sort of campaign, coming as it does twice each year, is one of the most effective ways of awakening and reviving interest in accident prevention, and we are thoroughly sold on the idea. Of course, we have to devise new and novel stunts from time to time to maintain the interest.

It is our belief that the chief responsibility for safety rests with the supervisory organization, and it is our custom to hold our department superintendents and foremen rather strictly accountable for accidents occurring in their departments. In order to impress them collectively with this responsibility, safety is a subject that is discussed at the foremen's meetings, and their responsibilities are outlined to them by the executives in charge.

Our foremen and department superintendents have a club known as the Armour Plant Executives Club. This organization grew and developed from safety meetings with the foremen, and safety is still one of the predominant factors in the club operation. For many years we had the custom of holding an annual safety dinner for foremen. At these dinners various executives addressed the foremen on the subject of safety. The experiences for the year were thoroughly reviewed by the people in charge of claims and the foremen were exhorted to greater efforts for accident prevention during the ensuing year.

After one of these meetings, some eight years ago, it was suggested that the next meeting be turned over to the foremen themselves and that they should select their own chairman and their own speakers. There was a committee appointed to work this out, and the following meeting was one of the most interesting that ever had been held. There were five papers presented by the foremen on the subject of safety, and these indicated clearly that great thought and study had been given to their preparation.

As a result of the success of this meeting the Armour Plant Executives Club was formed, and it is now the outstanding organization in the plant. As I said previously, its fundamental consideration is safety and it promotes this work through its membership, which is comprised of the supervisory organization.

There is just one other point that I want to touch on in organizing for safety, and that is the success that we have had in the use of safety inspectors. In our plants which are large enough, a safety inspector has been selected from the ranks and he gives full time to the handling of safety work. I won't go into the qualifications of such a man any more than to say that he must be a regular fellow, able to command the respect of both the supervisors and the workers. He must have patience, enthusiasm, perseverance, and a great quantity

of that much abused qualification politely termed "intestinal fortitude." He must be a leader and must be able to sell safety to both management and men and break down the barrier of old time employees who are opposed to new ideas and who are prone to think that safety is a fad.

He should be able to speak with force and conviction, and to be the inspiration of the entire safety movement in the plant. Such men are rare, but we have been particularly fortunate in our selections in securing men who have done a very effective job for us. They have in each case been men already employed in our plants, usually in some branch of the maintenance division, and we have developed them as safety inspectors with very satisfactory results. They not only know the plant and know our foremen and workmen, but they are able to correct dangerous conditions themselves by devising safeguards which are effective and at the same time practical. With a little coaching and practice these men have become rather convincing speakers and are able to address employees effectively.

The Goal Beyond Organization

This has been a rather sketchy review of some of the activities that have proven of value in our own case in organizing for safety. I do not imagine for a moment that there is anything new or original about them, in fact, we probably started all of them on the strength of some one else's experience.

We are thoroughly convinced that a safe plant with safe working conditions is only a start toward the solution of the problem of preventing accidents. The only way that the greatest accomplishment can be secured in this work is through safe workmen. We are further convinced that the problem of making the workmen safe is one of organization. It is a matter of eternal vigilance and of constant organizing effort. The impulse may at times be toward too much organization work, with the result that the movement becomes too blatant and in the minds of the workmen is apt to lack sincerity. We are trying to avoid this possibility in our own case.

We are trying hard, through our organizing efforts as I have outlined them, to impress our people with the idea that thoughtfulness is the only price that they have to pay for their own safety, and that one of the vital considerations in the daily performance of their work is the ever present thought; not only "Am I doing this job the quickest and the best way at the lowest cost, with a maximum of quality production; but, am I doing it in a way that will avoid injury to me and those around me?" If we are ever able to get to that point we will feel that we have accomplished wonders, but it is a problem of ever continuing organization and education. It is not one of those things that you can do once and then leave with a satisfied feeling of accomplishment. It will always be a case of eternal vigilance and ever continuing effort.

CHAIRMAN DEBLOIS: Gentlemen, we have five minutes for the discussion of Mr. Ellerd's very excellent paper. I am sure you have questions to ask him.

MR. COLE (U. S. Gypsum Co.): I would like to ask if the Armour Company are self-insured?

MR. ELLERDS: Yes, they are.

MR. COLE: In all operations?

MR. ELLERDS: Yes.

MR. COLE: Just how far do you go in the matter of strict enforcement or policing responsibility? I don't want to talk in generalities, but I want to know. It is a problem we have had come up, and I would like to have a few words from you.

MR. ELLERDS: I presume you mean disciplinary measures. I think that has to be left as a very common-sense proposition. Discipline must be exercised and men must obey certain rules. When they go beyond a reasonable limit, there is only one thing to do and that is to get rid of them.

I don't know whether I have spoken on your question exactly. It is one on which you could speak at great length. But we have been rather strict in a good many of our rulings. Where we have established a standard safety practice, we have insisted it be followed out.

MR. COLE: That answers part of it. We all talk of selling safety. I might say that our company has come to regard the salesman end of it rather as you spoke of it, as all balleyhoo; but just how much weight do you put on it in comparison with holding accountable the men who are controlling the situation? I am trying to get an idea as to how far you go on your selling and where you draw the line.

MR. ELLERD: You can see that we have two weeks out of the year where we put on a balleyhoo stunt, where we try to arouse their thinking through some novelty and some competition. In the remaining 50 weeks of the year we use the other methods, the bulletin boards and plant paper and disciplinary methods. The balleyhoo does arouse some thinking on the subject of safety. I think it has a place, but not an especially weighty place. You can do only a certain amount with it.

Sometimes I think of safety from that side of it as I do of religion. Every once in a while you have to have a revival, with an evangelist around. Then everybody gets religious and gets back into the fold.

MR. MCCLELLAND (Armour & Co., Chicago): I might state that Mr. Ellerd overlooked an answer to your question, which is that a statement goes out monthly which shows the number of men working, the number of accidents and the percentage compared to the rest of the departments in the plant. Therefore, the department superintendent or head of the plant knows how many accidents have occurred in his department. If it runs too high in actual percentage, he is bound to hear from the superintendent.

R. B. KELLEY (Anaconda Copper Mining Company): What do you do in connection with foremen not trying to prevent accidents?

MR. ELLERD: I don't believe I could lay down a general principle. I don't believe there is any specific line or rule. I think each individual case would be considered on its own basis of fact. I think we would have to determine whether a foreman was really negligent. If he were, I think we would use severe measures.

We try to hold the foreman accountable. We let him know that it is his responsibility to prevent accidents wherever possible.

CHAIRMAN DEBLOIS: We will have to give each speaker his allotted time. If there is any time left when we get through with the papers, we will have a general discussion on the whole subject.

Our next paper is going to be given to you by an "old war horse," Henry Reninger. I don't know exactly what he is in his own company, the Lehigh Portland Cement Company, but he seems to run a large part of the safety work of the entire cement industry. He is vice president in charge of industrial safety for the National Safety Council.

Securing the Cooperation of the Plant Management

Henry A. Reninger, Lehigh Portland Cement Company, Allentown, Pa.

There are many different ways of securing the cooperation of plant management just as there are many ways of getting from New York to Chicago. It is a matter of deciding which is the best way, the safest and quickest. The same thing applies to interesting management. The situation must be studied carefully. Many times I have been asked—How do you interest this concern and that concern in the National Safety Council? What did you do? How did you do it? The only answer I can make is, to find out the type of man I must do business with and then make up my plan accordingly.

In the large organizations there is no use of trying to put safety into the plant until you have the executives of the company sold absolutely to the safety idea, for until the official order comes from headquarters to the plant management authorizing safety you cannot get anywhere, no matter if the manager or superintendent himself believes in safety. He will not go ahead with it wholeheartedly unless he knows he has the backing of the officials. It has always been my endeavor to get executives and officials interested in safety work from the humanitarian side. However, when this fails the only thing that is left to do is to show them actual facts and figures as to what it means in dollars and cents. We cannot forget that in both large and small organizations, management is at the head of the organization. They spend money to produce money for its stockholders and owners—and we cannot blame them entirely if they cannot see the value of safety when presented to them from the standpoint of theory and sentiment. Manufacturing conditions and costs have reached the point where they feel that their entire effort must be put into production. Therefore if the humanitarian side does not appeal we must endeavor to show them that safety will help them in production and in cost.

Every executive, no matter how busy or how hardboiled he may be, is interested in his employees to some extent. Today, with the great industrial organizations we have throughout the country, the executives do not come into personal contact with the employees as they did years ago when the plants were small. Therefore the personal contact between men had been lost, but today I believe that the safety movement has brought back the personal contact between men and management and the organizations that are doing real honest safety work are reaping the whole benefit. In our own organization our executives believed in safety, but like many other executives of the big corporations they did not have time to go into the detail work or visit the 20 plants throughout the United States. However, the vice-president and operating manager (whose personal contact and experience with his men made him see the value of it) backed up the safety movement from the very beginning, and it was his wholehearted cooperation with the department that has made our work so successful.

Plant Executives Became Thoroughly Sold

In the beginning our executives went along and were willing to grant any requests made, but after two or three years, when they began to see the results and figures in accident reduction and had a chance to attend some of the safety meetings of the National Safety Congress, they came out wholeheartedly and in the strongest language on behalf of safety.

At the Buffalo Congress our president came out wholeheartedly for safety when he made the statement at a Sectional meeting, as follows:

"Safety work improves efficiency. Nothing has ever been introduced into cement plants which has touched the hearts and spirits of the employees as has the interest of the management in their physical welfare. The work of the Safety Committee, the prizes for good records, the rivalry between plants for the least number of days lost, brings about an *esprit de corps* which could not otherwise be developed. In my opinion as an executive, safety work has become as necessary and essential to the successful operation of a cement mill as a boiler house or laboratory."

Superintendents and foremen are just as much responsible for the safety of their men as they are for production. When once we can get the executives of industry to make such statements to their organization, how can any plant management or superintendent fail to cooperate in this great work when he is held responsible absolutely for safety and production?

I worked out a report several weeks ago which I showed to the president of our company as to the number of men employed, pointing out to him that in our organization, of which he is the responsible head, he had over 6,700 children under

16 years of age that were dependent upon him in many ways for support and education.

A report such as this made a great impression and brought out very clearly the great responsibility that rests upon the president and other executives of corporations.

I do not think I have ever worked out any report for our executives which seemed to affect them so much as the report showing the number of married men and the number of children in our organization under 16. After going over it very carefully, one of them made the remark, "I never realized before that I, as president of this company, am responsible for the education and the raising of 6,700 children. My family is a great army and I can see where this company must carry on its safety work if that responsibility is resting on my shoulders."

Managers Want to Eliminate Waste

Any efficient manager is easily approached when you can show him that he can eliminate accidents—which means the elimination of waste; that by the reduction of accidents he can reduce his cost of manufacture; by preventing accidents through the efforts of the Safety Committee he can instill a better relationship between himself and his men; that carelessness in the matter of safety by foremen and men indicates the same thing in production, and if it is possible to change the mental attitude of the men from wastefulness and carelessness and instill in them the desire for cleanliness and good housekeeping, then you have reached a point that means increased production.

The attitude of the plant management in the organization of the Safety Committee and their attendance at the meetings will be reflected in the foremen and the men. Placing direct responsibility upon the foreman for his machinery, good housekeeping, cleanliness, and fire prevention, will make him keep his department in such a condition that the men will like to work there.

When departments are once kept in such a condition, then safety has reached a point where all intelligent workmen will realize that the company is interested in their welfare and they will begin to cooperate in any safety program presented. A safe, clean plant makes labor therein more pleasant and means that men will remain on their jobs; steady, satisfied workmen, plus accident reduction, means less labor turnover. If you can show any manager that through safety work he can reduce labor turnover, you have a hold on him. Every manager is interested in a productive organization and improved leadership; and where is there a better opportunity to train your men for leadership than with a good safety organization?

I find a great many of our safety men (safety engineers as they are often called) discouraged, because after spending six months on the job they cannot see any great improvement. Let me say here that the man who becomes discouraged at the end of six months, a year or two years, has not become imbued with the real safety spirit. Safety work cannot be established in any organization on a firm basis in six months or a year or two years, and when I say that I refer to conditions as we see them. In a great many organizations when the slump comes, what happens? In nine out of ten cases when curtailment takes place, the safety department is the first hit. If that is the case safety has not been placed on a firm foundation. This should be the very last department to be touched. In too many cases we find a safety engineer in a position where he is called a necessary evil. I have heard some superintendents express it in that way. It makes the situation for the engineer and the superintendent one which is not at all satisfactory. It is only when the safety engineer and the manager are working absolutely hand in hand and where safety is an operating problem, that we can feel we are getting to a point where neither one will be able to do without the other.

In the large organization the safety department should hold the same place that

is held by other departments and should cooperate with every department, cooperating in every way with the plant management furnishing them with all the information possible on safety problems and make them realize their responsibility. Plant management is continually harassed by details of production which many times the safety department is not familiar with. No matter what authority the safety department may have in the plant, it should never take advantage of iron-bound rules and regulations, but when the various problems come up they should be freely discussed with the management at the plant so that both sides of any question are fully understood and each may cooperate with the other to work out a solution.

We are all creatures of habit, and what we must endeavor to do is to educate our people to the safety habit. Slow work, to be sure, but once we get them in the habit of safety we have reached that point where we can feel we have attained our goal. Clear, concise reports of work accomplished through safety, as to the cost of production, labor turnover and reduction in frequency and severity of accidents, must be kept before the plant managers. Results are what management wants, and when these can be definitely shown, then we have the full support of the plant manager.

Safety work has been the entering wedge that has removed the old spirit of aloofness between employer and employee, which so often leads to disastrous results. With the idea of safety and the safety committee for better industrial relations we have produced a feeling of friendliness that has brought forth a closer understanding between men and management. It has saved the industrial situation from its sinister labor aspects and makes men feel that management, foremen and men are all brothers in industry, each working side by side with the others, and all putting forth their efforts to produce and to secure for themselves those things which rightfully belong to them, viz: a home, and in that home a family and children who, through their efforts, may receive the education and blessings to which they are entitled in this great country of ours.

Safety has removed the barrier the old country was so familiar with, that of slave and master. It has brought them together as fellow-men with the rights and privileges granted them under our constitution.

Awards For the Best Safety Records

CHAIRMAN DEBLOIS: Major Reninger has turned our thanks and five minutes more time for discussion. You see, I am running the meeting on your schedule as I can. The floor is open for discussion.

E. A. STAMP (Swift & Co., Chicago): I would suggest that if Mr. Reninger's paper is going to be published in pamphlet form, a copy be sent to every member in the meeting.

CHAIRMAN DEBLOIS: I will be very glad to refer that to the officers of the Council. Of course it will be published in the transactions. Some papers are separately printed. Are there any questions?

MR. COLES (Wyman-Gorman Company): I would like to ask the speaker what he does in the way of awarding prizes for a good record? I think he made some reference to that.

MR. RENINGER: For seven years we have conducted a No-Accident Campaign in June. Each year we award a small prize to the plant going through the month of June. The first year we awarded cups, and it was necessary to furnish five cups. The following year we awarded a large American flag. We did that at the suggestion of two safety committees.

Other awards consist of a big safety flag of our own design. At the last campaign in June 1927 we awarded an additional safety flag, seven by fourteen, to the mills that went through most of June without a lost time action. We have 20 mills and we furnished 20 flags.

At the end of the year we have a permanent safety trophy that goes to the mill which makes the best record in accident prevention. By that I mean days lost per 100 man-hours. As figured out originally, the idea was that the trophy should go to the mill and they would retain it for a year; any mill that won it twice would retain it permanently. I am glad to say that this contest has been going on for ten years now, and this year I have to buy a new trophy. It was designed by Gorham Company of New York, the silversmiths, and it is quite a beautiful trophy.

In addition to that, in the cement industry, as you may know, the Portland Cement Association awards a trophy to the mill making the best record in accident prevention in the United States or Canada. That is a beautiful, concrete trophy standing about eight feet high and three and one-half feet across, with a design on it which was worked out by an artist. There was a contest held in the United States about six years ago with prizes of \$1,000, \$500 and \$250 for the best design.

In addition to that, two men from the plant winning the prize attend the Portland Cement Association meeting to receive it, with all expenses paid. The meeting may be held in New York, San Francisco, or anywhere in the United States, but two of the men attend it. This does not include the superintendent. They are selected by the safety committee.

The mill making the best record for the year and winning the Lehigh trophy also sends two men to the National Safety Congress. We have one plant that has sent four men to New York to win the Association trophy and eight men to the National Safety Congress in the last ten years.

I am not a great believer in money; I never have been. We found out that a cup or a flag or some trophy of that sort works out a great deal better. What we have done for those mills in outlying districts where they can't very well get to a safety meeting or a local contest meeting, is to send them \$100 for a dinner.

When those checks are sent to every safety committee at the end of the year, I have often wondered what they did with them, because the minutes that I get don't always show a dinner. I found that one plant, two years ago after that disaster in Southern Illinois from wind storm, turned the \$100 over to a Red Cross contribution. I know one mill which for the past four years has turned over its check to the nurse to buy layettes for new-born children of the employees. I find that most of the money sent to the men for dinners has been used in one way or another for the benefit of their own employees.

CHAIRMAN DEBLOIS: The third paper this afternoon is entitled, "Interchange of Plant Experiences." It is to be given by Mr. H. G. Hensel, who has charge of the safety work in the Western Division of the Youngstown Sheet & Tube Company. We have had as speakers, first, a mining man; and then a cement man; we now have a steel man. Mr. Hensel has had much experience in steel safety work and he has been with two other steel companies—the West and Tube Company of America and the Inland Steel Company. I take great pleasure in introducing him to you.

Interchange of Plant Experiences

H. G. Hensel, Safety Director, The Youngstown Sheet & Tube Company,
Chicago, Illinois

I assume that all here are agreed that the value of having a safety supervisor of a group of plants or mines is to provide a means for quick exchange of safety ideas and accident records between the various operations.

There must first be some designated person at each operation, and preferably a safety inspector, to whom items for exchange can be sent. This person should be trained to send such items to the party at that operation who is most likely to be interested, and this same safety inspector should be on the alert for items

and records which he thinks will be of interest and value to other plants and mines of the company. In my work the various items interchanged between works and mines are as follows:

Monthly Accident Records—

Each safety inspector is advised as to how his monthly accident record compares with the records of other works and mines of our company. This is done on several bases. First, we have the accident record on a dollar and cent basis wherein we compare the accident cost per \$100 payroll, accident cost per ton and accident cost per man. We also make comparison of accident frequency and accident severity.

Reports of Serious Accidents—

A report of a serious accident is quickly passed on by my office to each safety inspector in the district so that he may use this record of an accident in preventing a similar occurrence at his works. He very often passes these reports on to department heads and foremen in a similar department at his works, and I have no doubt but what the exchange of these reports assists us many times in heading off a similar occurrence in another works.

Safety Devices and Safe and Unsafe Practices—

Through the medium of a safety supervisor's office, the various works and mines can be easily advised of any new safety device that has just been investigated and the value of it can be clearly explained to the plants where it is needed. We are engaged in a drive against unsafe practices, and in fighting unsafe practices it is also a fact that we must devise and put into effect safe practices. A record of these safe and unsafe practices is passed along to the various safety inspectors so that they can secure from such lists any items that will apply to their operation.

When There Seems to Be a Let-up in Interest

Safety Supervisors Assisting Safety Inspectors—

Many times our accident records show us that a certain department in a certain works is apparently letting up on their drive to prevent accidents and it is certainly the safety supervisor's duty to step in at such a time and assist the local safety inspector in bringing such a department back into line. It may require a talk with the manager of that operation to determine just what is wrong, and I have never talked with a plant manager about the poor accident record of any certain department without hearing from him almost instantly that the production record of that department has also slipped, which indicates more and more to us that production and safety go hand in hand. It seems to be an almost unbroken rule that when a department head, for any reason, begins to be lax in his attitude toward the safety movement, his production is also suffering.

Keeping Up Interest in Accident Prevention—

It is certainly one of the duties of the safety supervisor to assist the local safety inspector in providing new means and stunts for keeping up interest in the accident prevention movement. We find that we secure great help along this line from the various publications issued by the National Safety Council and by many companies who issue safety bulletins. I have found that within the past two years our safety bulletin, issued for the use of superintendents and foremen to be used at safety meetings of the men, has helped our work considerably. These bulletins give the foremen items of interest to take up at their safety meetings for the men and they also tell them of the kind of an accident record their department and their plant is making as compared with other departments and other plants.

Keeping Up "Pep" in the Organization—

The safety supervisor must keep his organization, which no doubt consists of one or more men at each works or mine, "pepped" up in the accident prevention work, and even though the best of records is not made every month, it is the duty of the safety supervisor to keep his organization working for better records and have them carry the right feeling towards the movement at all times so that they in turn, in their contact with heads of departments, foremen and men, can impart to them to some extent the necessary amount of "pep" and enthusiasm to put the work over and make the results what they should be.

We have tried out one scheme which seems to stimulate interest in the accident prevention work and that is urging workmen to talk at safety meetings. Our meetings of the men are held by the foremen, and at a great many of them a representative of the safety department is present, although not always; but we found that interest in the meetings was lacking somewhat and that the workmen felt that they had no part in them. One of our foremen hit upon the plan of asking a certain workman to talk at the next meeting on any subject of safety that he desired, and this fellow, much to our surprise, prepared a fine talk on the subject. We had never known that he was so well sold on safety, but he certainly covered the subject well, and we found that his fellow workmen were very much interested in what he had to say and his talk brought forth favorable comment from them.

Men Who Talk Safety Are Deeply Interested

That one instance started the ball rolling and we have tried it in many departments and find that men are glad to take part in these meetings and it certainly has a good effect. We feel that when a man gets on his feet and expresses himself as being much interested in safety and calls attention to unsafe practices which his fellow workmen should avoid, that he will naturally go back on the job and practice what he has preached. He will also feel that his fellow workmen are watching him and he will likewise watch them. It will also keep him thinking safety and he will be on the alert to prevent accidents.

We find that workmen, in talking at these meetings, have been more observant of articles printed on the subject of safety than we ever supposed. They frequently quote some newspaper and magazine articles, and this shows that they are deeply interested in the subject and are following it up.

It is necessary in some departments to schedule the meetings of the workmen which the foremen hold. While it is a general rule in our plant that each foreman hold at least two meetings a month of his men, still we find that unless these meetings are scheduled for a certain date or time the foreman is very apt to neglect to hold these meetings, but when he has a schedule before him he usually lives up to it the same as he does his working schedule.

It is at these meetings of workmen held by foremen that you can drive home to the men the cause of the accidents that have occurred in that works, mine or department, and time should be taken to go into the causes of some of these accidents in detail.

It is also well, at such meetings, to let it be known what discipline is used for the violation of safety rules. There are certain cases, from time to time, where the management feels it is necessary to use discipline, not only as to a workman but as to foremen, and we find it does no harm to broadcast that discipline has been used. In every case that we have mentioned in our meetings the men always comment on this and say that the right action was taken by the company in view of the circumstances surrounding the occasion for it.

It seems imperative to me that an arrangement for the interchange of plant accident experiences be in effect in the small organization as well as in the

large, the same as an interchange of operating experiences to make any organization as efficient as it should be. I fully believe that being forewarned is being forearmed, and we certainly should profit by the experiences in one department to prevent the occurrence of a similar accident in another department or another works and not allow these warnings to go unheeded.

As many of you know, safety bulletins are issued by many companies in this country and I know that I find it to be of great advantage to be on the mailing list to receive these various bulletins, as many times they have records of accidents that we can use to advantage in our plant in preventing such occurrence there.

I cannot urge too strongly the interchange of plant experiences between the various plants of any organization, no matter how small or large the plant may be.

100 Group Safety Supervisors Were Present

CHAIRMAN DEBLOIS: Gentlemen, this was another very excellent paper. Before we start the discussion, I want to satisfy my own curiosity. I would like every man here in the room who is a salaried safety man having charge of more than one plant, that is, having more than one plant under his jurisdiction, in other words, any man who is really a group safety man, to raise his hand.

(About a third of the men present raised their hands.)

I estimate at least a third. We have about 300 men present. It means we have 100 group safety supervisors, or very close to it.

E. R. LAWLER: (U. S. Rubber Co., Hartford, Conn.): I would like to ask if these meetings of the employees are held during working hours or after and if you pay the employees for the time spent on the meetings.

MR. HENSEL: The meetings are all held on the company's time. They are held during working hours, and I might add the time most advantageous to that department is selected. We, of course, don't go in and ask a department where there can be no shut-down to let us have all their men at any one time, but we see to it that in those departments where the men cannot all be spared at once, they are in a meeting twice a month. Those meetings are held at various times; in some departments we have to have from four to six meetings to get all their men in.

R. B. KELLY (Anaconda Copper Mining Co.): What has been your experience in the use of posters? How do you use them? Have you any program?

MR. HENSEL: I presume you refer to the National Safety Council posters.

MR. KELLY: Yes.

MR. HENSEL: I might say that my own way of handling that is to allow the safety inspector from each organization to select the posters from the NATIONAL SAFETY NEWS each month and I supervise it by having his order sent to me to see that he is ordering what I think best fits his operation; although I think each man on the job perhaps knows as well as, perhaps better, than I what really answers his purpose.

These posters are placed about the plant, some on bulletin boards outside where they have to be covered with glass, others on open faced boards on the inside of mill buildings.

A. F. GRIGGS (Walworth Co., Kewanee, Ill.): I would like to ask the speaker what he thinks of what they call "humorous bulletins," that is, the cartoons:

MR. HENSEL: I think the so-called humorous bulletins have a place in safety, but I do not like to see the use too general. I don't think safety is anything we can make light of. I think a humorous subject can be handled right, however; and it is by a number of organizations that issue their own posters. I think we have to use great care in getting up such a poster. We often see examples which we

would not care to use. I think you have to leave it up to the judgment of the plant safety supervisor.

L. H. BRUNO (Chicago Brick Exchange, Chicago, Ill.): What means do you take of reporting accidents, in many cases minor accidents, that might develop into serious accidents? What means do you take of having those reported to your office? Sometimes a man might be injured and let it go two or three days until it developed into a serious matter. You would be uncertain whether the accident had happened in the plant or at home when he was splitting kindling wood.

MR. HENSEL: I might answer that in two or three ways. I might say first of all that every accident reported to our first aid room for treatment is also reported to our safety department and to my office.

If you ask whether we exchange between plants a record of accidents which perhaps are not very serious but may have been serious, I may say that if we see a case we would call a very "near-serious accident," we write it up in a special accident letter. If the accident is of a trivial nature, it is not exchanged between various plants.

CHAIRMAN DEBLOIS: I want to take this opportunity to make a comment on the so-called minor accidents.

I wonder if you realize how much there is to be learned from the minor accident. Now what really happened, a good many years ago in this country was, that we more or less arbitrarily drew a line across the center of our accident experience and said, all above the line is reportable and on it we will base our frequency and severity rates; all the experience below the line is a good thing to keep a record of and to draw some general lesson from, but we won't base any rates upon it.

Stressing the Importance of Minor Accidents

I do not wish to question the policy of doing this at the time, but I now think what we did was practically to throw overboard a lot of exceedingly valuable experience. Small plants—relatively small plants, employing under 100 men—do not have enough accident experience in a year to give them a credible frequency rate and, much less, a credible severity rate. By this I mean that the rates are subject to such violent fluctuations, particularly the severity rate, that in a small plant even after years of experience no one can tell whether it really has a good rate or a poor rate. It may have had a run of bad accidents, but it is possible to tell whether they represent the normal conditions or a chance distribution.

One of the best accident statisticians in the country, Dr. Chaney of the U. S. Bureau of Labor Statistics, when he compiles the rates of the entire steel industry, employing thousands of men, is not satisfied to publish in his charts the rates based on the experience of single years; his charts are based on a three-years moving average.

Now, if we knew more about our minor accidents, gentlemen, we would know more about the accident trend of the small plants. Our accident rates would have a higher credibility, if we draw the division line at a lower level. I just want to leave this thought with you. Don't neglect your minor accident records.

L. G. HADLEY (Utah Copper Co.): May I refer Mr. Hansel back to his method of conducting his departmental form of safety meetings? Did I understand him to say the foremen conduct the meeting every two weeks and use the entire force for their audience for those meetings? What is the duration of those meetings?

MR. HENSEL: The meetings do not always contain all the men in the department. There may be certain departments where we cannot spare all the men at one time, but those men who are not brought in the first day are brought in the next day to a second meeting.

As to duration, the meetings run from 15 to 20 minutes and sometimes a little beyond.

E. A. SMITH (Titanium Pigment Co., Carondelet, Mo.): I understood Mr. Hensel to say something about assessing a penalty of some kind for accidents. What is that penalty?

MR. HENSEL: I think I mentioned discipline, if that is the question. Our people do, as the speaker before me said, use discipline and it is put up to the plant management as to where and how it shall be used. You certainly do have to use common sense as to whether a man is to be called in and talked to on a matter, whether he is to be given a day or a week off, or whether he is to be dismissed from the service. We have had cases of all types. I think it depends upon the rule which the man has disobeyed.

CHAIRMAN DEBLOIS: The time is up; our next paper is on, "Inter-Plant No-Accident Competitions." We have as a speaker a gentleman who is well-known to many of you. I always think of him as an automobile man, but I have looked over his past history and find he has been in the paper industry, in lumber and in civil engineering. He used to be the safety man of the Buick Motor Company. He is now safety director of Jones & Laughlin Steel Corporation. **MR. EARL BLANK.**

Inter-Plant No-Accident Competitions

E. F. Blank, Jones & Laughlin Steel Corporation, Pittsburgh, Pa.

Feeling that more practical value will come from general discussion of a subject of this nature, I will make my presentation as brief as possible, dealing only with fundamentals and hoping that if anyone present is interested in details, the same will be brought out in the discussion to follow.

I believe that the greatest problem of any safety engineer today is: How to arouse and maintain interest in safety. Most of our accidents result from the thoughtlessness of some one. If we could get our employees to think of safety at all times, there would be very few accidents. Of course, machinery must be guarded, ample working space and sufficient light provided, but I am taking it for granted that this work has been done in your plants, and though it has been done, you are still having accidents. From 60 to 90 per cent of our industrial accidents are due to causes over which only the human element has control—accidents which could not possibly be prevented by mechanical or physical means—therefore, our problem is: How to keep "Safety" in the thoughts of our employees at all times.

Why not make a game of it? The average American is a great sports fan. He likes to watch a ball game, a race, a boxing exhibition, in fact, any kind of a contest where strength, speed, endurance or skill in any line is featured. If one is acquainted with the contestants, the interest is greater; and if one has the opportunity to participate in the contest in any way, the interest is still keener. Why not create interest and a competitive spirit by matching one department against another or one plant against another, with the elimination of accidents as the aim of the contest? In a contest of this kind, it is possible for all employees to participate and if properly conducted, it will create an interest that would result in a reduction in accidents.

The first thing to establish when it has been decided to have a safety contest is a set of rules for the competition. These rules should be as simple and equitable as possible and should meet with the approval of a majority of the persons competing. Care should be taken that every one understands the rules and the basis of competition at the beginning of the contest. It should be decided what will be the period covered by the contest and how the winner is to be determined. The method of determining the winner, of course, is a

very important matter in any contest. The following are some of the most popular plans:

- (1) Longest period without a lost-time accident.
- (2) Best accident severity rate.
- (3) Best accident frequency rate.
- (4) Best adjusted severity rate.
- (5) Best adjusted frequency rate.
- (6) Greatest reduction in accident frequency.
- (7) Greatest reduction in accident severity.
- (8) Combined accident frequency and severity rates.

One of the first things to be decided in any of these plans is: What shall constitute an accident? This should be clearly defined. Most contests are based on lost-time accidents. According to the National Safety Council's standard, this is an accident which causes death, permanent disability or loss of time beyond the shift on which the accident occurred.

In contests based on accident severity it is necessary to know the number of days lost from injury. For temporary disability, the actual number of days lost are counted. In case of death or permanent disability, the standard scale of time losses is generally used, 6,000 days being charged for a death, 300 days for a finger, and so on in accordance with the seriousness of the injury.

We who have been using the national standard method of computing accident rates for a number of years have come to talk rather glibly of frequency and severity. It may be well to explain at this point that accident frequency is the number of lost-time accidents per million hours worked and accident severity is the number of days lost per thousand hours worked. This takes into consideration exposure which is calculated in terms of hours worked. Every hour worked is an hour's exposure to hazard. The time records of most are kept in hours and it is not a difficult matter to get these figures.

Four Safety Contests Simultaneously

The competing units in a safety contest are usually determined somewhat by the division of supervision. It is well to have the units as near the same size as possible. This helps to make the contest more equitable.

We are conducting in our steel plants at the present time four safety contests. One is an inter-works contest between the three chief operating units and the others are inter-departmental competitions in each of these works. Besides these contests in the plants, our two railroad subsidiaries are competing in the same sort of contest. All of the contests are on an adjusted severity basis, or a "severity per hazard" basis, as we call it. Each department is given a hazard rating which is based on the compensation insurance manual rate for the occupation or operation. By dividing the accident severity by this rate or hazard factor all departments are reduced to the same basis for comparison. Each plant is rated compositely by multiplying the number of men in each department by the hazard rate and dividing the sum of the products by the total number of men in the plant. In departments where there are several classes of work, each occupation is rated and a composite rate for the department computed in the same manner.

The contests run from month to month, a trophy being awarded to the winners, who hold same until it is won by another unit. At the end of the year the trophy will be permanently awarded to the department, works or railroad which has the best adjusted severity rate on an annual basis. This gives us a chance to award the trophy to the department with the best record each month and to make a permanent award at the end of the year. The monthly

competition keeps the interest in the contest alive and all have their hopes of permanent possession of the trophy.

We have selected as the trophy for the inter-works contest this year a bronze sculptural group depicting the steel worker's safe return home at the end of the day; for the inter-departmental competitions, bronze plaques, suitably inscribed and showing the monthly winners; and for the railroad contest, a silver loving cup.

The intrinsic value of the prize matters little. It is the thing for which it stands that counts. Every one who has ambition strives to be a winner or a top-notch in something and these contests give departmental groups a chance to exert their prize winning ability, thereby stimulating departmental cooperation and pride and reducing accidents at the same time.

The standings of the departments are computed each month from our accident records and a monthly safety standings report is compiled and sent to all foremen and superintendents and is also posted in all bulletin boards so that employees can see the standings of their departments.

Details of the Bulletin Boards

We also have some large special boards made up which show the number of accidents in each department for the current month, the severity for the last month and the year to date, and the rank of the departments for last month and the year to date. These boards also designate the departments in the plants which have won the contest each month and the plants which have held the inter-works trophy. Our largest bulletin board is 9x16 feet and is mounted in a conspicuous place at the main entrance of the plant. Showing the current accidents during the month tends to keep the interest alive and spur the workers in each department to greater efforts against accidents.

Our first intensive safety campaign was conducted in November, 1926, in cooperation with the Western Pennsylvania Safety Council which was sponsoring a Thanksgiving No-Accident Month. We felt that November was a particularly appropriate month to hold a campaign as figures for a number of years indicated that accidents increased in our plants in November and that the months of November, December, January and February were our worst months for serious accidents. This was probably due somewhat to the seasonal increase in production activities and perhaps somewhat due to the advent of cold weather.

It was decided to conduct a contest between our Aliquippa works, at Woodlawn, Pa., and the works in Pittsburgh, on an adjusted severity basis, the winner to receive a bronze tablet especially designed for the occasion.

Considerable publicity was given to the campaign prior to November and when the contest opened, every employee was on his toes to make a record. On October 19, a safety rally was held in the Moose Temple at Pittsburgh, where about 1,000 superintendents, foremen and key men gathered to hear the challenge from the safety engineer at Aliquippa and its answer, and to learn the details of the campaign. On October 21 a similar rally was held at Woodlawn with about 1,500 supervisors in attendance. News letters were sent to all foremen giving the details of the contest and asking that they call their men together before November 1 and pass on the information.

Special posters announcing the contest were displayed on all bulletin boards during the last week of October and special display posters were exhibited during the month. Eight-foot banners were displayed to show which plant was in the lead. The Pittsburgh banner was a green rectangular flag with the inscription in white, "Pittsburgh Works—November—No Accidents." The Aliquippa flag bore a similar inscription with green letters on a white background.

These banners were arranged on the main flag pole at each plant, with the flag of the leading works on top so that the workers could see the position of their plant in the contest each day. When the flags changed positions, the telephones in the safety department were kept busy with inquiries regarding the reason for the change. Blueprint charts were also printed showing the daily record of days lost through injury so that department heads could follow the progress of the contest from day to day.

The result of the contest was a 78 per cent reduction in accident severity as compared with the previous November, and 74 per cent reduction compared with the previous month. Frequency rates were also reduced by 40 per cent.

I believe that a great deal of the success of this campaign can be attributed to workmen's meetings which were held by the departmental foremen during the month. At the Aliquippa works every foreman had his men together for a while each day to talk to them about safety in order that they might reduce accidents to a minimum. A safety pledge was signed and sent in to the safety department each day by each departmental foreman stating that he had talked to his men about safety. More than 10,000 pledges were sent in, indicating that more than 10,000 meetings were held in this works alone. These meetings are a regular item in our safety program and were merely intensified during this campaign. Some departments hold these meetings normally each week, some bi-weekly, while others hold one a month. A report on each of these meetings is made to the safety department, stating the amount of time consumed, number of men present, and safety matters discussed.

You can readily see from this outline of activities that to get results more is necessary than simply to announce that a safety campaign is going to be conducted and expect accidents to be thereby reduced. The entire organization must be thoroughly sold on the idea; it is somewhat similar to organizing a Community Chest or Liberty Loan drive. Considerable publicity and "hurrah, boys," stuff is necessary to arouse interest and enthusiasm and get the whole plant to enter into the spirit of the thing.

Far-Reaching Effects of the Contests

We feel that our contests have accomplished a great deal in interesting our employees in safety work. Malingering has almost been eliminated and our problem is more in seeing that the men do not get back on the job too soon rather than seeing that they get back soon enough. This, of course, is left entirely up to the doctor, who will not let his professional judgment be influenced by department heads, safety men or any others who might be too ambitious to get men back on the job too soon, thereby aggravating their injury and prolonging their disability.

This brings up the question of returning an injured man to work on a job other than his previous occupation. I might explain our policy in this respect for this is a much discussed question whenever contest rules are considered. We have been asked a number of times: "Do you give injured employees light work in order to save lost time?" I do not like the term "light work" in this connection and would rather call it "special work," for that is what it is in our case. If a man is injured in such a way that it is impossible for him to perform his regular work without aggravating his injury and the foreman of his department can re-arrange his men in such a way that this man can work satisfactorily and someone else in the department do his regular job until he is sufficiently able to handle it himself, this is perfectly legitimate. For instance, if a man had a hand injury and his regular job required the use of both hands at all times he might be temporarily transferred to a lever job which required the use of only

one hand, or in the case of construction work a laborer might act temporarily as water boy and the regular water boy be transferred to the labor gang.

In no case shall a foreman make a job that did not previously exist for an injured employee. The convalescent employee must be able to perform 100 per cent the job to which he is assigned. This, of course, works somewhat of a hardship on departments whose employees must be able-bodied in all respects for it is impossible for them to find special work for partially disabled men. However, it would be just as much of an injustice to say that a man shall not return to work other than his former job, because in a good many instances he is able to produce 100 per cent on other work.

So far this year our severity has been reduced about 66 per cent and our frequency approximately 26 per cent. This is a comparison of the experience of the first eight months of this year with the first eight months of last year. We believe that our competitive safety campaign has had considerable influence on this reduction. I believe that any well planned safety contest will result in accident elimination to some extent. The basis of the contest and details for best results depend on local conditions. There is no set of rules which would answer for all cases. The competitive idea is just a means of arousing and maintaining the interest of the employees in accident prevention and is also a demonstration of the management's interest in the safety of the employees. If you have not tried it in your plants, I would strongly advise you to do so. It will be worth the effort.

Planning the Inter-departmental Contest

CHAIRMAN DEBLOIS: I think we should be grateful to Mr. Blank and to all our speakers today for giving us very practical, sound papers, coming out of their own personal experience.

We want a discussion on Mr. Blank's paper. He has brought up a great many interesting points and some on which there is not a unanimous opinion.

Unfortunately I have to go to another meeting, and I shall ask Mr. Peake of the American Radiator Company to take the chair. I hope as many as can will stay through to the end and get into the general discussion of all the papers. You will undoubtedly have more questions to ask as we have heard some very real stuff and the speakers are at your disposal to give further information.

(Mr. C. L. Peake took the chair.)

CHAIRMAN PEAKE: Without waiting any longer, we will go into the discussion.

MR. COLE (Wyman Gorman Co.): I should like to ask the speaker what he would say about conducting an interdepartmental contest, in a plant of say 600, where there may be considerable difference in the hazards of the various departments and possibly in the number of men employed.

MR. BLANK: As I said, we use a hazard rating or hazard factor which is based on the compensation manual rates. That takes care of the difference in hazard by using either frequency or severity rates. You are taking care of the difference in the size of the departments because your common denominator is the number of hours worked.

Of course these rates don't mean a thing except as factors. Our manual rates will run anywhere from .60 to 1.90. I think, which is perhaps one of our highest rates. The minimum rate for insurance is .60. By dividing your severity rates by these hazard factors it brings them all down to a common basis for comparison.

I think this could be worked out as well in a plant of 600 men as in a plant of 1,000 men.

M. D. MOORE (Ward Donnell Co.): Referring back to the statement that Mr.

Blank made in connection with the return of injured employees, I would like to ask if I understood him correctly to the effect that the injured man usually returned to the department in which he was injured and was given work therein that he could immediately do.

We had a case of a man losing an eye. He was a punch operator and it was almost impossible—in fact, the doctor advised against it—to return him to his former job, and it was pretty hard to use him in the steel plant because he might get hurt in some other way. As he had only one-half his former vision.

What would your supervisors do in a case like that?

MR. BLANK: We try to get the foreman in that department to take him back on another job in that department, if he can't do his own work: but in a good many cases the foreman in that department doesn't have any special work he can do and we prevail on someone else. You know everybody kicks about taking someone else's cripple, but we cooperate pretty well. They usually say, "Bill can use him on such-and-such a job."

A. BRANMORE (National Carbon Co., Cleveland): It might be interesting to say how we handle cases of that sort. When it is necessary to transfer a man from one department to another, we generally pay the man (that is, recharge the department receiving the man), as much as he actually earns, and we bill the difference back to the department where he was hurt. In that way we satisfy everybody.

Contest Rules Must Be Simple As Possible

CHAIRMAN PEAKE: Before we get off this particular subject of the contest, I want to ask Mr. Blank if he uses the improvement basis. I don't believe he does. I wonder if there is anyone in the group who uses "improvement" as a basis similar to the Carnegie Steel. They have been doing it for a number of years. They use "improvement" and frequency as a basis.

E. R. LAWLER (U. S. Rubber Co., Hartford, Conn.): We have been taking severity at 50 points, frequency of lost time accidents 25 points, cost per thousand hours work, 20 points, and frequency of minor accidents 5 points, which gives you 100. We take the rates of those four different groups for three years back and work up a rate. Then the factory making the greatest improvement in 1927 over the three previous years is the winner in that contest.

They worked that out and decided that severity was the one for which you should receive the greatest credit, so you get 50 per cent on what you improve in your severity and 25 per cent on frequency of lost time, etc. The factory that shows the biggest improvement is the winner.

CHAIRMAN PEAKE: It seems to me that one of the most important points in laying down rules for a contest is that the rules be as simple as possible, so the workmen and certainly the foremen will understand how it is set up.

Mr. Blank mentioned the hazard factor. I wonder if he found that its use has decreased interest in the contest?

MR. BLANK: That hazard factor is a simple proposition in our case. The monthly report we put out shows hours worked, number of lost time cases, number of days lost, accident severity. If anybody is using accident severity as a basis of comparison, so far it is the same as our report.

The next column is the hazard rating and then severity for hazards, as we call it. Severity is divided by this hazard rate, and that brings it to the same basis for comparison. They understand; each department has a hazard rating. They don't care about the history of it except that they hope it has been selected fairly, and in this case, having used it for a number of years they have got so they understand it quite thoroughly.

I might say this, in regard to this improvement proposition: We had a very interesting discussion a few weeks ago in regard to the basis for our November No-Accident Campaign, which we are going to conduct again this year. We were setting up our rules for it, and before we actually adopted this standard we wanted to find out whether everybody was satisfied with the rules we used last year in the November contest. So, before our superintendents' safety meeting at one of the plants this subject was introduced and we asked them which they would sooner have—last year's basis or an improvement basis. We could only go back two years because that was as far back as we had a comparable record.

We started January 1, 1925, to use this system. So we proposed they compare their November record with the record from 1925 to date, that is, January, 1925 to date. You should have heard the squall that came up because of the fact that if a fellow had an excellent record for the last two years and ten months, he was going to have a hard time to beat it, whereas, if a fellow had had a fatality in his department or a bad record, he would have a good chance of winning. So they finally decided to go back to the old system.

A very interesting thing came out in that connection. When we had the last race on the plants ran along neck and neck until about November 20. There was no serious injury, except one man lost a finger and there were 300 days charged up. On November 20 a man lost a leg. The other plant went ahead, but they weren't elated over the thing at all, because they felt badly about their fellow-employee losing his finger. Pittsburgh finally won the contest, but it made the fellows think about the loss of a finger more than they had about a fatal case before.

Charge Lost Time to the Month It Occurs

MR. STARR (Indianapolis Power and Light Co., Indianapolis, Ind.): I should like to ask a question in regard to keeping time on lost-time accidents. For instance, take the illustration cited—a man losing his finger, 300 days. Does he count that in one month, the month the accident happened?

MR. BLANK: We charge that in the month the accident occurred. A proposition of 300 days is easy. You just charge it in. Suppose you have an accident that disabled a man for six months. The doctor's estimate is taken and charged into that month. It isn't spread over at all. That severity rate reflects on conditions in that month and no other month.

Somebody is going to ask if I won't explain what we do if our estimates are not right. A man might say 30 days is the estimated disability. Perhaps infection sets in after ten days or a week and the man is off for several months. All that is charged off is the 30 days, but we carry along the severity for the year and the corrections are made in that year to date, so that at the end of the year all those little misses of a few days one way or the other are ironed out. You would be surprised to know just how little that difference is of giving and taking when you come to the end of your estimate and have gone a year beyond. You may be just a few days out. Sometimes the estimate is a little too high and sometimes it is a little too low.

MR. GREEN (Western Cartridge Co.): I would like to know how Mr. Blank figures an injury of a minor nature. According to the national table the loss of a finger is to be counted as 300 days. You may have a minor injury that doesn't involve any loss of time but maybe six months from now it will involve compensation loss of \$25. What procedure do you take in figuring lost time?

MR. BLANK: You mean he hasn't lost any time at all at first?

MR. GREEN: Yes, that happens once in a while.

MR. BLANK: That is taken care of in our corrections. It is too late to get into that month's figures, but it goes into the year's figures.

That is one place I don't agree with the scale of time losses. We have been using it for six years. Someone has proposed that we change it. I think it would be a mistake to change it. Although it isn't equitable the way it is, if you change it, it is going to change your experience. Where it isn't equitable, is in that while your compensation laws allow so much for half a finger, by the national council's scale if there is an amputation, you charge the full amount.

MR. GREEN: I understand that, but you can have a disfigured finger nail, for instance, without any loss at all.

MR. BLANK: You mean: Do we add the \$300 or do we deduct it?

MR. GREEN: You haven't any finger loss, but a little disfigurement.

MR. BLANK: We don't have any disfigurement in our state, but if we did, it would have to be figured on a percentage basis. We don't have any disfigurement of that nature as you do in New York State or in some of the others.

MR. BARNES (Algoma Steel Co.): I would like to ask Mr. Blank how far his company would go in the matter of safety work before putting on these contests. Would you get your safety rules pretty well drawn up or would you recommend the injection of this contest at any time?

All Safety Rules Thoroughly Understood

MR. BLANK: Of course, in our case safety work has been done for a good many years on the ordinary basis of using posters and safety committees, etc., and safety rules are pretty well established. It is very important to have all of your rules, etc., thoroughly understood, after which a safety contest or competition could be started almost any time. A lot of publicity is necessary. You have to get enthusiasm and interest stirred up and the more you get of it the better results you are going to get.

You can start a campaign any time and give it a little publicity in advance and have your rules thoroughly written up and understood, and I don't believe it would make much difference.

MR. BARNES: I mean your safety rules, rules governing the safety operation, safety practices, etc.

MR. BLANK: We don't have many hard and fast rules. We have general rules, but most of our rules are common sense operating rules. We have special rules for train operators and train repair men and such occupations as that, but most of our rules are safe practices and those are set down by the departmental head. It is an operating problem. Our safety work is an operating problem entirely. The operating department have entire charge of the safety work. The safety engineer is himself just an advisor who helps to promote these schemes, but the actual work has to be done by the foreman or the superintendent, the man on the job. He is the fellow who enforces the safety rules and practically makes them as far as that is concerned.

MR. MOREY (Hartford Accident & Indemnity Co., Hartford, Conn.): I would like to know just what difference you find in the accident figures between the men working days and the men working at night. Is there any difference?

MR. BLANK: I can't answer that. We never made a check of that. Years ago I made some studies of time of day and a lot of these occupational studies, etc., and after making them several times, I came to the decision it was a lot of useless waste of time.

I don't know how that would stack up. The chances are you would probably have a few more accidents per force at night. I think it would be natural to expect that, but I couldn't say because we haven't made an accurate check.

CHAIRMAN PEAKE: I think you can state this with perfect confidence, that after any outfit has introduced a night force, after they have been operating only a day

force, the accidents go up. Whether, after it has been carried on some time, there are more accidents among the night force than among the day force, is a question.

MR. GRAY (People's Gas Company, Pittsburgh, Pa.): When we first started our accident prevention work in 1925, we started off in January with a contest with no hard and fast safety rules. The contest was based on reduction in frequency rate. Our experience was that we did make a reduction in our frequency of about 98 per cent the first year.

MR. COLLIER (General Industries): Mr. Blank made the remark that his foremen conduct campaigns in regard to the prevention of accidents. How do you educate your foremen in safety prevention?

MR. BLANK: We have a number of ways of getting to the foremen. We have these rallies of which I speak. We have them throughout the year, but we have a more intensified program of rallies during a campaign like the no-accident campaign. At that time we get the foremen together and have speakers. Perhaps somebody from the general management talks to them about what they expect from them; sometimes the safety engineers talk.

We also have as a regular part of our program what we call the foremen's safety news letter, which we send out to approximately 750 foremen periodically. We don't have any stated time—weekly, bi-weekly or monthly. When we have anything, we send it out. It contains any information on safety that these men might use in their workmen's meetings. You see we have to keep feeding them something of interest for those meetings.

Safety Meetings Are Bringing Results

We rely a good deal on the meetings. We started them a little over a year ago and they are getting results. I will say for the benefit of you who are plant speakers, who go out and talk to these fellows, that I think the idea of having the foremen do the talking is 1,000 per cent better. I have gone out and talked to foremen and talked to groups of men, but when the foreman calls that group together and tells them about safety and tells them what he wants them to do, as he is the man who hires and fires them (and if he is in earnest), they line up. If the safety engineer goes out and holds meetings, they say, "There comes that guy with a lot more bunk!" I have heard the same thing said when somebody else was doing the talking: "Here's that guy that is going to fill us full of hot air!" But I think you get away from that when the foreman is on the job.

W. N. CLINTON (Metropolitan Life Insurance Co., New York City): If Mr. Blank still has breath left, I would like to ask if he will outline the hazard factor table, giving us the classification of it and what each factor is according to occupation.

MR. BLANK: That is quite a job. You are going to have me reciting from the compensation manual rates. Of course, we in Pennsylvania have a different manual than they have in the rest of the states. We have our own compensation manual, but it is based on the idea that the compensation insurance companies come in and rate your plant. They give your plant a certain rating depending entirely on the hazard and it is, of course, determined by years of experience, as you know, being in the insurance game. We feel there is enough experience to justify using such figures as our basis.

But if you want to know what some of the rates are that we use, I will say our rolling mill rate is \$1.20. The rate for the Bessemer department is \$1.40; for the pattern shop, 75 cents; for the roll shop 75 cents, that is, the machinshop classification.

Sometimes we have to interpolate a little bit in picking a rate. We can't find

that rate in the manual, so we select a rate that is the nearest thing to that kind of job and use it. The job of rating is a pretty intricate one, but once you have your rates established, if your departments don't change, your rates don't change, unless your manual changes. Your manuals change from time to time. There have been some drastic changes in rates. If any of you fellows have punch press departments, you will remember that the first rate was \$18.25. The next rate was \$8.05. They just knocked \$10 off. That came through safety work. Now it is down to \$4.85 or something like that, which shows how the general experience is reflected.

MR. CINTON: These rates are published or printed so the men all understand them?

MR. BLANK: In order to get it, you have to get your insurance manual.

CHAIRMAN PEAKE: You can do that where you have your rolling and your blast furnace. Some of us, who are rated as a whole, cannot do that. That will apply to some industries but not to others. That was why I was particularly interested in having the matter of improvement made out, which was brought out by the U. S. Rubber.

For some time the American Radiator Company had a trophy which was awarded on the basis of improvement. We had our group together to decide on a wording for the next year's trophy, and we found definite opposition. On the other hand, we hesitated on making it a straight-out accident contest, because some of our plants have a hazard which without a doubt, is higher than others. The boiler plant, for instance, is rated exactly the same in the insurance manual although the hazard is greater than in the radiator plant. Some are mechanically operated and some are hand operated. It doesn't seem fair to put them on the straight-out basis.

Individual Awards Are Sometimes Given

J. C. MADLEY (Connor Company): I would like to ask Mr. Blank if, in conducting these departmental interplant groups of safety contests where the winner is awarded a trophy for his department, do they ever award individually the men taking part? For instance, do you pass cigars to the fellows who win the contest?

MR. BLANK: That isn't done as a plant proposition. However, some of our smaller departments are running contests of their own. The gang get together and they run a little contest from month to month. The department that has had the worst experience buys the cigars for the one that has had the best experience. They work that out themselves. We have never given individual prizes but once.

A year ago last November we gave watch fobs to the foremen in the departments that had the best records. But I really think the trophy idea goes over better. It is easier to handle and I think it is just as much appreciated. We gave a fob with the mill insignia and the inscription "Safety Award." We started out to award these to the foremen of the department that had the best record in cash plant. We found, when we got through with the contest, that there were a lot of departments that had 100 per cent and no accidents, but some other departments beat them because of the fact that they had a larger force. So there was a winner and still some other fellows that were 100 per cent. So what we did was to give sterling silver fobs to the winners and bronze fobs from the same die to those who had no accidents.

We like the trophies better. Last winter we had that sculptural group for the inter-works trophy. Last November we had the bronze tablet. That is a picture of it down there (pointing). They have it permanently in the main entrance. They also had the interdepartmental trophy for this year and they had them all lined up together. It just happened they were the winners for the interdepartmental inter-

works trophy and had the others, last year's trophy and the trophy for the month of November.

I don't believe the kind of trophy makes much difference; it is just putting something up for them to fight for. The same sculptor who made this group for us last year is working on a new one for this November. It is going to be more or less in the shape of a tablet. If any of you were down in Philadelphia last year and saw that steel statue down there 60 feet high, I might mention that it is the same sculptor who does all our sculptural and trophy work.

RALPH HAYES (Florida Mutual Insurance Co.): I believe Mr. Peake could work out a basis for his accident the same as Mr. Blank. You will have a classification you could use also for your machine shop and for your foundries, which I believe could be applied on a fair basis to your improvement. Each year if you could reduce your number of accidents and losses you are bound to have an improvement reduction in your experience which you can use as an improvement basis.

MR. BLANK: Mr. Peake, in answer to your question of rating in the foundry occupations, etc., I see Mr. Dunham back there. Mr. Dunham is from the General Motors Corporation. They use the same rating. They have malleable foundries, machine shops, and assembly plants and pretty nearly everything in industry. Perhaps Mr. Dunham can explain their system.

MR. DUNHAM: We use the same system Mr. Blank has outlined, but several fellows brought up the question that in a small company or in a line of work that is not diversified you have trouble. The Fisher Body have done effective work in safety through the awarding of the tax bonus. They called in every superintendent, got them together, and among themselves these superintendents agreed which was the most hazardous. They said, "We will set this at 100. Here is another line of work. Do you fellows among yourselves think this line of work is 80 per cent as hazardous as this one?" When they got the superintendents agreed, they used that hazard as the hazard rate.

I think when you have a line and can't get different code classifications, you should get your department heads or superintendents together and let them, among themselves, decide the relative place of each line of work.

CHAIRMAN PEAKE: The main essential is to have it definitely decided before the contests starts.

ADJOURNMENT

**SIXTEENTH ANNUAL SAFETY CONGRESS
NATIONAL SAFETY COUNCIL**

General Round Table

Thursday, September 29, 1927

GEORGE HODGE, Chairman

**Assistant Manager, Industrial Relations, International Harvester Company,
Chicago, Ill.**

IRA V. KEPNER, Assistant Chairman

Safety Director, Pennsylvania Salt Manufacturing Company, Philadelphia, Pa.

The General Round Table of the Sixteenth Annual Safety Congress was called to order at two-ten, Mr. George Hodge, assistant manager, Industrial Relations, International Harvester Company, Chicago, Ill., presiding.

CHAIRMAN HODGE: We have a large arena here for the fight this afternoon, which gives those who fight and run, as we witnessed in a recent fight, plenty of opportunity. There are certain rules of the fight, however, that we want to observe. The referee will be Mr. Ira V. Kepner, safety director of the Pennsylvania Salt Manufacturing Company, Philadelphia. He is an old pioneer of the safety movement, and knows all the rules of the game. I think you will find him on his feet ready to give you the count if you don't come up to scratch in observing the rules and regulations of the meeting.

The first number on the program, will be, "First Aid Everyone Should Know." It is a demonstration held under the direction of Dr. Hart E. Fisher, Chief Surgeon of the Chicago Rapid Transit Co. It gives me a great deal of pleasure to present Dr. Fisher.

Some of the Things You Should Know About First Aid

**Hart E. Fisher, M. D., Chief Surgeon, Chicago Rapid Transit Company,
Chicago, Ill.**

We have a demonstration in store for you today which I know will interest you greatly, both from a standpoint of education and novelty. Fifteen years ago we started teaching laymen the principles of first aid, by a systematic and standardized course of instructions. This course included the teaching of what to do to save life, minimize pain and other essential factors, which, properly put into practice, would hasten the convalescence of a patient.

The first aid man is instructed to function only from the time of accident until the properly authorized medical man arrives. Many of these accidents occur in remote and isolated places where many valuable minutes, and often hours, must of

necessity elapse before the doctor arrives, on account of distance, and even though the doctor is available, precious minutes pass while he is on the way. For this reason, it became essential that laymen be trained to function in a crisis and to render first aid in the first few minutes after an accident.

Men were selected according to their position with the industry, their mental ability, amenability to discipline, capability of absorbing instructions so that they could function efficiently in time of emergency, and who knew their limitations and would not try to become so-called "self-made" doctors, or usurp the prerogatives of regularly constituted medical authority.

Employees who are selected to be trained as first aid men attend a regular first aid school for a definite course in first aid, with lectures and demonstrations by the students, until they are able to function smoothly and efficiently. They pass a prac-

The prone pressure method of resuscitation.

tical examination under the direct control of the medical department and receive diplomas from the company, upon graduation. A yearly banquet is held for all graduates, at which gold medals are presented to those who have actually saved the life of a fellow man, either by rescue or efficient first aid, while on duty or away from company property. Incidentally, the greatest number of gold medals have been awarded to employees for saving life away from the job. This year 500 employees will be awarded diplomas, and this promises to be the banner year in our first aid school. These graduates come from five different companies of which I have the honor of being the chief surgeon, and not from one company.

Now I want to say a few words about the first aid equipment necessary in any industry for service at time of injury. The accepted method today is for a smooth talking salesman of first aid supplies to talk the man in authority into purchasing his particular outfit as the best obtainable. Here, gentlemen, is where so many well intentioned first aid systems in industry stub their toes. There is no first aid salesman who can come into your plant and tell you what to use and why, what sort of a container or how much you should buy. This knowledge is obtained only by actual compilation of figures.

Sit down with a pencil and a blue print of the physical property of your own particular company. Plot the location where each accident, resulting in injury, has occurred during the previous two years, for comparison. Then plot the nature of each injury sustained and the part of the body involved. From these two graphs you will see where it is necessary to locate first aid materials for use in time of injury, either by the first aid man or the surgeon. From the classification of injuries you will be able to work out what supplies are actually necessary to attend the injuries most liable to occur. You will be agreeably surprised to learn how few

First aid for the arm fracture.

supplies are really necessary for efficient treatment of injuries. The fewer the supplies the better the first aid rendered.

The type of container can only be worked out by knowing the supplies and quantity required in each outfit. I might suggest that you secure a container that will best suit your needs. Fill it with the essential supplies and after a few years trial, you will be able to choose from experience the best container and method of packing supplies in the container, in order to avoid useless expenditure of money for needless materials and waste.

The average first aid outfit sold is either over-supplied with a poor selection of supplies, over-priced, or put up in such a form that waste is the largest factor. It is essential to avoid fluids in first aid boxes wherever possible, on account of waste, lack of sterility, breakage, or freezing in winter. It is far better to know how to use a few essential first aid materials well than to have only a confused idea of how

to use a large number of materials. A blanket and stretcher are essential equipment in a well organized first aid outfit. The last requisite is a first aid marker, designating the location of a first aid station.

Having discussed with laymen, who are to render first aid, the manner of instruction, and having said a few words about the method of selecting supplies to be used in first aid work, I will now mention the most important factor in efficient and safe first aid work, namely, periodical inspection of first aid equipment by a man, chosen on account of his ability and training, to see that these outfits are maintained in a

One man carries more than his own weight.

complete and sanitary manner. In our companies, this inspection is made every three months. On Tuesday of each week a regular first aid requisition is sent in to the medical department for new supplies, to replace those used in treating injuries. Each first aid outfit has a case record card on which is tabulated the name of the patient, nature of injury, date and what was done for him. These cards are collected and aid in checking the number of trivial injuries, injuries where no time is lost, cost per treatment of first aid, cost of maintenance at each location, and furnish necessary information whether to reduce or increase the number or kind of supplies. Last, it serves the medical department as a check against infections, etc., as it is evidence whether the injured employee reported for medical attention after first aid was rendered in the plant.

In addition to the periodical inspection by those intimately connected with first aid work, the regular inspection of physical property is made more frequently by the various officials and supervisors, who report their findings. The safety engineer is one of my most ardent inspectors, and how he loves to bring to my attention that some first aid outfit is not what it should be. I welcome Mr. Bridges' valuable

Championship team using the prone pressure method.

Beginning the prone pressure movements.

criticisms, as it is only through constructive criticism that we attain the near perfect.

Gentlemen, you will now have the opportunity of seeing the actual results of first aid training and the visible evidence that it is of value, in the ten gentlemen who are now about to perform a few first aid features for your information. These ten men have each been awarded a Gold Medal for saving a human life. These medals are either the Gold Medal of the individual company, the Britton I. Budd Medal for the Saving of Human Life, the Samuel Insull Medal, or the McCarter Medal. They are only a few of the medal winners in our respective companies.

Four of the girls' team in special demonstration.

Three companies are represented here today. The Chicago Rapid Transit Company, the Chicago North Shore and Milwaukee Railroad Company and the Public Service Company of Northern Illinois.

The first demonstration is the obsolete Sylvester method of artificial respiration. It speaks for itself, as compared to the easy, one-man Schaeffer Prone Pressure method, which we use exclusively. Its many advantages over the Sylvester method make comparison useless.

The second demonstration is the treating by first aid of fracture cases.

The third demonstration will show the different methods of transporting injured people.

We have shown you first aid in industry, and for the fourth demonstration, we wish to present eight charming ladies who will show you first aid in the home, by doing the Schaeffer Prone Pressure method of resuscitation.

For the fifth and last demonstration we will present to you a group of school

children who have been taught this work in connection with 463 lectures and demonstrations given to over 183,000 school children. Thus, we are aiming to inculcate the spirit of what to do in time of emergency until the doctor comes, to those in industry, in the home, and the rising generation.

From a public relations standpoint, the training of your employees in first aid shows that you are interested in mankind and in something else beside your particular product. However, the greatest reward is that many lives are saved each year which would otherwise be lost. Needless suffering of many workers is averted by quick action, long periods of convalescence are made unnecessary by efficient

A group of school children demonstrate first aid.

first aid to the worker, and as this means he is returned to his work sooner, it is a big economic factor both to his family and employer. And last, but not least, infections in trivial injuries are reduced to a minimum.

The medical profession is fast coming to look upon efficient first aid to injured in a more favorable light, but it takes a long time to forget what first aid meant a decade ago, with all the incompetent and disastrous results obtained by poorly trained laymen who did not know their limitations.

CHAIRMAN HODGE: I am sure this applause expresses a great appreciation of a very fine demonstration. Certainly there is no finer work in the world than the conservation of human life and limb. We certainly thank you, Doctor, for this splendid talk and demonstration.

DR. A. C. SELMON (Kellogg Co., Battle Creek, Mich.): I wonder if the Doctor has a manual to cover this work.

DR. FISHER: We have various little pamphlets that show this activity, but we haven't any here. If anybody cares for those, and will write us, we will be glad to send them, giving full results of what we have done in this work.

F. SWENSON (Western Electric Co., Cicero, Ill.): It seems that you had about two off and two on in the resuscitation. The Red Cross book doesn't tell it that way. Which is correct.

DR. FISHER: I am going to take the liberty of asking Mr. Wills MacLachlan to reply to that same question. In all the cases of resuscitation that I have experienced, and have seen and talked about with those who have saved people by resuscitation, no one has ever adhered to a textbook as to the amount of pressure to put on and how often to put it on. Your textbooks teach you to put it on and off and simulate actual breathing, 15 or 16 to the minute. That is all right for normal people. When a person is electrocuted or asphyxiated from gas or is submerged, they lack air, which must be brought into the lungs. When you have that condition, it is the same as the condition you have in pneumonia; the air goes into the lung at a more rapid rate because there is an air hunger there, the tissues demand more oxygen, therefore nature itself produces a more rapid respiration. Why doesn't that apply in electric shock and such other cases? You have an abnormal condition. You are trying to put air into the lung and oxygenate the tissues with the air you get into the lung. To tie a man down to fifteen to the minute or sixteen or eighteen is all right in training in order to inculcate discipline and routine so he will function in time of stress or crisis automatically like the solder does under fire, but no man doing resuscitation has the time to stop to count his one, two, one, two. It would be folly if he did. I have seen a number of them put on as high as twenty to thirty. It was not electric shock. The idea is to get the air in the lung and out again; it is the oxygenation of the tissues and stimulating the respiratory centers that you want.

Resuscitated After Eight Hours of Effort

I am not a disciple of any particular time. Mr. Wills MacLachlan is doing a lot of work along that line. He is familiar with the time and the methods of resuscitation. I am sure you would all be pleased to hear him give you a few words along this line.

WILLS MACLACHLAN (Consulting Engineer, Toronto, Canada): In connection with the time or period of resuscitation, the reason that we are teaching them to go slow is to get them over the excitement of the minute at the time of the accident and to give them confidence to carry on.

In connection with one point that has not been emphasized, I should like to take you to a case that happened the 20th of last May, in which a man received a shock at two o'clock in the afternoon. He was lowered from the pole and resuscitation started at the base of the pole. He was then taken to a hospital and resuscitation was carried on in the ambulance. They worked on him continuously. Between seven and eight at night he became quite black. At ten o'clock at night he was breathing normally, after eight hours' solid resuscitation work. That is one of the reasons we are trying to emphasize the training of the men in the correct way. Have them practice it, and don't give up for anybody until your patient breathes or there is definite onset of rigor mortis.

I can speak feelingly, as the chairman of the Insull Medal Awards Committee. It is a divine function to give life, but it must be a wonderful thing to be the agent of the Divinity in restoring life that but for your action would have passed out.

H. W. HINKLEY (Carbide & Carbon Chemicals Corp., Charleston, W. Va.): There seems to be some discussion as to the use of hard objects, such as stones or

sticks, affecting the nervous system in controlling hemorrhage. I should like to know if it has been your experience to find that they do cause further damage.

DR. FISHER: In applying tourniquets (and they are applied in only those cases of severe arterial hemorrhage of large blood vessels), they are applied under the direct caution that they should not be tied too tightly, just sufficient to stop or control the bleeding. If your tourniquet is properly applied above the elbow or above the knees (there are only two places on the body where a tourniquet ever could be applied), the tissues are of such consistency and of such bulk that you do not require a great amount of pressure to get control, therefore you do not do any damage; but great damage can be done in the use of a tourniquet by leaving it on too long or by an improperly applied tourniquet, exerting too much pressure and thereby causing a temporary paralysis of the nerve. But that generally comes back of itself, it is only temporary, not permanent. It would take a tremendous amount of pressure to permanently damage the nerve. The greatest caution is not to leave the tourniquet on too long.

In fifteen years of industrial surgery, I can truthfully say I have seen only about five tourniquets that ever had to be applied to control arterial hemorrhage. Most of those were in cases of amputation of the limb. There are many other ways the boys are taught to control hemorrhage without the use of the tourniquet, but the tourniquet is essential and we must have it with us. We must use some discretion in the manner in which it is applied and the length of time it is left on.

The Petroleum Resolution Starts a Discussion

CHAIRMAN HODGE: Thank you very much, Doctor. This concludes our discussion on the first aid work.

A resolution has been passed to the Chair. "May I suggest that your Section vote on a resolution addressed to the Executive Council as follows:

"WHEREAS, The National Safety Congress is more efficiently and economically held in its headquarters city, and

"WHEREAS, The city favored by the Congress when moved from point to point gains only at the expense of the delegates and their employers, be it therefore

"RESOLVED, That this Section is in favor of holding the Congress in Chicago regularly during the last week of September in each year."

I am going to ask my good friend Mr. Kempner just to say a word with reference to this resolution.

IRA V. KEPNER (Pennsylvania Salt Mfg. Co., Philadelphia): For the past ten or twelve years it has been the policy of the executive office of the National Safety Council to hold their meetings in the various cities throughout the United States to stimulate the safety idea and to organize the various cities for safety. It has been more or less an expensive proposition, but in the early stages of the Council it was very essential. For the past five or six years it has been almost impossible to find a city with proper hotel accommodations. We went to these various cities with the best intentions in the world in order to help them with their safety propaganda. In some cities we have been successful, in others not quite so good. It has always been more or less difficult for some of the delegates to find proper hotel accommodations, particularly at the headquarters hotel of the Council. I am just expressing my own personal opinion regarding the need of finding some place where these meetings can be held under one roof, and this is the first hotel that we have ever been able to occupy that will take care of the entire Congress.

Our first meeting in Detroit some years ago could be accommodated very nicely in the Hotel Statler. The last time, we were at the Hotel Statler, the

Book-Cadillac and the Tuller. Our sections were scattered and we had the delegates all over the city; when they tried to find somebody it was almost impossible. The same thing occurred at Cleveland where we had to hold our meetings in various hotels.

I should just like to have some thought and a vote on this resolution that has been presented.

At one time a majority of our members were in the East and Middle West or in the vicinity of Chicago, and a convention held either in the East or in Chicago was fairly well attended. We now find that we have members and large sections of members as far west as California, and when a meeting is held in New York or in the East it is almost impossible for those delegates to come.

I should like to have a vote of those in favor of meeting in Chicago. It says in the resolution "always," but I think the Executive Committee of the National Safety Council would be willing to change that when they saw a need for making the change.

Will those in favor of meeting in Chicago each year at the discretion of the National Safety Council please raise their hands? Those opposed?

(Majority in favor of meeting in Chicago, only three or four voting against.)

The Object of the Resolution is Explained

MR. WALTER (General Electric Co., West Lynn, Mass.): I think a great many are situated the way I am. I am representing a member of the Safety Council and I do not feel that I have any authority to make a suggestion to the committee as to the place of meeting. I think the influence of this Council meeting in any section of the country is a contribution of such value that it should not be confined to one place for all time. I think if the matter had been left to open discussion before the vote was called for, you must have had a different vote.

CHAIRMAN HODGE: It is always a good thing to have an assistant chairman and a chairman. As chairman I can overrule the other vote and take another one. That is why we have two. If something goes wrong, the other fellow can do something else. Isaiah Hale last year just had to take whatever they gave him.

QUESTION: Had you thought of excluding the Chicago vote?

CHAIRMAN HODGE: It is your meeting. The chairman has no thoughts on it at all. I do think that the gentleman from the General Electric put a little voltage into the room when he arose. I got his flash and I think he is quite right. We heard a statement in favor of holding the convention in Chicago, and I am quite sure that it would meet with Mr. Kepner's approval in taking that vote if we permit a little further discussion and take another vote.

E. P. DURPHY (Hamlin & Co., New York City): I make a suggestion that we leave this question with the Executive Committee of the National Safety Council. The National Safety Council has prospered by the guiding force of the Executive Committee for fifteen years in conducting its Congresses. If it be further the desire of the chairman, I would augment the resolution by saying that it be submitted to the individual members by letter instead of trying to obtain a unanimous opinion in this city with so many Chicago delegates present.

MR. KEPNER: The object of this argument was to have something for the Executive Committee of the National Safety Council to go on. They want to hold the meeting where the delegates want it. I might say for our friend from the East that we held one convention in Boston. If he attended, he knows why we don't want to hold another meeting so far east. It was almost impossible for those much further west than Chicago to attend. The majority of these delegates

have a lot of other duties to attend to, and when they have a trip as far east as Boston or New York, it is difficult.

It is a problem to get a hotel to accept a convention when they have to put almost everybody out of their rooms in order to take that convention for a week. The majority of the hotels that are well established will hardly turn over more than one-third of their rooms. You gentlemen who have attended the various sections here can realize what it means to have a hotel even of this size give us adequate rooms for the delegates to meet in. Just give it serious consideration.

We are not going to solve the problem. That is up to the Executive Committee. They merely would like to have an expression of opinion. This being one of the largest meetings that is held, we feel that we can get an honest opinion. If it were not for the appearance of railroading this through (of course, coming from Philadelphia, they might think that I use steam roller methods in politics), I should like to see a vote. But that is not the idea; it is just merely to get an expression of opinion.

H. E. KAVANAUGH (Commonwealth Edison Co., Chicago): This matter was taken up at the Public Utilities meeting this morning, and I believe it was referred to the Executive Committee to be submitted to the individual members for voting.

H. V. SCHLACKS (Western Electric Co., Cicero): In view of the suggestion that the Chicago vote be excluded, perhaps it is a good suggestion because we can practically assume that all the Chicago people wish it to be held here.

Chicago Delegates May Favor Other Cities

CHAIRMAN HODGES: Speaking as a representative of at least one Chicago member, I would ten times rather have the convention in another town. If you live in Chicago and you go to your office, that means that you don't get to the convention; but when you are out of the city you can give it your undivided attention. I am quite sure that if you took a vote of Chicago people most of them would vote for an out-of-town place.

The Chair will entertain a motion as to what this session desires to recommend to the Executive Committee.

ARTHUR J. JOHNSTON (Massachusetts Safety Council, Boston): May I move that this round table session take no action on the resolution before the house. (The motion was seconded).

R. S. BONSIB (Standard Oil Co. of N. J., New York City): I think that is following the policy of leaving a hard problem unsolved. I don't see any harm at all in showing an expression of opinion. I think that is only fair to the Executive Committee. They want to know how the men feel about it. Personally I have been to all of the Congresses. Anybody who has been to the last two can see the disadvantages we have been up against until we came here. We are not saying this is the best hotel or the best run hotel; they have got a lot to learn yet, but they are new. I believe in having a meeting in a regular place such as this. In the first place, it is easy to get to. There isn't any part of the country that can't get to Chicago very easily.

I, for one, am very strongly in favor of holding the meetings here, and I think it is a very weak stand simply to let it go without decision. If you are for it, say so; if you are against it, say so. Have courage enough to say what you think.

MR. JOHNSON: May I support my motion by saying that votes are taken by membership. I don't readily see how 75 delegates from one member can cast 75 votes on this resolution.

Let's not make monkeys out of ourselves by expressing an opinion one way

or the other and have the Executive Committee of the Congress do as they darned please, as they certainly will. They will go into this thing so much more thoroughly and with an unbiased opinion and get the right answer without the help of a flock of delegates.

CHAIRMAN HODGE: The Executive Committee has submitted a resolution to us. All they want is to get the feeling of the various Sections. What further action they take on it or how far they go in writing to the individuals and getting their expressions and so forth is up to the Executive Committee. They have asked the Round Table session to give them an expression of whether they would like to hold their meetings regularly in Chicago. I think we should tell them.

The gentleman made a motion that we take no vote. There was a second to it. The Chair can only put the motion, and if you don't want that we can kill it and take another vote.

It has been moved and seconded that this session take no vote on this question.

MR. SUTTON (Postum Co., Battle Creek): You say this resolution has been submitted to us by the Executive Committee. I think if you will look at the signature you will determine that is not the case.

CHAIRMAN HODGE: It was submitted by the Petroleum Section to the Executive Committee.

MR. SUTTON: This is not a section. Probably all the ladies and gentlemen here have attended another session and had this proposition put up to them, and it has been voted on in the other organized sections of the Council. I supported the gentleman's motion that we do not take action on that resolution.

(The motion to take no action on the resolution was put to vote and lost.)

MR. BONSBIB: I move you that the General Round Table session endorse the resolution as read.

(The motion was seconded and carried.)

CHAIRMAN HODGE: Well, now that we are all acquainted and have had a very frank expression here—most of my time is spent in acting as chairman of works council meetings and I certainly do feel at home now.

The next subject on the program is "How I Would Seek Safety in a Manufacturing Plant," which will be presented by Mr. A. D. Kaems, safety director of the Simmons Company at Kenosha, Wis. I am sure that Mr. Kaems needs no introduction to any safety group.

How I Would Seek Safety in a Manufacturing Plant

A. L. Kaems, Safety Director, Simmons Company, Kenosha, Wis.

I can give an answer to the subject that has been assigned to me in two words: Educate management. I would first get hold of the manager and try to convince him that he had not been properly educated. We have been for 20 years telling management that only 25 per cent of all the accidents can be avoided by mechanical means and 75 per cent by education. How they have arrived at this I do not know, for I have tried for years to get some definite figures on it, and yet I have not succeeded to my satisfaction.

The manager has done his share, as he believes. He has put in all the mechanical safeguards that he could. He has gone on and tried to help in reaching the 75 per cent by putting in organizations in his shop and educating his foremen. It has been thought all the time that the big men who put this across are the foremen. Let us see what a foreman really can do. We must know whether the foreman is the man or not.

I am going to try to point out some of the things that the foreman must do. First, he must get out production, without which no plant can exist. His production must be up to the standard. If a man wants a raise in wages, to whom does he go? The foreman. If a man is dissatisfied with his job, he goes to the foreman. On top of that, we try to say that he ought to be the man to teach safety to the men, besides. I am just wondering, if we have that kind of foremen in the industry, whether they would stay foremen long or whether they would have a position rather than a job.

Since we couldn't get any statistics on this matter (and we have tried so hard to make men realize what accidents are), I have taken our plant and compiled our statistics for seven years. We have kept close track of every accident that has occurred in which one day's time or more was lost. That showed that we had 25 accidents in the 25 per cent class, and 1,451 accidents in the 75 per cent class.

I have classified the accidents into bruises, cuts, sprains, infections, fractures, burns, and eyes. I believe that covers about the ordinary accidents that occur in any plant. Of these accidents, there were 400 burns, 344 cuts, 263 sprains, 192 infections, 89 fractures, 81 burns, and 83 eye cases. The total lost time was 15,557 days. I would go to a manager and I would ask him, if he were a full-fledged, 100 per cent safety man, how many of those 1,451 accidents he would have been able to reduce?

Every Accident Should be Analyzed for Cause

We have to find out what causes those accidents; and if that man had gone out and made an investigation of every one of those 1,451 accidents, I assure you there would have been very few which a foreman could have prevented.

Let us take the 400 cuts, due to handling of material. If you take men who must continuously handle material, pile it up in unusual places for which it wasn't intended, you are going to have bruises and cuts; there are no two ways about that. Could a foreman stop that? Of course not. If you were handling ten million pounds of wire and sheet metal a month and were handling a million feet of lumber a month, you would expect that you would have cuts. No foreman could prevent that.

How are you going to stop sprains? Sprains have no way of being prevented. A man will get sprained in spite of how careful he is and how cautious he is.

We know that infections come when we take the best of care of wounds. I have had one example of that in my personal experience. Several years ago I had to go to Grand Rapids, Michigan, to give a talk, and somehow or other I had cut my finger. I had it dressed in the first aid room properly, and yet I had a peach of an infection. I haven't yet heard the last of going to a Safety Council meeting with an infected finger and giving a talk on safety.

As long as you are going to handle materials in your plant you are going to have fractures. I will assure you it isn't due to the foreman's being negligent. Fractures can happen at any time, due to falling on bad floors or almost anything. Can a foreman help having a bad floor? That is the maintenance man's duty.

The same is true of burns. I could mention many of these things which no foreman could prevent, but someone higher up could.

The great trouble is that we have not started out in this work to analyze and investigate our accidents. If we did that, if we made an impartial investigation and put the blame where it should be, you would be surprised what would happen. We have had many sprains in our plant due to men stumbling over a bad floor. We put it up to the maintenance department and said the floor ought to be kept in good condition.

In spite of what he wanted to do, that floor could not be kept in shape, due to the fact that the building was put up to carry a certain load; at one time no truck went over it with more than 2,000 pounds, and today it is nothing unusual for us to find a load being taken over that same floor with 10,000 pounds. Is that floor

going to stand up? How can a foreman do anything about that? That is for some one else to do. That is for management to look after.

In the case of the 95 accidents, the lost time was 76,595 days. Where should we begin to try to reduce those accidents? Should we begin with the 1,451 or the 95? One of the great troubles has been that the 75 per cent class has never given us the figures that the 25 per cent have. Sixteen per cent of our accidents took 85 per cent of the lost days, and 84 per cent of the accidents took 15 per cent of the lost days.

Suppose a man had a number of machines that were giving him a lot of scrap; he would call in his general superintendent and find out what caused the great scrap. The superintendent would tell him that he had a few machines that were causing 85 per cent of that scrap. What would he say? Would he still say that they would start on the large number of machines that only gave a little scrap, or would he say, "Why don't you fix those few machines so we won't have any scrap?" Suppose the next month another such report came to his table, would he still say, "Well, that is too bad." No, he would call in his superintendent and say, "You have a few of those machines. Fix them. If you can't, we will get someone that can." Shouldn't the man who is getting hurt get the same attention as the scrap would? Certainly. But the trouble is we are not taking that same attitude in our safety work. Scrap is in the overhead; fingers aren't so much. That is why they don't get the same attention that scrap does. Yet is human life so cheap that we don't give the same attention to it that we give to material?

Our great trouble is that we do not take safety in the real sense in which it should be taken. Safety work is nothing more nor less than an engineering proposition, and if we don't follow that up we are not going to get any real results.

When We Know the Cause Then We Can Stop Accidents

As I have pointed out, the safety work is given to the foreman who is overloaded with his work, as it is. We all agree that accidents do not happen, they are caused. We all agree to that. One time we didn't, but we do now. Yet we are continuously preaching that a foreman is the big man, but with all the work he does he ought to find out what causes the accidents and ought to remedy the causes. Only by finding out what causes accidents can we remove the cause and reduce them. Management must first come to the point that it realizes it must send its men home in the same way they came to the plant in the morning. Management can not do that until it becomes really interested in how it must feel to be injured. I would just ask the manager how he would feel if he saw marching before him two groups of people, one of them, 1,451, going by and he couldn't see anything the matter with them, but when the second group came, the 95, there was a finger gone, another finger gone, a hand gone, and so on until at last some poor woman with her kiddies on her skirts came by. Where should we begin to do our work? Would it be with the 25 per cent or the 75 per cent? I believe he would agree that we would have to start with the 25 and do our share before we could ask the others to do their share.

He cannot begin to be a real safety man until he can imagine how it must feel when these poor people are injured. How would he feel if the first one who went by was his boy or the second one his girl, or it was his wife going along with the kiddies? That is what must come to him first before he does his utmost. He must realize that all those accidents are due to disinterested management.

This is not charity at all; it is a paying proposition. Since we started in 1920 to do this work in our plant, we are today producing 30 per cent more than we did at that time, with 20 per cent less trouble. If we can get the manager really interested in this work so he will demand that safety must come first and production second, there isn't any doubt at all that he can get real results, for in the first six months of this year we had 68 accidents in the 25 per cent class, with 628 days lost, and we had none in the 75 per cent class. That is what can be accomplished when we get management thoroughly interested in safety.

CHAIRMAN HODGE: Thank you very much, Mr. Kaems. I am sure that you have brought out several points that we would like to discuss, but we will go on to the next subject before we have discussion, "My Way of Seeking Safety in a Manufacturing Plant," to be presented by Mr. S. H. Slaymaker, Fairbanks Morse & Co., Beloit, Wis. It gives me a great deal of pleasure to present Mr. Slaymaker.

My Way

S. H. Slaymaker, Fairbanks Morse & Company, Beloit, Wis.

When states first began passing compensation laws some 17 or 18 years ago, employers, with the aid of state agencies in some cases, started to look about for methods and ways to eliminate accidents to workmen and the resultant costs thereof. In isolated cases the humanitarian and good business phases of accident elimination had already become apparent and appreciated, but we must admit that the greatest factor in bringing to the fore and speeding up accident prevention activities were the new and at that time startling laws being passed that made the employee responsible in any accident.

That was your real start. Employees were wrought up over the law that erased the assumption of risk, want of ordinary care and fellow servant defenses and for some new unexplainable reason the dollar paid the injured seemed greater than the two formerly paid the lawyer.

I am bringing this point out to show you that the big boss, the man Mr. Kaems spoke to you of, was at that time very much on the job. It had not become a routine matter to him. It was a very live subject. He was, in fact, rather wild about it.

And so he began spending money and using brains in an endeavor to eliminate accidents—and compensation payments. Guards for this and that began to appear and later were improved upon. Rules were adopted and rule books full of "DON'TS" were distributed by the hundreds of thousands.

Those of you who were in the game at that time will remember well the enthusiasm engendered. Nothing to these accidents. There was or would be a guard or a rule for every hazard. It would be fool proof. In no way could a workman be injured.

All right, rules were made, points of danger guarded, but accidents to workmen continued to happen. Time was taken out to check up and the most optimistic were forced to admit that guards and rule books alone had reduced accidents but 10 or 20 per cent.

Then began a search for the reason for the failure, and it wasn't long before they came to appreciate that they were dealing with the human element as well as with power saws, punch presses and planers. The light dawned on them and they saw that the human mind and human heart must be guarded against habits, thoughtlessness and carelessness. To begin in the early training of the child was the proper time and place and so safety was introduced into the home and school where possible.

But the problem of those already in industry had to be met. The workman was being injured or was injuring himself in spite of all engineering could do. They found they had to get back to the individual. A shop was only as safe as the individuals who worked therein, and to have a safe shop then the individual workman had to be made safe. Therefore it was necessary to reach the workman and teach him by word and example that in case of accident he is the loser and that the best possible safety device is the careful man.

Then the question arose how could hundreds of employers and safety men get personal contact with many millions of employees. Bulletins helped, mass meetings were beneficial, but the personal day after day contact was not there.

In the olden days when industry was a large group of small craftsmen the boss worked side by side at the bench or machine with his men. He knew the personal

life of each of his helpers, his worries and his happiness, they were just "Bill" and "Jim" to him. But as industry grew and combined, the boss, out of necessity, soon got farther and farther from the workman, until in many cases he faded entirely from the picture as far as the workman was concerned. The owner is now often a great group of stockholders scattered nation-wide, represented by a board of directors, at best a mythical thing to the workman, unknown and unseen. Officers elected or managers appointed by this board, division managers and even superintendents are a long way from the present day workman and only the foreman remains to take the place of the former owner to know the personal life, worries and happiness of the workman.

Here, then, is the man who is to the workman, the owner. The man he looks to for his daily bread. His word is shop law and him he will follow.

To the foreman we must turn for personal contact with the workman. Teach the foreman, for he is not too many to reach, that his men are under his care and that it is his sacred duty to see to it that each man returns to his family each night sound and uninjured. Let us not say that the production duties of a foreman make him the illogical man to guard those in his charge. Certainly he must keep up production and quality and keep down his waste, but if safety aids production and accidents are a waste, then the objection is answered, and you put it squarely up to the foreman to prevent accidents as the important part of his recognized duties.

The Foreman Considered the Keystone of the Arch

To prove my point I will not take the time with the pronouncements of hundreds of industrial executives, safety leaders, and economists or will I more than call your attention to the many times the importance of the foreman in accident prevention has been stressed at former safety conventions. All I will ask is that you look up any of your good safety records. Consider, examine, and analyze the department that has had the best accident experience in your shops and you will find, back of it all, a foreman who through the respect and confidence of his men has led them away from danger and installed in them the desire to make such a record.

Some one at our last safety conference at Detroit, I've forgotten who it was, in comparing the safety movement to a Roman arch, placed the foreman above all else as the keystone—on one hand absolutely responsible to the management for the prevention of accidents, and, on the other hand, looked up to by the employees for advice, for to them he is the management.

Probably the former speaker, Mr. Kaems, would liken the big boss, the general manager, to the base of the arch, the part that carries the weight of the superstructure, but for my part, I can only allow him the place of the corner stone, the part on which is inscribed a title and which alone can in itself never be an arch and which supports only that which is above it and even then only by leaning on the keystone for support.

And so I say to you, tie up to that man who is the keystone of the safety structure, the man who is a workman because he knows and is close to the workman, who is the management because to the workman he is the management. For he he a hard shell or a soft shell or just a "Bull of the Woods," he can break you or make you in your safety endeavors.

CHAIRMAN HODGE: I didn't know that Mr. Kaems and Mr. Slaymaker were going to take rather opposite sides on this particular question, but we have a few moments now in which we can discuss the remarks made by Messrs. Kaems and Slaymaker.

A. BERQUIST (Youngstown Sheet & Tube Co., East Chicago, Ind.): I would like to ask Mr. Kaems what he is going to do with the 68?

MR. KAEMS: We are going to reduce them to a certain point and to a certain point only. If any of you safety men ever got it in your heads that you are going to eliminate all those 68 accidents you have got another guess coming, because it won't

be done. I don't care whether it is you or me, those things will happen. Why did I get an infected finger? I couldn't help it. We are going to have just a certain number. In seven years and a half those accidents have gone about ten days per accident. There is something wrong with that which we can't get away from. A man hits his finger. He is insured in two companies. If he stays off three weeks he gets paid for the first week, and I'm going to tell you that he stays off three weeks, in spite of what you do. If you once cut out the 25 per cent, the others will go down of their own accord.

MR. BERQUIST: You say you're satisfied with the 65?

MR. KAEMS: Of course I'm not—

MR. BERQUIST: (Interrupting): If you are, by God! you'd better quit.

MR. KAEMS: You can't do away with them entirely. I'm going after that other bunch.

MR. BERQUIST: Well, I'm not satisfied. I'm going after the 68. There's some way of getting them.

MR. KAEMS: I'll take off my hat to you when you solve that problem. I've been at it 25 years.

MR. BERQUIST: Do you mean to say you are not going after the 68?

MR. KAEMS: Yes, I am.

MR. BERQUIST: How are you going to do it?

MR. KAEMS: By having the management interested in it.

MR. BERQUIST: Do you say the management is responsible?

MR. KAEMS: Yes.

MR. BERQUIST: Why did you put it in there, then?

MR. KAEMS: We are going as fast as we can, and I think we did a pretty good job.

MR. BERQUIST: Your argument doesn't hold water at all.

CHAIRMAN HODGE: I am feeling more at home every minute.

The Meeting After a Man Lost His Finger

MR. KAEMS: Let me give one concrete example. It was the hardest thing in the world to get that wiped out. I'll show you how it happened to be done. The superintendent of the department had constructed a die, and when it was brought to the foreman they told him to set it up, which he did, and an hour later a man had a finger off. Then we had a real meeting and the manager called every last one of them in, from die setter to shop superintendent, and told them that safety must come first and production second. He turned to those men who were responsible for the accident and said that if that occurred again they might be in the right church but they were in the wrong pew, and they knew what he meant.

MR. BERQUIST: That is your example. Let me take a minute. You say the foreman is not responsible for the conditions that exist in his department?

MR. KAEMS: I didn't say that.

MR. BERQUIST: Suppose you have a hole in the floor and you are moving a truck across the floor, with material on it. A man runs into that hole in the floor; he is supposed to see it and avoid it. It is up to management to see that that hole in the floor is taken care of. Possibly that man runs that truck into the hole in the floor, dumps the material, and it hits a man on the other side; and you have a double accident. You have to replace the material on the truck and take care of the injured man. What has the management got the foreman there for?

MR. KAEMS: The foreman was not to blame and he could not possibly be the one to take care of those holes. The trouble was that the floor was weak, and the big thing was that the manager would have to strengthen the floor first.

MR. BERQUIST: The manager has to come out of the main office and find it?

MR. KAEMS: He doesn't.

MR. BERQUIST: Who is going to tell him?

MR. KAEMS: The superintendent.

MR. BERQUIST: Who is going to tell the superintendent?

MR. SLAYMAKER: Let me say one word. A year ago now, Mr. Kaems and Mr. Slaymaker were invited to open a one-day meeting. Mr. Kaems talked from the point of the management and Mr. Slaymaker from the point of the foreman. We got a real battle started, as we did here. You must all realize that Mr. Kaems is right and Mr. Slaymaker is right, and we are both wrong; it is a combination of the two, of course. That is the solution. I think Mr. Kaems will bear me out in that.

CHAIRMAN HODGE: We will pass along with the other talks on the program. I am sure that there were plenty of things brought up in these first three rounds to provoke considerable discussion. Little did I think, when I called this an arena when I started, that it was going to work out that way. We will come back to some of these questions if the program will permit.

Mr. George Widua, Wood Brothers Construction Co., Lincoln, Nebraska, is going to present some unusual accidents that can happen anywhere and the lessons learned from them.

Some Unusual Accidents Are Described

GEORGE WIDUA: The talk that I am about to make was demonstrated here by the surface lines at the opening of this session. Our work, general contracting, takes us on navigable waters; we build sea walls, do pile driving, river embankment work, etc. Therefore, I am going to relate an accident which happened to a lineman, not in our employ, but a sub-contractor's employee. It happened in July of this year. I did not see the accident, but I got the report from the superintendent.

The current, taken from the main line and delivered over to our dredge, which we were using at the time to dredge sand back of the sea wall that we had completed, was 13,000 volts. This line was carried over to a bank of shore transformers and was stepped out at 2,200 volts. The 2,200-volt current entered the pop-heads at the edge of the water and was carried over by a submarine cable onto a steel pontoon. On this pontoon there was a pole about 10 or 12 feet high. One of these cables became loosened, and the lineman working for the electrical company immediately came over. Our dredge was working at the time. The lineman climbed on the pole and came across the 2,200 volts, which knocked him into the water, so there was not only the electrocution but the drowning hazard.

Our men on the dredge saw this. The dredge was 250 yards in the water. They immediately got the skiff, got hold of the man, put him on the pontoon, and used the prone pressure method of resuscitation. They worked on the man for at least an hour, and after that time the man was seen to be breathing. He was taken to the hospital, lost three days' time, and was then back at work.

We have about nine jobs now on the Mississippi and the Missouri which include river-retard work. At the time of my employment with Wood Brothers, two years ago, I was very much a believer in the prone pressure method of resuscitation. Before I came with Wood Brothers I understand they had as high as five drownings a year, due to the men slipping, falling off the pile drivers, and different causes. This year we had one drowning happen to a boy on the fourth of July when the works were not operating. He went into the water to take a swim and was drowned.

I am a great believer in the prone method of resuscitation in our work. We also have other work going that includes concrete construction. We have the hazard of nail punctures. By assigning one or two men, depending on the size of the job, and making them solely responsible for good housekeeping and cleanliness, we help to reduce that hazard. We have cut our nail accidents down to a minimum. We hardly hear of one any more in a gang of 400 or 500 men working day and night.

A nail puncture is a very serious infection if you don't get it right away, and if you do get it, don't try to take care of it yourself, but give it to a doctor as soon as possible.

After investigating the cause of the accident of the man who was electrocuted and partly drowned, I found he was supposed to wear rubber gloves, as all employees working on voltage with any high tension are required to do. They didn't throw off the current at the transformer; they just took a chance on trying to fit it without throwing off the power. If it had to be done with the power on, he should have worn rubber gloves.

CHAIRMAN HODGE: I think we had better run the talks in connection with the unusual accidents that happen anywhere and the lessons learned from them, as we do on a public golf course—run a time for some and slip in others between. Between the talks scheduled on the program we will be glad to have anyone present some unusual accidents that can happen anywhere.

We are going to get out of this meeting exactly what we put into it, and I want to give you the opportunity of getting in your own experiences and let the convention session profit thereby.

Another Fatal Accident is Described

M. L. RICE (Frisco Lines, Springfield, Mo.): In Springfield about four months ago, a public utilities power house had sent a man up to the coal mine to get some coal. The assistant fireman took the pick and went down to the coal bin, and the first thing they knew in the boiler plant, this man was gone. They heard the yell, and about 18 hours afterward they got him out of the coal. Recently the state factory inspector of Missouri recommended to those people that they put on a safety belt and let the man tie the rope to the coal bin and go down that way. As I see it, he should have recommended two men to prevent a similar accident.

CHAIRMAN HODGE: Mr. A. S. Johnson, American Mutual Insurance Co., Boston, Mass., is on the program to talk on this subject.

MR. JOHNSON: I wish that I could be dramatic; I don't know how. If I seem a little bit tame to you, please let the words carry the message which I feel is all-important in this discussion.

Picture with me just for a minute a shop, I don't care where. (This actually happened, you know. These are supposed to be bona fide accidents.) Take any shop where some machinery is operated by a belt from a line shaft. Production has increased so rapidly that the number of machines is not adequate, and you install another machine. You start, shut down at noon-time, and spend Saturday afternoon, Saturday night and Sunday getting in the new machine; because you can't take care of so much change at one time you extend the line shaft by a short piece with a coupling. It is a temporary hook-up. The next week end you will take down the whole line shaft and put in a new one without a coupling.

In this particular case the line shaft was really a jack shaft about a foot above the floor, driven by a large belt from the overhead line shaft. The coupling was put on, two pieces of shaft joined together. Late Sunday night everything was ready, and they tried it out and the coupling slipped. At a loss to know what to do to make it safe, they took out the set-screw and put in a long set-screw that they could put a big wrench onto. It worked. Monday morning the men started their machines. The superintendent was there, the plant manager was there, the millwright was there, the master mechanic was there. The new piece of shafting in the coupling had not been guarded. The oiler turned to the superintendent and said, "How about oiling these bearings?"

He said, "All right, go ahead, but look out for that coupling. There is a set-screw in it. Be very, very careful." His second step from that spot was directly over the coupling. His overalls leg caught in the set-screw. A sponge, a pail and a vacuum cleaner picked up the remains.

Let's leave that for a moment and go to another. Another machine shop, wooden floor, plates, the usual balls that you sometimes find on one part of a machine shop floor where they may be doing heavy plate boring and reaming. Turnings, filings, scraps and bits of iron, pieces of pipe, shafting, plates (perhaps bad housekeeping), wall plugs here and there to put on portable tools. A portable tool is being used to do some work at a section of the floor where there is no machinery, and a claptrap, spread out over this floor. Alternating current machinery, neutral return grounding, rotten piece of extension cord with cracked and broken porcelain plugs to put several pieces together runs from the socket in the wall across the plates to the machine. There is a leak, and the wire is in direct contact with the plates on the floor. The wood insulation seems to be sufficient to prevent blowing the fuses.

A helper from the blacksmith shop across a little roadway comes over into the machine shop for some purpose. It is a rainy day, the roadway is wet, it is one step from the roadway to the floor of the machine shop. One foot on the roadway, one foot on the plates and metal chaff on the floor. One hundred and thirteen volts was found to be potential between the ground and those plates on the floor. It was sufficient to knock him down. His body was wet with perspiration, and as he fell he lay between the roadway and the plates on the floor, and before anybody could get to him he was dead. They used no prone pressure resuscitation; they needed no prone pressure resuscitation there; so the man was buried.

Temporary Hook-ups Are Frequently Unsafe

Let me explain the point I want you to carry home from those two accidents. I could tell you 22 or 222 similar cases. They were temporary hook-ups. One of the most serious hazards in all industry is the temporary hook-up. All portable electric fixtures which are plugged into sockets on the wall are temporary. Every rigging job, lifting material by cranes, is a temporary job. The lashing of the load is a temporary job. The installation of machinery partly put in and later the complete and permanent installation made, is temporary. I plead with you, gentlemen, to be sure, not satisfied, but positively sure that your temporary hook-ups are not accident hazards as you leave them.

CHAIRMAN HODGE: Mr. Johnson stated that he wished he could be dramatic. I think he has evidently attended the three classes of Professor Hardy in public speaking. He certainly put across his message in great shape. I saw Professor Hardy come in a few moments ago, and I am quite sure he must be proud of his work.

Now we are ready to run in a foursome that got up at four o'clock in the morning and didn't make a reservation a week ago.

G. A. HOYT (American Car & Foundry Co.): I would like to know whether or not Mr. Kaems' talk was sincere or whether this was a farce between the two gentlemen.

MR. BERGQUIST: As far as I am concerned, I didn't know anything about it.

MR. HOYT: I had the same idea in 1920 and '21. We employed some 25,000 men. We built freight cars as well as passenger cars, and I conceived the idea that we could eliminate the foreman. As a result of that, we paid \$200,000 a year in compensation. I found out that was not the right idea, so then we began to reach the foremen. At the present time and in the past six months in 1927, our compensation losses have been only \$20,000. I leave it to you whether or not it pays to teach the foremen.

CHAIRMAN HODGE: Mr. Kaems wants to answer that, but I am not going to permit it right now. We will go right along with the subject that is before us, and I hope we will have time to come back to this all-important main bout later.

We will hear from Mr. J. E. Walters, General Electric Co., West Lynn Works, West Lynn, Mass.

MR. WALTERS: I guess I was a victim of the seventh round, so I am back. Before going to the unusual accidents, may I treat with a very usual accident for which I have seen an unusual treatment.

We all have the lame back cases, and I guess very few of us know what to do with them. I saw a surgeon treat one of them and effect a cure. He had an idea that it was a fake case, and he was going to treat them all that way. The gentleman came in and he applied a porous plaster and told him to go home and come back the next day. The next day he took hold of the porous plaster and ripped it off and put on another one. He said, "We will leave this one on for two days," and he repeated the dose. He effected a cure and he has had very few lame back cases since that.

I had to go back into the records some years to get some of these cases. In one of the foundries, the toilets, shower baths and washrooms are located together. One Saturday the attendant forgot to shut off the water heating system, resulting in building up some steam pressure in the hot water system, which backed up into the cold water line. The first man to flush a toilet on Monday morning filled the compartment full of live steam and he was severely burned, as the compartment door had a lock on it and it took him some time to get it open. Since that time, the locks have been removed from the doors and non-return valves placed in the supply line.

Accidents in Using Hard Steel Hammers

A man was chipping with a hammer and chisel. His chisel was of the highly tempered variety used in pneumatic hammers. He thought he felt something strike his eye, although he was wearing goggles. He went to the doctor, who could not find anything except that his eye was somewhat inflamed. Later, he lost the sight of that eye, and a consultation of physicians decided to remove it on account of possible infection of the other eye. After this eye was removed, it was dissected and a piece of steel, the longest dimension one sixty-fourth inch was found in the eye. The next largest dimension was about half that length, the third dimension was not measured. The piece was semi-circular in shape when viewed under a microscope and probably turned after it went into the eyeball so that the magnet would not pull it out. It is believed that this particle went through the side screen of the goggle, as the mesh would have allowed it to do so.

An apprentice in the tool room, while breaking up obsolete fixtures made of steel, for salvage purposes, instead of a soft metal hammer used a hard steel hammer; a particle flew off the fixture and hit the man in the top left inner side of the eye, passing through the eye-lid. It was traveling at such speed that it went almost through the thick portion of the eye and was removed from the opposite lower corner to which it entered. Although passing directly back of the lens of the eye, the young man has no impairment of vision. In other words, the Lord was with him in his foolish mistake.

Another instance of using hard steel on hard steel occurred in our assembly department. A particle flying off the face of a hammer penetrated four garments of clothing and imbedded itself two inches in the man's abdomen, necessitating an operation for removal.

During some construction operations on roads, one of the colored laborers was standing underneath the chute which empties the sand and gravel, etc., into the concrete mixer, and for some unknown reason the chute dropped down, landing on the man's head. By a queer coincidence, no damage was done to the portion hit, but a bone in his ankle was fractured. He was a colored laborer. I guess the lesson there is, if you want to reach a colored gentleman, get after his shins.

A pipe had been installed in a stair and elevator tower several floors high. Through some oversight, no collars were placed around the pipe to protect the space between it and the floor openings. A man on one of the upper floors had

been using a crowbar, and in looking for what he thought was a safe place to put it, jammed it in between the pipe and the hole in the floor. Another man on the floor below leaned against the pipe while waiting for the elevator, springing it over just far enough to allow the crowbar to come down through, striking him on top of the head. Put on your pipe flanges, and don't let your crowbars stand up, lay them down on the floor.

We had been changing over one of our departments, and a number of holes were left in the floor where wiring conduits had previously been put through. New machinery was placed before the holes were plugged, after which such holes as were in sight were plugged up. A machine operator dropped a large nut which struck the floor, rolled under the machine, dropped through a hole which had not been plugged: at the time another man was passing underneath, giving him a cut on top of the head. Lesson: Fix up your floors or any other repairs before you move in.

A hydraulic press used on an experimental job had been fitted with four steel disks, about three-eighths of an inch thick, located one on top of each of the four stops on the machine. The experimental job had been finished, but the disks left on top of the stops, one of which, however, had apparently later been knocked off. A slow leak developed in the supply line, resulting in the press gradually rising without anyone noticing it. It got to the top, and apparently due to unequal pressure on the stops, with one of the disks missing, caused the press to buckle. One of those disks squeezed down to a tapered shape, approximately full width on one side and knife edge on the other, flew out, went about 100 feet across the room, striking a sweeper just above one eye with the thin edge, his eye being practically cut out of his head. When you get through with a temporary job, clean it up.

These unusual accidents teach us one other lesson that I think is very general, although I find in some plants it is not. It is the safety man's job to go out and analyze and study each and every accident. I do not care how similar they are to anything that has occurred, each one of them has its individual lesson.

The White Collar Man Also Gets Hurt

Another hydraulic press in the same department while in use had a job on it where a filler piece consisting of cast ring about ten inches outside diameter, three inches high, and about one and a half inch thick, was being used, as the pressure was not wanted on the center of the job being done. While the pressure was on, a quarter section of the filler piece broke out, went out the window behind the press, crossed the alley-way and struck a corner of a building, making a hole sufficiently large that four whole bricks with some pieces had to be used to fill it up. No one was injured.

You know the fellow in the office, the man with the white collar, gets hurt once in a while, too. A gentleman was sitting at his desk using his telephone. The telephone on the next desk rang for him. As he turned to get up, he slipped and fell and fractured his hip. So you see the accidents are not all confined to the factory.

A young man was taking a letter to a mail basket. Approaching the basket, he threw the letter in the general direction of the basket, missed, and it went down between the desk and the wall. On reaching after it, he slipped and pushed his arm through a window, cutting a number of tendons. Believe me, if you want to close some of the windows on the Chicago buses around here, be sure and put on some good arm protectors.

An operator in the cold header department, not long ago, attempted to jerk the loose end of a wire out of the roll, and it suddenly flew up, the end running up under his glasses and penetrating the eyeball. It was necessary to remove the eye.

A certain accident happened, when, by the grace of God, a tremendous casualty was avoided. It happened when a 12-inch high-pressure (200-pound) steam main broke in a turbine test. This occurred at night just as the plant was shutting down,

and there were 15 boilers behind the steam main. It was due to a poor job of welding. If this had happened at any other time, you can imagine the results, with that pressure.

A sub-station operator was told on a Saturday forenoon to shut down his station. He pulled out all switches, including the overhead disconnects, and apparently availed himself of the shut-down to clean his board. He was alone at the time and consequently we could only estimate what happened, but from appearances he cleaned everything within reach of the floor and climbed the framework, dusting parts as he came to them, and apparently forgetting all about the fact that the buses above his disconnects were alive, as we found a partially dusted insulator supporting a live 11,000-volt bus. Fatal. Since that we have protected these points.

I hope the few instances that I have quoted may be of some benefit with their resultant remedies, in assisting in the good safety work. I wish to thank the referee for permitting me to last out to the count of nine.

An Unusual Accident in An Elevator Shaft

MR. COOK (The Travelers Insurance Co.): I may not be able to paint a picture such as Mr. Johnson painted, but I trust that the bare facts will drive home the lesson. In this state a couple of months ago an employee was disinfecting a grain elevator. He started at the top, using carbon tetrachlorid as a safety measure, and carbon disulphide, which, of course, might cause a fire hazard. He continued to go down through the elevator, sprinkling the carbon tetrachlorid as he went. It happens that the vapors of carbon tetrachlorid are about five times the density of air. As the vapors formed, they slowly followed him on the way down, becoming more and more concentrated. Finally, when he reached the basement of the elevator, the vapors had preceded him, and he was overcome in the basement. When he was found there, he had succumbed entirely to the poison carbon tetrachlorid fumes. The lesson to be drawn from an accident of this sort, it seems to be, is to beware of these heavier-than-air vapors. With only two exceptions, the vapors which are likely to cause trouble either from fire or from poison are very much heavier than air. The two exceptions are hydrocyanic acid and carbon monoxide. With those two exceptions these vapors will always seek the lower levels, and concentration at those lower levels may be very much greater than is supposed. Consequently, they are a bad hazard because of asphyxiation or fire.

CHAIRMAN HODGE: Mr. C. J. Alger, Corn Products Refining Co., Chicago, is next.

MR. ALGER: I am not going to discuss a number of accidents, but I have one in particular which we in our company seem to think is unusual and can happen anywhere. About six weeks ago, at one of our plants, which happens to be of the old-type construction, a workman entered his department on the first floor, and, seeing a freight elevator standing there, decided to run the elevator up to the sixth floor where he was supposed to work. The hour was quarter to seven. At seven o'clock a regular operator was employed for that purpose. He had proceeded on the elevator to about the fourth floor when suddenly he felt somebody jerking on the tiller rope. He yelled to him to stop. It had no effect. The next thing that happened, down came the elevator to the basement, with the result that this man's leg was fractured.

We have in our company perhaps 45 or 50 freight elevators. I am sure everybody here has at least a few freight elevators under their jurisdiction. We have assumed in the past that our elevators have been in first-class condition because of the fact that we have three inspections.

After this accident occurred, immediate investigation was made. As I said, this was an old-type elevator, double belt drive from a line shaft, with a loose pulley, one belt for the uplift and one for the down. When the accident was checked up, it was found that the belt on the down drive had slipped off the pulley. We started checking up again to see what the cause was. We found that the day before, the

mechanic had replaced both belts and had used rubber instead of an endless belt of leather. The chances are that the belt was not properly fitted. Nevertheless, if that condition had not existed, with both men pulling on the tiller rope, things would probably have gone along all right.

We have tried to enforce the rule in our company without exception that no elevator of any kind should be operated without a regular operator. That rule was violated. We also have a rule which is enforced that elevators should be locked at position with a padlock. That was also violated. The man who pulled on that tiller cable and raised the gate in order to do so violated the rule. We had the accident and the man had a fractured limb.

When that report reached us in Chicago, we wondered how our elevators were at other places. We were able to obtain the services of two competent elevator men. I accompanied them on an inspection. We found 50 per cent of our elevators in a defective condition. In at least half of them, the slack cable adjustments were not operating, belt governors were not operating in case the elevator fell, and in one instance we found a governor which had been set in the wrong position.

The message we want to bring to you in connection with elevators is that everybody engaged in the safety line should begin right now to check up on the inspector boys before they have somebody checking the safety men.

Testing An Underground Storage Tank

CHAIRMAN HODGE: Mr. L. M. Rice, Liberty Mutual Insurance Co., Chicago Ill.

MR. RICE: We had one accident where a man was testing an underground storage tank for gasoline and oils. This man was 64 years of age and had been in the employ of this particular company for 28 years, as an all-around man and inspector. On this occasion he was testing one of these tanks. The tank was made of three-sixteenth-inch steel, six feet long, five and one-half in diameter, the seams electrically welded, and in addition, three flanges welded on the side. He plugged two holes and inserted a one-inch pipe, and on that he had a T. On one side of the T he put the gage and release valve, and the other connected to the hose line. That hose line runs to the main air line, which in this case carried 100 pounds pressure. They were expected to run the pressure to about five pounds in making the test. They used soapy water and a brush, applying it along the seams. If bubbles are shown they indicate defects in the seam. On this occasion the tank let go and struck the man, threw him against a girder, and killed him almost instantly.

In investigating the accident, the committee found the tank badly bulged. They checked up the seams very minutely and could find no defect of any kind, but they did find that the reducing valve which the man was supposed to use was in his tool box. Therefore, we had the accident. The man thought that he had done it so often he could get by with his judgment.

In another case, doing exactly the same job in another plant, the man had a Watson reducing valve. After the examination, they found the tank bulged in the same way. We examined for defects in the welding and found none, but the committee came to the conclusion that we should put on another reducing valve because if anything gets in the valve it lets the pressure right through. In most cases they have to do that or put in special equipment.

This led up to another thing that developed through the committee in this shop. They said, "Do you know that these range boilers that we make for heaters are being used all over the country for air tanks?" Nobody had thought of that. Immediately we made a check on some 15 or 20 plants where there were no regular mechanics, and very much to our surprise we located two of them that were in very dilapidated condition. One of them was carrying 40 pounds of air and the other 60. We ourselves got a lesson from that.

CHAIRMAN HODGE: Mr. R. G. Buchanan, Edward Hines Lumber Co., Lumberton, Miss.

MR. BUCHANAN: I want to talk about two accidents that we never yet have been able to find out the cause of, but those two accidents taught us what we can do in the industry. Some time ago we had a shortage of logs. We wanted some logs in a hurry. The sawmill superintendent went to the telephone and called for the logs. The logging superintendent asked him how many he wanted. He said, "Thirty-five cars." He jerked the 35 cars off the side tracks, put them on the main line; the woods trainmaster came along and said, "Take these two engines, couple them together, and take the logs to the mill. They are in a hurry for them."

We have a curve on our main line railroad from the woods into the mill that has a 73 curve and a one per cent grade. These engines are 90-ton engines, and they had 35 cars of logs behind them. They were going over this grade. They struck the curve, and nobody ever has been able to understand why that engine that was leading went off that track. It went off the track straight as an arrow out into the woods, turned over the engine, killed the engineer, cut off the legs of the conductor on the engine, and hurt two or three other men who were on the two engines. We learned from that that we can't double-head a train with any safety.

I told that to the vice-president of one of the big trunk lines some time ago, and we happened to be on a train coming out of New Orleans. That morning they had run a second section of a passenger train carrying a delegation of letter carriers to El Paso, Texas, and they wanted to get that engine back to the terminal. I took occasion, when they coupled that engine, to go up and see if this man had paid any attention to it. I saw that the second engineer had no control over the engine at all. That is something that I don't know is being adopted by all trunk lines, but I know it is on that division of that railroad.

We learned that we cannot double-head a train. Now we bring our logs out in 15 and 16-car trains, put them on the main line or run an extra engine over the hump and put them the other side of the hump so one train can come along and pick up 30 or 40 and take them to the mill.

A Strange Accident with a Steam Skidder

Another accident we had about 60 days ago was in connection with a steam skidder pulling logs. That is the most dangerous thing you can use in logging and lumber. The steam skidder is the most dangerous piece of machinery that we've got. Those logs don't come in slow. When they get to high-balling those logs they pull them just as fast as the wheels will turn over. When they get them up to the skidder they put a short line on them, and project the end around so the loader that comes around behind the skidder can reach out and pick them up and put them on the cars.

We had a logger connect the rope on this end of the log to pull it around. Some way or other, this end became hooked up with something, we don't know what it was, and it bowed the log just in that position. This end flew out from whatever it was against and it flew 40 feet through the air. There was a negro standing on the end of the skidder, and that log hit him. Of course it killed him. It hit him right in the head. That is the only log we have ever had fly through the air. We learned from this that what we thought was the safe place around the skidder turned out to be the most dangerous place.

This negro was standing there and the logging superintendent was standing in exactly the same place where that man was standing. The logging superintendent stepped away, the negro stepped in, and the log hit him. We learned from that that there was no safe place around a skidder, I don't care where it is. If you go around and look at skidders, you can see where logs come in and jump and knock holes through the water tank; they tear up the machinery. You can't keep a skidder in repair.

I heard the shop foreman say some time ago that he hoped some day to get hold of the man who invented the steam skidder, that he wanted to bring that man into the shop because he wanted to kill him on first sight.

In investigating this skidder accident, we came to find out that there is no safe place around it. We have made this order, that any man standing around a skidder must stand behind the tank; then if the log does fly, it has to come through the tank to hit you.

CHAIRMAN HODGE: Mr. Kaems has just asked for one more round with somebody on the other side, and I think in justice to Mr. Kaems we ought to give him a few minutes, and then we will adjourn the meeting.

MR. KAEMS: You know everyone is rather touchy on some one thing if you can only find out where the place is. I just want, for this gentleman's benefit, to tell him that there isn't money enough in this country to bring me up here and make a farce of this sincere and important thing. I have spent 25 years, the best years of my life, in this work, and I have been successful in my work. When Mr. Cameron asked us to put on this subject, I wasn't stuck on it, but we thought it would bring out discussion, and therefore I consented to do it. This man told what money he saved by going back to his foreman's plan, and I am glad he did. I can say to you that in 1919 we cut off 37 fingers in our plant, and last year we cut off one. The biggest thing that was said to me was by our president, Mr. Simmons, when he said, "August we can pay for everything else, but when we take a man's fingers or his hands or his life we haven't got money enough to pay for it." That has been my motto.

After the Loss of Twenty-two Fingers

I had the pleasure, at one time, of being invited to a meeting of our chairman's organization, and among other things they said they had done 40 million operations without the loss of a finger. We run seven presses; we have a rolling mill; we have woodworking plants; we have foundries; we have every kind of hazard there is, and I am telling you gentlemen that I am proud of what we have accomplished.

I have one other thing in mind. Years ago when I worked for the commission, a concern had cut off 32 fingers. I asked the commission to let me go to that plant, which was a very finely organized one. I succeeded in having them do it my way, and they ran 22 months without an accident, and this summer Mr. Slaymaker and I went to visit that plant. The two departments that had taken off the 32 fingers had \$8.50 and \$11 respectively to pay in compensation.

I just want to say that I couldn't be bought to make a farce of this. That is all I want to say.

CHAIRMAN HODGE: I think probably there isn't any question about the sincerity of the work that you have done, about the sincerity of the work that Mr. Slaymaker has achieved, about the fine, splendid work that Mr. Kaems' company has done. I am sure that they have made a perfectly wonderful contribution to the safety movement. I know we have sent men to visit their plants, and I suppose you all have probably been at either the Kenosha Simmons plant or have had a desire to go there. I think we had better close our discussion, because we have to vacate this room for the "Smile Party."

MR. HOYT (American Car & Foundry Co.): There have been recommendations written about the foreman being the key man. Do we want to go back and undo all that the big safety men of the country have undertaken on this subject? Personally I don't see that we can get along without the foreman as the key man in safety, and with all sincerity and all the charity back of this statement, I would like to ask Mr. Kaems not to permit his talk to go into the proceedings of 1927. That is a personal matter, though, but I don't think that we ought to try to get before the young man who is just coming into safety work to believe that we can eliminate the foreman from this accident prevention work.

CHAIRMAN HODGE: Our session is held for us to present our various experiences. We have had those who believe in putting the responsibility for accident prevention on the management solely; we have had those who believe that the responsibility is

up to the foreman; we have had the various phases, and, like the *Literary Digest*, we try to give you all opinions and you can make up your own minds. I want just one more minute to present Mr. Isaiah Hale.

ISAIAH HALE (Sante Fe, Topeka, Kans.): Fellows, two or three weeks ago a stock shipper in the far west was walking around on top of the fence between the pens at one of our stock chutes. He lost his balance and fell off. In falling he naturally grabbed at something. He had a ring on the third finger of his hand, and he caught it on the head of a nail protruding from the side of the fence and literally tore his third finger from his hand. Fairness compels me to grant you that rings are not frequent, but on the other hand fairness must cause you to grant that rings are not infrequently worn by workmen in industry, and to whatever extent they are worn, I am beginning to wonder if they are not in fact more of a potential hazard than they are generally thought to be.

ADJOURNMENT.

*SIXTEENTH ANNUAL SAFETY CONGRESS
NATIONAL SAFETY COUNCIL*

Fire Prevention Session

Friday, September 30, 1927

FRANKLIN H. WENTWORTH, Chairman
Secretary, National Fire Protection Association,
Boston, Mass.

The Fire Prevention Session at the Sixteenth Annual Safety Congress was called to order at nine-forty o'clock by the chairman, Franklin H. Wentworth.

CHAIRMAN WENTWORTH: This is the first Fire Prevention Session National Safety Congress has ever held. It is called this year because of the rather widespread demand among members of the National Safety Council for a discussion of this important problem, and it is certainly gratifying to find so many of the members here to participate.

We are to consider this morning a single division only of this great general subject, but the final division—that is, the application of the accumulated knowledge and intelligence which we have to local conditions.

Another division of our subject is the continuous education of the public. That must go on indefinitely. Generation after generation must be educated to a proper appreciation of fire hazards and fire prevention. That seems a very great task but we must realize that every generation has to be educated in everything else. It simply means that, beginning as early as we can with the child, we must instill into him the necessity for public safety, including fire prevention.

Fire is a good servant, as has been said many times, but a bad master. Our lives are becoming more and more complex, the great elemental forces are more and more being called into the service of men, and the only way in which we can make life possible to the masses of the people is to so train them in the handling of these forces that the race won't be wiped off the face of the earth. Public education—that is one great division.

The second great division is the technical or engineering phase of our work. We must not only realize the need for controlling these great forces, but we must have the technical knowledge which will make control effective. That work, the preparation of standards for the control of the fire waste, has been carried on for 30 years by the National Fire Protection Association, which has long worked in close cooperation with the National Safety Council. That work is being done through a great many committees. All the various technical subjects are being kept in continual review in order that those who desire it may have at hand, generally in popular form, the latest information respecting the technical control of these natural forces.

The application of these principles to our civic life is just beginning. There was organized at the last meeting of the National Fire Protection Association, a Chamber of Commerce and Safety Council Section. The chairman of that section is Mr. Clifford Penland of the Safety Division of the Memphis Chamber of Com-

merce. All you Council men know him. Mr. Penland and Mr. H. L. Shearer, of the Detroit Board of Commerce, are now perfecting an organization which shall do for the cities what you gentlemen are doing for your plants—take this knowledge which has been collected by the engineering research of the last 30 years by the National Fire Protection Association, and apply it to the city, as if the city were one large plant. All the hazards that exist in your plant exist in the city, and taking the city as a unit, as you take your plant as a unit, we may apply these methods of fire prevention. That is the public phase of the work we are to discuss this morning.

There is no situation, there is no force in nature, that man with a proper expression of intelligence and interest cannot control. We know that. We don't know much about the Over-all Intelligence; the Deity, we might say, is simply a creation of our minds, so far as we can actually know. We know that the greatest intelligence in the world today resides in the brain of man, and that step by step, as he develops his life and as his needs develop, he is coming to know that these forces, however great, however mighty, however powerful, will respond to intelligent control.

So we do not believe that there is a single situation, a single hazard in our lives, that cannot be controlled through the application of man's intelligence.

Our first subject this morning, "Studying Plant Processes to Prevent Fires," is an exceedingly interesting one.

We all know that in plants the fire prevention work falls easily into two divisions, the division of the common hazards—lighting and heating and all those things, the use of fire for common purposes—and the special hazards, the hazards peculiar to the processes carried on in those plants.

There is probably no one in my acquaintance who is better equipped to develop this theme than the speaker who is to present it this morning. The thing which has always impressed me about this speaker is his fine sense of proportion. Most of us see things in certain aspects, certain facets, and it is only through varied experience that we come to have that sense of proportion which sees a problem from the proper point of detachment and thus may more easily point out the specific forces which will yield to control.

I have great pleasure in introducing Mr. Benjamin Richards, Manager of the Underwriters' Service Association, Chicago.

Studying Plant Processes to Prevent Fire

Benjamin Richards, Manager, Underwriters' Service Association, Chicago, Ill.

Fires in manufacturing properties are usually divided into two classes, technically designated by the underwriters as those occurring under common hazards and those caused by special hazards. Common hazard fires are those which originate from rubbish and other uncleanness, heating, lighting, power, including boilers, chimneys, and also fires from lightning are included in this class. Special hazard fires are those originating in or in connection with some special processes necessary to a particular industry. Common hazard fires run about the same for all classes while special hazard fires vary quite a little among the different classes of manufacture, which facts leads to some broad separation by classification of risks by underwriters such as woodworkers, machine shops, paper mills, cotton mills, etc.

In a general way the cause of all fires is *improper maintenance*, and it is right here that a defect, so far as fire loss is concerned, in the modern industrial management may be discovered. In most industrial plants the general maintenance or upkeep department of the plant has in charge such matters as heating,

lighting, arrangement of power drives and such other features as may include the causes of all, so called, "common hazard" fires. A while ago when industrial plants were smaller and the management less involved, we could look to the maintenance department, or at least through that department to the general manager, to guard also the special hazards incident to the process work, and under such conditions the maintenance or proper safety against fire in the process as well as under the common hazards could be fairly well controlled.

Of late years manufacturing processes have become highly specialized, volume of production has been greatly increased and the values involved in any particular process have doubled and tripled over the former conditions. At the same time the general type of construction has materially changed toward a tendency to get many or all processes concentrated into one large room, the whole aim being to concentrate and to speed up work, especially the assembling and finishing processes. All this development is traceable to the employment of technical specialists whose efficiency and skill of production is one of the new wonders of the world.

Specialization Divides Authority

Like all specialists, however, these well meaning gentlemen have often failed to look beyond their specialty, and through their persistent effort toward efficiency and efficiency only, sometimes have neglected safety and possibly other important factors which should enter into the manufacturing problem. These men differ very materially from the old style manufacturer who under his daily task was compelled to consider many or all manufacturing problems, whether they related to finance, construction, purchases, sales, production, maintenance, employment or safety. Specialization has resulted in a divided authority in these matters with usually such a complicated organization that an appeal over the head of the management of one of these departments to a superior officer can be made with difficulty; and when such appeal is made, more often than not a fair, informed and unbiased judgment of the point in question is not obtained. The production man is usually a highly paid official, more or less dominating the whole organization, and as he is either indirectly or directly responsible for the profits of the whole, his words naturally go a long way when the question of overruling him, or compelling a change in his plans in the interest of safety or other desirable end, is under discussion.

Fortunately there are exceptions to the prevailing type. Indeed, all of these production men would be the last to acknowledge that they are sacrificing safety to accomplish their ends, but to one who has for years studied their methods and talked with them it does appear that there is a marked tendency on the part of these specialists, who are so successful in their own lines, to ignore the ideas of other specialists equally familiar with their own particular lines, especially when such specialties lie outside the scope of the usual work. Some of us who have studied manufacturing processes in their relation to the tremendous fire losses of this country, have been often told by these production experts that their process was entirely safe, or that the particular conditions under which they were operating were in some respects superior to those used by everybody else, so that they could not suffer losses to property and life as do their neighbors under some such similar conditions.

Very often the defect in management is higher up than the production man. This defect may be best expressed as a false idea of economy, due mainly to the ignoring of the experiences of others who have lost their properties through fire, and to what may be called lack of balance in management whereby the management is too much interested in certain phases of manufacturing rather than showing a broad general interest in the entire manufacturing problem, as best exemplified by the old type manufacturer who bought his own stock, supervised its manufacture, employed his own labor and sold his own goods.

An attempt is made in the large industries to parallel the old condition, so far as it is possible, by meetings, or so called conferences, where sit the heads of all the different departments; but so far as fire protection and general safety is concerned it may be assumed that seldom more than half of those sitting at the table know anything about the subject at all. I remember one such meeting of the department heads of a very large industry at which they decided that a fire pump (almost essential to the safety of the plant) involving an expenditure of two or three thousand dollars could not be afforded; after which they promptly recommended an appropriation of about twenty thousand dollars for a swimming pool for the employees. Again, the larger the concern the closer it usually is to high finance and the high finance is usually a long way from the plant, so that even when a recommendation for safety is locally approved it has a tendency to dwindle in importance as it goes up the line until, when carried up to those holding the pocketbook, it appears to have no importance to them at all. Somebody in every large plant should have a liberal appropriation to apply to fire protection and general safety without question, as his best judgment may dictate, assuming of course that such a person knows his business.

Shall Protection Be Charged to Maintenance or Production?

Another discovery we commonly make covers a matter which might well be called a defect in accounting. Under the arrangement we have in mind the production man may be thoroughly cognizant of the need of safeguards surrounding his proposed high pressure production layout, but the cost of the protection, both fire protection and safety to life, is charged to the production of his particular department. He must under such conditions work against his own good judgment, as he cannot very well take the position of recommending protection expense to a process which he is selling to his superiors on the basis of the savings which it will produce. Very often when an appeal is made and the management insists on the protection, there is then conflict as to whether the cost of the protection shall be charged to the maintenance department or to the production department. I believe that this modern attitude toward protection has been an indirect cause of many a fire loss.

Very many of our large losses and most of the small ones can be charged to these general defects in management. Bear in mind that no process, however dangerous, can be worked out by production specialists which cannot be reasonably safeguarded, both from a fire and loss of life standpoint, by those who are expert in this particular and highly technical work. The fire protection engineers are not a step behind the process engineers, and indeed often plans of protection have preceded the general introduction of some hazardous process. The responsibility for losses therefore is entirely upon the industries themselves and they have in their hands, and always have had, means for making all these processes safe.

Of course occasionally there may be a concern whose financial standing will not enable it to build good buildings in which to house a hazardous process or to safeguard such processes after they are housed, but these cases are exceptional and do not apply to the large modern industrial plant which we are here discussing. Unfortunately the larger plant often employs people who have been brought up in a plant of this inferior class, and they are quite likely to surround themselves with the former conditions, to the detriment of the modern plant, which again is a question in management.

We have seen excellent fireproof buildings made veritable fire traps by production managers or maintenance men filling them with wooden partitions, platforms, hanging shelving and other products of the lumber industry, although

for years there have been on the market many non-combustible materials from which partitions and enclosures may be built, even at less cost than if built of lumber. We see production managers store skillfully purchased stocks of goods and supplies in the same room with, and alongside, a very hazardous process, where all the profit of the low price obtained by the purchasing department could be destroyed in ten minutes by a fire in the process; yet the production man seriously tells you that he cannot produce economically unless this million or so dollar's worth of supplies is ten feet from his ten thousand gallon tank of naphtha paint: neither he nor the management could possibly convey these goods to the assembly chain through fire doors in a brick wall or by means of automatic conveyors through similarly protected openings! When the ridiculousness of this position is finally impressed upon those in charge, they are more likely than not to resort to the statement that the fire wall will interfere with light and air, although it is generally recognized that such a wall would make ventilation easier, and artificial light is burning in any case, or light for the process is being furnished from the roof.

I once observed a case where a rare raw stock necessary to the industry had been collected at a tremendous expense after two years' work, the stock coming from isolated places at the ends of the earth. The stock itself was worth over a million dollars and must have cost at least fifty thousand dollars to collect, yet, when it arrived at the plant, it was placed in a large wooden shed partly used for a garage where it all could have been destroyed by fire in twenty minutes; and under the market conditions of raw stock at that time this could have shut up the plant indefinitely.

All Your Eggs in One Basket

The essentials of safety in any industrial plant, so far as fire is concerned, are very simple. They are best expressed by the common expression, "Do not put your eggs all in one basket." Raw stocks and supplies should be separated from the process and production departments by good fire walls, or preferably be in a separate building. Goods just as soon as made should be immediately passed to another fire division for storage, packing and shipping. Various modifications of this principle, as may involve valuable patterns, dies, jigs, rare stocks, etc., should be further considered.

Of late years the craze for housing under one roof without walls, all in one large area, all processes, stocks and finished goods of the industry, has what some consider strong arguments in favor of such a plant arrangement. While undoubtedly there are some advantages for such a type of plant, it may be safely assumed that it is a very expensive type to operate, unless one assumes 100 per cent production for 300 days in the year perpetually. With such a plant many acres are unnecessarily heated and lighted and involve other heavy overhead expense in spaces which are used for storage only, a condition which would ruin some of the older industries working on close margins. Storage buildings can be moderately heated and lighted for about 10 per cent of the cost of heating and lighting an ordinary work room, and the cost of heating we have in mind will cover the expense of heating the rooms, say 40 degrees, to prevent sprinklers from freezing and in order that the expense of a dry pipe sprinkler system may also be avoided. Modern conveyors and escalators to receive the goods from the siding and distribute them throughout the warehouse and to feed them by gravity to the processing and assembly rooms all tend to further economy and fire safety. Storing finished goods in a manufacturing room subject to the fire hazard when such goods represent the maximum of values in thought, labor and material expense can only be described as foolhardy. Finished goods should be stored in absolute safety in

rooms of a warehouse involving no special fire hazard, that the goods may be shipped and one's trade maintained even though the manufacturing plant may be shut down temporarily from a process fire.

I once had a mill that used a stock not procurable in this country, in fact the stock has to be procured from waste places of the earth, like the South Sea Islands, and the industry was absolutely dependent on that stock, there being no substitutes. This particular plant, which was a very large one, sent a crew of men all over the world to collect this stock and they were gone two years. It cost anywhere from \$50,000 to \$75,000, possibly \$100,000 to collect that stock, and as a result of the two years' labor it came in by ship to our port and was shipped to this plant and represented a stock upon which the industry could be assured of continuing for two years. When the material arrived at the plant they stored it in a large wooden shed, the end of which was occupied for a garage, with no sprinklers. The stock itself, representing \$3,000,000 and two years' work, could all have been destroyed in twenty minutes, and that industry at that time could not possibly have continued because there was not enough of that stock in the world at that time to continue. It illustrates the point I have here, showing what thoughtless things are done sometimes. Of course when we appealed in that case above the local management, to the top, the executives saw the error right away and put the stock under sprinkler protection.

The same principle of subdivision applies to the process work itself. As a rule, the average manufacturing plant has only one or two spots which are very dangerous from the fire standpoint. For instance, in a cotton mill this is the picker room, and about 75 years ago the industry learned to cut off this department so that it might enjoy as many fires as it pleased without interfering with the other processes or the business as a whole. The old agricultural implement factory usually consisted of many buildings located 30 or 40 feet apart, the idea being that more than one of them would not be lost at one time. The latter arrangement of course is impractical under modern economic conditions but the practice as represented by the cotton mill picker room is used today and is just as practical to meet the modern conditions as it was 75 years ago, yet this principle is notoriously ignored by plant designers, architects and production engineers.

Carefully Segregate Flammable Materials

Assuming that a slight saving might be made on production by having all the processes in one room, when figuring the matter on a production basis only, it may yet be easily seen that, if all factors are figured into the problem, such as the probable cost of interruption by fire, insurance costs and other matters relating to safety and isolation of the hazardous process, even at the expense of the pride of the production specialist, subdivision is essential. Why destroy acres of non-hazardous production machinery because of one hazardous necessary spot in the whole assembly? However, as to the matter of expense it may be safely assumed that in 99 cases out of 100 there is no ultimate extra expense involved in providing safety.

Fortunately safety measures fit nicely into plans for low production costs. We have seldom, if ever, sold an industry any elaborate fire protection but that industry has later acknowledged the part which this protection plays in earning its share of the low production cost. Just as proper warehousing saves heat and light, general overhead for repairs and maintenance, so safeguarding a manufacturing process saves on production in many ways. Knowing of the safety, the help appears more efficient, a better class of help may be employed, the process may be speeded up without increasing the danger, and as fires in

certain processes are absolutely unavoidable the losses from shut down become unimportant. For instance, the automatic foam protection which the insurance companies some years ago developed for the protection of the large automatic dipping processes in the automobile plants has reduced the time of shut down from these fires to (in one case) 20 minutes where formerly the same machine without the fire protection was shut down a week by a fire. Besides there was practically no loss in the one case as against many thousands of dollars loss in the other.

There has been no loss of life under this modern foam protection, where there were many cases of death before.

Know Your Plant—Best Possible Solution

Any production manager is, or should be, familiar with the particular part of his production where fires may be expected. In a machine shop the heat treating department involving the use of fuel oil is the dangerous place. In other metal working and woodworking plants the finishing, such as the use of paints and lacquers, is the most hazardous process; in the textile mills the preparation of the stock; in paper mills the wood preparing or other stock preparing buildings. All these departments can be easily isolated, and with little more cost can be housed in fireproof buildings, so that the fires which occur in them cannot interfere seriously with the work. Formerly the heart of the industry, the power plant, was found defective, but the importance of building fireproof power plants has for some years been recognized and we have little, if any, trouble from this defect in the modern plant. The use of pulverized fuel and the burning of oil has resulted in some serious fires in these fireproof plants but these are again matters which can easily be safeguarded if one is interested in conforming to the rules of the underwriters. If this same principle, long recognized as necessary to power plants, can be recognized in building and arranging that portion of the plant housing hazardous processes, a very great gain in safety can be easily made.

This appeal for a sensible internal arrangement of stock processes and goods in the plant is one which we cannot over-emphasize. The problem is especially severe for the smaller plant, such as the woodworker, where, assuming a three or four story building, for light and air the painting process is placed in the upper story. The painting process causes most of the fires. When the fires occur they are of such a nature that a large amount of water is usually necessary for their extinguishment, either from sprinklers, hose streams or both. In such a plant the assembly or work room is just below this floor, and down on the lower floors and possibly in a basement finished goods and stocks are stored.

The ridiculousness of this arrangement, from a fire loss standpoint, can be easily recognized when we observe that every little fire in the paint department, and they are many, must necessarily cause a wetdown of all the processes and goods below. In other words, a three or four hundred dollar fire in the paint room is quite likely to run into hundreds of thousands of dollars on account of the defective arrangement of occupancy. We are trying to help the situation some by developing some waterpoor floors for such rooms in the hope that most of the water can be diverted to the outside of the building before it gets to the stories below, but this is a difficult and expensive cure for a fundamental defect. Obviously the only proper cure is to confine the finishing to one building or one fire section, and the process and finished goods to other sections. Such an arrangement can be worked out just as well for a small plant as for a large one.

So far as the protection of the more highly dangerous hazards is concerned there is more or less controversy. Quite a few people, mostly within the industries but unfortunately many connected with the insurance companies, are likely to assume that ordinary means of protection, such as the chemical extinguishers, hose, sprinklers, etc., will safeguard these hazards. In the general proposition this may be true, but even if such fires are controlled by these devices there is usually a needless loss involved in their extinguishment. It is essential therefore that special engineering service be obtained to outline the special protection needed for any particularly hazardous process, and assuming such advices come from a reliable source they should be promptly complied with, as all possible arguments favor such special protection.

There are particular underwriters' rules governing the use of fuel oil; and for severe cases even more safeguards than outlined in those rules can be proposed, such as automatically shutting off the oil by sensitive heat detecting devices which can operate before the operation of the ordinary sprinkler. Dip tanks, tempering tanks and other open tanks of highly flammable liquids can be automatically protected so that when they flash fire the fire itself will automatically operate foam devices, drains or covers with the result that the fire is promptly extinguished with nominal loss and no danger to life. Enamel and other bake ovens can be automatically filled with steam or inert gases and they can be provided with explosion vents to avoid all possibility of loss of life or interruption from fire or explosions.

Paint Spraying Presents Hazardous Problem

The most recent and possibly the most hazardous process we have to consider today is the prevailing method of applying paint and especially pyroxylin lacquer by the process of spraying. This involves a serious consideration of arrangement and protection that these fires may not result in loss of life and in damage to other processes and goods. The serious losses in this process have been due mostly to ignoring the danger on the part of certain of those interested in production and to improper fire protection. It is safe to say that all these fires may be easily controlled. It is only necessary to recognize that they are extremely quick fires, releasing a large amount of heat in a very few moments, so the ordinary fire protection cannot cope with the hazard. Much more water is needed than can be applied through an ordinary sprinkler system and much prompter action is necessary in applying this water than is obtained through the ordinary operation of the fusible link now used in sprinklers. I just heard the other day of the sixth fire in one of these rooms where the hazard is very great. The first two losses were serious, as proper protection had not been provided; but the last fires, and this last one in particular, although the fire was as great as ever before, involved practically no loss, the protection provided having taken care of the fires nicely. These hazards may be easily controlled by certain supersensitive devices arranged to turn on a large amount of water upon development of the first rise of heat, and arrangements are made whereby this large amount of water discharged for extinguishment may be disposed of without involving a loss on other property or goods. There are underwriters' rules for caring for this paint spraying hazard which do not call for any sacrifice in modern production methods, and the records to date indicate that when such rules have been complied with there has been no material fire loss in such protected areas and no loss of life.

To sum up, you will note that I have dealt with the need of studying fire hazards in a broad way as they relate to the general production and manufacturing management. The particular details for the protection of all these hazards are available to all interested, so our problem is not so much the dis-

cussion of these details as the discussion of their general neglect. The title of this paper is "Studying Plant Processes to Prevent Fire," and this is an appeal for the actual study of these processes to prevent fire and to avoid danger to life upon the part of the production experts and those having in charge the management of our industries.

It is fair to assume that this safety feature is just as important a factor as one of the items to be studied on introducing a new process as are the construction, occupancy, finance, labor and production problems which go with it. Possibly more progress could be made if the production man were relieved of the burden of expense for fire protection, as it is now charged to his process. It would seem that all costs of insurance, fire protection, safety to life and co-related matters should be grouped into one account, called a protection or safety account. Very often the cost of insurance is kept separate from these things and the management is much misled as to his cost of protection, of which total cost the actual money paid for insurance premiums is but one item. Fire protection is an expense chargeable to all industries and if the cost of upkeep of fire apparatus and protection, with the cost of insurance, were charged to such an account the actual cost of the protection as a whole would be accurately determined. The cost of fire protection, regardless of conditions and the quality of insurance purchased, is always about the same, being the sum of insurance premiums plus the cost of fire protection and its maintenance. The higher the premiums paid the less the cost of fire protection, while a high cost of fire protection involves low premium payments. There is therefore no reason why any special fire protection cost should be applied to a particular process or be chargeable to that particular department, as it is a fundamental overhead charge for protection, perfectly legitimate, and represents a cost to which all departments of the industry should contribute and a saving in insurance cost reflected back on the overhead of all departments.

Where There's A Will There's A Way

This point is respectfully submitted to those industrial managers who have not given this matter careful consideration, as the first principle to apply in studying methods to reduce fire losses from processes and other causes. With this principle established there will be little resistance to expenditures for fire protection throughout all the departments, and protection will be recognized in the daily planning and estimating of the work and so become one of the necessary and ordinary subjects for consideration in all plant layout work. Having proceeded thus far, the working out of the detail for protection is a simple matter for where there is a will there is a way and, as I have before stated, there are ample rules and regulations and advisors always ready to give freely all the time necessary to those interested; and they are making a sincere effort to prevent property and life losses and to secure the attendant benefits of continuity of production and ultimate saving in manufacturing costs which such efforts are bound to produce.

This last statement may be questioned, and in anticipation of this thought I might state that while it may be undoubtedly true that some insurance agents and representatives of some insurance companies may not be able to point out a clear way to solve these special problems of fire prevention, yet it is a fact that any insurance companies which are worthy of the confidence of manufacturers who must place with them responsibility for carrying liabilities of millions of dollars and thereby recognize their necessary financial integrity, have, through their highly trained engineering organizations, large and experi-

enced agencies, laboratories and company associations for underwriting large risks, ample facilities for meeting and mastering all problems involved in the hazards of manufacturing processes.

Moreover these company organizations are always ready to meet their clients more than half way in offering advices on construction, occupancy and all other features incident to a manufacturing plant even though not involving manufacturing hazards. This service is offered freely without cost. Manufacturers who have the good habit of submitting to the underwriters all those things while in the blue print stage save thousands of dollars by the simple fact that it is much less costly to change a plan on the drafting board than to tear out and rebuild after work is completed. All architects and engineers (as some are already wisely doing), should voluntarily and without the suggestion of the property owner present construction plans to the underwriters, who undoubtedly would appreciate such cooperation which would enable them to learn as well as criticise.

We also hope that the day is not far distant when we all may assume that a production engineer who prepares plans for a hazardous production lay-out without including therein adequate provision for its safety is incompetent and does not know his business.

Doubtless you know of the very large amounts of money and time spent by the underwriters in general, impartial study, investigation and propaganda, all offered to the end that tremendous and unnecessary fire losses, together with their attendant loss of life, may be curtailed.

Did the Mule Kick Close Home?

CHAIRMAN WENTWORTH: Mr. Richards' paper is so rich in content that it is rather difficult to know where to begin to discuss it. It is something to be read and pondered over when it appears in our proceedings.

As I listened to the paper, it seemed to fall logically into two divisions:

One, the plant management and its special responsibilities, and the other the engineering phases of coping with these special hazards.

Mr. Richards certainly pays his respects to the production manager. It reminds me of the story of the darkey who was asked if his mule ever kicked him. He said, "No, sah, he never kicks *me*, but he sometimes kicks pretty close to where I just *was*."

Mr. Richards kicks pretty close to the production manager who is so keen to produce goods that he overlooks a very necessary element in the safe production of those goods.

He also attacks the methods of bookkeeping which place upon the fire prevention department a wholly unjustified burden of expense. He calls for the distribution of that expense over the whole production process, as it properly should be made.

The engineering phases to which the discussion may very well contribute is the idea of the segregation of the hazard. Pick out the special hazard and so protect it that fires may occur continually, daily, and yet the production of the factory may not be interfered with.

The other point is the protection of the stock in order that the stock may not be depleted by preventable fires.

What is the experience of the members of the Council along those special lines? It seems to me that Mr. Richards has enunciated the principles, his paper is the preliminary to the discussion of the specific incidents which may very well go in the record to illustrate the points that he has made. Has any member any special experience relating to the segregation of a special hazard or the penalties for not doing so and the protection of stock and the penalties for not doing so?

Are all your plants so perfectly disposed in these matters that you need to give

them no thought? Have you any questions that you would like to address to Mr. Richards?

BENJAMIN RICHARDS (Underwriters' Service Association, Chicago): There is a representative here of a very large organization which has not the defect which I pointed out. I think Mr. Abbott, of the Fisher Body Corporation, could enlighten us quite a little if he would tell us of the excellent cooperation between his safety department and the head of his concern.

MR. ABBOTT (Fisher Body Corporation): I have a very great appreciation of the paper which Mr. Richards has just read. I believe there is food for a great deal of thought in what he has told you this morning. That is especially true concerning a subject which has been discussed very much recently, and that is the spray finishing operations. Those of you who represent the automobile industry know, of course, that the pyroxylin finishing operation has been one of the very revolutionary things which have come into the automobile industry. Not only in the automobile industry but in other lines of industry has it almost completely replaced the former methods of painting and varnishing.

Good Housekeeping and Ventilation Go Hand in Hand

The Fisher Body Corporation, of Detroit, which I represent, has probably finished between four and five million bodies in pyroxylin finish, and I think I am safe in saying that the plants are safer today with pyroxylin finishing operations than they were under the old methods, providing the hazard is studied and proper safeguards are applied. It is almost entirely a matter of good housekeeping and proper ventilation. Sometimes we hear the question asked, what is proper housekeeping and what is proper ventilation? Those are individual conditions which must be analyzed according to the conditions under which the process is being used.

There is one advantage in pyroxylin finishing operations in regard to housekeeping. The residues, which constitute most of the hazard, are of a dry nature, whereas in paints and varnishes the residues were adhesive and it was almost impossible, under some conditions, to maintain good housekeeping.

We are practicing with all of the finishing operations, the installation of waterproof floors, with drains, adequate ventilation, properly protecting the storage of raw materials, and a thorough cleansing and cleaning of the booths and the ducts each day or at the close of each day's production. We have made a careful study of the safety of the finishing department, and as a result we have had no serious fires.

Inasmuch as we are the largest users of pyroxylin finish in the world today, there seems to be no reason why the finishing hazard cannot be adequately protected, and as Mr. Richards and Mr. Wentworth have said, fires can occur without severe losses in time and production. If the departments are properly segregated, properly protected, there is no reason why we should have any more severe losses than we had under former methods of finishing.

I should like to touch just a moment upon this thought. There seems to be prevalent in the field an idea that there is something extremely mysterious about pyroxylin finishing fires. I should like to say that there is nothing mysterious about it, that there is nothing about pyroxylin finishing that cannot be adequately protected or understood by any intelligent person who will apply a little thought and study to the process.

I think in a way it is much easier than it used to be with paints and varnish, because under the old methods it was like a snake in the grass; you never could tell when spontaneous combustion was going to occur in your plant at night or at times when the factory was not in production. If the pyroxylin is properly segregated and not mixed with other materials, there is very little danger from spontaneous fires. I don't think we have ever had a fire in our plants from spontaneous sources from the pyroxylin finishing. If you have those hazards to contend with in your

plants, it is just a matter of making use of facilities which are now at your command. Through the National Fire Protection Association and the various engineering departments of the insurance companies, I think the hazard is thoroughly understood at present, and competent engineering advice will be given by these agencies to any concern that desires any information on the subject.

CHAIRMAN WENTWORTH: Mr. Abbott's remarks are certainly reassuring and emphasize our belief that any processes can be controlled by the proper application of intelligence. It is true that in all the records of fires which the National Fire Protection Association has in its files, not a single one of these spray finishing plants that has burned can point to proper installations and proper housekeeping. If the regulations will be followed the fires will not occur or can easily be controlled.

Give the Inspector a Chance!

C. E. FOHEY (Willys-Morrow Company, Elmira, N. Y.): I might speak about the effect of an underwriters' inspector's report that we recently received with regard to inspections made in our plant. Naturally when the report came in, and it covered quite a good deal of detail, the first inclination was to resent quite a good many of the things that the inspector reported. But after sitting down and studying the thing very carefully, those of us in charge of that work were forced to admit that perhaps we had overlooked a great many of the important features that the inspector was able to discover in his rounds of the factory.

There is one thing that I do want to say. After we cooled down and thoroughly digested the report we had to admit that it was one of the finest reports from the standpoint of fire protection that we ever saw. This inspector went through our plant, and he didn't miss a thing. He got everything that was there. To us it seemed those things were not there until we finally took the report and went over the plant and checked each of the details that the inspector covered. We found lots of things about our plant that we never knew existed that might be considered fire hazards.

I bring that up simply to show that if we had received that report and continued to accept it in the frame of mind we were in in the first place, we perhaps would have overlooked many valuable suggestions from the standpoint of fire protection.

Of course, there were lots of things that seemed minor and trivial, but at the same time they were potential fire hazards. I simply want to throw that out to the fellows who are here today; if an inspector comes through and makes a report, it is worthy of attention, it is worthy of serious consideration, because there may be something hidden away some place that you in your casual routine going over the factory will not see nor view in the light of an outside inspector. We consider such inspection valuable and you can depend upon it that our company is going to give it every consideration.

J. E. GRANGER (Fire Department, Cleveland): May I ask Mr. Abbott to explain a little further the method of cleaning these booths? There are three different methods, to my knowledge, and all of them are in their infancy. I believe it would be an advantage to those using pyroxylin finishes to know what the Fisher Body Corporation is using most successfully at this time.

MR. ABBOTT: The cleaning process varies somewhat with the nature of the installation. I think the most efficient and the safest is, where you have waterproof floors and they are properly drained, to wash out the installation every night thoroughly with a hose stream. In our later installations we are providing high pressure lines; we go right into the booths at night. The maintenance men wash the ducts, wash the interior of the booths, the floors and ceilings and walls of the spray room, if necessary. We have found this to be the most adequate way of getting rid of the residue.

In some cases where it is not possible to afford the waterproof floors and so forth, dry cleaning must be done. There are several ways in which that can be accom-

plished, and accomplished safely. One thing in maintenance is handling the dry residue, and that constitutes, I think, 75 per cent of the hazard in pyroxylin work. Most of the fires which have occurred up to the present time, have been traceable to one of two things: either the lack of proper maintenance or improper methods of maintenance. Some have been due to friction sparks igniting the dry residue while it was in suspension in the air. Others have occurred from allowing the residue to become combined with other residues which were of an oil base and, therefore, resulted in spontaneous ignition. In dry cleaning where you haven't the water process, I have known of some cases where coatings of soft soap were being used successfully to spray the interior of the booths.

We do not allow any change in the method of maintaining our booths without an order from the fire prevention department, and before we make any changes in maintenance methods, those changes are very carefully analyzed to determine whether or not the change is going to be more efficient than the method which may be in practice.

Soon after a disastrous fire in Detroit some time ago, I was flooded with a deluge of literature from different concerns which had a cure-all for all pyroxylin fires, substances that you could spray in the booths. Our orders are that no spray of any description shall be used in the booths without an order from the fire prevention department; and anything that has advanced along that line is, as I said, analyzed to see if there is any virtue to it.

We are considering now and are making some experiments (not merely one or two, but over a period of a month), to determine the efficiency of some of these so-called coatings for interiors of booths. Sometimes it is soap, sometimes it is a paint. There are several grades that have been put on the market for that purpose. In the maintenance, care should be exercised, whatever method you use, that non-sparking implements should be used where you are handling the residue dry, and it should be immediately submerged in water as soon as collected, for safety, because as soon as it is wet there is no danger.

Gas Often Mistaken For Smoke

Some of you may not know that fires occurring in the residue first decompose it into flammable gas. That gas should not be mistaken for smoke. When it reaches the proper density, it will in turn take fire and burn. I recall investigating one fire not long ago where the residues had been combined with other residues in the plant and left in a truck over night instead of being removed from the building, as should be the case with all residues collected during the day, for safe practice. They never should be left stored in the plant over night.

This fire occurred at about midnight from spontaneous ignition, which occurred from paint residues combined with the pyroxylin residues.

The chief of the fire department came in on the fire call and said, "What in the world was in that truck?"

One of the maintenance men said, "Why?"

He said, "There were huge volumes of smoke coming from it and then the smoke would take fire and burn up in the air."

That was merely the gases which had been generated by the burning residue.

In the later installations where we have the washdown, we have open-head sprinklers in the ducts and in the stacks which are on manual control valves, and during the washing process at night these valves are opened and the ventilating stacks and ducts are washed down by the sprinkler lines, open heads, the same as the inside of the booth is washed with the hose lines.

CHAIRMAN WENTWORTH: Is this residue readily soluble in water so that it is a perfect cleaning operation with the hose stream?

MR. ABBOTT: Yes. There is absolutely no danger. It is soluble in water. There

is no danger as soon as you have it wet. We have found in some cases that the residues collecting on the roof or on the outside of buildings near the exhaust stack, after a period of time, seem to be non-flammable. For a time, maybe the first one or two wettings, and then when dried out, it will burn, to some extent. It is also slowed up very materially by the combination of other dry dust, such as atmospheric dust, but we always treat it the same as if it were the clear lacquer dust, so far as safety features in connection with it are concerned.

ROBERT SCOTT (Atlantic Coast Line Railway Company, Wilmington, N. C.): May I ask Mr. Abbott, where automatic sprinklers are installed in the building and in the booths, do you use the deluge system?

MR. ABBOTT: Our attitude in connection with the deluge system is that where the hazard justifies the installation we are installing it. We have one plant where we have just put in a deluge system. I extend an invitation to any of the members present to come to Detroit at any time, and I will be very glad to show you the arrangement on this particular floor. We had a test on the valves last Monday night: by putting fire in the booth and operating the release device the booths were completely deluged automatically in eighteen seconds.

Is the Deluge System Justifiable?

MR. SCOTT: From the experience that you have had so far in the employment of the deluge system, do you feel that that experience is justified?

MR. ABBOTT: We do in large installations where the hazard justifies it. That is entirely governed, I should say, by the extent of the operations, the location of the hazard in the building, and the exposure which it creates. If we were doing pyroxylin spraying in the third or fourth floor of a six-story building, and we had female employees below in a trim shop, our building might be ideally situated, a fire resistive building, the booths properly constructed and the proper ventilation, yet there might be other things which would make the deluge system highly desirable from the standpoint of protection to human life as well as property. In some cases we are looking at it from that standpoint.

In spraying operations, for instance, in a building on the fourth or fifth or sixth floor, when you have quite a number of employees in that building, the safest way is to put out your fire as quickly as you can. We are installing in some cases entirely from that standpoint.

MR. SHAW (Hercules Powder Company): I understood the speaker to say, in answer to your question, that these pyroxylin residues are soluble in water. As I understand it, the chief ingredient of the residue is nitrocellulose, and that is not soluble in water. If I have misunderstood, I should like to be straightened out and see that the record does not convey any misunderstanding to others.

CHAIRMAN WENTWORTH: Mr. Shaw makes the point that nitrocellulose is not soluble in water. Perhaps Mr. Abbott would like to extend his remarks to cover that point.

MR. ABBOTT: I think that is more of a technicality of chemistry than the subject that we are just discussing. What we were getting at is the safe handling of the residue rather than the exact chemical technique of the residue being soluble in water. As soon as it is placed in water there is no further danger from the fire hazard as long as it is kept wet.

MR. SHAW: That is correct, I agree with you, but I don't think the record should show that these residues are soluble in water, because they are not.

CHAIRMAN WENTWORTH: The next item is "First Aid Equipment for Fighting Fires." Most of you, I think, are familiar with the organization which the next speaker represents. Thirty years ago, at the time of the birth of the National Fire Protection Association, Underwriters' Laboratories was also born. It was born out of a real need. When we came to make the standards for metal window frame

protection, for example, we found the need of actual laboratory tests. We could not make a rule for window protection without a definite experimental experience. That was one of the items which gave the impulse to the creation of Underwriters' Laboratories, which now possess the most wonderful shop of its kind in the world.

Outside of the original tests at the laboratories, which are so interesting, has been developed an inspection at the factory, of devices and materials. Underwriters' Laboratories has developed a most important service which assists the purchasing public, when it buys a fire prevention device or buys any device or material related to fire protection, giving a certification that that device will do the thing which it is designed to do.

The Department of Factory Inspection and Label Service of Underwriters' Laboratories is presided over by our next speaker, whose ability, executive force and intelligence are well known to many of us, Mr. Curtis R. Welborn, Superintendent of Label Service of Underwriters' Laboratories.

First Aid Equipment for Fighting Fires

Curtis R. Welborn, Superintendent, Label Service, Underwriters' Laboratories, Chicago, Ill.

One of the attempts to explain how humanity acquired the use of fire is handed down to us in mythology in the story of Prometheus. This Titan, who evidently possessed all the dash and courage characteristic of his race, stole from the gods some glowing embers for mere mortals. For his transgression he was chained to the rocks and an eagle was directed to devour his liver each day.

That story, if we are to think of losses from the use of fire in terms of dollars and cents, is carried to a very satisfactory conclusion. A very proper punishment for a rash act because something was placed in the hands of careless and indifferent human beings without instructions as to combating it in event it became unruly, that was to prove a curse as well as the benefit for which it was intended.

During the year that has just passed, the colossal stupidity of individuals in our country and Canada has left us with a 560 million dollar ash heap, to say nothing of the loss of life. I think all of you will agree that we do not have to be interested in, or fanatics on, the subject of fire prevention, or even straight thinking fire prevention engineers, to shudder at the figure. It is a tragedy, the economics of which should cause, and is causing, (thanks to the efforts of the splendid secretary of the N. F. P. A.), the business world to take cognizance of the unwarranted loss of life and property. This, however, is not a problem for the fire prevention expert and business man alone and it will not be solved until every man, woman, and child has been made to realize that it is a personal responsibility.

In my opinion its solution is predicated on one thing, and that is enlightenment. Without fear of contradiction, I believe that a substantial percentage, yes—even 90 per cent of all fires—could have been extinguished by the intelligent application at the right time of any standard fire extinguisher; and, from my point of view, the matter of curbing this unwarranted waste resolves itself into two major divisions, namely:

- (a) Creating the demand for first aid fire appliances.
- (b) Instructing purchasers in the procurement and use of the machines.

The first division is perhaps essentially the job of the manufacturer, the insurance fraternity and the N. F. P. A.; but the latter is the business of everyone interested in saving life and property from the ravages of the demon and may be separated into three phases:

- (a) The procurement of proper standard equipment.
- (b) Correct distribution.
- (c) Adequate maintenance.

Incipient fires have different characteristics and thus necessitate different methods of combat. The different characteristics, due largely to the kinds of material being consumed, necessitate the selection of different types of first aid equipment.

These fires have been grouped into three classes with respect to character, and into two classes with respect to means of extinguishing them. The classifications with respect to character of the fire are A, B and C, and with respect to extinguishing them are cooling and smothering or perhaps a combination of the two.

A class "A" fire is one originating in ordinary combustibles like wood, paper, and rubbish.

A class "B" fire is one originating in oils, grease, etc.

A class "C" fire is one originating in electrical equipment where a non-conducting stream is essential as a safety measure.

My purpose in defining fires is to emphasize the fact that the installation of first aid hand fire appliances is a study, and failing to study the premises with respect to the existing hazards may result in an unwarranted loss, to say nothing of the unfavorable impression created with respect to the use of such appliances. It, therefore, becomes a responsibility of those of us interested in the reputation of first aid fire extinguishers to see that unfavorable impressions are not created and this may be accomplished in only one way—by advising the prospective user of, and securing for our own use, the class of device that is best suited for the particular premises and at the same time assuring those interested in installing such apparatus that standard extinguishers are readily identified by the inspection manifest of Underwriters' Laboratories attached to the shell above or integral with the manufacturer's name plate.

It is unfair to these hand appliances to demand them to be a panacea for all ills. Each type and design has its limitations but these limitations have been determined and the devices classified accordingly. For convenience to the users, Underwriters' Laboratories' label conveys the information concerning the adaptability of the device for an A, B or C fire and just how many extinguishers are considered a unit of protection. This unit is composed of from one to five first aid fire appliances, depending upon the extinguishing value of the kind of appliance comprising the unit and is designed to protect 2,500 square feet of floor space where ordinary combustibles are involved. Care should be exercised in the location of the device. These distances from the hazards to be protected have been tabulated by the National Board of Fire Underwriters in their publication known as "First Aid Fire Appliances" and which may be obtained upon request. It is my thought that every plant superintendent should have this document in his personal library and institute some program of determining whether or not the regulations are complied with on the premises under his jurisdiction.

Dangerous to Neglect Fire Extinguishers

The last, but by no means the least of the three phases of everyone's business is the item of maintenance. My position requires that I spend a great amount of time in manufacturing and distributing establishments of this country and Canada, and quite naturally one of the things that always attracts my attention is the fire fighting equipment provided. Many of the industrial risks have a system of inspection that compels them to designate some properly qualified individual for the maintenance of first aid hand fire appliances but many other places neglect them. Neglect is the death knell of fire extinguishers. There are two things of major importance in the matter of maintenance of the majority of extinguishers and these are: Protect them from freezing and discharge and recharge them annually, taking special care that the manufacturer's recharges are used in the respective devices and their directions carefully followed.

Gentlemen, I have not attempted to discuss the mechanism, operating characteristics

and technical details of first aid hand fire extinguishers for two principal reasons; firstly, because it would take most of the day if it were attempted and secondly, because I am not an extinguisher technician. As for what extinguishers are and how they work there is a document assembled by the N. F. P. A. that presents the heart of any extinguisher speech, discussion or what not that may be made on the common types. The pertinent facts pertaining to these devices, originated in our published advices to users so we are more than pleased to receive and answer questions regarding them.

There are just two more things I wish to emphasize and they are the relation existing between first aid hand fire appliances and safety and comfort to human beings. Early in my talk the statement was made that a substantial percentage of all fires could have been extinguished by the intelligent application of a standard fire extinguisher. If the distribution of these machines had been adequately made during 1926, 10,000 seared souls probably would not have entered eternity. It is rather a cold blooded way of treating such a subject but have you ever considered the worth of 10,000 human beings in terms of units of fire protection? Suppose that of this 10,000 people, 7,000 were adults capable of earning \$1,000 per year, and that, I believe, is rather conservative figuring. In other words, seven million dollars in one year is lost to our economic structure, to say nothing of its contribution to our domestic welfare and happiness. In all probability this potential wealth would not have been contributed to society in this manner but if we estimate the average cost of an extinguisher at \$10, that amount of money would place an extinguisher in 700,000 American premises.

Shall the "Red Demon" Govern Our Tax Rate?

With reference to the comfort of human beings, I feel quite safe in saying that none of us enjoy paying an exorbitant tax to the city nor a very high insurance premium on our worldly possessions. After the "Red Demon" has devoured any, or several, blocks of any of our cities and towns, do you suppose the cost of administration will be adjusted proportionately to the reduced revenue from this loss, or do you suppose the insurance premium will be lowered when they are based primarily on losses? It is my guess that neither will be the case and most likely in the first instance the administration cost will be prorated over the remaining untouched area and in the other case there is a splendid opportunity for an adjustment of rates. In other words, the sane and careful people of this country are at the mercy of the careless and indifferent and those of us interested in this problem are paying for it. It is my hope that the time will come in this country, when things go up in smoke somebody goes to jail, and stays there until he satisfactorily explains that the conflagration was unavoidable.

Present conditions are inexcusable blunders affecting the future and, gentlemen, what finer monument can we build for posterity than that which we erect when this enormous annual fire loss becomes a negligible quantity!

It is your responsibility and mine to try to stop it, and we can contribute effectively by encouraging the use of hand fire extinguishers. Leave the construction details to the manufacturers and Underwriters' Laboratories and do your part by equipping your premises with an adequate number of properly distributed standard machines and *maintain them*.

CHAIRMAN WENTWORTH: Mr. Welborn brought out the points, what first-aid devices are for; the character of building in which they are installed; the proper distribution. And then the very necessary point of proper maintenance. Those are the points to which our discussion should be addressed.

E. S. LICHT (Empire Gas and Electric Company, Geneva, N. Y.): I should like to ask Mr. Welborn why it is that sometimes fire underwriters say that fire

hose must be installed in hydro electric plants and substations. If they were ever used in the case of an electrical fire you could see what the result would be. Why is that?

CHAIRMAN WENTWORTH: Mr. Licht has asked why the underwriters sometimes request the installation of hose in electric generator stations where the projection of water might injure the machinery.

MR. WELBORN: That problem lies wholly with the local underwriters having jurisdiction.

CHAIRMAN WENTWORTH: If the underwriters can't properly make out their case for the installation of hose, then perhaps the industry will be unconvinced. There are certain occasions, if a building gets on fire, after the electrical fire is extinguished perhaps, where hose streams might be very valuable in case the station contains combustible material.

Systematic Charging of Extinguishers Important

MR. GRANGER (Cleveland Fire Department, Cleveland, Ohio): In referring to the annual charging of extinguishers, I would suggest that be made semi-annual for two reasons; first, to give a demonstration and experience in the handling of them, and next it would be additional security against some misuse or failure to operate when badly needed. I think a year is too long. It is not much expense to do it semi-annually. I believe charging semi-annually is at least well worth the cost.

BENJAMIN RICHARDS (Underwriters' Service Association, Chicago): I should like to see in the record a little statement respecting what the other gentleman brought up. I think there is quite a little misunderstanding about the use of water in electrical fires. I don't know much about electrical apparatus myself, but I do know that a manufacturer protects a large dynamo by water spray sprinklers in the fields of those machines, and I also know that the electric people put outdoors—subject to rain, snow and ice—bare terminals under very high potentials. I also know that there are thousands of cases where a little hose stream of water from a sprinkler on an electric fire would avoid a very large loss. Fire happened in one case I have in mind at a switchboard. The fire department came and put hose streams in, in this case seven of them, where one sprinkler on the switchboard would have prevented the loss. That loss ran over a hundred thousand dollars. With sprinklers, in spite of short circuits and other technical defects, the loss would have been very nominal and the station would have been operating, probably, the next day.

I don't know, myself, what is correct in the argument between the electrical experts and the others, but I do think that there is quite a misunderstanding, especially as some of these machines are already equipped with water sprinklers and therefore a hose stream won't hurt them any.

Usually the short circuits are on the switchboard before the water is applied and a little extra water can't do much harm. Again, we have paper mills specifying that motors, dynamos, and so forth, should be waterproof. One mill I know required the General Electric to run the machine under water a certain time before they purchased it so a few hose streams around the electric apparatus are not quite so harmful as one might think.

R. B. KELLY (Anaconda Copper Mining Company): I should like to ask Mr. Welborn if he considers that the installation and use of a carbon tetrachloride or similar fire fighting apparatus is sufficient as first aid fire fighting.

MR. WELBORN: In the N. F. P. A. booklet I distributed this morning there is very clearly outlined the limitation of the various types of apparatus as published in our list of approved devices.

MR. KELLY: I should like to say a word in connection with what the gentleman

said in regard to fighting fires in electrical machinery. The Anaconda Company uses very high voltage in its substations and also a high voltage in the operating departments. We frequently have some severe fires due to lightning. While we are, as we consider, well protected against lightning, it frequently develops fire. We do not use, however, a fire hose stream, we use chemicals, and we have never yet failed to subdue any fire that may have occurred in any of the generating machines or on the switchboards with those chemicals.

We have come to the conclusion that it is far better equipment to use than to put in what is known as the sprinkling or deluge system in an elaborate electrically equipped plant and perhaps ruin the entire installation by the use of water. We had an experience of that kind years ago, and our experience in using the chemicals has taught us that they are amply sufficient in subduing the average fire that may occur in an electrical substation or generating plant when the employees or the operators are trained in the use of apparatus and are prompt in adopting its use.

W. T. FILMER (Youngstown Sheet and Tube Company, Youngstown, Ohio): Concerning these N. F. P. A. pamphlets I believe it would be just as well if we would all go back home with them and emphasize the fact that they represent an authority as to what is the proper field for the various first aid equipment. Many people are inclined to be overcome by the argument of a salesman, and a salesman will sometimes advise the use of equipment which is not the best suited for the particular hazard involved.

I know of a case where people purchased a large amount of equipment which proved locally unsuitable for the hazard. We ought really to look at these devices from the standpoint of the National Fire Protection Association and see whether or not the equipment we are buying is the proper equipment.

Never Too Young to Learn

C. P. REMMEY (Captain, Fire Department, Memphis, Tenn.): I want to cite one instance of the value of teaching school children the proper use of fire extinguishing equipment. Three years ago in our public schools we found that the state law was not in any sense of the word being observed with reference to proper and adequate fire extinguishing devices. That situation has been well taken care of in the city of Memphis. The school boards cooperated handsomely. We now have an adequate number of the proper kind of extinguishers placed. But we consider a very important point in the operation of fire extinguishers just this: No matter how correct the directions are on that canister for use in time of fire, it is unreasonable to expect a layman to know how to operate it in a smoke-filled hallway where visibility is cut off, and he cannot be expected to stop in such a time of excitement to read the directions. We recognized that situation in training our 40,000 children in the public and parochial schools in the proper use of these devices in time of "peace." In time of peace be prepared for war.

The importance of this was emphasized very clearly a year ago. In a school which three years ago had only a one-quart extinguisher for over 105,000 square feet of floor space, there was a fire last year when it was equipped with 21 two and a half gallon soda and acid containers. This fire occurred under a \$45,000 auditorium addition, due to a strictly preventable cause, the storing of waste paper bailed. There seems to be a tendency on the part of our wonderful Parent-Teacher Association to economize, and to make money from any source whatsoever, and they have a policy of storing this material in auditoriums.

The fire occurred at 4:15 in the afternoon, after school had been dismissed. The building was not occupied, but fortunately on the court a number of basketball players were preparing for a game. One of the young chaps saw smoke issuing

from beneath the storage room door under the annex. We have a boy in each school trained who is called fire marshal. It is his duty to be observant at all times and make adequate reports to my office.

Sixteen of these extinguishers were used effectively. I want you to mark the training of those chaps. Under the direction of the fire marshal, the aids went throughout the building, collected the extinguishers, brought them to the doorway. The panels of the door were not broken in until the extinguishers were already assembled, and then such a charge of fire extinguishing fluid was put into that roaring inferno as is beyond your estimation. The enthusiasm and efficiency of those trained school chaps put out a fire that would have cost \$45,000. In the short space of twenty minutes the fire was practically extinguished, before the fire department arrived and laid their first line. That showed, I believe, the value of training.

In times that are free of excitement the directions on the extinguishers are dandy, but in the excitement and stress you don't read directions. I have seen them picked up and thrown down. They thought all they had to do was to take them off the wall, set them down and they would explode.

Teach the school children. That is the best bet. In the homes where the equipment is placed they will be good firemen, they will beat the fire department at its own game.

Extinguishers on the Wall but Useless

CHAIRMAN WENTWORTH: Captain Remmey's statement regarding the protection in the schools reminds me of the experience we had when our field engineering department made a survey of the Plymouth, Massachusetts, schools last year. You know Plymouth was the landing place of the Pilgrims. Our field engineer found the new high school had purchased a dozen nice new two-and-a-half gallon extinguishers. They were hung on the walls in their proper places, but they were all empty.

Mr. Bugbee suggested perhaps Raymond Hitchcock was right, that it might have been better for civilization, if not for thirst, if the rock had landed on the Pilgrims rather than the Pilgrims on the rock.

MR. RYAN (Chicago Fire Department, Chicago, Ill.): I might say that in Memphis a great thing might be overlooked. One of the real things that everybody should be taught is to have somebody call the fire department first and then fight your fire afterward. That fire department was pretty slow—twenty minutes.

CAPTAIN REMMEY: I take great pleasure in answering Captain Ryan. I probably lengthened the time very much because I was not at the scene of the fire, but the history of the Memphis Fire Department is outstanding. We have nothing to be ashamed of when our engine houses are visited. I have the same to say about Chicago, but our time is second to nobody's.

CHARLES SWEGER (Matthiessen and Hegeler Zinc Company, LaSalle, Ill.): Nothing has been said so far about the danger of using carbon tetrachloride around sulphuric acid.

CHAIRMAN WENTWORTH: Has anybody any special ideas about that? Mr. Welborn, do you wish to say anything about it?

CURTIS R. WELBORN (Underwriters' Laboratories, Chicago): I have had no experience with it.

CHAIRMAN WENTWORTH: The antagonism of different chemicals to one another is a question by itself. The general subject, I think, has been discussed to the point where we realize that the need for the proper extinguisher being selected is first, the proper distribution is second, and the proper maintenance third, all of which are set forward in the N. F. P. A. pamphlet which Mr. Welborn has so kindly donated.

If any of you desire a copy of that pamphlet drop a postal card to the National Fire Protection Association in Boston, and one will be promptly sent.

The next paper is on "Fire Brigades." It is unnecessary to say to this distinguished company that the trained fire brigade is a very different organization from the volunteer fire department. We find in our discussions in the N. F. P. A. that sometimes the layman confuses the factory fire brigade with the village volunteer fire department. The volunteer fire department is not, of course, held in quite such high regard. You remember the story of the school girl who was asked to transpose the sentence, "The fire was extinguished by the volunteer fire department before much damage had been done."

She transposed it to read, "The fire was extinguished before much damage had been done by the volunteer fire department."

The fire brigade properly trained, properly operated is a wonderful adjunct to any large going concern. Our speaker of today, Mr. R. G. Landuyt, of Montgomery Ward & Company, has been chief of such a department in the great concern that he represents for 25 years. He concludes this year his 25 years of service, and he is to receive, to my knowledge, a gold watch and fifteen paid-up shares of the company's stock.

You will be surprised when he comes to the platform, to see what a youthful fire chief he appears to be.

MR. LANDUYT: Mr. Chairman, Mr. Richards, Gentlemen of the Council—First of all I want to thank our Chairman here for the introduction. It is customary for me to appear as responding to a fire alarm instead of receiving an introduction.

I always like to follow the army style and that is "put it in writing." If you will pardon me I will read my paper.

Fire Brigades

Reni G. Landuyt, Fire Marshal, Montgomery Ward & Company, Chicago, Ill.

This is the first time the National Safety Council has had the subject of organizing private fire brigades on its Annual Safety Congress program.

About five years ago, the officers of Montgomery Ward & Co. appointed a committee to study private fire alarm systems, fire brigades and fire drills. Even though we are in fire-proof buildings equipped with fire-fighting equipment and are covered by different kinds of insurance, our first consideration was to safeguard the lives of our employees.

With the idea of safety to lives in mind, the committee agreed that exit drills and brigade maneuvers, both under tests and in actual emergency, can be conducted to much greater advantage under an installation of a private automatic fire alarm system, such as is required as a matter of law in many states.

A fire brigade is valuable in exact proportion to the quickness with which it arrives at the scene of the fire and begins to function. In other words, reaching and attacking the fire in its incipient stages is the important consideration. Similarly, fire exit drill is valuable in proportion to the speed and precision with which non-brigade members are safely evacuated from the involved area.

Fire drills if properly conducted can be confined to a very few minutes. It is quite important the elements of surprise be present at the time of drill, that is, that the alarm be given without warning.

Organization

The motive underlying a fire organization is fundamentally one of mutual protection; manager and employee, alike, are vitally concerned with the preservation of

life, and the permanency of position which the safe guarding and protection of the plant insures. The interest of each party is the common interest of both. Fortunately, the conditions which render many so-called fire drill and brigade activities inadequate and ineffectual are not traceable to a failure on the part of either the employer or employee to understand the relationship or to appreciate how vitally important are these activities. The necessity of the fire brigades and fire drills is almost universally recognized.

Why then, are such organizations so seldom perfected to the point of effectiveness? There are a number of reasons. The failure may be due to imperfections in the method of building the organization, e.g. failure to observe the greatest care in the selection of the members or to establish proper regulations, particularly with respect to discipline or, as frequently happens, it may be due to restrictions placed upon the conduct of the drills. Brigade activities are sometimes side-tracked for matters of but momentary importance. This is bad because the fire problem is one of ever-present concern. It is dangerous for by falling short of being effective, brigades really constitute a menace—a weak substitute which employer and employees, alike, are quite generally misled into accepting as a source of security.

It is my purpose to describe what is right conduct in these matters and at the same time point the way to the development of an ideal organization.

Scope

A fire brigade necessarily must conform to the size, the location and the structural and occupational peculiarities of the plant; must take into account the number of employees, particularly males, the kinds and amount of extinguishing apparatus, etc. It is necessary, therefore, that any plan of organization intended to reach several plants, to be practicable, must be very general in scope; must, on the one hand, allow the manager or superintendent some freedom of action to work out the details best adapting the scheme to the needs of his own plant, but yet must rely on him to do this in a way that will approach the ideal brigade as near as possible.

Brigade Membership Generally

At the outset it should not be overlooked that membership is a real responsibility. The importance of creating an appreciative attitude in this direction can hardly be exaggerated. Members who really feel their responsibility for the safety of fellow-workers and of the plant are more than likely to feel that brigade membership, of itself, confers a distinction.

Only intelligent, cool-headed, strong and active men should be chosen. Once chosen, each should be immediately and thoroughly informed as to the location of the stairways, fire doors, fire escapes, elevators, fire appliances, values, etc., and made familiar with the fire call numbers.

In order to afford members the requisite special knowledge in their duties in the brigade, it is essential that each be instructed and trained to perform any of the duties should it be found necessary at the time of fire to switch from duties regularly assigned.

Chief of the Brigade

So much depends upon the proper functioning and co-ordination of the fire-fighting forces and egress drills that it is false economy to employ other than a high-grade man for the position of chief, or to divide his time with other activities. In plants of any size he will have little time for other work if he continuously produces an efficient brigade organization; if he conducts frequent drills and performs the inspection and maintenance work with the attention and care it requires.

In addition to being physically strong and mentally fitted by experience, the chief's status in the plant should be such that his position will command the respect of the

employees, thus giving reasonable assurance that his instructions will be carried out. A distinctive uniform for the chief is very desirable.

The chief should have charge of all matters pertaining to exit drills, practice maneuvers and organization and should designate all persons to fill the positions in the brigade proper. He should personally supervise the conduct of all drills and rigidly enforce measures of discipline for failure on the part of any employee or any member of the brigade to fully observe all rules and requirements. He should by personal daily inspections, see that sufficient unobstructed space is given to aisles and passageways to permit quick access to all exits; he should see that all fire equipment is in place, in good order and unobstructed; that recognized good practice in fire prevention is employed. He should prepare an accurate semi-monthly inspection report, on blank provided for that purpose.

Assistant Chief

He should be qualified to perform the duties of the chief in the absence of that officer and perform such other fire services as the chief may direct.

Battalion Chief

Where the department is divided into battalions, a battalion chief should be assigned, and his selection should be, so far as can be done, based upon the same qualifications as assistant chief.

Captains

The utmost care should be exercised in the selection of captains, as upon them largely depends the efficiency and success of the drills, and in cases of fire, the direct supervision of the active fighting operation. Therefore, strong, active men accustomed to the control of employees, capable of a fair degree of self possession, of reliable judgement and of acting quickly in an emergency, are essential. It is important that they have the trust and confidence of their employees generally.

Captain Plays the Important Role

The captain under the supervision of the chief, should have immediate charge of all employees in his area, in all matters pertaining to the brigade and exit drills; should be held responsible for enforcement of all rules and report to the chief any employee who wilfully neglects their property observance; he should see that each movement corresponding to the alarm signal is properly and promptly executed; be responsible for the condition of all aisles, passageways, etc., in his area.

When, by pre-arrangement, in drill practice, or as a result of an actual fire, it may be necessary to depart from the regular instructions or procedure, such change should be made at the sole direction of the captain or chief.

Hose Men

In no case should there be less than three (3) men assigned to each line of hose to be operated. Hose men should be strong, active, and gritty, capable of taking lines of hose under pressure upstairs and able to withstand considerable fatigue, heat and smoke.

Extinguisher Men

An adequate number of men should be selected to handle the chemical extinguishers, fire pails and other small auxiliary equipment. This equipment forms a very important part of the protection and must not be roughly handled. Instructions in the handling of it should be so devised as to eliminate carelessness and abuse.

In case of actual fire and if it is necessary to use hose, extinguisher men can act as hose men with those already appointed.

Door Guards

Door guards should see that the marching from the rooms, and in descending the stairways is orderly, without crowding and at a uniform speed, with careful observance and spacing between files. They should be especially watchful of

persons stumbling or falling, to prevent trampling, and no conditions should be allowed which will involve a halt after the exit march has started.

Guards should be stationed as follows:

(1) One guard on the room or interior side of each door available as an exit from the room involved, who should see that the door is promptly opened after the first signal and is kept open until all the occupants not assigned to brigade duty, have left the room, and who should then, personally, immediately close the door.

(2) One guard on landing midway on staircase descending to the next floor below.

Searchers

There should be at least one man and one woman—cool headed and strong—appointed as searchers for each fire area who should immediately upon the first alarm, visit the toilet rooms and any other rooms in which there may be occupants who might not hear the signal to give the alarm.

Elevators

Elevator attendants should be instructed to take cars immediately upon the sounding of alarm to certain designated floors.

Telephone and Pull Boxes

The phone call and pull on city box are not to be made, except in cases of actual fire. The switchboard operator in turn should notify in the order named, the fire department, the fire chief, the plant engineer and the manager.

General Alarm

Should a fire assume such proportions that it is necessary for all employees to leave the building, a signal should be sounded indicating complete dismissal.

Cooperation with City Fire Department

To promote intelligent and harmonious relations, the public fire department officials should be invited to inspect the property periodically. This will insure their familiarity with the arrangement of buildings, and with the best means of access and escape; will acquaint the department with the nature and location of materials housed, particularly such as might involve an explosion, or the rapid spread of fire, and in other ways work to our advantage. Consultation between the brigade chiefs and City Fire Department men are helpful in keeping up-to-date in fire fighting methods.

The fire marshal should accompany all inspectors while making inspection trips through the building.

Montgomery Ward and Company has followed this plan of organization.

Installed a private automatic fire alarm box and gong in each section of the building.

Organized a private fire brigade. The building is divided into many battalion areas and a fire brigade for each battalion area is under the direct supervision of the deputy fire marshal.

Printed fire discipline bulletins, fire drill instructions for employees and a fire department manual for members of house fire department.

There is a special marking on the salary card of every employee who is a member of the fire brigade, and in the event that a member of the brigade is removed from the employee of the company, the timekeeper immediately notifies the fire marshal and another employee is appointed to fill the vacancy.

The fire-alarm system is operated daily for fire drills.

When an alarm is turned in for a drill or fire, the signal of section is sounded four times on all the gongs in the building, in less than a minute's time.

All employees in section of signal, walk in an orderly manner to the section beyond the adjoining section or down stairways two floors below section of signal.

The fire-brigade members respond to the section from which the alarm has been sent and take the position to which they have been assigned.

When a fire drill is completed, a fire extinguished or other emergencies taken care of, a release signal is sounded, indicating that all is well. Then we have roll-call for the members of the fire brigade.

We also have A. D. T. Company fire alarm boxes on every floor and our entire sprinkler system is under A. D. T. Company supervision. That also means we can turn in a city fire alarm signal, by creating a sprinkler or fire-hose water flow.

The Fire Department's Manual

MR. LANDUYT: I will take a minute's time to describe our house fire department manual. When we prepared this manual it consisted of 20 pages. The committee agreed it was too much to give the fire department members a lot of pages of reading matter to cast to one side. So we made it very, very brief. The first page covers fire alarm signals, second page, three different kinds of fire alarm systems we have in our buildings, and how to send in alarms, general information, organization of the house fire department, the duties of the house fire department members from the chief down to the very last man.

Our battalion consists of two companies, a fire fighting company and a dismissal company, the fire fighting company to extinguish the fires and the other to take care of the employees. Total responses to each fire alarm signal, 24 men, and in case the "strike-out" signal as it is called by the City Fire Department is not sounded within a period of less than a minute and a half after every fire drill, additional men are instructed to respond to the alarm at once.

The different companies are night watch, early morning and day.

We have in the building many valuable records, money, jewelry. In case a signal is turned in from any one of those sections, the house police department also responds.

We have the location of the house fire department boxes and the location of the city fire alarm boxes.

The last page has a typical floor plan showing the location of every fire alarm box, and also a skeleton plan of the building showing the battalion area and fire alarm signals for each battalion.

We have two kinds of fire alarm boxes in our building, the private fire alarm box and the city fire alarm box.

This is the private, marked with two white stripes.

The city fire alarm box: I also want to call your attention to the glass in the box. In my experience in traveling with the different manufacturing plants and institutions, every fire alarm box I have seen has glass in it. Our own house fire alarm boxes have glass that is painted with a white circle. When you are at least 100 feet from the box you can still see that the glass is in the box and it is set ready for use. The same with the city fire alarm box. This point may be a little far fetched, but the city fire alarm boxes have a spring behind the door. The moment the glass is cracked the door flies open. What is exposed? The lever. If there is any city fire alarm box in your plant and the door is open, some curious employee comes along and wants to know what it is all about. He pulls the lever all the way down, the result is a false alarm, and in this big city of ours the city firemen have responded to many false alarms and sometimes had a fatal accident amongst the members of the Fire Department and also citizens.

The point I am trying to bring out here is to mark the glass to show that your fire alarm box is set as it should be.

Our sprinkler system is also marked. We have many hundreds of drain valves and sprinkler valves. These are the types of cards used hanging in a frame right below the valve.

CHAIRMAN WENTWORTH: Mr. Landuyt's paper is largely a matter of detail and it will afford us splendid material for inclusion in the records so we may study it at our leisure.

There are, however, a number of points which he may wish to discuss, particularly that the fire chief of an organization should have no other job. I suppose that depends somewhat on the size of the organization.

He also makes the very good point that the local fire chiefs, brigade fire chiefs, should keep in close touch with the City Fire Department. In some plants, to my knowledge, that has not been done as successfully as it might.

ROBERT SCOTT (Atlantic Coast Line Railway Company, Wilmington, N. C.): It seems to me that this paper is so complete and so replete with information there is nothing much for us to ask about, but I should like to suggest a rising vote of thanks to this gentleman for such a fine presentation of his subject.

(A rising vote of thanks was extended to Mr. Landuyt.)

How Is Interest in Volunteer Fire Brigade Created?

MR. HARDY (Youngstown Sheet and Tube Company): This paper has certainly been a revelation to us people who have not exactly the same condition as exists in such large houses as Montgomery Ward's. We of the iron and steel industry have different conditions under which to organize and maintain our fire brigade.

I should like to hear a discussion on methods and manners of securing and maintaining interest in a volunteer fire brigade organization in an institution of large proportions. We can't do it in smaller concerns, but where we cover areas and have departments covering the whole territory, and battalions of eight and ten companies and perhaps ten battalions at that, to keep the interest of the members keyed up to the extent of being ready and prepared and working all the time is the question which I believe bothers the large volunteer organizations.

CHAIRMAN WENTWORTH: I think this is an interesting point, how we can maintain the interest of the fire brigade—what keeps the men on their toes? Have any of you any special ideas on that subject?

MR. ABBOTT (Fisher Body Corporation, Detroit): We had an experience some time ago which may illustrate that point and the method used has been productive of very good results. We were a little skeptical as to just what the interest was going to be among the men when we organized the department. We started out by taking all of the men who had been selected on the fire brigade, over to one of the leading hotels and giving them a banquet. That was attended by all the managers and by the general manager of that particular plant who acted as chairman and introduced the speakers of the evening. It is remarkable the interest that was prevalent all through the plant immediately after that meeting, with regard to fire protection, where we didn't have the number of men that we wanted who were chiefly foremen and sub-foremen. The next morning before the plant opened, the fire chief of the plant had applications from nine more foremen who wanted to act on the fire brigade. The night before we thought we were going to be short. We now make a practice of giving the fire department in that plant an annual banquet at the hotel. We have created a lot of very good interest in that way.

MR. LAVORGE (Missouri Pacific Lines, Houston, Texas): I just want to say in connection with the interest of the men in the fire brigades, our idea is to bring the men into Houston, and devote the morning to safety and the afternoon to fire protection. We seem to have succeeded in arousing considerable interest in regard to the records made by the various fire brigades.

That came about in a rather peculiar way. I happened to write to the magazine about a record by one of our fire brigades, and when I went to San Antonio one of the members of the fire brigade said: "I see where you said something very fine about the Quincy, Louisiana, fire brigade."

I replied, "Yes, I did. They made a very good record."

"We can beat that," he said.

"If you can, that is fine."

That was the start, and from then on each and every one of our brigades has been trying to outdo the other. When we had the shopmen's picnic we had a little contest fire for the fire brigades. We erected an old shack and it was set on fire. Each shop had its brigade on the ground, at some distance of course, and the first ones there, and those making the best performance (we had judges appointed) were the winners of the prize, whatever it might be.

We give the members of our fire brigade and safety committees passes also. Those passes designate whether they belong to the safety or fire brigades, and we find that by doing those things we have succeeded in arousing a great deal of interest. It is a real pleasure to go around among the men because they are continually asking what is it that so-and-so is doing.

When we bring the men to Houston we assign a man to discuss the care of the hose, the care of the Foamite extinguishers, the care of other types of extinguishers; to another care of organization of fire brigades. It has worked out splendidly.

MR. LANDUYT: I am going to tell you how we keep up interest in my private fire department organization. There are many times when a department manager says: "Chief, do you know of a good man?"

"Yes, I have a man on the third floor, a member of the house fire department. Give him a chance." And many of the boys have better positions today because they are members of the private fire brigade.

MR. RYAN (Chicago, Ill.): Chief Landuyt read his paper. The paper is very fine for daytime. I should like to know what occurs at night.

MR. LANDUYT: I mentioned in reading over the house fire department manual that we have a night watch company. They use the city fire alarm boxes and the house fire alarm boxes.

The entire staff of the engineering department are also members of the night fire brigade.

Volunteer Service Made Attractive

MR. RUTTAN (Eastman Kodak Company): We have a domestic fire department, yet it is hardly what you designate as a volunteer department. It is a designated department. We have a fire chief and two assistants and full time paid men with motorized equipment.

We employ in the neighborhood of 8,000 people in our works, in almost every sort of occupation under the sun, with almost every hazard under the sun. We manufacture pyroxylin, we manufacture film. It is a business where those who are familiar at all with the processes can readily understand it is hazardous.

The men are selected on the basis of their familiarity with and their knowledge of the hazard in particular buildings.

Our equipment and maintenance men, such as men in charge of water works, men in charge of special machinery and of ventilation and light, are all represented on this department. They are called together by a whistle. This alarm, in our opinion, is necessary to gather together some 100 hand-picked employees, and they represent nearly all the buildings, as I said before, of which there are 118.

The interest stimulated in the men is more along the line of giving them a special treat. I mean by that the most of those who actually do the work, outside of heads of departments, draw vacations with pay. They are recognized for promotion and advance as being employed in their regular work. If they are being found trustworthy it is a marker in their favor of selection for a step higher up. However, in our plant we base our first aid in case of fire upon an intelligent, trained employee

system of training in the schools. We don't permit any man or any woman to work in a hazardous department without first passing through this school.

Every course, as I said before, is used. There are a number of departments and we have specialized our instructions so that there are about a dozen different kinds of instructions issued, but seldom two instructions to the same employee. If he is to work in building number so-and-so, he gets a specific instruction, educational in nature, which explains everything he has to handle, and just what he is to do. That is done simply as an assistance to the foreman. He is then allowed to go to work in the department and is not allowed to go to work in that department without those instructions.

If he is transferred from one position to another, that is to say from one course of employment to another, he again goes through the school to get his instructions as to the proper thing to do, and the laboratory tests are illustrated so that he knows exactly what he is to do when he goes into that department. It makes it very easy in that way to promote men and consider them for promotion, first as to their actual function, and the indebtedness of the company to them, carrying with it certain favors.

We rely strictly upon policy. The company has a policy. Safety is a policy and fire fighting is a policy. It is just as incumbent upon each employee to take part in the protection of the job, of the building, of himself from injury, or the like, as is his employment itself. For instance, he pledges himself to be careful at all times before we employ him. If he does not, we have a penalization system whereby we lay him off a day or three days or a week prior to dismissal if we find he is a hazard to other employees or the plant.

CHAIRMAN WENTWORTH: The final paper this morning is "Plant Housekeeping and Its Relation to Fire Hazards."

The speaker to present this is Eugene Arms, engineer of a group of companies insuring flour mills. You can imagine how keenly necessary absolute cleanliness is in that sort of property. The speaker is admirably equipped, therefore, by his own consciousness to dramatize this subject to us. Mr. Eugene Arms, manager of the Mutual Fire Prevention Bureau, Chicago.

Plant Housekeeping and Its Relation to Fire Hazards

Eugene Arms, Manager, Mutual Fire Prevention Bureau, Chicago, Ill.

John Wesley might have been thinking of fire prevention when he said, "Cleanliness is indeed next to Godliness." Certainly filthiness is very closely related to the fire demon.

Cleanliness is a habit, even as filthiness is a habit. Habits, as deeply rooted as those, are not changed in a day, nor without effort on the part of the individual or individuals concerned. The street urchin does not suddenly decide to take a bath and thereafter keep himself clean. Neither does the owner of a poorly kept plant order his foremen to clean up and keep the place clean and get results. Habits are too deeply formed to be broken with so little effort.

Let us consider for a moment why cleanliness is so all important to fire prevention. Ignition must, of course, first take place, then the fire feeds on whatever combustible material it finds, and is finally detected and controlled or not, according to the means available. It simplifies our fire prevention work materially to make these three divisions and consider each separately. Now let us see how filth affects each division.

Spontaneous combustion is one of the very common causes of fires. This is the term applied to gradual oxidation of porous substances. The heat generated increases the rate of oxidation until the ignition point is reached. Fires from spontaneous combustion are particularly destructive because they usually

factor. Dirt and filth start fires, spread fires and make methods of control ineffective.

An important point, possibly the most important point, is the effect of cleanliness on the habits and actions of employees. We are told that soap has been one of the greatest factors in the civilization of the world. Personal cleanliness creates higher ideals. Just so, plant cleanliness creates careful employees. Only the most slovenly smoker would throw his cigar stub in the center of a clean floor. He seeks justification in the fact that others have discarded their litter in a corner, and, finding it there, adds his stub to the pile. It is human nature to follow where others have led, particularly if that is the line of least resistance.

The very effort necessary to cleanliness creates a higher morale. Pride on the part of the owners and managers carries down through the ranks. A clean bearing is seldom out of repair. The pride that induced cleanliness insures a smooth running bearing, while the bearing that is buried in grease and dirt runs until it is too hot to continue.

We naturally distrust the man with a week's stubble on his chin, soup spilled down his vest, and the mud from many rains on his shoes. That man is careless in everything and we should distrust him. A certain amount of pride is essential to well being. So it is with an industrial plant. Bad housekeeping is a direct result of carelessness, and carelessness is responsible for a very large proportion of fires.

Study Your Plant and Study Your Man

Many of you gentlemen are fire prevention engineers, and I do not need to preach to you the doctrine of plant cleanliness. You learn it from all of your text books, all of your instructors, but most of all from that greatest of all teachers—experience.

Your question is how may we best impress the plant manager and superintendent and get results? The first step is to draft your program. The plant must be examined very much as a physician diagnoses his patient. The chronic disease of uncleanness may have its seat in one place, or the entire anatomy of the patient may be diseased. Find, first, the cause and then prescribe the remedy. That sounds difficult, but it seldom is. It may be that the design of the plant and the condition of the machinery and the process of manufacture are such that the entire organization, from the owner down, is discouraged from a serious attempt to keep it clean. Such being the case, the program must include a general overhauling. Or the fault may lie entirely with the carelessness of the management. I believe it was Elbert Hubbard who said that no imitation is greater than the length and breadth of one man's shadow. Then find that man. Much time and effort are expended talking to the wrong man. Not always, but usually the right man is the highest man that you can reach in the organization. Start on him at least and get his endorsement of your program. No set rules of approach can ever be devised.

I have little sympathy with that school of high pressure salesmanship which teaches that salesmen must beat their prospects into submission by force of argument. It certainly does not work on me, and I do not believe there are many men in responsible positions on which it can be worked. Desire must be created, certainly a desire to own or manage a clean, well kept, orderly and efficient plant. Study your plant and study your man. Accompany your fire prevention argument with an appeal to pride, the safety and well being of employees, higher morale among the employees, or all of these things, and such others as are suggested by the conditions.

In our work we have found the organization of an inspection and fire brigade among the employees to be the most practical means of enlisting the interest of the men. On the inspection work the plant is divided into departments, and two men are selected from each department to take their regular turn on the weekly inspection. All suggestions are submitted to a committee composed of the management and workers. On the fire brigade each man is assigned a job when the fire alarm rings, and each department is put under one head, with a fire chief over all. That is the bare skeleton of the organization. The details must be suited to the industry and to the plant.

Pride in an industrial plant must originate with the management and emanate down through the ranks. It cannot be expected to originate with the employees. It, therefore, becomes the duty, and it should be the pleasure and pride, of every management to make housekeeping one of the major subjects of its industrial program and be content only when the highest standards are maintained.

CHAIRMAN WENTWORTH: There is hardly room for discussion of Mr. Arms' valuable paper regarding the value of cleanliness. He makes the point which we may well remember, that the very effort for cleanliness creates a higher morale in the organization. You know yourselves that when you go home tired from your work, in your working clothes, when you are weary and dirty, you are not very ambitious, you haven't much courage; but after you have your bath and get into an evening suit you immediately have a higher respect for yourself. It is the same way generally. Cleanliness, an up-and-coming attitude, gives you courage and raises your morale generally.

Are there any questions you would like to ask Mr. Arms? Are there any special points you would like to make regarding good housekeeping and its relation to fire hazards? It is so obvious that unless you have something to illustrate that fact, it is hardly necessary to discuss it.

Plant Cleanliness a Matter of Education

Mr. PIGFORD (Flintkote Company): I think Mr. Arms has brought out some very splendid ideas.

Mr. Arms brought out the subject of keeping the plant clean. I think the best way to keep the plant clean is by education of the employees. All employees from the manager down to the small office boy or the junk man should be educated.

I should like to ask Mr. Wentworth if the N. F. P. A. has considered the issuing of fire prevention posters, such posters perhaps as we see up here by the National Safety Council. Posters issued weekly or monthly would enable us to do great things toward educating our employees. We could reduce fire losses in that manner all over the country.

CHAIRMAN WENTWORTH: The N. F. P. A. has issued a series of pamphlets on common fire hazards, cleanliness, and so on, but of course as the years go round other ones are desirable. I shall be very glad to give thought to the suggestion of the speaker that the N. F. P. A. bring out a series of posters on plant fire protection especially, including this very important element of cleanliness.

We express our appreciation to Mr. Arms for his very valuable paper.

There are one or two items which I should like to bring before the convention. One is the matter of fireworks. At the meeting on home safety the other day there was introduced the idea of abolishing fireworks for private use, keeping them out of the hands of individuals. This resolution was considered and it has come to me to present to this meeting. I should like to see if it finds favor with you; if it does, if you care to, vote and pass it.

"Whereas, There is great annual loss of life and property in America due

to the private use of pyrotechnics by young children and adolescents of all ages in observing the holidays, Independence Day, Christmas, and Chinese New Year, and

"Whereas, It is desirable to substitute as soon as possible for the present orgies of fire and noise rational methods of observing these holidays, it is, therefore

"RESOLVED, That all private purchase, possession, discharge or firing of fireworks or pyrotechnic display of every sort whatsoever should be prohibited, public display of fireworks by properly qualified agencies under the direct supervision of experts in handling of fireworks only being permitted."

How do the members feel about prohibiting private use of fireworks altogether? My own experience as a parent is that I can't keep fireworks out of the hands of my children because the neighbors have them, and if they can't shoot them off at home they will sponge on the neighbors' supply, and they think their father is a pretty hard parent anyhow if he doesn't let them have them. This is something we must do collectively. I can't alone protect my children against those hazards.

On the other hand, we find, with ordinances prohibiting fireworks as exist now in Chicago, Evanston and elsewhere about here, bootlegging in fireworks goes on just outside the limits of these cities. Fireworks booths are set up, and naturally the fireworks may be purchased and lugged across the line, as certain other things come in from Canada.

Will Fireworks Also Be Prohibited?

Are we entering on a new prohibition idea by advocating the entire abolition of fireworks in the hands of the common citizen? What is your thought on that? If any of you have any clear opinion let's have it and vote on this resolution.

H. E. CARR (Youngstown Sheet & Tube Company, Indiana Harbor, Indiana). It seems to me the way to defeat that is by education. If we could undertake a very definite campaign for a period of even six weeks before these holidays, we could emphasize it so that anybody who got hurt would only have himself to hold responsible. I believe that would be better than to try to establish another form of prohibition which cannot be enforced.

CHAIRMAN WENTWORTH: The idea advanced by the speaker is to precede this sort of legislation with education, but education has been going on for many years and a great many cities have already prohibited private use of fireworks. That is something, and the more cities that attempt to prohibit private use, the more such ordinances are discussed, the better opportunity for public education. We cannot defer very well our movement for the enactment of these ordinances.

The National Fire Protection Association has been working to advance this idea for a good many years. There is no logical connection between patriotism and orgies of fire and noise, any more than there is any connection between Christmas and fireworks. In the South they have their fireworks during the Christmas holidays. What relation have fireworks to the birth of Christ? It is rather remote. It is just a notion, a desire to break loose and make a racket. It is a very juvenile, adolescent idea, it is an ungrown race which desires to express that sort of thing. It would be a good deal better for the youth of our country to concentrate on the idea of independence rather than the idea of recklessness and making noise.

MR. ARMSTRONG (Eastman Kodak Company): The gentleman speaks of education. For the past two years I have been doing educational work in an industrial plant. When it is absolutely impossible to educate the parents to a point where they will not allow their children money for the purchase of fireworks, we are up against a pretty tough proposition. We haven't been able to do anything with the parents. Every year and every year the same thing goes on. In every city of any size there are two

or three or four hundred injured, and two or three or four eyes lost. It always happens to kiddies eight or nine years old.

I think there is just one thought that ought to come back to all of us. It may be our kiddie next year, and I think the only way to eliminate this is to get legislation which will absolutely prohibit it.

W. A. WILSON (Frank Graven Sash, Door and Metal Company, Los Angeles, Cal.) It seems to me, gentlemen, that we can approach this also from another angle, advocating fireworks at such times as administered by the municipalities. The city in which I have the privilege of living controls this by having on these days large demonstrations in the public parks that are supervised by the fire department, and especially over in Pasadena they put on wonderful demonstrations at those times. It is done for a fireman's benefit fund, in order to help them carry on this work, but the people contribute very largely to it, and outside of this large place where it is conducted, there are no fireworks of any type.

C. A. BROOK (Homestake Mining Company, Lead, S. D.): We are getting around it this way: We go up on top of a hill and have experts come and set off the bombs and shoot off the skyrockets. That keeps the kids from wanting so many firecrackers, but at the same time they do buy them.

We are getting away from it gradually. We are trying to get an ordinance so they can't sell them. Last year we had three or four bad burns, from firecrackers.

CHAIRMAN WENTWORTH: The American Legion last year outside of Evanston maintained a row of bootlegging fireworks stalls.

MR. RYAN (Chicago): Where did the idea of prohibition of fireworks originate?

CHAIRMAN WENTWORTH: I think it started with our organization a great number of years ago. We first undertook the campaign in 1910 when the figures of the American Medical Association showed the loss of life every year was so astounding that we thought something should be done. We enlisted our members throughout the country to make a campaign before the Fourth of July in 1910 and gradually over five years we reduced this loss of life. There is still too much of it. As Mr. Armstrong has said, every year there are children blinded for life, dying from tetanus poisoning, burned to death from even the little "Sparklers" also which are reputed to be innocent and innocuous. We want to get it out of the minds of the children that they must play with fire. It is foolish. It is true, as Mr. Armstrong says, that some of the parents are worse than the children. My neighbor lays in a stock and shoots them off obviously for his children, really for himself.

Grown-ups Are Still Children in Many Ways

There are grown-ups just as crazy to make fire and noise as there are children. The masses, like children, will always crave spectacles. It is the suggestion of our friend from Los Angeles that the city take this matter in hand and give them their fill of something to gape at at a specific time, then prohibition of individual usage becomes easier.

Are you ready for the adoption of this resolution? Are you ready for the question? (The resolution was adopted).

CHAIRMAN WENTWORTH: The next item which we were asked to discuss is the subject of smoking. Our statistics show that smoking is the present greatest cause of fire loss in the United States and Canada. How are we to cope with it? You know how enormously smoking has spread, not only among our male youth but among our female youth. The smoking by young women and old women has extended so rapidly as to swell this tremendous loss, and you know how the tobacco companies have successfully increased their output of cigarettes by treating the tobacco and wrappers with nitrate. The old ones were not so treated. The old Sweet Caporal that I smoked when I was a small boy, clandestinely, if you put it down it would go out. The modern cigarette, being treated with nitrate, burns rapidly, increasing the con-

sumption tremendously, but also increasing the fire hazard because it burns to its complete end. Tobacco companies do not seem to be interested in fire prevention. We have attempted to interest them, especially in our cleanup campaigns, to convince them that if they will assist in our cleanup work it will reduce the hazard of their product, because a cigarette, as Mr. Arms has said, thrown upon a marble floor won't set fire, but a cigarette thrown in a rubbish heap, causes fires.

Is there anything in your minds that we can do to make smoking a safer operation except to work as hard as we can for greater cleanliness, better housekeeping, the abolition of rubbish? Can we do anything with the smokers themselves?

You know what a nation of fire-throwers we are. The other day in Boston, going into a matinee, a Harvard college boy flicked a cigarette into the lace dress of a woman and set it on fire right in the crowd. I was watching the marathon race in Wellesley last summer and a boy threw a cigarette into a baby carriage and ignited the covering. It began to burn. The nurse saw it at once and extinguished it. That is the way we throw fire about, and it is the careless user of fire, the careless smoker, who has us all in his power.

What can we do to reach the consciousness of the smoker? There are so many of them and they are increasing so rapidly. I have taken perhaps more time as Chairman than I should, but I wanted to introduce the subject as adequately as possible to save time. Matches are a part of the smoking hazard, of course.

The Common Match Must Go

MR. ARMSTRONG (Eastman Kodak Company): We have done practically everything possible along fire prevention lines. Mr. Wentworth is very familiar with our plant. We have a very beautiful plant which we don't want to burn down. We are doing a great deal of educational work. We have a regular school to which we have employees go. One thing we have not been able to do is prohibit the bringing into the plant of the common match. That is our big problem. We don't have smoking in the plant, but although we furnished for a good many years packs of safety matches like this, we still have common matches. We have had fires from these packages being in a man's pocket. When two packages get together, one end gets underneath and sets them off. We had several fires in men's pockets. Then we went to the Vulcan type match and we sell that match at less than cost. The employee can buy at the gate as he goes out, a dozen boxes of these matches for five cents. Still the common match comes in. We find them around the work rooms where we have inflammable solvents and vapors and nitrocellulose. Where you have that sort of material you don't want common matches around on the floor.

I think the only way we are going to keep the parlor match from coming into the industry is to prohibit its being brought in. I don't think that will work any hardship on the match manufacturer because they will consume as many matches anyway.

CHAIRMAN WENTWORTH: Do you mean by the parlor match the strike-anywhere match?

MR. ARMSTRONG: Yes.

CHAIRMAN WENTWORTH: The old "parlor" match head was not inert; it would fly off. That has practically been suspended.

MR. ARMSTRONG: The strike-anywhere match can be lit by stepping on it or running a truck over it on the floor. We have actually had it happen in our plant. Our problem is to get the other side of the family at home to use the safety match. The men don't seem to be able to put it over. We have discussed this with our management. In fact I discussed it just before I left Rochester. We are willing as a company to go on record as desiring to create any necessary legislation to prohibit, if necessary, the manufacture of strike-anywhere matches.

CHAIRMAN WENTWORTH: That is an interesting observation, that the Eastman Kodak Company would vote for legislation to prohibit the manufacture of any match except to strike on the box.

MR. SWEGER (Matthiessen & Hegeler Zinc Company, LaSalle, Ill.): It is up to the foreman. In our plant I have never seen a case where anybody found anything but a safety match because it is up to the foreman to find them. In regard to smoking, in some departments we allow smoking and in some we do not. In places where there is possible danger and a place is provided for the men to smoke, we have notices that the men appreciate it and take special care of those places. In some places it is all right for the men to smoke. In other places it is really dangerous. The men where they are allowed to smoke seem to appreciate it. We consider that is safer than to prohibit their smoking, in which case they smoke and when the boss comes around they throw their cigarettes in a pile of trash.

Women Smokers Present Difficult Fire Hazard

MR. ARMSTRONG: We provide those places for men to smoke in our plants, the same as the gentleman has just spoken of. We also have a blank for an employee to sign. This blank reads, "I have examined my pockets and found no matches." We permit the carrying of safety matches into the plant. We permit the employee to keep them in the locker. They are furnished with a steel locker, and perhaps you will better appreciate our problem when I tell you that we have in one plant 8,500 employees to deal with. There are about 2,500 women and practically seventy per cent of them smoke, including the women. We make no distinction now in regard to our propaganda on smoking and carrying matches. I will tell you, gentlemen, you folks who have fire hazards in your plant probably have not thought some of you of this. The women carrying the strike-anywhere match are your greatest hazard, due to the fact that a woman takes to her machine, and carries with her always, a pocketbook, and she carries in that pocketbook her matches if she smokes. Those matches can be set off by vanity cases and keys and materials of that kind.

If you have the female carrying matches along with the male, your greatest hazard is with your female employees, due to the fact that they carry them to the machine and lay them on the machine.

MR. SWEGER: I might mention that the biggest fire we had in the last twenty years, and it wasn't much of a fire at that, was caused by mice getting into the foreman's clothes in a wooden locker. The foreman was the heaviest loser. There is nothing but safety matches in that plant.

ROBERT PERRY (Fisher Body Corporation, Detroit): We have smoking rooms provided for our men and they smoke in those rooms. I have never caught a man sneaking a smoke since those rooms were established.

We have no women smokers at the Fisher Body Corporation.

CHAIRMAN WENTWORTH: This is a rather positive statement. I can say quite positively that my daughter doesn't smoke, but I couldn't take oath to it.

MR. ARMSTRONG: I should like to ask Mr. Abbott what they do in their plant in regard to matches.

MR. ABBOTT (Fisher Body Corporation, Detroit): We recently started a campaign in one of our plants to eliminate the ordinary strike-anywhere match. We have done it in one plant. Other than that we have never had any restrictions on carrying matches in our plants. I know of but one fire that I can directly trace to a match being dropped on the floor and being stepped on. That was definitely known because it was observed in front of a paint spray booth.

Other than that I don't know that we have any fires or ever have had in our plants any fires that are directly traceable to matches, although there is no doubting the fact that it is dangerous to allow them in many departments where there is highly combustible materials.

I think sometimes, gentlemen, that we get at these subjects from a very illogical point of view. What has been said here about providing a place for employees to smoke will accomplish more, in my estimation, than to tell them they can't smoke.

We are having so many laws and ordinances and we are being told on so many hands today that we can't do this and that we can't do that.

I hunt and fish a little and smoke a little and I am constantly being told in my hunting that I can't do this, in my fishing that I can't do that. I must have a license to fish and a license to hunt and a license to drive my automobile, and I remember as a child that the Fourth of July was one of the days of the year that I looked forward to because I enjoyed the fireworks and shooting the firecrackers, and somebody asked why we do it. Mr. Wentworth gave us a little display of his knowledge of history by telling us where the Pilgrim fathers landed and I guess some of us forget that we had a Declaration of Independence. We like to remind ourselves of it once in a while with a Fourth of July celebration. That is where it originated. I guess it took guns and firecrackers and a lot of those things to accomplish what we had done, it is a reminder in a way of our national history. I think every child enjoys those things, and if we attempt to tell the child that he must not have them, I think we are not going to be able to quench his desire. It is natural in every child's life that he should want it. I do think that we accomplish more in educational work on these subjects than any other way and I think there are many things that have gone over that have been accomplished by education, rather than prohibitive measures. Knowing as much as we do today of volatile liquids and their hazards, suppose we never had the automobile and we were told tomorrow that we were going to have millions of automobiles in our streets, each one of them with a tank of gasoline of from five to ten or fifteen gallons on the rear end with a red light burning over it every night. We would hold up our hands in holy horror and probably say that the world would be blown up. We probably would have some special meetings of the National Fire Protection Association immediately.

I say that because I think it is a matter of education. The average man uses an automobile and uses gasoline today and does it safely. There are a few accidents, of course, but there always will be a few at the best.

I believe in educational work along those lines rather than any other way except where the question is extreme.

Even Mice Are Becoming Educated

MR RYAN: About ten years ago didn't the National Board of Underwriters make a test of mice with matches? Didn't they have a cage full of excelsior and a number of matches in the cage, and the rats starved themselves before they gnawed the matches?

CHAIRMAN WENTWORTH: Tests have been made, I don't know how thorough or complete. It is pretty generally believed that mice and rats do not ignite matches with their teeth. They do build nests. Rats are pretty active animals. If you have slept in a country hotel you have thought a team of horses, probably, was going down the partition. They are pretty rough animals and they might like to sharpen their teeth, perhaps, but they don't eat phosphorous, I think.

We have had an interesting session. It has seemed eminently worth while. I think we can go back to the officers of the National Safety Council and say that this has been an exceedingly interesting meeting, profitable to all of us, and we will all look forward with pleasure to reviewing these excellent papers in the record.

On behalf of the Congress I thank you for your attention and your sustained interest in this important subject, and perhaps the Council may have it in their hearts to give us another such meeting next year.

ADJOURNMENT.

**SIXTEENTH ANNUAL SAFETY CONGRESS
NATIONAL SAFETY COUNCIL**

Health Service Division

Tuesday Morning, September 27, 1927

LOYAL A. SHOUDY, M.D., Chairman

Vice-President for Health, National Safety Council; Chief Surgeon Bethlehem Steel Company, Bethlehem, Pa.

The Informal Conference of Industrial Physicians and Surgeons was called to order at nine-thirty o'clock by the chairman, Dr. L. A. Shoudy, Vice-President for Health, National Safety Council.

CHAIRMAN SHOUDY: Our subject this morning is: "How far should medicine and surgery go? What is the limit that we should attempt in industry?" In other words, not only your particular industry, but in all industries. What are our limits? What are our beginnings? What should we strive for?

I don't know all who are with us this morning, but I shall call on some of you and I wish you would consider this an informal gathering and tell us what problems are bothering you in your particular industry. Bring it up in a general way and let us see if we can answer it.

I shall call first on Dr. Sawyer. How far should medicine and surgery go in industry?

DR. WM. ALFRED SAWYER (Medical Director, Eastman Kodak Company, Rochester, N. Y.): That is a pretty big question to answer offhand without considerable qualifications. It is a question that interests me, too. I sometimes check up and wonder whether we are doing all we can in the Eastman Kodak Company. Our problems are largely medical, or sickness. We are interested in the question of education. We are interested in the care of those who are sick—in their getting well as fast as possible. I suppose it is an individual matter. You can go as far as you can, sell to the organization and profession ideas that are good and sound; but no business will go on with things long if they are not sound and do not seem to be producing some result.

I have been talking with some of the men about being able to prove the value of these things. It is difficult to put it down in dollars and cents. I haven't been able to do it. I know it is good and you know it is good, and I have often said we couldn't get along without it any more than we could get along without the telephone. I had an experience a few years ago in Philadelphia with the John Wanamaker stores. During the summer vacation, when John Wanamaker, Sr., was away, Rodman Wanamaker liked to do new things, and one of his stunts was to test out whether the things they were doing for the employees were appreciated. He said: "We will close down the cafeteria, the medical department, the rest rooms, and several other employee activities. Close them all up tight." He said he wanted the people to take a vacation.

Well, I wish you could have heard the protests that went on. They had more trouble than they could handle. Everybody fainting—a lot of people got hurt

in that store—all had to be sent to the Jefferson Hospital several blocks away, and they were just in hot water all the time. When it was all over they said: "Never again!" They couldn't get along without it.

I think that is true with any medical work in industry. It becomes an integral part of the business, and if you cut it out you swamp your supervisory force with the responsibility. Studies have been made as to the cost of this work. The National Industrial Conference Board tried to find out what they were spending per employee. They found it ranged from \$2 to \$10 or \$12. There are organizations spending \$70 and \$80 per employee—all depending on the problems, of course.

I should like to hear some of you, who have specific data or proof of its value, talk upon this. One of the men said yesterday afternoon that he thought the way to prove it to your managerial force was to cite specific instances where you did good and prevented this and that. It seems to me, after all, it is the actual, concrete incident that convinces the average person.

If we are going to put industrial medicine over we must do it through the executive force of the company, no matter what the size of your organization, small or large, start physical examinations of your executive force. Make it a real program, and they will soon see the value of it; and when you sell them you will have no trouble with the men at the bottom, of course.

The Corporate Measure is the Monetary Standard

CHAIRMAN SHOUDBY: Dr. Sober, how far should medicine and surgery go?

DR. F. J. SOBER (Fisher-Body Company): That is rather a hard question. Corporations usually measure everything by our monetary standard. Of course that is a matter which is hard to determine in dollars and cents. When we bring a case to their attention, where we feel we have accomplished some results, it is hard to convince them. How are you going to get it to them so that they understand it? Just how are you going to put dollars and cents value on it? If there were a definite way to determine that—a man's health was worth so many thousand dollars and you deduct a certain percentage for the day that he didn't feel 100 per cent or anywhere in that neighborhood—then we might be able to get the thing on a basis that the management could see.

Of course, most of our large corporations are manufacturers, and they wish the public to consume their product; and among the public who consume a great deal of the products of large manufacturers are physicians, and when we go too far out of our way, seemingly, in our efforts to keep up the health of the workers, we do definitely cut in on the income of the man who is not connected with the industry and who is out practicing his profession. It seems to me that in the larger cities where a great many doctors gather and locate for geographical reasons, for reasons of density of population, that the physicians in those centers should at least be very careful of the extent he carries on his work. He should not take all the work away from the doctor in the city. It is a different problem for the physician in the small community, in which the industry is the backbone of the town. In the small town it is a case of taking care of practically all of the inhabitants because the provider of the family is probably employed in that industry.

CHAIRMAN SHOUDBY: What is the policy of the Fisher Body Corporation when a man comes to you sick?

DR. SOBER: We give him temporary relief, if possible, and let him have the preference of calling his own physician. We have never made it a policy to make him feel that we should take care of him. We take care of him temporarily if he is taken ill at the plant. One of the reasons for that is because we have no benefit association. Of course, we are interested in the health of the

individual, but not to the extent of having a benefit association. However, industry is requiring some medical service as a part of the contract.

CHAIRMAN SHOUDY: To my knowledge this is the first time we have had a chance to hear from the United Fruit. Of course, the problems which United Fruit has in places like Cuba are entirely different, but I should like to hear from Dr. Crawford and have him tell us how he would look after the sick and injured men. How far should medicine go in industry?

DR. F. X. CRAWFORD (United Fruit Company): In the tropical divisions it is entirely a United Fruit proposition. These places are entirely fruit ports and we take care of them industrially as well as taking care of them while sick—we take care of both sickness and injury cases. Everybody in the South pays two per cent into a medical fund. That fund entitles him to treatment, no matter how long he is sick. If he is not sick he still contributes. That, with the company's money, takes care of him and his entire family.

In the North, in our Raviere Sugar Refinery, we take care of the injured man and hold him if we can. We feel that if a man is injured in our plant we should try to hold him, notwithstanding the fact that we are taking something away from the man outside who is practicing medicine.

In illness, we give him first aid treatment and I think we do refer him back to his family physician. We don't intend to keep the men under our care if they are merely sick and not injured. If the man insists, we gladly do it, but we refer him first to his family physician.

CHAIRMAN SHOUDY: What are your own views as to how far a medical program should go in industry?

Medicine and Surgery Should be Fraternal

DR. CRAWFORD: I believe, as I am doing in accidents at the plant. I think from the financial standpoint, from the cost standpoint, I try to hold them if I can and treat them at our plant. If not, we refer them to their own physician after the initial treatment. We hold, probably between 80 and 85 per cent of our accident cases.

I believe that is an all-right proposition in the illness cases. I feel I have no right to take away from the outside man the question of livelihood when a man is ill and we don't pretend to treat him. That should be left to the family physician.

CHAIRMAN SHOUDY: Dr. Cheney, of the Armour Company, how far should a program of medicine, taken with surgery, go with industry from your experience? Now leave Armour behind for the time being and tell us what you really think.

DR. V. S. CHENEY (Armour Company, Chicago, Ill.): I cannot leave Armour behind. We are doing what I think ought to be done. There are a few things which we must work out. I maintain that medicine and industry should be fraternal, not paternal. Years ago when the industry was started by P. D. Armour, he took it upon himself to take care of the injured employees. He took care of them personally. If a man wasn't right they would send him away and Mr. Armour was personally responsible; but as the organization grew he couldn't do that. The medical department was organized and that duty has now devolved upon us.

In our organization we take care of all cases that come in to us, both medical and surgical. Even injuries that occur outside of the plant are brought in to us. They come to us in an advisory capacity, they want advice. We give them the facilities of our laboratory, of our organization, and then we send them back to their private physician with what information we have gathered. The doctor can accept our diagnosis or not, as he sees fit. They ask for our

cooperation. We have gone even a little further and have had them bring their children in for examination.

The physical examination is also a part of the medical work. We were disappointed in not being able to give them a general physical examination. We had unusual difficulties in giving these examinations because our men work in gangs, and when they need men to work in a gang they can't give them a thorough examination; so we make a superficial examination before each man starts work, but we extend to him our assistance and make him feel that our medical organization is for his benefit. If he is sick or a member of his family is sick and he wants advice in regard to that, we will give it to him. We will even examine a member of his family if we know he is worrying about his family. It affects his efficiency. But we don't try to treat him. He comes to us for advice and we give it to him. We refer him to his family physician.

A Program of Extensive Tests of Executives

With regard to matter of physical examination: We are now making extensive tests of our executives. We think that is the place to start, as Dr. Sawyer said; and these examinations are periodical once a year, or twice a year, or three or four times a year, depending on the man's condition.

A man cannot be promoted from one position to another until he has passed the physical examination. A man even in the outlying districts of Cuba, before he can be promoted, has to come to Chicago and pass a physical examination. We are trying to impress upon our executives the importance of keeping themselves fit, that it is up to them to keep fit and not up to the company. It is up to them, with our advice, to maintain their physical health.

I have always likened our organization to a great big family, of which I happen to be a medical brother. In regard to their families, we don't try to take care of active cases of illness, either of acute or chronic cases, but we get them into the hands of a good physician and see that they are properly taken care of.

When a man is reported sick, or the employee has reported sick, we are notified for a certain number of days. We get in touch with his doctor, if he has one, if not the visiting nurse from the Metropolitan Insurance Company calls on him and sees what the condition is; and in that way we keep in touch with the doctor who has charge of the case. If we think a man ought to go to a hospital and he cannot afford it, we find a way and give him the care he needs.

Recently our men have been put under group insurance, both in the general office and in the plant. Practically 90 per cent of the employees have availed themselves of group insurance. It is not compulsory. With that group insurance we get a nursing service and now the cases are reported to the nurse. Every case of absence is reported to the nurse after they have been away for a few days. She makes the examination and investigation of these cases. She does not report back to us if the people are not sick. She says they are away for personal reasons, but it isn't spying upon them. That is one thing we objected to. Our foremen and superintendents thought that as physicians we ought to see if a man is really sick. We won't do it. We have to maintain their respect and their feeling of loyalty. We want them to think we are their friends. We won't spy and do anything of that kind. The whole system, as I see it, is that of a fraternal medical supervision. We believe that is worth while.

DR. SAWYER: Do your men do bedside work?

DR. CHENEY: We have no nurses. The Metropolitan Insurance Company takes care of them. They do bedside work.

CHAIRMAN SHOUDY: I should like to hear from Dr. Clough.

DR. F. E. CLOUGH (Home State Mining Company): I should like to take the other extreme of Dr. Cheney and say industrial medicine should be a benevolent despotism and not a brotherly affair at all.

Looking at the history of industrial medicine, I am a gold digger. Naturally, you say, it is easy to put over a medical concern. It isn't, because gold is the only thing remaining standard in price through all the rise of other commodities. We started our medical service in 1877 and have been at it ever since. So I think I am an old timer.

Why did we start it? Well, the gentleman from the Fisher Body gave the reason. We were out in a little isolated community. There weren't any doctors, and in self-protection the company had to put in men to do the work. What did we do first in industrial medicine? We took care of the injured man a little ways, and then a little bit further; and then we found out that we were taking care of the injured men, and we decided to take a whirl at doing medical work. So we started charging them a dollar, or a dollar and a half, a month per employee and gave as little as we could and stuck as much as possible in our pocket. That wasn't satisfactory and it reflected against us. I say we are coming to this, and I don't know if you can prove it in dollars and cents, but I believe that in the large cities you are not going to give unlimited service to the employees and those dependent upon them. In the smaller communities, it is ideal. I have been in the industrial concerns all over the country and I know if the workman realizes the company has any type of medical service he will get it. If you eliminate it you have a sad employee and if you give him that medical attention you have a better employee.

The Sky the Limit of Industrial Medicine

I believe, therefore, the only limit there is to industrial medicine is the sky. From the time that the baby is born, or before the baby is born, up to the time that an employee or any member of his family dies, the care belongs to the industry. It is a question of how far the medical concern can go in helping the men.

We have given unlimited medical service to the families of our men. It costs us a lot of money—more than many concerns like to spend. I say that where you are manufacturing a commodity where the price can be passed on to the consumer, the cost between first grade and slipshod service (I don't mean in quality but in quantity), the cost you are passing on to your consumer is not enough to make any difference. It is walloping our brother practitioners to take away a certain amount of work from them, but if you are a real 100 per cent surgeon first you don't consider the outsider at all. You consider only the employee and the company for which you are working; and when you do that you will give the best type of service you have.

When it comes to estimating this service in dollars and cents, there are places where you can show that you are actually making money. Every once in a while you save a sick case—perhaps an employee or executive—perhaps an ordinary accident comes up in which the medical department does signal work and great results are obtained. Every one of those cases, perhaps, avoids a serious accident. Perhaps the management thought the man would die, and you save the cost of a death benefit, and if you are running government statistics you have run off 6,000 days. You have saved your concern

\$3,000 in our state. Where you have a death benefit you figure you have saved money, saved almost the cost of running your department.

I don't know, to me this idea of just plant hygiene and giving a little bit of first aid treatment when they are sick, and tell them to see somebody, is a joke, so far as industrial medicine is concerned. I don't think that is industrial medicine at all. With all due respect to you who are doing this work, we should realize that this work should be just as efficient and thorough and complete as the running of any company department and be considered a part of the overhead of the company's cost, just the same as running the machinery department. The health of the employees is just as important as keeping up the machinery.

In spite of the fact of state medicine, I think the further the company goes in giving this type of service to the employees and their families the stronger they will be with their employees.

Medicine is Accepted as Part of Operative Cost

CHAIRMAN SHOUDY: The difference of opinion is what we want. Men, I think that we are all safe in saying that industry has accepted medicine as a part of an operative cost and a part of an overhead to be considered in the cost of production; but the question of how far we should go and what we should do will depend a great deal on how far we ought to go and how far we are able to sell it to the concern for which we are working. It so happens that Dr. Clough has been able to put it over 100 per cent in the community in which he is working. I don't know in a big city whether that plan can be put over. The Endicott-Johnson people, one of the eastern concerns, has taken over the whole medical situation 100 per cent. What should the medical department of any industry do? I should like to hear from Dr. Cunningham of the Kohler people.

DR. M. D. CUNNINGHAM (Kohler Company): Our system is very much in accord with that of the last speaker.

CHAIRMAN SHOUDY: I know you men have your own experience. You must have back in your head a number of things that I would like to see done that we don't know. Dr. Cunningham, we want you to tell us what you think ought to be done.

DR. CUNNINGHAM: We go as far as we can, make the sky the limit, and we feel that we are getting a great deal of benefit from that as well as the employees. We are limited as to how far we can go because, up to the present time, we have had some trouble in getting the entire cooperation of the employee himself. However, we are overcoming that by rendering real service and we find that on our periodic examination. We try and give the man everything we can possibly give him and we are limited in our examination. Then we refer the man to where he will get the best possible treatment at some special department of medicine or surgery.

CHAIRMAN SHOUDY: At whose cost?

DR. CUNNINGHAM: At his own cost, if it is a case of illness, but if it is a case of industrial illness then at the cost of the company, from beginning to end.

CHAIRMAN SHOUDY: Dr. Schram, not from the standpoint of the Fairbanks-Morse people, but from your views, what should industrial surgery include and how far should it go?

DR. C. F. N. SCHRAM (Fairbanks-Morse Company, Beloit): I am glad you put it that way—those things for which the state makes the company responsible. I think the company physician or surgeon should have absolute, complete control. For those things for which the state does not make the company

legally responsible, I think the man should absolutely have his choice in regard to a physician or surgeon. If that means that the company takes care of him, why the company takes care of him, and when the company takes care of him they should assume the financial obligation. The sky is the limit on preventive medicine. If the medical department is going to function it is a human maintenance department, and if it is going to help the people it is not a question of doling out a cathartic or dose of salts; it is selling health to the individual from the day he starts to work, and keeping him well; and when industry steps in and does that it is going to function as a real department. Until that time comes I don't believe it is going to function as a full department in a part of industry. I am not in sympathy with crowding out the man in private practice, at all. I do want to go as far as Dr. Cheney goes in trying to give the man a full diagnosis. I believe in giving the man and his physician, should he choose an outside physician, all the helpful aid possible in making a diagnosis.

CHAIRMAN SHOUDY: Do you believe then that the company should take care of the man and his family or just the man?

DR. SCHRAM: According to the community—absolutely limited according to the community. In the big city I question the advisability of going into the home except as an advisor. We offer the service just as freely as can be and if the members of the dependent families wish to avail themselves of the diagnosis we help them all we can.

Does the Company Get Value for its Money?

DR. WM. ALFRED SAWYER (Medical Director, Eastman Kodak Company, Rochester, N. Y.): Is there anybody here whose organization offers to employees medical service at a cost price as a voluntary thing? Do they say: "We will give you service if you want us to?" Has that ever been worked out?

CHAIRMAN SHOUDY: Is there anybody who offers cost service to their men? Do any of you tell a man to come to you and you will give him the service at cost?

DR. F. X. CRAWFORD (United Fruit Company): There is nowhere else to send them in the tropics.

CHAIRMAN SHOUDY: In Cuba they have a "Central" where they take them.

DR. CRAWFORD: Can some one tell me the company's return on money expended? What is the return from every dollar expended?

CHAIRMAN SHOUDY: Do you mean whether he puts the money in if he gets the return?

DR. CRAWFORD: No. What return does the corporation get from the dollar expended?

DR. MCKITTRICK (Indianapolis, Ind): I don't know whether I can answer that as to the exact dollar. I can only answer it in this way: The reduction of the insurance rate. In other words, I have one plant that has a manual rate of a dollar and a half per hundred dollars payroll. This plant is under medical supervision at the present time and for the last five years it cost 50 cents on the hundred dollars. Now I think that this is a point on which we have to talk with the average industrial man. If we are able to prove to him that we can reduce his rate from a dollar to 55 or 60 cents per man per hundred dollars, that man will pay some attention to it; but if you go in and try to show him the nice side of your work wherein you are taking care of his sick employees, injured employees, taking care of his family, keeping his men at work, keeping his men in a condition that they will give 100 per cent efficiency, you are likely to have a man tell you about what one told me one day when I was trying to put this over. After I had made my speech he blew cigarette

smoke into my face and said: "Doctor, you are a poor salesman." It is dollars and cents that you must use and the only way I can do anything is to show them that we can reduce the rates.

I am talking of industrial insurance. Of course most of our states have it. Indiana has an average industrial law, under which all must work. Under this law all employees, of course, are cared for, that is, injured employees. Sick employees have no concern with this.

Quite a few of our industries are taking care of their sick. I am mighty glad to see that this subject brought out a number of points, and particularly one which I think we should look at very seriously; that is the point of state medicine. I am afraid if we do as the gold digger expressed himself, that we are going to sell our employees to that point that he, in the future, may try to control our state legislatures in having the state take care of our sick. That is something we don't want. I do think that there should be some provision, some care for the sick, for the family; but I don't believe that the industrial employer should have to pay that expense altogether. It is my opinion that the best thing we can do as industrial physicians is to act in an advisory capacity as diagnosticians. Then steer the man and his family to the proper physician in the territory in which he lives to take care of him. Of course, that meets with exceptions for in small territories you cannot get to specialists, but I am speaking of the large centers.

Another point, I believe, should be brought out. You have asked us how far industrial medicine should go in industry. I feel that there is quite a chance for us, as medical men, to assist the personnel department, the safety inspector, and such men as that, and give our employees much more benefit, much more help than the mere matter of giving the sick a headache tablet and so on. Even in the small sized plants there is always some problem for the medical man to solve.

The Physician Should Watch All Unhealthful Conditions

In our automobile plants in Indianapolis we have trouble in solving the problem of gas which accumulates in the rooms. You will say your industrial man ought to be able to take care of that by putting in the proper ventilation. You will be surprised how ignorant some of them are in that line. Some of the men get dermatitis. These conditions must be met. Our rubber plants, like the Rubber States Rubber Company, have problems such as dealing in dust and oils that are continually giving the employees acetanilide poisoning. These conditions must be remedied. Our men say they have sufficient suction apparatus to take care of this, and I find the suction apparatus is not working at all. We must deal with these points just as much as taking care of our sick.

CHAIRMAN SHOUDY: Dr. Schram brought up another question when he mentioned free choice and how far that should go.

Dr. Stewart, what is your reaction as far as the relation of the injured man is concerned? How far should the doctor go?

DR. L. STEWART (Pennsylvania Bituminous Casualty Company): In answering that question I think one must be guided by the reaction of his associates, his fellow practitioners, who are in the majority, in any large community at least.

Within the last year in Pennsylvania we have made a decided effort to improve our compensation law to make more provision for the injured man, and in return make more provision for the physician who looks after him. The bone of contention in that direction has been whether the industry will have the right to select the physician or whether the man will. It was felt no progress could be made in getting any legislation that would improve the

condition without stipulating that industry would have the privilege of selecting its own physician and in Pennsylvania we have, notably, Dr. Shoudy heading the Bethlehem Steel Association. It is absolutely impossible for an organization of that sort to be hampered by any stipulation at law whereby a man would have a choice of his physician.

I don't think any man in industrial medicine desires taking the injured or sick man away from the general practitioners or the community physician. It seems to me today the answer must be a compromise. It must be possible, it is absolutely essential. If Bethlehem is willing to expend enormous sums of money and provide physicians and hospitals, it is obvious their employees must accept that superior service. However, after the limits of the law have been complied with—I am speaking of compensation, there is a 30 days limit in Pennsylvania—it seems to me that if the injured man so wishes he may seek attention elsewhere, but always under the supervision or under the benevolent watchfulness of the medical organization of the industry under which he was injured. I was impressed by what Dr. Cheney said of the attitude of Armour. I have talked with Dr. Sawyer about their attitude at Rochester. I believe the industrial surgeon cannot advocate his cause to the exclusion of the man who is not an industrial surgeon. Therefore it is not practical to oppose care of the injured or ill men by the community physicians, but certainly it is possible to take a benevolent or friendly, brotherly interest in these men who are ill. Certainly it is right and proper to have the nurses of the organization or the physicians check up on their progress and make sure proper medical attention is being given to the men.

The Efficient Way of Caring for Employees

I don't think that is a proper solution but I think it is the only solution. If this were to be done 100 per cent efficiently, every organization would take care of the man from the time he was injured or became ill until he recovered. That is the efficient way of handling the work and that is the way in which the organization will save money, not only in dollars and cents but in the health and efficiency of its men. But I don't see how it is possible to have a division of the industrial physician and the general physician.

A point has been raised in this connection as to the cost in dollars and cents, or as to a way of estimating the cost of service to employees. I can see, from the discussion, where an executive in the Armour Company, if he realizes that he must be fit physically, will take care of himself if he is ambitious. I can see where the efficiency of all the members of an industrial organization can be vastly improved by medical supervision. That is an intangible thing. You can estimate that only in the success of your organization. It applies to the Fisher Body Company, The Armour Company, The Eastman Kodak Company. That is intangible. You cannot estimate it in dollars and cents.

However, some years ago, working under the compensation law of Pennsylvania, I attempted to show the directors of my corporation wherein surgery was able to save them money by giving the employees the proper medical attention. I didn't have to do this. But at the inception of the compensation law my organization agreed that it was good business to give all needed attention to injured men and that has been our policy. However, after years passed, and this started in a small way, I went back through our statistical department and took 23 consecutive, unselected cases of injury and banked the type of injury against the provision of the Pennsylvania Compensation Law. For instance, if it was a loss of a leg or potential loss of leg we banked \$2,580. (I think that is the cost in Pennsylvania.) We banked that against what it cost to rehabilitate that man and put him back to work.

In these 23 consecutive, unselected cases our potential cost was \$6,000, approximately. Our actual saving was approximately \$39,000 or \$40,000. It has been some time since that was compiled and I am not clear on the details, but our saving, roughly, was approximately \$30,000; and when you have the compensation law under which you are operating and able to bank the type of injuries and the actual cost of the work, you get an accurate way of estimating the cost. Among those 23 patients there were two deaths. One was a hernia. The man died from invalidism. The other was a fractured femur. Even considering those two deaths in the cost, we saved \$30,000 on that.

CHAIRMAN SHOUDY: Dr. Benedict, what should, and how far should, the industrial medical problem go? Be careful, don't tell us what Alabama Power Company does to maintain a medical department but tell us what you think ought to be done.

In Preventive Medicine There is No Limit

DR. S. R. BENNETT (Alabama Power Company, Birmingham, Ala.): I have been very much interested in what has been said and I really feel that the subject has been covered thoroughly. My personal opinion, and naturally my personal opinion works in with my organization, is that I feel in preventive medicine, including examination of employees, the sanitation, the health of the employees in your plants, etc., there is no limit. That is very essential; that is something that I feel every organization owes its employees. From the standpoint of the accidents the same is true. Some of us have compensation laws under which we work, and under those compensation laws we are practically compelled to take care of the employee. Of course, some of the compensation laws, many of them, have a limit. We do not, and I think the corporation should not, consider the amount expended in bringing a man back and placing him in an efficient position again. The question of how far we shall go in the treatment of the employee from the medical standpoint is one that has to be handled with gloves. Only recently the state of Alabama medically was turned topsy-turvy due to this question: How far should the physician and surgeon go in industry? As a consequence we got into the state association, there was a terrible fight, and the fight is still smoldering, as it has not been definitely settled.

As I see it you give medical attention to the employee or to the employee and his family. Taken from the standpoint of the employee: If in a big city where there are plenty of private physicians, private practitioners, the medical man of a corporation takes it upon himself to deliver all medical attention to that employee, that is simply putting in one more peg towards state medicine. The same is absolutely true, I believe, so far as the family is concerned. You divide that. You say, "Well, what about the man, for instance, the gold digger's proposition?" The gold digger's proposition is entirely right. He is isolated, he cannot obtain for his employees medical attention of the proper kind. Therefore it is his duty and it is money well spent for the corporation to take care of that employee and at the same time increase the efficiency of the worker. I don't see how he can do otherwise; but in the city the proposition is entirely different than it is in a town of 15,000 or 20,000 people, because here we have competition from the industry supplying all needs to the employee, and that in its turn gets the enmity of the local physician. Don't forget that where we have one industrial physician there are ten men in that community who are not industrial physicians and those men have just as much to say in a state medical society as we have. It is one to ten that we lose.

Therefore, I feel that we ought to treat the employees in small towns,

but in cities we ought to cooperate with the employee to the fullest extent. However, I think it is a mistake to treat the employee's family in large cities. It might be better for the employee; but remember this, that when you take away from the employee his respect and say to him, "You must have doctor so and so," you almost invariably create a dissention because they have their private physician. In isolated points I think it is the company's duty, where there is no doctor for 15 or 20 miles, as we have in a number of instances near big dams and steam plants. I think it is the company's duty to take care of that employee just as the gold digger did because he cannot get the proper medical attention. The nearest doctor has to come 20 miles. His charges are large and from a standpoint of efficiency I think taking care of the employee is essential.

Therefore, I say this: It is my opinion that in the small town and in the city, industry better watch its step so far as taking care of the worker and his family is concerned. In isolated points where medical attention is distant, the corporation should go the limit and give everything to the employee and his family that it possibly can.

CHAIRMAN SHOUDY: Gentlemen, I have called on some of you. Is there anybody else who can contribute to what the doctor should do in industry?

Another Point of View on the Problem

DR. W. C. NORDHOLZ (Automatic Electric Company, Inc.): You are talking about what the doctor does in industry and his place, and we were talking about the employees just as so many pears. A year ago I did some social settlement work and there was one lesson I learned; it was that you shouldn't give something for nothing. If the man is injured while he is at work you must do everything you can to help him, but when you are giving him something for nothing you are taking that away which you can never give him back again. It is his independence. That is a problem. Are you going to make all these men paupers? They have done it in Germany and they are doing it in England. We have a plant in Germany and a plant in Liverpool and London, another in Belgium. That is what you do. We haven't nearly the efficiency in our plants in European countries, where they get everything for nothing, that we have right here. Our plant is three times as efficient as any of those abroad.

If we are going to take care of the families of the employees we are working into state medicine. We are going there fast. When you do that you are taking the individual's incentive for really doing something for his fellow man away from him. In place of what you are going to do for our people in the industry, think of what we are doing to them.

CHAIRMAN SHOUDY: In what way?

DR. NORDHOLZ: In taking that away from them which you cannot give back. If he is working for your plant or mine you pauperize him. You bring him back to state medicine. I say, don't let's make him pay taxes. That has been the ruination of your own medical profession and your men there. With all the efficient men we have in our European plants—they are very efficient men—our mechanics in our American plants will turn out several times as much work because in Europe they are No. 1 or No. 2 on the payroll and nothing else. The government is controlling their medical situation.

CHAIRMAN SHOUDY: That is true in Belgium.

DR. NORDHOLZ: It is just as true in England and Germany. We have the same condition in London and Liverpool. Our own statistics show that with a plant three times the size we have in America, our plant right here on the West Side

is turning out just as much work as the English plant. We have more efficient machinery but our men turn out three times the amount of work. They have something to work for. We don't give them something for nothing. We advise them, but that is all. We talk about headache pills and so on. That is quite an essential thing in industrial medicine. He needs something to relieve him for the time being. I don't think that ought to be booed, at all. You give him something that takes care of the belly ache. I think that has a big place.

CHAIRMAN SHOUDY: We come back to the same thing every time I get together with a group of medical men: How far should you go with your men in industry? But going back 10 or 12 years, I can see that I have been helped by coming to the different meetings and getting the other fellow's ideas and seeing what he said and did and thought that could be applied to my own problems; and I am sure we get a great deal of benefit from this.

First and foremost, we should agree on the doctor's and surgeon's contribution to the industry regarding physical examinations, and so forth. The degree depends on what you want to do in your own plant. That is the first thing. The medical man comes in contact with the employee. Then, if you please, a compulsory examination and tell him: "Here is what you can do and on a certain day we would like you to come back and see us. The medical department is open." Advise with the man. Isn't it right that we in the industry should see that one of the biggest things that we should furnish to the man himself, is, that he is able to function or perform his work that has to be performed from day to day? If he is sick, to see that function is restored to that man to work the same as before. The restoration of function is one of the first things the doctor could offer to the injured man.

The House Must Be Kept in Order

So far as sickness is concerned. It is up to us as physicians to see that in so far as we can the man has a livable place in which to work, that he is healthy as it is possible to make him under the conditions of the job which he has to do. Isn't that our work? If the man is sick and he comes to you for relief, if you can relieve him, shouldn't you relieve him? Isn't it well for us to maintain in our own workshop a clinic that will be able, as far as it is possible, to diagnose the trouble of the man, especially if the trouble originated in the industry in which he was employed? If it is spray-painting, is spray-painting responsible? If the man comes to you and you tell him what is wrong, isn't it proper under present conditions for us to tell that man: "Here, we feel you are sick and should consult your doctor." Aren't we doing wrong at the present day if we don't say to the doctor who is not in industry: "Doctor, maybe I can help you. Here is the man's examination chart when he came to us. Here is what we do know when we examined him." If he knows he is not able to meet certain requirements the doctor should call on you for help. So far as the care of the man is concerned and letting him pay his bills, isn't it better in the majority of cases to let him pay and go to the doctor he chooses and work with that doctor in your community rather than handle everything for nothing and say you will take complete charge?

If you kept your house in order, if you saw that when a man came in he was given an examination, that you gave his doctor the privilege of coming back and checking against that chart occasionally, if when the man is injured you have told your company you feel it is their responsibility to give that man absolutely the best possible surgical and hospital attention to restore the man's function 100 per cent, haven't you done everything you could?

In relation to the outside medical world, balancing them against what you owe the man in your plant, haven't you done under present conditions 100 per cent when you have done all these things? This is what we feel you should do. If you get

in touch with his doctor on the outside and tell this doctor: "This is what we know about this man and we should like to help you," isn't that as far as we can go today? In the isolated cases we must take care of them 100 per cent.

DR. H. E. BRICKER (Philadelphia Rapid Transit): I have been here listening and it sounds to me as if the doctor in industry or the industrial physician is giving himself chiefly the question of being intimate. I don't think he is there because he made it himself, at all. I don't believe his progress will be helped by him or hindered by him. I believe the doctor in industry is a victim of circumstance. His chief job is to keep the brake on the other fellow. He must go as far as the employee may demand that he go. In my particular industry, and fortunately I had the privilege of starting it, the medical department was started with nothing in mind excepting to improve the grade of people we took in. It wasn't long, however, before the compensation act and the men who worked there began to demand certain things and my chief job was to keep the brakes on so they wouldn't go too far. I had to give them what they wanted. You may have a lot of things in your mind that are advanced. I believe diagnostic medicine and preventive medicine is part of his job. He must do it. But the other thing is that this curative side of industrial medicine is entirely up to the man. You all have had experiences in your plants in which a man has come to you and demanded something and you put the brakes on: "I am sorry, son, but we can't do it." It will eventually come back to you, not because you want it to, but because you don't want it to.

I have gone from a two by four room to a 20-room department and there is still more to come, not because I want it, but because I don't want it. I think we are going a little too far, in my own mind, but I cannot keep it back. There is one thing I will keep back and that is attention to his family. We must know something of his social condition, but not accept responsibility for the family. We don't have to sell it to a soul.

That is our idea so far as curative medicine and surgery is concerned. The law takes care of one side, the man will take care of the other.

The Workman Who Goes to the Large City

CHAIRMAN SHOUDY: Is there anybody else who wishes to speak on this subject?

DR. RISKE: I have listened with interest to what the last speaker said. In isolated industries the industry had to go to the sky. If workmen were all nailed to one spot that might be a good thing, but your state medicine is developing from the isolated spot. The man working in an isolated spot works for four months or a year. He is given every attention. He goes to the big city. He demands everything he received from the other place. That fact is distributed throughout the multitude and gradually the citizenship is going to demand that the employer take care of him. As the employer widens out he is creating a materialistic feeling, he is robbing that man of his incentive, of his self-respect, he is taking from that man something that cannot be replaced in any way; and the further you go the further you will have to go, but it is all gradually leading to state medicine. Even in the isolated communities, while the employer should take care of his injured man and there should be no limit to that, even in Pennsylvania the state law of thirty days limit is wrong. He must be rehabilitated. I think in the isolated community the physician should charge the man a fee for anything that industry is not accountable for.

CHAIRMAN SHOUDY: Do you feel industry owes a man anything so far as helping him diagnose his condition?

DR. RISKE: Well, I think you can go along with him, but if it comes down to diagnosis you would have to have an equipment equivalent to the clinic in Cleveland. You have to have a staff, an immense staff, particularly where the industry is a large industry, and I think if the community offers that the industry should not be required to go into diagnosis of diseases outside of industrial diseases.

CHAIRMAN SHOUDY: How about the other standpoint of the industry going along 100 per cent and helping the local hospital?

DR. RISKE: I think it is better for the industries and for the local hospital to let the man contribute financially and thereby let the man stand on his own feet.

CHAIRMAN SHOUDY: Is there anyone else who desires to add anything? I know it gives you all, as it gives me, something to think about when you go back to your job, when people ask how far should we go, and what should we do; and it is up to you to put the question up to the people who really want to do what is right. Dr. Benedict, somebody wrote me the other day about this question of state medicine. He said the biggest buffer of state medicine was the way in which industrial men, surgeons and physicians, were working in industry today, that they were one stumbling block to the people who wanted to put on state medicine, that we were cutting out state medicine. What was it you said to me?

The Problem of Medical Attention to the Employee's Family

DR. S. R. BENEDICT (Alabama Power Company, Birmingham, Ala.): This is a mooted question and comes up so much I would like to see this conference go on record; and I think it is the place where it should go on record as to what we really feel and how far we really should go.

We are all in accord when we say that the sky is the limit in preventive medicine, sanitation, etc. We are all in accord in the prevention of accidents—we don't disagree on that. We come down to the question of medical attention to the employee. How far shall that go?

Then again the other question is: Shall we render any medical attention to the family? As to the medical attention to the employee, I believe this association, this conference should take a position as to whether the physician renders only attention from a medical standpoint, of obtaining a diagnosis and cooperating with the outside physician or whether he eliminates that and does not render that service.

There is also the question as to whether the employee and his family should receive medical attention at isolated points. I think that if it is to be boiled down and if this conference could go on record as stating a clear-cut position it would be a wonderful help in boiling down and finally arriving at a conclusion and placing before the medical profession this matter which I feel sure all of you realize is in the minds of a great many of the physicians in this country. It would be quite a step and I really feel this thing should be brought to a head now.

CHAIRMAN SHOUDY: It has been suggested that a committee be appointed to draw up a resolution and bring it before the conference this afternoon for passage.

DR. BENEDICT: I should be glad to make that as a motion.
(The motion was seconded and carried.)

CHAIRMAN SHOUDY: I shall ask Dr. Sawyer, Dr. Benedict, Dr. Clough and Dr. Stewart to serve on that committee.

Now I want you to listen to somebody who is not a doctor. I have had scraps with him, but I have always thought it over afterward and looked at it from a different point of view. I should like to have Mr. C. B. Auel, of the Westinghouse Company, talk to you on what we have been talking about this morning, of the man, of the physician and of the surgeon in industry. Mr. Auel, we have been discussing how far should medicine go in industry without doing wrong and still doing right.

C. B. AUDEL (Westinghouse Company, Pittsburgh, Pa.): This is one congress where I had determined to come and simply absorb information and knowledge. I have refused to appear on any of the programs, but I guess I shall have to violate my determination at Dr. Shoudy's request.

I might say I am absolutely convinced in my own mind that health is going to

prove to be the greatest single phase of the safety movement; and while there are mighty few who think of that now there will be a big majority in due time swing over to that same viewpoint. I don't believe that the gentleman who spoke, saying that the employee will compel you to go the limit in connection with his ailments, is wholly right. I think there is a combination of circumstances that are driving the employers to go the limit, and that limit will be more and more extensive as the years go by. Possibly in union-ridden shops the employee will drive the employer. In other shops it is the employers who are compelling one another to go the limit; because if there are two employers in any one neighborhood and one of them does a whole lot of things that the other does not, he is going to get the cream of the workers in that neighborhood. So perforce the other employer must do more or less of the same thing, whether he wants to or not. It is an absolute fact that compensation laws are being construed more and more liberally and in ways that the originators of the compensation laws possibly never had in mind.

There is still another factor which is compelling the employer to go more and more into the physical condition of the employee. Many of the states have clauses in their compensation laws reading something like this: Any accident arising either in course of or out of employment is compensable.

The Law in Pennsylvania Is Quoted

In Pennsylvania the law reads: "in the course of," in other states it reads both. I take it that a phrase "out of employment" would mean something like this: If you had a man employed in your brass foundry and he works a number of months or years, and for some years, perhaps to better himself, he leaves your plant and then develops the shakes, the ague, nevertheless you are still responsible because his ailment arose out of his employment with you. But would you believe it that in Utah within the last year Swift & Company had a verdict rendered against them for a man killed while crossing a railroad track en route to his job, even before he arrived at the Swift plant? The law says: "Accidents arising out of employment," etc. They took the stand that he would not have had to cross the track and therefore Swift & Company are responsible.

In our works practically all the accidents that we have now are due to unmitigated carelessness and we are at our wits end as to the next step we should take. Some years ago in analyzing carelessness, after passing it up year after year, we arrived at the conclusion that carelessness was an effect rather than a cause. In trying to arrive at the cause of carelessness we felt that probably two of the biggest causes were worry and ill health; and going further into ill health we found that the main troubles were tuberculosis and venereal disease, and also intoxication. That in turn led us to put in physical examination, among other things. The worry we passed up for the time being, but when asked: "Bill, how the hell did that happen?" He said: "Damned if I know. I came to work in the morning. I was up all night with the missus and kiddies. I didn't have any sleep. The machine came down and my finger went off." The same thread of thought appeared so many, many times. We felt we were compelled, in a decent sort of way, to get back into the homes of our employees; not that we wanted to, but to have a contented workman on the job we were compelled to get back into the homes in many cases, and where it is done decently the workmen are only too glad to have you help them.

Our legal department helps our doctors get into the homes, but with no intention of cutting out the family physician. For every case we take away from the family physician we throw a dozen to him. We are up against this thing. We reject ten per cent of the applicants and that percentage has risen until we feel we have reached the limit in rejections; yet if we were to do the right thing we should reject more than ten per cent. But if we do that we cut down production. What must

we do? A physical examination is not going to keep all the undesirables out and when you let them in you increase your accident risk. If you aggravate their existing conditions you are wholly responsible.

It seems to me, whether you want it or not, you are going to compel the state to take on some of this work, and I have drawn up a bill which is now before the Pittsburgh Chamber of Commerce in the hope they will back it before the next Pennsylvania state legislature.

Briefly, I would like to have every workman with a handicap registered by the state at one of the state employment agencies. This is a big job. It must be taken piecemeal; so in the beginning I would have the state register only men with visible handicaps, like one eye, one leg, one arm, and when they register such men give them cards, which those men should present to you; then if you can find jobs for them the fact that they are registered will absolve you from payment of compensation in the event of further injury.

The Meeting is Enthusiastically Endorsed

After the state has had an opportunity to digest what it will cost them and they tell him it will cost really very little, I would then have the state go a step further and take men with more serious handicaps; perhaps both legs or totally blind, and I would eventually include fellows who have never been hurt in industry but fellows with handicaps which they have had from birth, totally deaf, or men subject to epileptic fits or with weak constitutions generally. It seems to me that that is where we are heading, and I say that we are absolutely against state insurance of any kind. We don't want it but we feel if the employers are decent enough (and the employers are going to make a great mistake if they let this opportunity go by) to give the handicapped employees an opportunity, then the state is doing no more than right in taking on the compensation risk; in that way we will keep our poorhouses from becoming filled and tend to elevate the grade of self-respect among our workers.

DR. WM. ALFRED SAWYER (Eastman Kodak Company, Rochester, N. Y.): Why don't you get an expression from this crowd if they like this sort of thing?

CHAIRMAN SHOUDY: This is our first attempt to get together and talk it over. Do you like this kind of a meeting? (Unanimous applause.)

This is just a beginning. Next year we hope to do this. How many are in favor of conducting an informal meeting next year? We will make it this way—we will pick out one big problem, send it to you beforehand, and ask you to bring in what you have that vitally affects your industry relative to that problem. We will try to make it so you will bring us your honest opinion as to what you think.

One other thing that comes to mind is this: What is the reaction of you men toward asking the National Safety Council to place a physician in their board of advisers? Would you like to see that done? I don't say they will do it. Would you agree with me if I make a motion that it is our feeling that the work of the Council would be helped if there was a physician in the staff at headquarters?

DR. S. R. BENEDICT (Alabama Power Company, Birmingham, Ala.): Mr. Chairman, I will be glad to make that motion.

CHAIRMAN SHOUDY: It has been moved and seconded that we believe the work of the National Safety Council could be aided if there were a physician on the staff at headquarters, in charge of all conditions relative to medicine, hygiene and allied subjects. (The motion was unanimously carried.)

ADJOURNMENT.

Tuesday Afternoon, September 27, 1927

The session of the Health Service Division was called to order at two-twenty o'clock by the chairman, Loyal A. Shoudy, Vice-President for Health, National Safety Council, chief surgeon, Bethlehem Steel Company, Bethlehem, Pennsylvania.

CHAIRMAN SHOUDY: It happens to have been my pleasure to be with the Health Service Division for the last 13 years. There are some others who have been in for 14 or 15 or 16 years. During this time we physicians, doctors, if you please, who have been present at these congresses, and who have worked with the Council on the problems of health and safety in so far as the doctor was related to the plan, have seen this work grow from a small beginning; we have seen the developments which we fostered grow. We have seen some of them drop by the wayside. We have seen others carried to a fulfillment, and we constantly have put up to us new problems which affect the worker in industry. We men who have been in industry during this time as doctors have tried earnestly to work with the other organizations of the National Safety Council to bring about better conditions for the man working in the plant.

This afternoon we present to you our program, and we ask you to discuss the paper. In discussing the papers, please be brief and do not recall too many personal things about "what we do in our plant," but bring out the points that you want some information on, or bring out the points by which you can give us information, and be short and snappy.

First, we will have a report of a committee from the meeting held this morning, outlining what we thought should be the aim or the work of the physician in industry. I will ask Dr. Stewart to give you the report of that committee.

Resolution on Preventive Medicine is Endorsed

DR. L. F. STEWART (Consulting Surgeon, Pennsylvania Casualty Company, Clearfield, Pa.): Your committee appointed at the morning session of the Health Service Division presents the following for action:

1. That this body believes that it is proper and right that industry, through its medical department, should take all steps possible along the lines of preventive medicine so far as the employee and his family are concerned. Sanitation, examination of the employee, and the general prevention of disease along the lines of health education and the general employee's welfare are not only proper but essential.
2. That it is the opinion of that conference that all accident cases occurring to the employee of a company in the course of his employment should receive proper surgical attention without limit under company supervision in an effort to promptly restore him to his usefulness.
3. That it is the consensus of opinion of this conference that so far as medical attention to the employee is concerned the policy of many corporations wherein they give diagnostic aid in cooperation with the families be endorsed, and that the company lend every assistance to the family physician in returning this employee again to his work.
4. That it is the consensus of opinion of this conference, except in isolated points, wherein it is impossible for the employee to obtain proper medical and surgical attention, that it is not advisable for the family to receive medical attention either at a stipulated stipend or at the expense of the corporation.

(Signed) S. R. BENEDICT.
W. A. SAWYER.
F. E. CLOUGH.
L. F. STEWART.

DR. MCKITTRIDGE (Indianapolis): I move that the resolution be adopted as read.

DR. HOURIGAN (Larkin Company, Buffalo, New York): I second the motion.

(The motion was carried.)

CHAIRMAN SHOUDY: The first paper on this afternoon's program, "What Does the Health of Workers Have to Do With Industry?" will be presented to you by one of the (I was going to say oldest, not in years but in point of service), men in the industrial medical field, and I assure you that it is with a great deal of pleasure I present Dr. Otto P. Geier of the Cincinnati Milling Machine Company, Cincinnati, Ohio.

DR. OTTO P. GEIER: Having attended a number of the sessions in the last few days, I feel very much inclined to cast aside the paper which I have prepared, because so many things have crowded into my mind as possibly more interesting than the thing I had prepared. One cannot, for instance, attend the Benefit Association group without realizing the tremendous necessity that faces industry in carrying that work forward, if for no other reason than to keep away that menace, compulsory sickness insurance, which faces this country as it has faced every other country abroad; and undoubtedly industry will take that dose unless America finds a better method than compulsory sickness insurance of meeting the problems of sickness and invalidism and death that come in connection with the care of disease.

If there were any arguments needed for the spread of industrial medicine, the care of the worker and the extension of Mutual Benefit Associations, certainly the problem of life extension to be substituted for one merely of cash benefits, as prevails under compulsory sickness insurance plan, would be sufficient reason. However, in order not to extend myself into the indefinite field, let me suggest before starting the reading of this paper, that I have tried here to suggest to you a new method, not a new method but a definite method of measuring your results in industry in the care of the industrial worker, rather by the death rates than by the reduction of illness or the morbidity rate; and that it would be possible (at least I suggest the possibility), of our finding new arguments to present to industry and society at large, for the earlier adoption of a more complete health service in industry.

We paid a good deal of attention to the matter of prevention of accidents but little attention to the prevention of death from illness, and yet the curve is eight or ten times that of the lost time from accidents. So merely suggesting this as a beginning, let me go to the paper.

What Has the Health of the Worker to Do With Industry?

Dr. Otto P. Geier, The Cincinnati Milling Machine Company, Cincinnati, O.

It would take the wisdom of a Socrates to answer that question in the brief period allowed here today. Economists the world over, health experts, actuaries of insurance companies, students in sociology, commissions of various types of international scope, along with scores of medical and health organizations, have tried to evaluate health as a factor in production. Industry, through the National Industrial Conference Board, made some notable contributions to the discussion.

In 1911, three years before I became associated with industry, I first became conscious of the problem in writing an article entitled "Shop Sanitation as a Factor in the Workman's Efficiency." In the 1914 Safety Congress a group of us physicians raised the question with the officials as to whether that organization should not be promoting sanitation in its broadest sense. By the next year the Health Service Division of this organization had its first meeting. Being then secretary of the section of Preventive Medicine of the American Medical Association, it was possible to introduce the subject of industrial medicine into the program of that section. The

following year the American Association of Industrial Physicians and Surgeons was organized. In 1919, through the courtesy of Dr. Wm. Mayo, industrial medicine was presented before the American College of Physicians and Surgeons. Directly after that, the American Medical Association took recognition of the importance of this subject and changed the name of its section on Preventive Health to that of "Preventive Medicine and Industrial Medicine."

In the meantime the problem had been presented by many speakers to engineering societies, trade associations and the like. Many controversies had been fought out between the industrial physicians and the representatives of the American Federation of Labor on the subject of physical examinations and the consequent "human scrap heap." But the World War and the pressing necessity for output brought labor and capital in harmony about the conservation of human energy through health work.

Throughout these years there was a gradually accumulating body of information on the subject coming through the medical and lay press. *The Nation's Health* was established for the purpose of promoting an interest in industrial health. The *Journal of Industrial Hygiene* began its appearance to meet the need for more exact scientific data on industrial hygiene. The books by Dr. Irving Clark, Dr. Harry Mock, Dr. Hayhurst, and other leaders in this line, contributed greatly to the appreciation of the fact that the health of the worker has much to do with industry.

However, when one views the zeal with which this new potential in industry was first presented to the business world, when the indisputable facts of lowered cost of production, less turn-over, less illness, fewer injuries, greater interest in the work, the better citizenship that comes with health supervision of the worker are recognized, it is disappointing to know that American industry has been all too slow in taking advantage of these new possibilities in social economic betterment.

Losses From Ill Health Greater Than From Accidents

My only explanation of this tardiness of action comes with the feeling that there has been no organized selfish interest to promote the wider introduction of health supervision in industry. Here we, apparently, have a potential agency far wider in extent than the safety movement in its possibilities of saving which, however, has lacked the energetic sales organization methods inherent in the National Safety Council. In the safety movement it has been somebody's explicit business to promote the spread of the safety habit and today we see perhaps more than four million workers benefiting from that scheme.

In the case of ill-health, where the losses to industry are eight to ten times as great as from accident, we have no agency like the National Safety Council to command the attention of management in its propaganda; to induce the habits of health with its life-saving and misery-saving results.

What organization, if not this one, shall take up this greater task, more extensive in its life-saving ability, more far-reaching in its saving of misery and poverty, more effective in adding profit to the manufacturer, and dollars to the pockets of the nearly 60,000,000 producers of the country whose aggregate purchasing power finally determines the nation's health and prosperity?

In no country of the world has management a higher standard of industrial thinking, better appreciation of good social economics. Certainly among the successful managements there is a feeling of civic responsibility, a consciousness that industry is vitally interested in what the State provides in the way of health work, in the full knowledge that good community health is basic to sane thinking and efficient work in his plant.

It is because of this high standard of management in so many plants of the country that industrial unrest is at so low ebb here as compared with countries abroad. It is because of the higher ethics in methods of employment, personnel work and safety work that so many contacts between management and men have been afforded

and a better understanding of their mutual relations and their mutual dependencies effected.

An opportunity to study these tremendous variances between the industrial conditions here and abroad was afforded me two years ago when, as a member of a commission of medical men representing nine countries, we made studies of industrial living and working conditions abroad under the auspices of the League of Nations. There I saw at first hand what enormous economic and social advantages the American workman enjoys over his European brethren in the matter of hygienic plants, the working hours and living conditions, the safety surrounding the job, but above all the relationship between management and men. After such a study one can readily understand why communism and socialism find so fertile a field abroad and so little opportunity to grow here. The great gulf between the executives and the men at the bench, the man in his frock coat in the front office and the man in blue jeans in the ill-lighted, unsafe shop. It is easy to understand the animosity, the ill-will, the lack of cooperative effort to produce. It was not surprising to learn that the Socialists were in the majority in the Belgium Parliament. It was equally consistent to see a shaggy-bearded, highly opinionated but ignorant Socialist at the head of some large medical institute and presumptuously supervising the work of trained professional workers.

Industry Needs to Be Sold the Preventive Medicine Idea

The American business man is generously purchasing today that which is sold him for the benefit of his organization, but managements at large are still all too frequently failing to understand the relative values of those purchasable factors which have to do with the health and well-being of their workers. He has bought safety service from the National Safety Council because it was sold to him by an organization which was of his own making; it was working without profit, but its employees have shown the same zeal as if it was their business. He has bought group life insurance because the insurance companies have forcefully urged the purchase of that commodity. But unfortunately the insurance companies have not been so industrious in the sale of group sickness insurance, nor have we had any agency that was energetically promoting the introduction of mutual benefit organizations within industry. Last of all, but perhaps most important, there has been no agency that has urged upon industry the employment of full time physicians as a part and parcel of a good productive scheme. With no one to sell it to him, the executive naturally did not buy a complete health service for himself and his employees.

American industry in 1926 paid to the life insurance companies more than 55 million dollars in premiums for group life insurance. Only one-eighth of the men covered by this five billions or more of life insurance were also fortunate enough to have provided for them insurance protection against sickness. In only a small section of this one-eighth was there any relationship between the life insurance and the sickness insurance plan. The plans were not tied together as a part of a scheme for protecting the worker against sickness, ill-health and death. There was no effort to unify the thinking of the worker and management upon the subject of conserving life and prolonging years of efficiency of those in the plant. Too large a percentage of the insurance referred to was of the non-contributory type and therefore little valued by the recipient. In my humble opinion the purchasers of this five billions of insurance protection may have pleased their inner consciences somewhat by having supplied about \$1,200 to the families of their deceased workers, but they received a much smaller return on their investment for the employee than they might have secured had they spent an equal sum of money in a broadly considered plan of health supervision with sickness and life insurance on a contributory basis.

Out of a plan of intensive medical supervision, tied up with dentistry and a sick-

ness benefit plan, the life of the average worker in their plants might easily, according to authorities, have been extended five years. When you extend the life of the worker for five years you place in his family's hands the equal of six or eight times the amount of money that the life insurance benefit usually provides. You have kept alive and at work the bread-winner and permitted him to enjoy his family for five years more. You retain a skilled worker for that many years more. You reduce the cost of turn-over and accidents. Incidentally you have saved to the community a producer as well as a consumer of world's goods for another five years in place of a family in need of charity.

You are all familiar with the simple experiment of the Metropolitan in giving 6,000 workers physical examinations over a period of six years at a cost of \$49,000. The actuarial figures prove that they sufficiently extended life to have made a profit of approximately 157 per cent on the moneys invested in these physical examinations. That is, they put off the day of dying, and widowhood, and collected sufficient additional premiums to show that profit.

The Immense Value of the Country's Male Workers

How insignificant are the results attained by physical examinations compared to the life extension values that come out of intelligent medical supervision in industry when it is closely tied up to a well administered sickness benefit plan including dental attention and diagnostic facilities!

I do not deny the great value of group life insurance, but I do hold that it is insignificant in value although it costs the same money as a plan of contributory sickness insurance, medical supervision and dental care. One induces the health habit and preserves the man for society and for his family. The other merely helps to bury him and provides a small balance, all too quickly consumed by his widow and children.

An article by the well-known actuary, Dr. Louis I. Dublin, in the November, 1926, *Harper's Magazine*, entitled "Life versus Death Values" is a challenge to the business man who supposedly understands life economics, to permit the present death rate of his fellow workers to continue. Productive life values are too frequently first recognized when ill-health interrupts the capacity to earn; when the costs of being sick mount high above the ordinary living costs, and most fully when death ensues and permanently interrupts productive value. We should contrast the high cost of living with the much higher cost of dying, especially if that dying be slow, or a lingering illness or invalidism. Dr. Dublin claims that, figured on an actuarial basis, the average person at 18 has a future earning capacity over expenditure of some \$29,000; that at 25 years his future net earnings are \$32,000; that at 50 they are \$17,000, and at 60, \$8,000. He makes the striking computation that the sixty million males in the United States are worth a thousand billion dollars as against our total national wealth of one-third that much. He estimates that illness, even on the low two per cent basis or seven days per year, costs the nation two and a half billion dollars annually. He further claims that one-third of the annual deaths are preventable, and that the capital annual preventable loss is six billion dollars.

In the past half century life has been extended for individuals on the average 15 years (from 40 to 56). Dr. Dublin states that the elimination of all deaths from accident would add one year on the average to the life of every individual; that the elimination of deaths from tuberculosis would add two and one-half years. It is his further belief that the universal expenditure of \$2.50 per capita per year for preventive health work would reduce the general death rate two points per thousand, and that this reduction would increase life expectancy from five to seven years.

Those who know Dr. Dublin have reason to have faith in his forecasts. I believe he can forecast reduction in death rates quite as positively as the business man is able to forecast the future profits in his business. It may be interesting, as partial

support of Dr. Dublin's statement, to add that according to published statistics insurance companies in 1926 collected \$55,000,000 from the employers for group life insurance, that they paid back to the families of the deceased about 74 per cent of that \$55,000,000. Roughly calculated, this means that out of every 1,000 employees having policies of \$1,000 apiece, that seven and one-half of those employees died during the year. Now since these figures are average, there must have been plants where the health conditions were not so good and where 10 workers died for every 1,000 insured; whereas in the plants where medical supervision, sickness insurance and dental attention prevailed, but five instead of seven and one-half men passed away. Now the plant with the complete health service can maintain this low average mortality rate and show a differential of two and one-half deaths per thousand per year. According to Dublin's above quoted statement, from five to seven years of life are added to the individuals of such a group. Therefore, I say to you that we are no longer dealing in problematical hypotheses, but we are dealing in facts. It is possible. It has been done. This reduction in mortality has occurred in plants where intelligent preventive medical health work has existed over a period of years. Such a plant may proudly adopt the slogan, "Work Here and Live Longer."

And now I come to you finally with this question: Can you imagine anywhere in this country any intelligent manager who would deny to his workers the right to live five years beyond their expectancy, assuming it was economically possible for him to provide that opportunity for prolonging life, increasing purchasing power and skill and therefore productive power? Do you believe that when management and the workers together recognize the opportunity to purchase this longer life at a very reasonable cost that they will deny it to themselves? But who is there who will make it his business to sell them this idea?

Life is the Nation's Great Natural Resource

Life is our greatest natural resource. To my mind its prolongation will provide the next great economic advance by America. Our restricted immigration laws will force society to conserve our man-power. Failure to anticipate and provide this economic asset may precipitate compulsory sickness insurance which is being offered so insistently as a means to combat some of the evils resulting from an absence of any plan to provide for the sick. The great opportunity is offered America to adopt a wide-angled sickness prevention plan rather than have forced upon it a compulsory sickness cash benefit plan in force abroad.

The problem that has been proposed today should be carefully studied from an actuarial basis so that the results in definite, easily understandable form may soon be brought to the attention of every thinking executive and every intelligent employee. The unnecessary shortening of life by five years or more is our greatest economic waste today. It is the most valued recoverable waste. There remains merely the task of so gathering the facts that they are indisputable. Then some forceful agency must take upon itself the task of selling the health habit from a dollars and cents program, just as the National Safety Council has sold the safety habit.

Health is a purchasable commodity. It can be secured to executive and employee alike. A voluntary health system can be instituted to the great economic advantage of employer and employee. It ought to be placed on a contributory basis to be most effective. It will eliminate one of the greatest wastes in our industrial life. It will pay big dividends in its longer life, the greater enjoyment thereof, the greater effectiveness, the larger consuming power. Compared to other plans of the financial wizards for economic profit to society, the results are staggering. It would spell a more permanent prosperity for all concerned.

CHAIRMAN SHOUDY: Dr. Geier, we thank you.

If there is no discussion of Dr. Geier's paper, we will take up the next which is

beginning at the beginning, and Dr. Sawyer of the Eastman Kodak Company will present to you "The Health of Executives."

Health of Executives

**William Alfred Sawyer, M.D., Medical Director, Eastman Kodak Company,
Rochester, N. Y.**

"Jonathan Jones, President of the G. & O. Corporation, aged 55, died suddenly yesterday afternoon at his home, 124 Chesterton Drive. He went to his office yesterday morning in apparently robust health. After a committee luncheon meeting at the City Club, he felt somewhat indisposed and instead of returning to his office went to his home. About four o'clock he was found in an unconscious condition in his bed room by one of the servants. The family physician was called immediately. All efforts to revive him were of no avail and he died at 4:45 p. m. His death was due to a heart condition of which neither he nor his family were aware. Mrs. Jones and sons are vacationing, etc."

I am sure you have all recognized the familiar sound of the foregoing. If you watch the press, you will see how often this sort of thing occurs. Fifty—fifty-five—sixty years of age—the prime of life—and their experience, training and wisdom are lost to the community.

An upstanding Scotchman, an executive in one of our larger industries, was evidently aware of this community loss. He died recently at 57 and during the year or so prior to his death, while he was somewhat incapacitated because of the condition of his circulatory system, several times he spoke as follows: "Why is it that just after I have reached a position where my experience and judgment can be of some real use to my organization and the community, I have to halt and think only of my health?" I did not then answer the question as I felt facts indicated it should be answered. It would have been too harsh to say that the habits of his earlier years and the ignorance of their results (as he, like most people, neglected any regular checking up of his physical machine), were undoubtedly responsible for his unfortunate state. Waiting till the damage is obvious, surely lessens the ability to recover and often eliminates even holding the malady in abeyance.

Here was a man 57 years of age, thoroughly able, beloved by his fellow men, desiring life, and needed, conscious that he was too soon to be cut off. He was stricken one evening at the table and a few days later died; he and the world deprived of perhaps 20 years of what should have been the best and most useful part of his life.

The business world is all too full of such pictures and I am convinced that it is well worth while for us to look into this subject and give it some earnest consideration. Executives, whether presidents, managers, superintendents or department heads, are all leaders in their respective groups. They are the key men, bearing large responsibilities in this ever increasingly intricate business life. Recognition of and consideration for, this fact is just beginning to be appreciated to the extent of doing something about it.

The dictionary says that an executive is one who is *active* or *efficient* in the management of an organization's affairs. Activity and efficiency are dependent upon the bodily energy. Energy, as pointed out by E. B. Gowin in his discussion of "The Executive and His Control of Men," is the true *basis* of leadership. Quoting him, "The body may be regarded as a chemical machine. Through the food which he eats—and digests, it must never be forgotten—the individual stores up within his body, for use when needed, quantities of highly complex compounds," which when acted upon by nervous stimuli are transformed into productivity or work. "The

ultimate source of executive ability is energy." It obviously follows then, that if much energy is required, plans must be made and carried out for its maintenance. An executive should give his body the same analytical attention and consideration that he gives his work and should follow the same methods of appraisal and control.

Executives are usually between 40 and 60 years of age, living a more or less sedentary life, without proper regular exercise or periods of relaxation; the usual result being overweight, constipation, headaches and undue fatigue. Such conditions lead to early incapacity following nerve exhaustion and the usual run of degenerative diseases.

As Dr. Loyal A. Shoudy points out in the August NATIONAL SAFETY NEWS, "The ailing executive may not be a direct hazard as is the crane operator with certain physical defects, yet the welfare of hundreds may rest upon his decisions. Poor judgment is often due to obscure physical ailments and its effects may be far reaching. Under pressure of business he postpones his visits to the doctor and dentist."

It is no uncommon thing for a company to take out large insurance policies on executives from \$500,000 to a million. It is beyond the bounds of common sense to deny that the executive man power of an organization is one of its greatest assets. The policy of preventing unnecessary waste needs closer and more efficient application in this particular. There are men so impaired by functional and organic disorders that they are unable to give more than a part of themselves to their work—this is inefficiency. They break down and end their careers long before they should and usually because of the continued neglect of what was in the beginning a minor affair. This point cannot be over emphasized. They do not give the care to their health which their automobiles receive.

The Waste of Life is Unwarranted

Marvelous and wonderful advances have been made in science and mechanics. The business world moves forward by leaps and bounds, but we are not making the progress we should in the conservation of human life. The leader cut off at middle life is delivering only about one half of his effectiveness to the world's progress. That is an unwarranted waste. And it is not only a question of keeping a man *alive* until he is 80 or 90 years of age. For the mere fact that a man is alive is no proof that he is of real worth to the community. Rather the objective is to keep him fit and alert, and the life expectancy will automatically increase. If removal by sudden death were the only question involved, the subject would still be worth consideration, but just living is not all of "being alive." A person lives who is not dead, while being "alive" implies functioning to the full—a state of health which enables one to sit on top of life's problems with sound judgment; to possess a store of energy that can be drawn upon in time of need; to know when to let up and play; and to appreciate the value of interest in other things—to have a sane and reasonable hobby as safety valve; to no more think of abusing the human machine than he would abuse, or allow others to abuse purchased equipment.

We can safely say that the time a person runs the gamut of competition and achieves a position of management, he has already stood a great deal of wear and tear, and may even suspect that all may not be one hundred per cent normal with him. He knows in a general way that his success depends upon his health and may even have learned to exert some care regarding it. Unfortunately most people seem to learn altogether too little through the wisdom and the experience of those best fitted to advise them.

Executives of whatever station are very largely specialists—bent on one thing. Indeed to be an executive demands a wide thorough study of the facts and factors involved—an intense application. Much of the time away from business is too apt to be spent in intensive sedentary and indoor social functions which do not off-set

the intense sedentary business life, but add to its strain. Anything of a mechanical nature is tested and inspected at certain intervals of time to be sure that the wear and tear of use has not weakened it beyond the point of safety, so there should be the same sort of safeguard for the human machine in industry, if continuous efficient service is to be delivered. I am sure that most of you have heard of periodic health examinations. Judging by the results obtained through groups of such examinations, it might be conservatively estimated that such examinations will save 70 per cent of the waste to industry, resulting from neglect of the human body. No business man will ignore an opportunity to make such a saving, and no modern physician, whether in industry or in private practice can ignore the prevention phase of medical practice if he keeps pace with the times. However, a real health examination involves not only an accurate test of one's bodily machinery, but a careful and detailed analysis of habits, recreation, rest, exercise and the like.

We have all forms of insurance on property loss and a cash payment will very largely make up such loss because you can purchase new equipment. The life insurance, while it pays in cash does not enable you to restore life nor in itself does it restore health. The annual check up or health examination is a form of life insurance plus, and is the *best* guarantee of a long and useful life. Of course, just checking up is not in itself efficient and amounts to but little, except as records, if the one examined does not cooperate. To have an executive really desire an opportunity to early check up his life status, is by all odds the best guarantee that the results will be effective.

May Still Consider Health a Kind of Game

Quoting Eugene Lyman Fisk—"Health Building and Life Extension": "The increase in the death rate and the ratio of physical defects after age 18 is *not* the result of a fixed biological law, but of ignorance and neglect."

Even in this enlightened day one finds many people who consciously or unconsciously regard health as a sort of game of "button, button—whose got the button"—a mysterious dispensation of providence neither to be added to nor taken away from. I cannot conceive that we will ever get to a point where individuals will look after themselves one hundred per cent. There will certainly need to be much more education on health than at present exists and to this end perhaps our greatest energy at present must be spent.

Through the printed page acquaint your executives with facts regarding the value of periodic health examinations. Reprints of well-written and authoritative articles are procurable and most convincing. See that these are distributed. Talk to them personally or in groups. Send out personal letters calling their attention to certain health facts. It is particularly convincing to send out a letter to the managerial group just after some important man has suddenly died. Capitalize such events. Use the sort of salesmanship that is in practice in other lines of endeavor. If you can't appeal to their reason, then even their fears may offer an opening.

I think it is better to propose that a routine periodic examination be made by the plant medical department in the beginning. It gives a true estimate of the physical status of the group and enables the physician in charge to know where his efforts should be directed. Perhaps it may be best to even insist that *all* such examinations be done by the plant physician. That will depend upon the type of organization. We started to enlist interest by offering a physical inventory to everyone in three of our plants, the aim being to secure the cooperation of the rank and file by the examination of the executives and the executives' willingness to submit to such examinations was obtained on the basis that he must set the example to secure the cooperation of the rank and file. In this way, each group, stimulated the other. In one of the plants, 50 to 75 of the employees were called together at a time, girls

and men in separate groups, and talked to by one of the executives and by the physician as to the value of periodic examinations. They were all asked to sign a slip indicating their willingness to submit to such examinations. This took a number of days. Ninety-eight per cent of the group of about 2,000 accepted it. In another plant, the proposition was first presented to the executives in assembly and sold to them and they in turn went back to their respective departments and through an employees' representative system, obtained the approval of the entire force. This went over 100 per cent. And the same was true of a third plant in which the executives handled the matter, convinced the employees under them that it was desirable and secured their approval. As a result over 3,000 examinations were done.

There were many interesting phases to this experience. I am convinced that there need be little difficulty in such a proposition if it is approached in an intelligent and sympathetic way. Anything so worthy can be convincingly presented, particularly if the man at the very top gives his hearty approval. This should always be sought first. We have not repeated such a performance yearly because we have been entirely too busy to handle it. Therefore, not so much because of a plan as a circumstance, we have followed up and re-examined only those whose status at the time indicated the need for further attention. To the remainder we urged that they seek a yearly examination elsewhere. We have never refused a request for such an examination and are continually taking care of such cases.

Executives Are Paying More Attention to Their Health

It seems to us that it is far better to have executives want such examination than it is to thrust it at them and insist that they accept it. We have shown them how and why.

What is the result among the executive group? Just this. They pay more attention to their health than ever before. They are taking more exercise, proper recreation is really playing an important part in their living. Vacations are more regular and of a better quality. A given number are going to their doctors regularly for a thorough overhauling and a number come to us and ask for check-ups. In some of the executives we discovered organic defects of which they were entirely unaware. We cannot yet show tables proving that mortality has been reduced, or that morbidity is less, but we do know that the executive force is "on guard," and much good has already resulted.

We are just now issuing a letter to the executives (from the foremen up) calling their attention to the examinations previously done and again pointing out their value, with the hope that they have carried on by having their own family physician repeat them. If not, it is time that they again took stock, and if the birthday is not a good time to have an annual check-up, then perhaps it is wise to start each year off fresh and fit, having their examination sometimes in January: or perhaps the beginning of the fall after vacation time, or in the spring when tired and frazzled after a hard winter.

We are urging them to go to their own doctor and have not only their vital structure studied, but their habits as well. They must not forget that habits are of the utmost importance for if they are what they should be, then they need have little fear of the machinery doing its part. With the fast and furious pace of modern days and the very best and utmost being demanded of us, man can only meet the challenge fully if he knows how to live and properly protect himself against the onslaught of the business world pace. We are offering our assistance in anything that we can do, such as X-rays, laboratory examinations, etc., and if they choose we shall be glad to do the whole examination. In a few months this letter will be followed by a similar one again pointing out some of the specific reasons for closer attention to one's health.

This plan may not be the ideal plan, but it is a plan and, as we believe, helping

to keep the subject to the fore and after all, that is what is desired. Any reasonable plan if intelligently carried out and fully explained to the executive will eventually do great good. In every industrial medical department where there is friendly contact between the executive and the physician, there is a great deal of supervision and watchfulness going on even without a preventative plan. And it is safe to say that many useful years of service are added to the organization. Executives often fail to achieve eminently because, although wise in the world of finance, production and distribution, they are either grossly ignorant of the needs of health or stupidly careless of its fundamentals. Many a promising man is "licked" before he gets a decent start because of wrong food habits, insufficient elimination, too little exercise, too much weight, or infection from within or poisons from without. The accumulation of these conditions over a period of years is the handicap which eventually downs him.

Quoting Clarence W. Lieb—*Hygia*—"Eating Hazards After Fifty." "Objectives are accelerating to achievement in health as well as in war or in business. Every man of 50 should have 100 years as his life span objective."

Essential Health Rules for the Executive

If I were asked what were some of the things to which an executive should pay attention to maintain his health and efficiency, I should give the following:

1. Yearly analysis and rating of his body. This it seems to be the first objective and the basis from which he can act to keep his health what it is, or even make it better.

2. Proper, regular exercise and recreation, preferably out of doors, is to my mind the second essential.

While there is a tremendous increase in the play spirit of Americans, yet men in big positions loaded with responsibilities, time filled to capacity, are often neglecting after forty years of age this most important of requirements. To quote Harry A. Scott on "Physical Recreation and Exercise for Business Men": "It is a well known fact that many men cease practically all physical activity once they enter upon the serious business of earning a living. This may be due in part to the lack of recreative opportunities in the community, but more often it is due to the "too busy" complex of the American business and professional man, and the universal habit of procrastination. In an attempt to determine the real status of the recreational life of business and professional men, a questionnaire was sent to approximately one thousand business and professional men. While the data is insufficient to be conclusive, it is at least indicative of certain definite existing conditions among those answering the questionnaire, as follows:

- (a). Approximately 50 per cent follow a regular program of physical activities.

- (b). The period of greatest participation is between the ages of 26 to 50 years."

3. Adequate vacations.

In some cases one period a year is sufficient, in other instances which, of course, depends entirely upon the nervous mechanism of the individual, two periods of vacation are essential. There seems to be a precedent and a custom in industry generally that two weeks' vacation is adequate and for certain types of workers it may be so, but I am of the opinion that many of our leaders would be greatly benefited, would be more efficient, have better judgment; and do much straighter thinking, if a more adequate and proper vacation were taken each year. The essential thing in any vacation is to make it of the sort which will give relaxation, quiet, fresh air and proper exercise, these things which recharge the reserve force and give buoyancy. It goes without saying that the change of scene and absence from routine will be included.

4. Avoidance of over-eating.

We know all too well that Americans all too generally are digging their graves with their teeth. Better head work results on the proper caloric intake.

5. Enough sleep must be had.

Too much night life, too many vicarious amusements, too much radio, too many parties, too much taking of the man out of his home by community activities and organizations, have reduced his supply of sleep beyond the limit of safety. No man can sit on top of his position and be in full command of his faculties who does not give nature a chance to restore through restful sleep the spent energy of the day.

6. All work and no play makes any executive an exceedingly dull individual. A hobby or an interest of some kind other than just work is highly essential. One of the saddest spectacles of advancing years is the individual ready to let down in his work but with nothing to which to turn to occupy his attention.

7. Last, but by no means least, a spirit of good cheer and an ability to smile. A sense of humor, being humble and natural amid all the conventions and exactions of life.

To be sure there are some difficulties in any program of health supervision and we must not fail to consider them with reference to executives. First of all, you will have many refusals or postponements in reporting for examinations. Numerous appointments and phone calls will be necessary.

Second. Undue anxiety must not be aroused over the little impairments and defects found. So often a physician alarms the individual unduly because of a haphazard statement and a failure to carefully consider the type of individual to whom he is talking. With a little care all of this can be avoided.

Third. Many of the executives will fail or delay in doing the things they are advised to do. Here it is a question of repeated warnings and reminders, but after all that is a part of the industrial medical work.

Fourth. In some industries the medical department will lack the standing and authority and this will greatly minimize its effectiveness in this sort of work. If it has the support and backing of the man at the top, if it is work of the highest quality, which naturally commands respect, and if the dealings with the men are handled in a tactful, sincere and straightforward manner, there need be little concern as to its success.

A Few Industries are Helping Their Executives

A limited number of industries are making a distinct effort to aid the health of their executives. Insurance companies holding large policies on executives are becoming thoroughly alive to the possibilities of health maintenance and urge and offer annual examinations to their policy holders. Through their experience we are convinced of its value. They have records which show that it reduces mortality. Organizations like the Life Extension Institute are doing much to provide the facilities for periodic check-ups. The machinery is at hand. That which is most needed now is the implanting of a determination on the part of the man himself to make use of these facilities which are at hand.

In the 1926 report of the National Industrial Conference Board, entitled "Medical Care of Industrial Workers," it states that. "In the Conference Board's study of 255 plants, it was found that in 49 cases executives were examined at regular intervals."

"Executives have been found who were on the border of protracted disability, if not a complete nervous breakdown. Others were discovered suffering from unsuspected but serious disease, such as diabetes, Bright's Disease, high blood pressure, and cardiac troubles, the nature of which is progressive and increasingly disabling.

In an effort to locate those organizations which are making some effort in this respect, I find that a good many are doing nothing, some are carrying out a small program, others are doing a very thorough-going job.

In those in which I was able to secure replies to the questionnaire sent out by the American Association of Industrial Physicians and Surgeons, the answers to the question, "What results have been obtained from these examinations that can be passed on to other physicians in industry," were of most interest.

In many instances, the results were not known. In some cases the examination blank is given to the executive named and it becomes his property. No records are kept in the medical department files of such examinations. In one industry this was used as a sales argument in putting over executive examinations. In some cases executives are given periodic medical attention by each one's private physician. The reply did not state whether it was an iron-clad rule that they go to their own doctor periodically for an examination but such a rule might be possible.

What Some of the Examination Records Show

No. 6 says: "Every year we find cases of diabetes, pulmonary tuberculosis, kidney trouble, high blood pressure, etc., that are giving no symptoms and measures are instituted to cure and check the disease.

No. 9 states that "A very decided influence in health and personal hygiene through advice as to diet, better type of care of teeth by showing results of X-ray studies of crowns, etc. The educational side is of decided advantage. Arnold's Bennett's 'Human Machine' is recommended for its psychological effect."

No. 19 replies that "Defects are found and called to a man's attention, and if they are capable of correction this is urged and followed up, or if defect is not corrected, our main office may be informed." Here we see evidence of the compulsory examination. In many types of industries such a method is doubtless justifiable. In others it would not be possible.

No. 13 does not speak of any results but reports that "in all periodic physical examinations we do complete blood count, Wassermann, twenty-four hour specimen urine and X-ray all the teeth. Also we X-ray any other part indicated and upon further individuals do blood chemistry, basal metabolism, etc., in our laboratories."

No. 3 begs to be excused for his delay in replying because the company was holding a conference of salesmen and it is the medical department's duty to examine each one annually before he returns to his territory again. Such work is excellent. I know of no group which need such examinations more. This company stresses examinations of their executives strongly, doing them every six months and going to great lengths to get them well, if found in need of medical attention. In their recent examination of one hundred four executives, defective vision, infection of the teeth, marked rise in blood pressure, acute kidney disease and diabetes all of which cases found existed without any accompanying symptoms and these conditions did not exist six months previously. Hence the value of a semi-annual check-up. Their average age was 43½ years. One out of every three wore glasses. Eleven of them had sixteen abscessed teeth (complete X-rays were taken) two had organic heart conditions, two had irregular hearts, four had high blood pressure, two had kidney complications, one had diabetes and four were ruptured. I think this doctor had done an excellent piece of work and gives ample proof of the need for it.

No. 11 states that X-ray of the teeth of ten shows up foci of infection. Blood pressure readings, urinary examinations and consideration of eyesight frequently show that advice as to diet, exercise, mental activity is needed. Letters are sent out each year urging that they avail themselves of certain examinations offered

by the Medical Department. The examination is entirely voluntary. Between 60 and 75 per cent avail themselves of it. A copy of the recent letter reads as follows:

"The Medical Department wishes to offer the following:

1. Urine Examination
2. Blood Pressure Reading
3. X-Ray of Teeth
4. X-ray of Chest.

It is very much desired that all take advantage of this opportunity. In order to facilitate this work appointment may be made at your convenience by calling 3829, shop phone.

Signed by the Medical Director."

Such a plan seems to me to have excellent possibilities—perhaps the offering of specific tests is a much better way to induce the man to come in than to call it a health examination or periodic examination.

A Very Comprehensive Plan of Examinations

No 5 replies that "My method of procedure is to make a health examination at stated intervals. The examination is made oftener than once a year, depending on the need of the individual. Each examination is followed up and in this way I am able to keep the needs of each individual before him so that the results are much more satisfactory than they were when this form of checking up was made only at the time of examination.

"At times it has been necessary to check some cases as often as once a month.

"The cooperation on the part of the group has been excellent. It has often been difficult to know just how much to ask of each one but in the series of examinations lasting over eight years, it has rarely been necessary to frighten anyone. It has helped greatly by being able to advise regarding the working hours and the vacations of this group. Each man knows he will get what he needs to keep him fit provided he gives reasonable cooperation. These examinations are voluntary." He continues, "The health of one group of ninety-one men made up of foremen, department heads, staff men and chief clerks is examined once a year and when necessary twice a year. A group of fifty major executives including the directors of the company is examined at least twice a year, sometimes oftener. It has been my experience that if I could get the men to correct one bad living habit or correct one defect during each year, progress had been made. Every three months this year we have been sending some health articles to each of these men examined so as to keep their attention more or less on the subject of personal hygiene and physical fitness."

In this same organization in 1926, a group of 91 minor executives on an average, lost a little less than two days each. (The lost time in this group has shown a decrease from 1924 to 1926.) The doctor in this plant has found also that these executives who have had the largest number of yearly examinations lose the least time. Altho there are fewer correctable defects than when the examinations were started.

May I add that in my own organization a group of department heads lost on an average, in 1925, of 3.27 days and in 1926 2.37 days each. How much health supervision has to do with it I am unable to say.

Dr. A. W. Colcord before the Western Pennsylvania Division of the National Safety Council says: "The examination of executives under 40, yearly, and of those over 40, twice a year, stressing, in the latter group habits of living, blood pressure, urinalysis, heart and blood vessel conditions with functional tests, eye and ear conditions, nerve reflexes, conditions of teeth, tonsils, gall-bladder, appendix, rectum, prostate, and, if possible, Wasserman's in all cases."

Dr. Colcord dismisses the cost of physical examinations for applicants and em-

ployees with the remark: "I merely say that if carried on in the right spirit they will always be worth many times their cost in increased efficiency, in decreased loss of time from sickness, in more years of working time and increased loyalty of the workers."

Dr. V. S. Cheney describes in the *Journal of Industrial Hygiene* the character of examinations for executives at Armour & Company. All executives under forty are examined once a year and all over 40 twice a year. The examination is made by the family doctor on a blank furnished by the company. This is sent to the medical department after it is complete where it is analyzed, and proper follow-up instituted. Dr. Cheney says, "Without good health a man cannot perform his duties efficiently. Good health is therefore his chief asset; it is the commodity that he is selling to the industry and it is up to him and not up to the industry to maintain the quality of that commodity. You see that he rates the periodic examination as a test to see whether the executive is doing what he should to maintain his health."

The Responsibility of Every Executive

Thus you will see the methods may consist of either a rigid compulsion regarding such examinations such as exist in the army or some of the railroads, or it is a voluntary affair entirely. Both are good. The response and effect depends on the spirit which pervades the organization and the manner in which individuals are handled. It is the responsibility of every executive to maintain good health. Industry has a right to expect it but in turn industry must exert supervision and see to it that he has adequate vacations and at times when they will be most helpful. Furthermore, I want to again stress my belief in the supreme importance of health habits for I believe a check on these in every so-called health examination is of chiefest importance. No value can come in telling a man he has this or that, if the things which are causing it, are neglected.

And lastly may I plead for more education among our key men of the business and commercial world regarding health. If industry cannot carry on routine periodic examinations, it can at least put into the hands of its most valuable group, literature bearing on the necessity of attention to health. Ponce DeLeon once looked to this country for the fountain of youth, but found it not. Were he here today we could direct him to it for at last through periodic health examinations we have that long elusive fountain.

CHAIRMAN SHOUDY: You men who are not executives, you men who are interested in the executives and interested in the problem of the health of the man, can take home with you the thoughts Dr. Sawyer has given you in that paper. You can sell the idea of health to the chief executives of your company, to sell the health to the men who work in your company. I will not ask for discussion on Dr. Sawyer's paper. There is very little to discuss about it, until after we get through with the other papers.

The other paper, "Some Observations on Industrial Silicosis," by Dr. Sayers, Chief Surgeon of the Bureau of Mines, will be read by Mr. Daniel H. Harrington, chief engineer of the Safety Division of the U. S. Bureau of Mines.

MR. HARRINGTON: The subject of silicosis as applicable to mines is one of the most important that can be considered. The general public has a feeling or horror as to explosions in coal mines, and it would probably be very much surprised to know (and it is a fact), that there are more miners dying every year from silicosis than are killed by explosions in coal mines; and this, in the face of the fact that there are about 600,000 involved in coal mines, and hence are subjected to possible explosions, while, on the other hand, there are only about 125,000 involved in metal mines who are likely to be the most involved in silicosis.

Some Observations on Industrial Silicosis

**R. R. Sayers, A. M., M. D., Surgeon, U. S. Public Health Service, Chief Surgeon,
U. S. Bureau of Mines**

Silicosis is a chronic disease, usually industrial, caused by breathing rock-dust containing silica or quartz. It is characterized clinically by shortness of breath, cough, and decreased expansion, which result in a lessened capacity for work; anatomically by increased amounts of fibrous tissue in the lungs. The harmful effects of breathing silica dust have been recognized from the time of Hippocrates. The disease exists among workers in the abrasive industry, pottery, tool grinding, sand blasting, brick making, quarrying and mining industries.

Etiology

It has been found in practically all the hard rock mining districts of the world that no nationality is exempt, and that all races are susceptible is indicated by the above statement as to distribution. The incidence of the disease is higher among the younger miners in districts where the rock contains a high percentage of free silica, and among the older miners where the percentage of silica is low. This is due probably to the fact that the rock containing a high percentage of silica produces the disease in a comparatively short time. The ages of the man in itself probably is no great factor. Previous occupation of the man may have a definite influence in predisposing to silicosis if he has been exposed to dust or to other respiratory irritants. Men who have worked in certain coal mines for several years seems to be less susceptible to silicosis than the average man. According to some investigators, animal experiments indicate that coal dust has this effect. Three groups of animals were exposed for a definite time as follows:

- Group 1. To free silica dust.
- Group 2. To mixture of coal dust and silica dust.
- Group 3. To coal dust and then to silica dust.

They were examined several months after exposure. Groups 1 and 2 had more silica dust remaining in the lungs than Group 3, although silica dust could be demonstrated in all groups.

Men who have had respiratory diseases, especially tuberculosis, are apparently more readily affected by silica dust. Men who have organic diseases of the heart, including the asthenic heart, are also apparently more readily affected by silica dust. In the gold mines of South Africa, where the conditions are good, the average time of exposure of men before simple silicosis can be diagnosed is seven and one-half years. The shortest period of exposure is reported to be two and one-half years. In other industries as well as other mining districts, the length of exposure to silica dust necessary to produce silicosis varies from a few months to several years.

Dr. Watkins-Pitchford emphasizes the importance of tuberculosis and the importance of detecting and isolating bacillus carriers from the mine at the earliest possible time. If this is as important as Doctor Pitchford indicates, it is interesting to note this fact as additional evidence of adult infection with tuberculosis.

Prevalence of Silicosis

The disease is known to exist in a great part of the hard-rock mining districts of the world. It was studied in Western Australia by Dr. J. H. L. Cumpston, who reported in 1910. He found that the death rate from respiratory diseases

among all male non-miners over 15 years of age was 167 per 100,000, whereas the rate among miners was 539 per 100,000. The death rate due to tuberculosis among males over 15 years of age was 6, whereas among miners it was 192 per 100,000.

In 1921, among 6,538 miners at Broken Hill, New South Wales, 373 were found to have some incapacity due to effects of dust on the lungs.

In 1922, in New Zealand 2,012 men were employed in gold mines, of whom 1,438 worked in quartz gold mines. During that same period 506 former gold miners received an annual compensation for incapacity due to effects of silica dust.

More work has been done in South Africa than in any other country on the study of silicosis, as a far greater number of men, from 12,000 to 15,000 whites and about 180,000 blacks, in a limited region are exposed to rock dust containing a high percentage of silica. For the years 1908-1909 the Miners' Phthisis Commission of South Africa considered that out of a mining population of 12,000, approximately 1,000 men in any one year would reach the stage of definite incapacitation.

On account of the heavy morbidity from miners' phthisis, a Miners' Phthisis Medical Bureau was established in Johannesburg in 1916 under Government auspices. By periodical examinations of the miners actually employed, 738 were found to be suffering from simple silicosis in the year 1916-17, 700 in the year 1917-18, 704 in the year 1918-19, 1,572 in 1919-20 (this year the antiprimary stage was included), 448 in the year 1920-21, and 434 in the year 1921-22.

The Situation As Studied in Great Britain

In Great Britain the subject has been studied thoroughly by Doctor Haldane, Doctor Collis, and others. The statistics collected by Doctor Collis for all occupational groups show that the death rate for tin miners from phthisis is greater than in any other industry in any period given. In 1910-1912 the rate of death from phthisis was 75 among coal miners, as against 678 among tin miners; so phthisis presumably is closely related to tin mining.

In another paper Doctor Collis states that the incidence of phthisis among coal miners, although low, and that of other respiratory diseases which is often high, are probably influenced by exposure to dust. He further states that tin and lead miners suffer from typical silicosis, the results of which are associated with the high mortality of other respiratory diseases and Bright's disease.

Investigations have shown that silicosis is present in many of the mining districts of the United States. In Missouri, in the Joplin district, Doctor Lanza found that 433 miners out of 720 examined had silicosis. He also found that 432 out of 1,018 examined in Butte were so affected. The disease has been found in Nevada, Idaho, Arizona and California. Jarvis and Hoffman and others have shown the mortality from this disease to be very high among granite workers in Vermont.

Table 1 gives the average death rates per 100,000 in certain states for silicosis, tuberculosis, influenza, pneumonia, and other respiratory diseases, as well as for all diseases among coal miners, metal miners, and the general population for a four-year period. The rate for tuberculosis among granite workers of the United States and Canada is also given for comparison, as this occupation is known to predispose to this disease. This table shows that the death rate due to silicosis and tuberculosis, among metal miners of the states given, is much higher than the death rate due to these diseases among coal miners or among the general population. The rates for these two diseases can be combined, as they are usually associated in this industry.

TABLE I

Average Death Rate Per 100,000 of Miners and of the General Population for the Four-Year Period 1917-1920, and of Granite Cutters of the United States and Canada for the Four-Year Period 1915-1918¹

Diseases	California			Colorado			Illinois ²			U. S. and Canada		
	Coal Miners	Metal Miners	Gen. Pop.	Coal Miners	Metal Miners	Gen. Pop.	Coal Miners	Metal Miners	Gen. Pop.	Granite Cutters

¹Exclusive of the last three months of 1918.

²Data for Illinois are for 1916-1919.

³Nevada is not in the registration area and the population has been estimated.

⁴No figures are given for 1917 by Census Bureau, as Illinois was not in registration area at that time.

⁵Anthraxosis.

⁶The high death rate per 100,000 for metal miners in Missouri may be fallacious. Many of the miners still residing in Jasper County (where the rate was much higher than in the eastern part of the State) are using the electric cars to get to their work in new developments in Oklahoma, consequently if any of them die, the record of death gives their place of residence and not their place of work.

⁷These figures are taken from Bulletin No. 203 of the Bureau of Labor Statistics, Department of Labor, by Frederick L. Hoffman, 1922.

Theory of Action of Silica

A number of theories are given as to why silica or quartz dust is the most harmful of those classed as non-toxic. The one to be given first and still accepted by many is the physical characteristics of the particles of dust, their sharp knife-like and needle-like form, and their insolubility. But it has been pointed out that some dusts having these physical characteristics, as carborundum, do not readily produce fibrosis. Furthermore, if the harmful effects are due to the ability of the particles to penetrate tissues, they should penetrate all soft body tissue, and this has not been found true. Doctor Haldane notes all silica dust without sharp and pointed particles, as precipitated silica, heated enough to dehydrate, if inhaled will cause changes similar to those produced by quartz dust.

Some investigators think that silica exerts a toxic action upon the tissue cells. In support of this, Myers found that silica dust collected in the mines of the Joplin-Picher district is soluble in water. Doctor Mavrogordato reports that silica is soluble in weak alkaline solutions similar to body fluids. He concludes that the solubility and chemical activity of silica are of great importance, and that hardness and sharpness are of but little importance in causing silicosis, also that ultramicroscopic particles or chemically inert dusts are not dangerous. Doctor Mavrogordato reports that possibly silica dust exerts preservative action upon the cells which take it up, that is not exerted by inert dust. Doctor Gye and Doctor Kettle found that colloidal silica, when injected into animals, is poisonous. Doctor Gye is of the opinion that the toxicity varies directly with the solubility of silica. Doctor Collis, in reviewing the subject states that when soluble silica is introduced into the blood stream, it reacts with liver cells causing fibrosis there, and also with kidney cells (by which its excretion is attempted) causing fibrosis there. In work done at the Bureau of Mines Experiment Station at Pittsburgh, suspensions of dust high in free silica, when injected into the abdominal cavity of guinea pigs, produced marked fibrosis. Doctor Haldane thinks that the most probable theory is "that dust produces phthisis in proportion as they are physiologically inert." He thinks that they act by being in the way, and when enough particles are in the cells the life processes of the cells are slowed. In 1924, Doctor Gardner stated the lymph stasis theory. This theory, which is very much in line with the opinion expressed by Doctor Haldane above, is as follows:

"By a study of inhalation experiments the primary lesion caused by dusts which migrate readily is established in the tracheobronchial lymph nodes. Sufficient accumulation of such dusts in these organs is followed by an obstructive fibrosis in the sinuses, which in turn leads to a stasis in the afferent lymphatic vessels. The pressure of the distended lymphatic vessels promotes an inflammatory response in the areolar tissues about them. Such changes are first observed within the sinuses of the lymph nodes, then in their immediate vicinity and gradually they extend toward the periphery of the lung. Such perilymphatic inflammation finally assumes the characteristics of scar tissue in the location of first appearance of such reaction in human pneumokoniosis. That it is not due to the direct action of the dust may be inferred from the relatively small amount present in these locations."

Doctor Sleeswijk states that certain sandstone, which contains 70-72 per cent SiO_2 and 13-20 per cent CaO , is found to be only slightly dangerous. Absence of lime, according to him, is more important than presence of silica.

With the object of answering the question whether colloidal solution of SiO_2 is really a "cell poison" as indicated by experimental data of Gye and Kettle,

Scheinin made experiments on the growth of tissue culture, according to Carrel, in the presence of a colloidal solution of SiO_2 . He found that such a solution exerts no retarding action on the growth of tissue culture; an emulsion of tubercle bacilli added to a nutrient liquid stops growth and also possibly may cause death. In the presence of SiO_2 and tubercle bacilli emulsion, however, the tissue grows, although less intensively. The author draws from this the conclusion that colloidal solution of silica cannot be said to be a "cell poison" in all cases.

Figure 1. X-Ray photograph showing a normal lung.

Although more investigation is needed to determine the facts, nevertheless there is good empirical evidence that dust containing a high percentage of free silica is most dangerous; furthermore, that only the very fine particles reach the lung tissue and remain there. The particles found by Doctor Watkins-Pitchford and Doctor Moir in the lungs of miners on the Rand were mostly less than 5 microns (1 micron = $1/25,000$ of an inch) long; only 1 particle in 2,000 was over 8 microns, and only 1 in 1,000,000 was as much as 14 microns long. When it is remembered that the cells, which take up the particles of dust, usually measure about 10 microns in diameter, larger particles evidently can not be ingested.

Reaction of the Lungs to Dust Particles

Much of the dust breathed, especially the larger particles, is deposited in the upper air passage of the respiratory system. Doctor Gardner and Doctor Mavrogordato have published the results of the findings after exposure of guinea pigs to dust for a period of time. Doctor Gardner found that, after exposure

of animals to Barrie granite dust (about 69 per cent total silica), no macroscopic lesions could be detected until about the seventh month. If at that time the unfixed lung tissues were carefully examined immediately after opening the thorax, a delicate green-brown tracery of dust deposit could be detected on the subpleural surface along the antero-inferior borders of the cephalic lobes. A few similar deposits occur on the vertebral borders of the caudal lobes. This coloration quickly disappears on exposure to the air, probably because of coagulation changes in the tissue which render them opaque. Zenker fixation, of course, obscures this pigmentation. Doctor Gardner states that microscopic

Figure 2. X-Ray photograph showing early silicosis.

lesions are of more interest; but to appreciate their significance it is necessary to compare them with control animals, one series made to inhale dust alone and another, tubercle bacilli alone. These lesions are therefore summarized under the following heads:

1. Pure dust changes. After about three weeks' exposure small amounts of dust may be found, enclosed in mononuclear intraalveolar cells, which often show mitotic figures. These cells are scattered everywhere in the alveoli from the pleura to the hilum. A very small amount of dust is caught in ciliated epithelium of the trachea and bronchi. At about two months some of these intraalveolar dust cells have begun to mobilize and have formed considerable collections, often so closely packed as to simulate giant cells. These cell masses lie in the alveoli along the course of the ductuli alveolares

and about and within the small lymphoid collections occurring in the periphery of the lung. Dust has already passed through the lung and lodged in small amounts in the tracheo-bronchial lymph nodes.

From 3 to 7 months the same process continues with a steady increase in the amount of dust deposit. The invasion of lymphoid tissue of the lung is more extensive and the larger nodules located at the bifurcation of the bronchioles and bronchi become involved. No dust has ever been found in the liver or spleen. Occasional small deposits occur in the intestinal content, but none has been seen in the mesenteric lymph nodes.

Figure 3. X-Ray showing advanced stage of silicosis.

If the animal be set aside after dust exposure the lung makes rapid and effective efforts to rid itself of the irritant. The clearing process has been observed only up to three months in animals dusted for seven months previously; at that time practically all the dust is collected within large aggregations of round or oval mononuclear cells which lie in the immediate vicinity of much enlarged lymph nodules. Heavy deposits occur within such nodules and within the tracheobronchial lymph nodes. Some dust still remains within the alveoli along the ductuli alveolares.

Doctor Mavrogordato states that when any dust gets into the lungs a large number of cells ("dust cells") are produced which take up the particles of dust. Many of the dust-laden cells escape into the air passages and are coughed up and expectorated. Those which remain in the lungs become fixed and may be

dangerous. The life of "dust cells" is normally brief. They may be carried off by the lymphatics or may die and be digested or dissolved by the body fluids and leave any dust, previously ingested, on the adjacent tissues. When coal dust is breathed and ingested by "dust cells," after a few weeks the dust particles can be found outside these cells on the outer surface of the blood vessels of the lungs at points where the cells on the outer surface of the blood dissolved. Much of this dust can and does escape into the air passages to be coughed up. Doctor Mavrogordato concludes that "it is the dust which can not escape from the tissues which is a source of danger and as long as elimination follows fairly closely upon the heels of ingestion not much harm is done. Coal seems to set up a sort of aseptic 'catarrh' in which there is a steady exodus of particles from the lungs."

When dust of free silica is breathed, the particles ingested by the "dust cells," unlike coal dust, remain within the cells. The cells become clumped together to form a mass similar to the masses of cells (tubercle) found in tuberculosis. These masses of cells, pseudo (false) tubercles, are first found near the surface of the lungs. At first they are separate, later they join together, become confluent, and assist in causing a uniform thickening of the pleura. As stated above, the cells containing silica particles do not die and are not digested or dissolved by the body fluids as is the case with those ingesting coal dust. When "dust cells" reach the lymphatics, they are not all carried off but accumulate and block the lymphatics. The cells gradually merge into fibrous tissue. The blood vessels may be surrounded by the fibrous tissue but may remain open or become plugged with the cells and finally filled with fibrous tissue. The earliest changes due to breathing silica dust in sufficient quantities are:

1. The accumulation of "dust cells" in masses or pseudo tubercles immediately under the pleura.
2. The formation of free pseudo tubercles.
3. The blockage of the lymphatics.

In well marked cases of simple silicosis, fibrosis has taken place in the pseudo tubercles and in the blocked lymphatics and blood vessels of the lungs, together with a thickening of the pleura.

Laboratory Studies

In the animal studies, the various investigators have tried to determine the effect of many kinds of dust. Gardner, in addition to the granite dust mentioned above, exposed guinea pigs to marble dust and another group to carborundum. He concluded that, under the conditions of the experiment, the greater portion of marble dust is soluble in the lung tissues; that the inhalation of this dust during the progress of a preexisting tuberculosis will be followed by the calcification of a certain number of the pulmonary and tracheobronchial lymph node tubercles; that the insoluble silicious matter (from 1 to 1.9 per cent) found in the dust will produce a moderate degree of silicosis after prolonged exposure; that this silicosis will in turn render the pulmonary tissues in some unexplained manner more susceptible to infection with the tubercle bacillus; and that the tubercles produced by the low virulent R1 strain of bacilli will, as a result of this silicosis, pursue a chronic course manifesting a definite delay in the resolution process. When carborundum dust was inhaled, the reaction of normal lung, as stated earlier, was surprisingly insignificant. A true fibrosis in the parenchyma of the lung has never been observed. In the lymph nodes, on the other hand, a definite fibrosis was frequently encountered. In the lung, in which carborundum inhalation is continued during the course of development

of an inhalation tuberculosis, *extensive fibrosis is common*. The most remarkable result in this experiment has been the alteration in the course of the tuberculous process induced by the inhalation of this low virulent tubercle bacillus. from a self-limited process, which usually heals by resolution, it has been transformed into a progressive tuberculous bronchopneumonia.

Figure 4. Silica dust particles greatly enlarged.

Mavrogordato reported that dust from hard rock, containing no free silica but entirely of fine spicular hard minerals, in which 89 per cent was estimated as feldspar, and the rest pyroxene and other dense minerals, when breathed by guinea pigs remained within the cells. The dust particles seem to have exerted some protective influence over the cells containing them, preventing the death and autolysis of the cells.

Technical drawing of a glass container (likely a beaker or test tube) used for holding granulated sugar. The container is shown in cross-section, revealing its internal structure and dimensions.

Dimensions:

- Top width: $2\frac{1}{2}$ "
- Internal width of the sugar layer: $5\frac{1}{8}$ "
- Height of the sugar layer: $2\frac{3}{4}$ "
- Height of the container body: $4\frac{15}{16}$ "
- Width of the base: $1\frac{5}{16}$ "
- Height of the base: $1\frac{1}{16}$ "
- Angle of the base: 30°
- Radius of the base: $\frac{1}{4}$ "
- Radius of the top opening: $\frac{1}{8}$ "
- Radius of the base: $\frac{1}{4}$ "

Materials and Components:

- 20 mesh monel metal screen
- 70 mesh monel metal screen
- 100 grams of granulated sugar
- Minimum thickness of glass, 2 mm.
- Least possible radius

Figure 5. Sugar tube; U. S. Bureau of Mines type.

In order to determine the suitability of different kinds of dust for rock dusting in mines, in addition to chemical and petrographical examination of dust, studies are being carried out on animals at the Pittsburgh experiment station. Animals

Figure 6. The Impinger.

are exposed in chambers to a known concentration of dust. The dusts used as basic types are coal dust, as the type to which men will necessarily be exposed, and quartz dust, as the most dangerous type of dust that might be added for

the prevention of explosions. Limestone dust, shale, and kaolin dust (practically a pure silicate) are also being tested. From these studies, it is found that the limestone dust has no more effect than coal dust in the production of fibrous tissues but the silicate dust has an effect similar to that caused by quartz dust. Shale dust, which contains varying quantities of silica with kaolin, limestone and other minerals, has varying effects. Some shales produce no fibrous tissue, others produce little, and still others produce a great amount.

Stages of Silicosis

Silicosis has been arbitrarily divided into different stages in various countries. In the United States the stages are called first, second, and third; in South Africa they are defined by law as antepimary, primary, and secondary. The earliest stage means that definite physical signs of damage to the lungs have been found, and that such damage has occurred during and in consequence of exposure to dust. The second stage means that definite and specific physical signs of silicosis are or have been present and that the capacity for work has been seriously and permanently impaired by the disease.

The symptoms of uncomplicated early silicosis are few and often indefinite. Slight shortness of breath on exertion, often with recurrent colds, is the most constant symptom. The general health is good. The patient may apparently be quite well and his working capacity not noticeably impaired. He may have a little less ability to expand his chest than formerly and the elasticity of the chest may be slightly impaired. This stage may exist for a long time.

As the disease progresses the symptoms increase in severity. No sharp dividing line exists between any of the stages. The second stage is indicated by a definite shortness of breath on exertion and perhaps flitting pains which attract the attention of the patient; also often by a morning cough, with little or no expectoration, and by more frequent recurrence of colds. Even then the patient's health may not be noticeably affected. He may not lose flesh and may appear quite robust. But his "wind is bad," he cannot work as well as formerly, and his chest expansion is noticeably decreased. In well-developed cases of this stage the chest is held in a state of partial inspiration.

In the advanced, or third stage, the shortness of breath is marked and even distressing; the patient coughs more often; the expectoration is in most cases slight but may be more copious. The patient becomes unable to work, loses flesh, his expansion is greatly decreased even with a forced inspiration, his pulse rate is increased, and his heart may become dilated.

The cardinal symptom, it will be noticed, is shortness of breath, especially on exertion. The cardinal sign is diminished expansion of the chest. These symptoms are slight in the early stages. The cough is that of irritation and may be brought on by having the man take a deep breath; it cannot, however, be considered as a cardinal symptom. Recurrent colds and pains in the chest are also important symptoms. The symptoms characteristic of tuberculosis—loss of appetite and strength, rise in body temperature, night sweats, and hemoptysis (spitting of blood)—are not found unless infection is present. Other symptoms and signs, especially the X-ray findings, are of great aid in diagnosing silicosis.

The X-ray of a normal chest shows the heart shadow about the center of the picture, merging with the shadow of the diaphragm below and the big blood vessels and spinal column above. On each side of these are parallel shadows cast by the ribs. Between the shadows the picture is clear except for the shadows cast by the lung structures. The hilum, or root, of the lung is composed of the large blood vessels and bronchi; the shadows cast by these are on

either side of the upper part of the heart shadow and are irregular in shape, with the shadows of the larger blood vessels radiating from them.

Dr. H. K. Pancoast and Dr. S. B. Childs, in this country, and Dr. W. Steuart, of South Africa, have had extensive experience in interpreting X-ray pictures of the chest of cases of silicosis. The writings of these men have been carefully consulted and, although they describe the various stages in somewhat different language, the findings of all are about as follows:

The first change noted in the X-ray of a man who is developing silicosis is enlarged hilum shadows; that is, the shadows become denser and more extensive, gradually involving the smaller bronchi and in time forming a generalized linear network indicative of perivascular and peribronchial fibrosis. In simple silicosis these changes are almost symmetrical throughout both lungs, except that the shadows are usually more marked toward the right base. All agree that these findings may be due to other causes and a definite diagnosis of silicosis in an individual case cannot be made at this time on signs on the X-ray negative without clinical findings or without X-ray negatives of the same case taken some months previous for comparison. For a group investigation, however, as that made in Broken Hill, diagnosis of pneumoconiosis in men who complained of no symptoms of ill health of any kind was made on the X-ray findings alone.

In the second stage, the hilum or root structure shadows are much denser and larger, the finer shadows found in early silicosis have increased in number and density, are less regular, and look beaded. Sometimes the effect is described as a generalized mottling.

In the third stage the entire area of both lungs is covered by many discrete well-defined rounded shadows.

Methods of Determining Amount of Dust in Air

The weight of the dust and the number of particles are usually considered in determining the extent of the hazard of breathing silica dust in air. Many instruments have been devised for making these determinations, among which are the Palmer apparatus, electric dust collector by Philip Drinker, the Owen dust counter, the Read water-spray dust collector, the Kotze hydrokonimeter, the sugar tube, the impinger, and the konimeter. The sugar tube method is used almost exclusively for weight determination in mining in South Africa. In the United States it has also been used for dust counts and in mineralogical determinations. Sugar tubes range from $\frac{3}{4}$ to $2\frac{1}{2}$ inches in diameter. The Bureau of Mines Type B is made of molded glass $2\frac{3}{8}$ inches inside diameter. One hundred grams of sugar are used. This must pass through a 14-mesh but not a 65-mesh screen. During the past three years the impinger, developed by Greenburg and Smith, has been used in air-dust investigations in the mines of the United States. In this instrument, as the air is drawn through a liquid-alcohol or distilled water—it impinges in a smooth surface. (Illustration of impinger and konimeter.) A half-inch tube, gradually reduced at the tip from 0.5 to 0.11 inch is inserted through a hole in a rubber stopper which fits a 500 c.c wide-mouthed bottle containing 100 c.c of liquid. A circular impinging plate is attached by three legs 5 millimeters from the end of the tip of the tube. The impinger has the advantage in that the errors due to impurities in the material are low and unimportant so that low concentrations of dust may be determined with comparative accuracy. Laboratory analyses may be made more rapidly. The disadvantage of this method is that some dusts are soluble in water or affected by water; other suitable liquids as alcohol, ether, etc., can be used to overcome this difficulty. By the use of the Kotze konimeter, a rapid

determination of the number of particles of dust in the air may be made. By this instrument, a small measured quantity of air is forced at high velocity upon a greased slide. Spots of dust adhering to slide are examined under the microscope. The size and number of particles may thus be estimated. At least two modifications have been made of this instrument, one in Australia and one in South Africa, in which a microscope is attached. This allows of making examination and count of dust immediately after sampling.

A tentative standard of dustiness of air in mines has been set at 5 milligrams per cubic meter of air, or 300 particles per cubic centimeter. In the latest reports from South Africa, the samples averaged 1.1 milligrams per cubic meter of air.

Methods for the Prevention of Silicosis

In preventing silicosis, it is obvious that men will be protected (1) if no dust is formed, (2) if when formed the dust is prevented from getting into the air (3) if once in the air the dust is removed from the air, and (4) if the dusty air is rapidly replaced by clean air.

Wet methods of operating have been recommended since 1713 when a British patent was granted for grinding flint by wet methods. Wet methods have been found to be of special value in the mining industry. In this industry water should be used to wet down the sides of the working place. It should be used in drilling from the time the hole is started, as collaring the hole at the start of drilling may be an important source of dust. The full bore of the hose should be used in supplying water to the collar. Drills with outside water jets cause somewhat less dust than dry drills. Axial-feed water drills of the Leyner type and wet-head axial-feed water stopers have been introduced into the hard rock mines of many countries. A typical Leyner drill allows some air to pass down the axial drill with the water to the bottom of the hole. This air and water mixture as it comes from the drill hole has been found to contain rock-dust. Rock-dust, of course, is just as dangerous to breathe when wet as when dry. Experiments carried out in South Africa have shown that sludging with water alone could be effective, provided the hole in the steel is large enough and the water pressure sufficiently high. On the basis of these to avoid the air-blow system of sludging as in the Leyner drill, the "long piston drill" has been developed in which water alone is used.

For some years wet grinding of tools was considered to be the best and is used in many of the edge-tool factories together with exhaust systems. A number of methods have been devised to prevent the dust from entering the air when formed. Winslow and Greenburg found in an ax factory that air with wet grinding contained far more dust particles than with dry grinding (15,800,000 and 154,500, respectively, or about 100 to 1, per one-fourth unit standard particles per cubic foot) where a similar exhaust system was used.

In the mining industry devices have been developed to prevent the dust from getting into the air. In Australia the Clifton Dust Collector was developed and for a time appeared to be successful. However, it proved too cumbersome and is not now in use. More recently Prof. P. H. Hay, of the University of Sheffield, England, described a method of trapping dust which he thinks will greatly improve the working conditions in stone drifts and increase the comfort of men employed as well as prove a great step in the elimination of miners' phthisis. Professor Hay's apparatus uses a rubber dish like that used on the Australian collector. However, instead of using water he filters the dust out by passing it through closely woven flannel or chamois skins contained in a bag. Exhaust air from the drill is used to draw the dusty air into the filter. Before any final

statement can be made in regard to the apparatus, careful studies will need to be made. In the opinion of many mining men any such apparatus will not be practicable in most metal mines.

As indicated from many statements in the above, wet methods alone and methods of preventing the dust from entering the air, while valuable, have not been able to keep the air free from dust. Ventilation is probably as important, if not more important, as a preventive measure. Mechanical ventilation in mining and many other industries must be used. Sufficient air, taken from a clean source, must be supplied to replace the dusty air at frequent enough intervals. In this way the silicosis incidence can be greatly decreased. In mining the general ventilation by the large surface fan must be controlled by special air shafts and air doors to carry the clean air up to the working face. Auxiliary fans in some cases are necessary.

While all mechanical means for eliminating dust materially lessen the amount of dust in the air and at the same time lessen silicosis and tuberculosis, they do not eliminate these diseases. As stated early in the paper, respiratory diseases predispose to silicosis. Physical examination of all workers is required by law in some industries prior to employment in Australia, South Africa, and Great Britain. In Great Britain and South Africa, periodical examination after employment is also required. The initial examination is made to determine whether the applicant has any disease, especially of a respiratory nature, which would make him susceptible to silicosis or tuberculosis. Persons suffering with silicosis should not be employed where they will have to breathe dust, especially silica dust; if they are, they should not be employed underground at all in the mining industry. Men having silicosis are very susceptible to tuberculosis. It is, therefore, of greatest importance that they come in contact as little as possible with people having tuberculosis. Tuberculosis progresses much more rapidly when an individual is exposed to silica dust. At the periodical examination silicosis can usually be recognized at a very early stage. Any man found with silicosis should be notified in order that he may seek other employment if he so desires. Any man found having tuberculosis should not be allowed to return to work in a dusty trade for his own protection and as a protection to those with whom he is associated. In some countries compensation has been provided for those having either silicosis or tuberculosis or both.

Physical examination is believed to be a very important preventive measure for silicosis as well as for tuberculosis. It must be remembered, however, that no one measure will be successful in preventing silicosis in these trades. All measures—physical examination of employees, good ventilation, and wet methods at least in some industries—must be made continuously effective.

Summary

1. Silicosis is due to breathing very fine rock-dust. Rock-dust high in free silica is found to be most injurious.
2. Silicosis is known to occur among workers in the abrasive, pottery, tool grinding, sand blasting and mining industries.
3. Silicosis is found among metal miners in New Zealand, Australia, South Africa, Great Britain, and in many of the states of the United States.
4. Silica dust is somewhat soluble in water and in weakly alkaline liquids similar to body fluids.
5. Some physicians have thought that silica dust by its sharp-edged and needlelike particles injures the lung tissue mechanically. Another belief is that the silica, being soluble in water and weakly alkaline liquids, injures lung tissue by its poisonous action.

6. The rate of development of silicosis depends upon the character of the dust, the amount breathed, length of exposure, past illness (especially tuberculosis), and physical fitness of the men.

7. Among gold miners in South Africa the average length of exposure to silica dust before silicosis develops is 7½ years, the shortest period of exposure for like results is 2½ years.

8. Silicosis is usually divided into three stages: The first shows symptoms and physical signs of damage to lung tissue caused by exposure to dust, but capacity for work is not impaired. The second stage shows definite signs of silicosis and capacity for work is impaired, although not seriously or permanently. The third stage shows that specific signs of silicosis are or have been present and the capacity for work has been seriously and permanently impaired by the disease.

9. The cardinal symptom of silicosis is shortness of breath, especially on exertion. The cardinal sign is diminished expansion of the chest. Both are slight in the early stages and increase gradually with the development of the disease. Other symptoms and signs, as coughing, frequent colds, pains in the chest, and X-ray findings, are very important in making a diagnosis.

10. Men having silicosis are more susceptible to tuberculosis than normal men.

11. Men with silicosis can improve in suitable surroundings to recovery in the first stage, can improve materially in the second stage, and somewhat in the third stage.

12. Many methods for determining the amount of dust in the air are available. The sugar tube method, the konimeter, and the impinger are chiefly used in the mining industry in the United States.

13. The elimination of silicosis among miners depends on preventing the formation of dust by wet mining methods—wet drilling and wetting sides, roof and bottom, muck, and rock piles; the use of sprays and water blasts to lay the dust after blasting; good mechanical ventilation to replace dusty air with clean air; and physical examination of all miners before employment and periodically thereafter.

14. All of these means of prevention must be practiced to insure success.

CHAIRMAN SHOUDY: Gentlemen, I am sure we are indebted to Mr. Harrington for reading this paper, and we are more than indebted to Dr. Sayers for preparing it. I know that some of you men (if you are not now), will be interested in the question of silicosis, and it is real information which Dr. Sayers gives us in this paper; it is a real contribution to the work that has been done by the Health Division of the Congress.

The last concluding paper of our program this afternoon is to be given by one of the allied medical (can I say) groups of the Health Service Division, and that is, by the nurse. It is a pleasure to present to you Miss Edna L. Foley, Superintendent of the Visiting Nurse Association of Chicago.

The Place of the Visiting Nurse in Industry

Edna L. Foley, R. N., Superintendent, Visiting Nurse Association of Chicago

To everyone who knows anything about the different phases of public health work, the "Visiting Nurse" is a well-prepared graduate nurse who goes into the patients' homes to give nursing care when it is indicated, to help the convalescent patient by instruction and advice or to put the patient in touch with other agencies when that is necessary. Naturally, her advice has to include the welfare of the family, for possibly the patient's condition has been caused

by a general disregard of rules of hygiene or is something that can be transmitted to others, unless the patient and relatives understand the necessary precautions that must be followed.

The advantage of employing only well-prepared and experienced visiting nurses is obvious to people who want experts in other special departments. Socialized medicine has made great progress during the past few years, and socialized nursing has more than kept pace with it. A good visiting nurse is a graduate, registered nurse plus many other things. She may be asked to give the most delicate kind of nursing treatment or she may be selected as an arbitrator between two types of investment. She may have to help find work for the children, because the father, her first patient and her real reason for going into the home, will be incapacitated indefinitely. She must know the resources of a community, its play-grounds, its public schools, special schools, hospitals, dispensaries, employment agencies and institutions. Last, and by no means least, she must know good nursing, for whether she actually gives care to a patient or teaches somebody else to give that care, she must know how it should be given. She must recognize symptoms and be able to make adequate reports to people most interested.

The Nurse Does Not Give Specific Medical Advice

No visiting nurse gives actual care or specific advice regarding treatment to patients who are not in charge of a physician. Anyone who stops to think understands that doctors are licensed to practice medicine; registered nurses are licensed to practice nursing; and the use of a specific drug or solution or even a treatment, except once as an emergency measure, is not tolerated by good nurses.

This is one of the big problems facing an industrial nurse; for the only distinction between an industrial visiting nurse and any other kind of visiting nurse is that the first works exclusively in the homes of the employees of the firm or firms contracting for her service. Years ago it used to be considered good business to hire a nurse. She was cheaper than a doctor and, in the minds of many people, just as good. A good nurse may be better than a poor doctor, but the better the nurse, the less willing is she to undertake responsibilities which the State does not recognize as coming within her province.

Therefore the industrial visiting nurse must have a physician's orders before she can care for his patients. Perhaps the patient has a private physician who will leave orders in the home or with whom the nurse can get in touch. The firm may employ a full-time physician who gives special orders for each individual needing the nurse's service. Sometimes a physician on part-time service leaves standing orders for simple conditions. The Visiting Nurse Association of Chicago has had standing orders sanctioned and approved by the Chicago Medical Society since 1913. It is taken for granted that these orders will not be used unless our work is known to the physician in attendance and that they will only be used on the first visit in order that the nurse may make the patient comfortable.

Such standing orders for industrial nurses should not include too many "p. r. n." (or "when necessary") orders for drugs, headache tablets, cathartic pills, etc. Most of us know, if we will but admit it, that a headache is but a symptom of something far more serious and while a tablet may be given once, in an emergency, it is a poor method to give the same worker tablets too often for the same thing. After the emergency is past, the worker should be got to the clinic or to the doctor's office or to the office of his own physician, the cause of the headache searched for and treated.

Many visiting nurses hold office hours in the plants by which they are employed, or maintain small first aid stations. In addition to giving first aid (and

here again it should be quite generally understood that first aid given regularly, daily, by an industrial visiting nurse is not an emergency), there should be standing orders if the physician himself is not present most of the time. By interviews, the visiting nurse, if she has had some training in social work, can be a very helpful interpreter to any employee who, without realizing it, is in pretty deep water.

Not long ago we were asked if we could not straighten out a misunderstanding between a firm and an employee who had been sick six months following an accident. The physician thought him able to work; the man insisted that he could not and threatened suit, for his arm had been badly injured. Visits to the home had elicited nothing but the sullen response that the man had not been helped by his firm.

As a last resort, the visiting nurse was sent out. It may have been her uniform, it may have been her personality, it may have been the sympathetic, business-like way in which she approached the man's need, but she had not been there long before she got his story. His arm had been badly injured; he had required hospital care and he had been on part-pay throughout the entire six months. All of his expenses—physicians, hospital, etc., had been paid, but until he refused to go back to work, no one from the firm had visited him and then the representative who came, scolded him. When the nurse reminded him that the firm had been most uncommonly generous and had done more than the law required, the man said scornfully that the firm had done nothing but send him a check once a week.

The Check Once a Week Was Not Appreciated

It took a long time to explain to this man that a check once a week was a pretty generous contribution and that if the firm had not done it, he would have been on the books of a public relief agency, after his first period of sick leave had expired. To the nurse the man admitted that he could use his arm some, but not as easily nor as readily as he had used it before the accident. In fact, he had not had ambition enough to try to use it and it was hard to say whether the arm was weak from lack of use or as a result of the accident. However, the man agreed to go back to work, but as a parting shot, he said, "If my boss had been half as much interested as you, a stranger, my arm would have got well faster." Almost any employer interested in human beings recognizes what most people would call the psychology of this remark.

That is only a sample of the attitude taken by a good many people of simple minds. They want understanding and sympathy just as much as they want bread and butter and a pay check, although without the check, neither sympathy nor understanding gets very far. We, unfortunately, are apt to put the worst interpretation upon anybody's actions, and we do not realize that folks are folks, whether they sit in the president's office or hold a laborer's job on the grounds.

A good nurse who is not an inspector for the firm nor too wholly in sympathy with the vagaries of the employees, can serve as a neutral go-between. She can explain the policies of the firm to the employee and at the same time bring back his re-action to the employer in such a way that the fair play, which both of them really want and need, is practiced. Everybody knows that contented workmen turn out a better product than discontented ones. Most of us admit that we can all stand big things, but the little things cause many human shipwrecks. The product of friction is usually more friction, just as the badly infected finger or arm may have begun as a simple prick overlooked and neglected.

The visiting nurse working in industry must understand other things besides

people. She has to understand how much the firm is willing or permitted to do for its employees. She has to understand workmen's compensation, firm insurance and other forms of benefits.

Fortunate, indeed, is the firm that can afford to employ a nurse to care for the families of its employees, for the gratitude of a worried workman is frequently greater when his wife or child has received care than when he, himself, has got it.

Statistics of all large visiting nurse associations show that women and children make up more than two-thirds of their patients. It has been asserted that the reason for this is that men, who are the natural wage-earners, do not give up until they drop and then they are so sick that hospital care is necessary; or that many sick men are sent to hospitals because their accidents make them fairly serious compensation cases.

This reason may be true, but I also believe that most men prefer to have their wives, mothers or daughters care for them. They do not like care unless they are seriously ill—typhoid or pneumonia, or have had a surgical dressing that must be done regularly. They and their women folks resent what they call the interference of an outsider. A visiting nurse frequently teaches a wife how to care for her husband and then apparently drops the case, although by going to the home occasionally to inquire for the patient or for the children or because she was passing by, she keeps very closely in touch with the patient's condition.

Experiences of the Visiting Nurse

The Visiting Nurse Association of Chicago has several visiting nurses who devote all of their time to home care of employees and employees' families. The entire expense of this is borne by the firms contracting for the service. It is given without profit by our organization for we realize we are in the field only to help people who need us, and we have but one grade of service to offer and that is our best. The chief advantages of such an affiliation are the supervision of nurses so placed, opportunities given them for contact with other public health nurses, substitutes are secured more easily and the nurses understand their work. Without exception, their services are more than welcome. The relatives of the dying wife of an employee of a very large firm never got over the fact that the firm cared enough for her husband to send a nurse twice a day to give care to his wife whom his employers had never even seen.

In another home where a visiting nurse was giving care to a patient, she heard the crying of a new-born baby. Surprised, she asked if there were a baby in the house and learned that it had arrived that morning and discovered that both mother and baby were sadly in need of care. While giving it (for the new patient proved to be the daughter and first grand-child of the pneumonia patient), a man with a badly infected arm came in and asked her to look at his hand. The visiting nurse discovered that he was employed by the very factory that sent her out to work among its families. When she asked him about his injury, she found that it was of forty-eight hours standing; the first dressing had been done in the doctor's office, he had been told to return, but he had been feeling badly, and his wife's condition and the condition of the home made it easy enough for him to put off a necessary trip. By getting a neighbor to stay in the home until the man returned, the nurse got the man back to the physician's office, where his hand received prompt and much-needed attention. Very likely the hand, neglected another twenty-four hours, would have caused a serious infection and what proved to be a compensation case of three weeks' standing might have dragged on for months.

The man was an ambitious young fellow, not ignorant of things belonging

to his trade, but in spite of the pain that he was suffering, he could not see that a day more or less made much difference with his hand; whereas a day might have meant that he would have lost the use of it. No amount of compensation could have made up to him for that.

The advice of the nurse, especially when it follows that of the physician but is given in sympathetic, more leisurely fashion and in more detail, is usually followed. Occasionally, however, we are surprised to see that without constant instruction and some assistance in getting the necessary treatment, perfectly good advice is not carried out because people cannot afford the treatment or really do not understand the value of it.

Not long ago, ten applicants applying for work were found by a certain dispensary to have 27 serious physical defects. In age, they ranged from 16 to 22; in education from eighth grade to college graduates. Their defects were listed as follows:

Ten Applicants With 27 Serious Defects

Eyes	5
Tonsils	7
Teeth	3
Heart	6
High blood pressure.....	2
Thyroid	1
Diabetes	2
Bright's Disease	1

One young boy did not know that he had diabetes. The other nine patients admitted that they had been told repeatedly of their conditions. A few had neglected to take the advice. The others really meant to take it as soon as they got to work and could afford to pay for the necessary treatment.

A good school nurse or visiting nurse following these patients would have helped them with the re-adjustment. Very often patients can afford to take the treatment if they realize the seriousness of the need. Other patients can be helped to get it, for it may be years before they can afford exactly what they require.

The treatment of a few of these patients would have cost nothing if they had been given instruction about right living. It is hard to wait until a boy or girl is ready to go to work before defects that will always interfere with their working efficiently are treated, and it is an unfortunate commentary on our school inspection and on the intelligence of the parents, that very serious conditions stand between the boy and his job.

Of course it is impossible to make any one individual—especially if he is of the type that knows more than the expert talking with him—understand that he should take care of his health. But if we could have more physical examinations of well people and more sympathetic, thoughtful follow-up of people who are not well but who can become so if they will carry out necessary treatment or instruction or both, we will reduce the daily tragedies that face the visiting nurses in their daily rounds. We know the treatment for tuberculosis; we know that diabetes can be helped; we know that early diagnosis and surgical treatment almost always help the patient who faces a tragic death from cancer. We know that a great many incurable heart conditions begin as very simple heart lesions following the infectious diseases of childhood.

By teaching this from the platform and in the home, we can get workers to assume some responsibility for their own health. Health, as a small boy once remarked, is something that you are fond of when you haven't got it. Health is a big asset to the average working man. There are very few people in the

universe like Steinmetz, who can do a tremendous piece of work in spite of bad health and poor physique, rather than because of it. If Steinmetz had not been an extraordinarily well-educated man, he probably would never have secured the opportunity to demonstrate his ability.

The visiting nurse in industry may not discover any potential Steinmetz, but she can prevent many of the hopeless tragedies that swell the pension lists of large firms and the charity lists of philanthropic agencies. She can help restore the worker to his job more promptly; she can also prove to the worker and his family that the firm is not a huge, impersonal creation, interested in the individual only when he is able to deliver 100 per cent of his energy, but that she, as one of its representatives, is the substitute for that old intimacy which existed in the little plant when the employer knew all of his employees and most of their families.

In some plants nurses are asked about conditions under which employees work and the lunch rooms, the rest rooms, particularly for women and girls, come under their supervision. If these are actually a part of the nurse's work, she should know something about food values, in order that the employees may be tempted to eat some of the things that are good for them as well as some of the things that they like. If the amount of dust in the work room, the amount of sunshine and of fresh air that are to be admitted are left to her, she ought to be able to deal with such problems. For the most part, however, safety engineers and frequently personnel managers handle these internal problems and the visiting nurse is exactly what her title pronounces her to be: a nurse who goes from the firm to the home of the employee, rendering whatever service the sick person needs—nursing care, instruction and advice, a friendly interpreter of the policies of the firm to the patient. She should not neglect to carry back to the firm a sympathetic explanation of what the patient's real needs and conditions are. In one sense the home conditions of an employee or his family are no concern of the firm. On the other hand, no good firm likes to be known as lacking in interest when the welfare of its employees is concerned and it uses whatever information the nurse may take back, solely for the benefit and welfare of this employee and possibly of others.

Whether the visiting nurse in the industrial plant works out from the staff of a local association of public health nurses or is employed by the firm, she should be well qualified to hold a difficult important post, for which she must be equipped by education, technical training and previous public health nursing experience.

General Discussion Upon the Papers

CHAIRMAN SHOUDY: Miss Foley, we thank you, but that is all too short.

The papers of Dr. Sawyer, Dr. Sayers and Miss Foley are now open for discussion.

DR. OTTO P. GEIER (Employees' Service Department, Cincinnati Milling Machine Co., Cincinnati, Ohio): Since Dr. Sawyer was good enough to say a gracious word about my paper when he started his, I can't help but rub his back as he has rubbed mine, pat it, anyway. I think it has really made, however, an interesting contribution to the problem that has been bothering all of us since industrial medicine has been established.

I hope that in succeeding years some way may be found of stimulating much greater activity and interest on the part of the managements in the furtherance of this conservation of power and life, so that we may succeed better than we have in prolonging life. Surely any of us who are working in industrial clinics, thinking of Dr. Sawyer's paper, may associate with that paper the necessity of selling the

daily service of the medical department to the executives. You as physicians want to popularize your medical departments and get your president and vice-presidents and chief engineer to use it, because if it is good enough for them, the employees will think it is good also for them.

In the group conference yesterday one man mentioned that his president came around to the medical department with a little rheumatism and within an hour and a half someone had examined the urine and found it all full of pus; and within an hour after that three teeth had been extracted and with no treatment those kidneys cleared up in ten days. So you might go on indefinitely. Some one else mentioned a case of a designing engineer who just at that time had an enormous problem because he was also involved in a patent suit; and he came to the medical department all in, saying, "Send me to some neurologist, I am going crazy; I can't sleep or eat." The man in charge had the good sense to take hold of the case and becalm him, particularly, and keep him out of the neurotic class and treat him as if he were a human being, and within a few weeks restored him.

Medical Advice That Had Great Value

The interesting part of that story is, done; but the comment of this particular engineer, after the end of the third week when the doctor said to him, "I suppose the medical department has justified the expense for at least one week by what they have done for you in this particular situation." He said: "Don't be silly. I don't want to be egotistical, but what the medical department did in that case would pay for the medical department's continuous service for six months at least, because the whole progress of the machine was unfortunately on me, and I was slowed up to a point where I couldn't think."

It has been to me and to Shoudy and all the rest of us who have been trying to think of this problem in the last 12 or 13 years, most difficult to know how we can gather the attention of worker and employer upon this subject, and I hope you may carry home with you at least that message that Dr. Sawyer gave you, one of the measures of efficiency is told by the mortality report. Then let me suggest one other, and that is the percentage of attendance in your industrial clinic, as a measure of the efficiency of the medical service in selling itself to the employees. I think it is a fair statement of fact that an inquisitor coming from one medical department to another, where he finds an attendance of half of one per cent of the total employees here today, he can say, "Here is an epsom salts man and an I. D. man," and the employee thinks nothing of it. Whereas, if the attendance works up to six, seven or eight per cent, you may know that the employees have profound faith in the nurse and the physician in that department. I think you will find it interesting, when you go back, to check your daily attendance upon the medical department. Then if you think it is too big, just stand and watch the procession for a couple of hours and see whether you would dare send any of them back on the jobs without giving them the necessary attention.

J. F. WULF (Western Electric Company): Dr. Sawyer's paper on medical examination for executives does not say what the family physician can do for us. That is to say, I do not believe that the family physician is always in position to give the complete examination that is possible in a company hospital, or an industrial hospital, and I am wondering whether he doesn't have to do that job in its final analysis.

CHAIRMAN SHOUDY: He possibly does. I can say, you are not all equipped as the Western Electric and the A. T. & T. is to do some of this diagnostic work. I happen to know what we do here in Chicago and also in New York and other offices where they have the facilities for diagnostic work. I think I can say for Dr. Sawyer and the rest of us who do not have all the facilities, that if we ask the executive to be examined by his family physician, we ask for a check on

what he does, to work with the family physician in checking over the men as they go for their physical examination, and if the facilities are needed, they go to the hospital and get them. But I can tell you frankly that all the industrial concerns do not possess the means for diagnostic purposes that you have out there, or that Dr. Watson has in New York City.

MR. WULF: I find he doesn't have the inclination to give you a thorough examination.

CHAIRMAN SHOUDY: We are trying to stir him up. I know from my own case, and I know from what the men said this morning, if he doesn't give us what we want, we will call him up and point out these things to him and say, "We would like to have you check on this, and if you can't get it, we will help you get it." If we have facilities that the family doctor doesn't have, we will ask him to let us submit these reports to him and interpret them with us. It is a question of education both from the standpoint of the doctor in industry as well as the family doctor in checking on the health of his patients.

What Is An Ideal Plan of Health Service?

DR. A. C. SELMAN (Kellogg Company, Battle Creek, Mich.): These papers we have listened to this afternoon have been very informative. I would like to ask a question of the doctor here. He states that the Health Service should be on a contributory basis, which I firmly believe. We are more apt to follow advice that we pay for than advice that is handed out on all sides. We can write to one of the daily papers, lay our case before it and they will tell us all about how to get well, without any cost to them outside of the postage stamp.

I would like to ask Dr. Geier if, in his experience or the experience of others, he has any sort of an ideal plan where this contributory basis is carried out—how it is worked, for example, roughly—how much do the employees contribute, because I am wrestling with that problem, and possibly others are. I think it is a very important thing, and I would like to ask Dr. Geier that question.

DR. GEIER: I hesitate to take any more time of the convention.

I have found in visiting plants that a very ideal plan which appeals to the average American workman, with his independent spirit (and that is the way we want to keep him) is for them to come in on a fifty-fifty basis on the whole plan of medical procedure as it holds for diagnosis through dentistry. In our plant I know we have helped sell the idea of health by having the employees include their costs of mutual aid. They have hired a professional man for the first time in their lives and they think well of their dentist, and, believe me, they use it and they use him. It was very interesting during the war when prices went up and salaries went up, how they finally boosted his salary. That was an experience with them; the cost to be shared on about a fifty-fifty basis as to all the work that is done in the plant on health except that which the industry should support of itself, the first aid, medical attention, diagnostic facilities and so on. That seems to be a comparable thing and easily comprehensible thing, the spread there of the cost between life insurance and sickness insurance and dentistry, say, as a base line, being the thing they should share on a fifty-fifty basis.

To those of you who are now on a contributory basis, I think this offers a wonderful opportunity for extending these finer facilities to your employees by selling them the idea of greater service in which they shall share. I wish I were in position to offer our men extension of our service, and the offer that they could help pay for that extension.

On the benefit plan, this little idea has helped us enormously in getting our reports back from those sick, since we give a man who sees his physician the first day, on the outside, when he is ill, an extra two dollars or an extra day's allowance of sick benefits. That has helped us not only in getting our reports in but

in getting the doctor on the job. We want early attention to disease. On the other hand, an inflexible rule which they have made themselves (and, believe me, if you don't let them help make the rules, they don't follow them) is if the man delays beyond the third day the report as to why he is away from the plant, every day that he goes beyond that and delays sending in his report as to why he is absent costs him an extra day of allowance of sick benefits, so that he is two dollars out every day he delays sending the doctor of the plant the report. That thing balances very well, and the two ideas are compensating. He could get something by doing it mighty well, by having the doctor the first day, and he would lose out a day or a week or two weeks by failing to get the report in.

E. E. BOSLEY (Goodyear Relief Association, Akron, Ohio): I would like to ask how many nurses you think would be necessary for 1,000 employees, and if 10 or 12 calls per day is a good average for a nurse to make?

MISS EDNA L. FOLEY (The Visiting Nurse Association, Chicago, Ill.): If 10 or 12 people are off every day and they are really actually ill, and your territory is scattered, you would need at least two nurses, and they would do better work if they each had cars. We have one plant in Chicago that employs three visiting nurses. It covers at least a third of the South Side of Chicago; in prosperous season it employs from 8,000 to 9,000 people. Each one of those nurses has a car; each one averages about 70 patients a month—about 30 to 325 calls a month—and the firm has often told us that the nurses more than paid for their own work because of the satisfaction in the homes, the speed with which really sick people were followed up promptly, and the speed with which some people who were acutely ill were encouraged to get well and get back on the job.

The Case of the Supposed Malingerer

Not so very long ago we were asked to see a man who had been off for six months with a badly injured arm. The doctor said he was stalling and could go back to work. The man said he couldn't go back. The visiting nurse, in talking with him, discovered that the arm was weak, but by no means helpless. It took her an hour to get him to go back to work, and she told him the firm had been uncommonly generous and decent. Just as she was leaving he said, "If my boss had been half as interested as you, a perfect stranger, have been in me, I would have been back at work three months ago."

I am not so sure he would have, because his arm was in bad shape. He received good hospital care, good dispensary care, but he didn't get the necessary exercises that he needed after he went home, and when he was able to begin to return to work, he wouldn't go because his feelings had been hurt because the firm hadn't once sent a representative to inquire for him. He said it didn't take very much brains or effort to send a check once a week. He thought the firm had been unusually generous and kind, and it took us an hour to make that boy see that a check once a week was more than a signature and putting a postage stamp on a letter.

I think you all realize that the number of nurses required for a plant depends upon the way in which you use them. If you use a good nurse to follow up absent people who are not sick, you can't keep her and neither can you keep your employees. If you use a nurse to follow up people who are reported ill, and who probably are ill, some slightly and some seriously, I think it depends upon your territory and the number of absentees you have.

In a very small congested territory one nurse can easily manage eight or ten absent employees a day, even if there is illness in two or three of the homes; but you can't possibly handle in a large territory eight or ten calls well without a car. You can't do eight or ten daily calls well even with a car if every one of those

patients requires a lot of nursing care. It all simmers down to just when you send the nurse: after the first day's absence or the second day's absence, or the third day's absence, or if you send her only when you have received a reliable report from the home as to the kind of illness or the reason for absence. We have found sometimes that one visiting nurse for a very large plant could do a good home service adequate at all times, except in epidemics, by not sending her before the third day of absence unless the illness was known at the plant or reported from a reliable source.

ADJOURNMENT

**SIXTEENTH ANNUAL SAFETY CONGRESS
NATIONAL SAFETY COUNCIL**

A. B. C. Sessions

Wednesday, September 28, 1927

C. L. PEAKE, Chairman

Director, Industrial Relations, American Radiator Company, Buffalo, N. Y.

The first meeting of the A B C Session of the Sixteenth Annual Safety Congress was called to order at three o'clock by the chairman, C. L. Peake, Director, Relations, American Radiator Company, Buffalo, New York.

CHAIRMAN PEAKE: Without any preliminary, as the hour is late, I shall call upon the first speaker of the afternoon, Mr. H. F. Webb, safety director, West Penn System, Pittsburgh, Pennsylvania.

Making Safety an Operating Problem—Not a Specialty

H. F. Webb, Safety Director, West Penn System, Pittsburgh, Pa.

It is recorded that one hundred and twenty-five years ago President Thomas Jefferson, being a gentleman of strong democratic principles, frequently laid aside state affairs and hied forth into field and forest in quest of whatever game might be flushed before his rifle. Further delving into the archives would probably discover records describing Jefferson's dissatisfaction with the quality of available gunpowder which had the peculiar habit of causing the leaden pellet to curve around the object at which his aim was directed, or failing altogether to explode. Anyhow, whatever the story, it is held a fact that Jefferson successfully persuaded his friend, E. I. du Pont, then living in France, to emigrate to America and manufacture a black sporting powder which would guarantee results and tend to preserve equanimity of disposition in the nimrod.

It is further recorded that during the year 1802 Mr. du Pont built his first powder mill on the bank of the Brandywine River, a few miles outside of Wilmington, Delaware, where it stands to this day. A peculiar building, this first powder mill, built of stone, with three walls, the open side facing the river, and a lightly fastened roof. The reason for this peculiarly constructed building is obvious, for although successive explosions may have removed the equipment and roof which required replacement, the walls were not only left standing, but acted as a guide that caused the debris to take an upward flight and into the river.

The moral of this story has suggested the subject for this paper—"Making Safety an Operating Problem—Not a Specialty." Were an open vote taken at this meeting on the question as to whether "Safety is an operating problem or a specialty," there could be but one response, since we of the safety guild know that the principles of this great humanitarian endeavor could in no way

be furthered by treatment of the problem as a "specialty." Therefore since there could be no survival of this world-wide enterprise were it considered a "specialty," we may wet sponge this phrase and deal strictly with the ways and means of weaving the safety threads into the industrial fabric.

Providing safe and healthful conditions in our industries should no longer be looked upon as simply welfare work, it should be a cardinal principle in every industrial operating program.

The manufacture of explosives, steel and other commodities, the generation and distribution of electric energy, the mining of coal, the operation of electric railways systems, and in fact the operation of all industries are fraught with dangers, and the exposure to hazards of each respective industry is such that every day risks of employment present a problem with which we must reckon.

Safety Work Calls For a Permanent Campaign

Some one has said, "Accident prevention is not a campaign; it is a permanent occupation of the enemy's territory." The truth of this statement has long been established, and now the safety engineer seeking success must know that a continual boring-in process, gradually gaining a permanent foothold here and there, counts much for progress. Perhaps a dangerous machine or a machine point of operation guarded today, a safety convert, either executive or rank and file tomorrow, and a slight change in operating method the next day, may be the net gain, yet such gain is permanent. Brief period campaigns, spasmodic efforts may accomplish an intended purpose, but the gain usually shrinks upon let-up much like a cheap suit of clothes exposed to the rain. Carelessness and other accident causes must be fought as a farmer fights weeds—with every available weapon *all the time*.

A measure of the success in accident prevention work depends largely on the amount of cooperation, goodwill, etc., that may be attained through the efforts of the safety engineer and his associates. It is necessary to popularize the movement to the extent of causing the safety idea to permeate throughout the whole organization, and to enlist this much needed cooperation from all departments and employees. Meeting and rubbing elbows with all employees on the job, at business and social functions, is of great value in building up a good company safety spirit.

Mechanical safeguards are both helpful and needful in the prevention of accidents, but are not entirely sufficient, for, while they reduce or eliminate the exposure to mechanical and physical hazards, they prevent only a fraction of the preventable accidents.

Accident prevention is more than an idea; it is something that must be learned, taught and persistently followed, if it is desired to establish a firm basis of economics in safety. Therefore education is the only practical means of bringing the individual to a realization of what an accident would mean to himself and his family—of his duty and responsibility with reference to the safety of himself and others, and to the protection of his employer's properties. The education must be continuous, constructive and interesting.

Several years ago I rounded out twelve years' service with the du Pont company, six years of which were spent in the study and application of safety methods to problems both common and special to this diversified industry. Being, as one might say, "an old-timer," during the period of incubation as a safety engineer, I must now confess that I overlooked many important safety measures which were a definite part of the operating code. But now just casual retrospect causes me to marvel at the way this company has, from the

building of the first powder mill, accepted and maintained safety as an operating problem. Several instances may be cited as noteworthy examples, viz.: barricading and physical separation of buildings, minimizing the number of persons in explosive buildings, safeguarding of all machinery and equipment, special clothing for workmen, operating safety rules, etc., etc.

To my mind this company stands out as a glowing example of one of the industries which has made "Safety an Operating Problem—Not a Specialty."

CHAIRMAN PEAKE: We shall take a few minutes after each paper to raise any questions and bring out any discussion that you have to offer on the subject covered by the speaker.

Some of you probably noticed in the *NATIONAL SAFETY NEWS* a number of months ago an article headed, I believe, "The Incidental Cost of Accidents," and in numerous sections it caused little short of a furor and we ought to have some discussion on that. Mr. Heinrich has arrived at some very startling conclusions on that subject.

We all have known for some time that there is a very decided incidental cost of accidents. I walked into a plant last week and some men rushed up to where I was for a stretcher. We went back and found that a crane, in backing out of the plant yard, had struck a high tension wire as it entered the power house, and they carried the crane operator out of his cab. When I got there the man was moving after artificial respiration had been used on him. In fact, the man reported to work the next day and would not be classed as losing time on account of that accident after spending the night in the hospital.

The significant thing was, when I walked down through that plant and out there in the yard, I didn't see a single man at work, although it was during working hours. Everybody had stopped work to ask somebody else why the stretcher was going through the plant. It was half an hour to an hour before work was resumed generally. There was also the time lost when the power was shut off throughout the entire mill.

The cost of that accident would probably run into the hundreds, or perhaps, with all the factors entering into it, thousands of dollars. It might have run even higher, and still there wasn't a single penny expended in that accident for compensation.

For that reason and on account of the fact that there have been a number of instances just like that, the paper which Mr. H. W. Heinrich is going to read will be of particular interest.

The Incidental Cost of Accidents to the Employer

H. W. Heinrich, Assistant Superintendent, The Travelers Insurance Company

When the fast-flying years have added another decade to the century in which we live and work, and when the existing nebulous practice of accident prevention has become a well-defined science, historians will record the conditions, acts and other factors that will be credited with having had major influence in the control of a most tragic waste in industry—preventable accidents.

Who shall now say what these factors are? We have the unselfish work of many individuals; we have national, state and municipal laws, regulations, codes and standards; we have the engineering staffs of great insurance companies; and we have the educational benefit of independent safety councils.

All these things now play a part. With the brilliant record of previous successful annual congresses, and the assurance that this sixteenth congress will surpass all others in real achievement, will anyone have the temerity to deny that a great measure of credit must be granted to an organization of nationwide scope, unselfish in its aims, efficient in its results, eager and enthusiastic,—

to the National Safety Council—and to you, its loyal members? But the National Safety Council and the engineers of insurance companies and other organizations that do not have legal authority must depend, to a great extent, upon *educational* methods. These methods are successful only in so far as they win the cooperation of the *employers*.

Compensation laws place the burden of accident responsibility upon the employer of labor. Educational methods reach the *employee* only through the *employer*. The guarding of machinery must be accomplished with the cooperation of the employer. The elimination of unsafe methods and processes is in the control of the employer. I assert that the *entire structure of accident prevention rests upon employer-executive participation and action*.

The prevention of injuries to employees is a most commendable humanitarian work. It is worthwhile for itself alone, and it will continue to progress on its own merits. We, however, are a nation of business men. Is it not logical, therefore, to assume that we shall reach our goal much more speedily if we add to the humanitarian basis of accident prevention a further foundation in the way of "business principle"—an incentive of a business or financial nature?

I maintain that *accident prevention is good business* and is entirely defensible *even from a purely mercenary viewpoint*. I hold also that this is *not universally recognized today* and that until it is accepted as a fact our progress is *bound to be retarded*.

The Accident Situation Calls For Emergency Action

American business executives have never failed to surmount obstacles in emergencies. During and shortly after the world war, when dyestuffs were unobtainable, immigration checked and labor scarce, and when wages were sky rocketing and delivery of raw materials uncertain, our executives made good. They did so because they wanted to and because they had to. The accident record of today constitutes another emergency *just as vital as many of the industrial problems that were brought on by the world war*.

I offer to these executives the "incidental" or, more correctly, the hidden or indirect, but none the less real, employer-cost of accidents as an incentive that should create the desire to take preventive action and the feeling that it *must* be done.

The many and varying estimates of the annual cost of industrial accidents are stated in terms of billions of dollars and are generally based on the lost TIME of the injured worker. This is largely an employer loss inasmuch as the employee is partially compensated, but it is not all of the cost to the employer. Travelers engineers estimate the remaining so-called "incidental" cost to be *four times* the compensation and medical payments. Expressed in another way, compensation payments constitute only one-fifth of the total employer accident-cost. This estimate is based upon careful research which now includes 10,000 specific cases taken at random from Travelers files. Its accuracy has been demonstrated by application to scores of specific plants.

I do not contend that it holds true with regard to any single industrial accident nor to any one individual plant, and I grant that in nation-wide application the ratio may vary; yet it has already been tested sufficiently to provide approximate confirmation of the facts.

This four-to-one ratio should prove to be a powerful stimulus to preventive action. It may come as a distinct shock, pleasant or otherwise—

To statisticians who will find by its use that cost generalities in billion-dollar terms are trebled or quadrupled;

To employers who complacently accept average losses as incidental to their operations;

To employers who do not worry about accident-cost because "they are compensated by insurance";

To employers who feel that "overhead-cost" is only slightly affected by accidents;
 To employers who consider accident prevention as something "for the other fellow to do";

To employers who are apathetic towards accident prevention or who are mildly interested only because of humanitarian reasons;

To employers who cannot "afford" to establish safety on an organized basis;

To safety engineers who wish to prove that their work has monetary value;

To insurance or other salesmen who will find that it enhances the value of the service that they sell.

The calculations from which this ratio was derived were based on the factors given here.

Factors in the Incidental Cost to Employer of Accidents to Employees

(Excluding compensation and liability claims.)

(Excluding medical and hospital cost.)

(Excluding insurance premiums.)

(Excluding cost of lost time, except when actually paid by the employer.)

1. Cost of lost time of injured employee.
2. Cost of time lost by other employees who stop work—
 - (a) out of curiosity,
 - (b) out of sympathy,
 - (c) to assist injured employee,
 - (d) for other reasons.
3. Cost of time lost by foremen, supervisors, or other executives as follows:
 - (a) assisting injured employee,
 - (b) investigating cause of accident,
 - (c) arranging for injured employee's production to be continued by some other employee,
 - (d) selecting, training, or breaking-in new employee to replace injured employee,
 - (e) preparing state accident reports, or attending hearings before Industrial Commissioner.
4. Cost of time spent on case by first-aid attendant and hospital department staff, when this time is not compensated by insurance.
5. Cost due to injury to the machine, tools, or other property, or to the spoilage of material.
6. Incidental cost due to interference with production, failure to fill orders on time, loss of bonuses, payment of forfeits, and other similar causes.
7. Cost to employer under employee welfare and benefit systems.
8. Cost to employer in continuing wages, in full, of the injured employee, whereas the services of the employee (who is not yet fully recovered) may be worth only about 50 per cent of their normal value.
9. Cost due to the loss of profit on injured employee's productivity and on idle machines.
10. Cost of subsequent injuries that occur because of the excitement or weakened morale due to the original accident.
11. Overhead cost per injured employee—the expense of light, heat, rent, etc., continues while injured employee is a non-producer.

This list obviously does not include all points that might well receive consideration, although it outlines the vicious and apparently endless cycle of events that follows in the train of accidents. The application of this set of factors to actual cases is illustrated by the following typical examples:

Example No. 1

Total cost of compensation and medical aid.....	\$209.00
Total additional <i>incidental</i> cost, paid directly by the employer.....	937.09

Note A: The following accidents occurred on a building erection job:

No. of Accidents	Type of Injury and Cause	Compensation and Medical Cost
3	Fractures and contusions, material hoist.....	\$106.00
18	Rivet burns, cuts, bruises, miscellaneous operations.....	76.00
21	Falling materials, miscellaneous operations.....	15.00
30	Slips and falls, miscellaneous operations.....	12.00

Note B: The incidental cost was computed as follows:

Time lost by injured employees, paid directly by the employer.....	\$116.00
Time lost by other employees in consequence of accidents.....	310.00
Time lost by foremen and superintendent as a result of the accidents	78.00
Property damage	158.00
Payment of forfeits (2 days) for failure to complete job on time	200.00
Portion of overhead cost loss during delay due to accidents.....	75.00

Note C: An interesting point developed by this analysis is indicated by the relatively high cost to the employer due to the lost time of employees *other than those who were injured*. This was due chiefly to one of the material hoist accidents. Shaftway enclosures were not maintained as good practice demanded and one employee, who was working in the vicinity of the hoist, was injured when he carelessly allowed a heavy plank to project into the path of the ascending car. The hoisting cables were torn from their fastenings, permitting the car to drop. Labor on the upper tiers was necessarily suspended pending completion of repairs.

Another feature worthy of note is the loss due to forfeits. The contractor himself estimates that delays caused by the accidents interfered with the completion of the job at the time agreed upon, thereby penalizing him to the extent of \$200.

Example No. 2

Total cost of compensation and medical aid.....\$ 66.00

Total additional *incidental* cost, paid directly by the employer..... 275.00

This example was obtained from the records of a hardware manufacturing plant and covers an experience of six months.

Note A: The following accidents occurred:

No. of Accidents	Type of Injury and Cause	Compensation and Medical Cost
1	Lost nail of index finger, punch press.....	\$61.50
1	Lacerated forearm, baling press.....	4.50
9	Cuts on hand, handling shered metal.....	0.00
10	Slips and falls, miscellaneous operations.....	0.00
	Dropping objects, miscellaneous operations.....	0.00

Note B: The incidental cost was computed as follows:

Value of labor and material in connection with canceled order.....	\$107.00
Time lost by injured employees (paid by employer).....	36.00
Time lost by other employees in consequence of the accidents.....	34.00
Cost of repairs to stamping dies.....	33.00
Unearned wages (employer paid slightly skilled employee ten days full wages—\$6:30 per day—receiving in return unskilled labor worth \$2.50 per day).....	38.00
Time lost by foremen and superintendent as a result of the accident	27.00

Note C: The *visible direct cost* in this example lies in the more serious but relatively infrequent accidents, while close analysis shows that a large part of the "incidental cost" is due to the trivial injuries.

One of the 32 injuries described on the employer's records as "slips and falls—dropping objects," occurred to a tool-maker, who, because of laxity of supervision, was indulging in a bit of gossip while operating an engine lathe. His attention being temporarily diverted from his work, he allowed the lathe tool to feed into a shoulder of a jig that was mounted on the face plate of the lathe, tearing the work loose from the face plate clamps and causing it to drop upon and jam his fingers between it and the lathe bed.

The jig (original value \$48.00) was ruined. I have not included the cost, however, inasmuch as it was merely being repaired for stock and the actual value at the time of the accident was difficult to ascertain.

What is of more interest, however, is that this skilled toolmaker was unable, because of his bruised and bandaged fingers, to undertake the building of a set of blanking dies that were ordered the same day that the accident occurred.

Another toolmaker was employed while the injured man was given work requiring less skill.

Thus, for a time, the employer paid the wages of two skilled men and received in return little more than the labor of one.

The punch press injury is also of interest from the viewpoint of incidental cost. Orders had been issued to the effect that the press room foreman must be called in the event that stock became jammed in the dies. These orders were not rigidly enforced and one of the press operators, observing that a blank had been pulled up by the punch and obstructed further feeding, attempted to remove it with a metal rod and accidentally stepped on the clutch pedal at the same time. The dies were thrown out of alignment and seriously sheared and at the same time the employee's finger was nipped under the spring stripper plate.

The delay incidental to repairs in this case was sufficient to cause cancellation of the order on which the operator was working, thus creating a labor and material loss of \$107, according to the manufacturer's statement.

Example No. 3

Total cost of compensation and medical aid.....\$ 0.00

Total additional *incidental* cost, paid directly by the employer..... 154.00

Note A: The incidental cost was computed as follows:

Cost of wasted materials\$ 93.00

Cost of time lost by injured employees..... 37.00

Cost of time lost by employees *other* than those injured..... 24.00

Note B: For a period of 60 days, following the inauguration of a no-accident campaign in this chemical plant, there was not a single compensable injury nor one that required professional medical treatment. There were, however, 66 *minor accidents*, chiefly acid burns, due to the carelessness of employees when handling caustic or corrosive materials.

Note C: One of the men, who, although not seriously injured, was nevertheless in no fit condition to carry on his work, was a skilled chemist and was being depended on to provide an analysis prior to the fulfillment of a large rush order. His absence forced the use of a less skilled employee, who bungled the job. Before discovering the error in the analysis the work of filling the order was begun, resulting in waste of materials, dissatisfaction on the part of the customer because of delay in the delivery of goods, and minor incidental cost.

Example No. 4

Total cost of compensation and medical aid.....\$ 59.00

Total additional incidental cost, paid directly by the employer..... 262.00

Here is the cost record of 36 injuries in an average woodworking plant manufacturing interior trim and doing some cabinet work.

Note A: The following accidents occurred:

No. of Accidents	Type of Injury and Cause	Compensation and Medical Cost
1	Hand severely cut, jointer.....	\$ 51.00
15	Cuts and bruises, handling material.....	5.00
10	Slips and falls and falling objects, miscellaneous operations.....	3.00
1	Finger slightly lacerated, band saw.....	0.00
1	Bruised forehead, struck against machine.....	0.00
8	Miscellaneous cuts and bruises, hand tools.....	0.00

Note B: The *incidental* cost was computed as follows:

Time lost by injured employees in consequence of accidents (paid by the employer).....	\$ 48.00
Cost of time lost by other employees.....	116.00
Time lost by foremen and superintendents, as a result of accidents.....	79.00
Spoilage of material.....	11.40
Broken and damaged tools.....	7.60

Note C: Here again a significant feature of the example is that the *incidental* cost due to the time lost by employees, other than those who were injured, was greater than the *incidental* cost of the time lost by the injured employees. A part of this cost occurred because fellow workers crowded about in sympathy or curiosity, or while giving assistance to the injured employees, but the major portion was due to the fact that a certain foreman, who for a period of one week was obliged to operate a production machine, was not readily available for consultation. This situation existed as a result of a preventable accident on the partially guarded jointer. This machine was being used at the time as a moulder and it was vital that production be continued. The foreman happened to be the only remaining available skilled operator. While engaged in operating the jointer considerable delay and confusion existed in his department. Employees in need of instruction and advice were obliged to wait. Loss of production is not included in my estimate of *incidental* cost, but the lost time of uninjured employees in itself constitutes an item worthy of consideration.

The Examples Are Confined to Incidental Costs

You will observe that these examples include no fatalities, dismemberments or permanent injuries. Such omission is deliberate and does not affect the ultimate ratio. To be sure, there are many fatalities resulting in a direct cost of thousands of dollars against a relatively small *incidental* cost. On the other hand, I can cite just as many or more cases where a minor accident costing but a few dollars in compensation or medical aid has caused an *incidental* loss of staggering proportions as illustrated by the following:

An employee of a steel-construction contractor who was tending the guide rope while a huge steel girder was being hoisted stumbled, bruised his shin, lost his grip on the rope, allowing the girder to swing and strike against a column. The jar displaced the clamps, causing the girder to tilt, slip and crash down upon a sidewalk shed, demolishing a section of scaffolding in his descent and damaging a hoisting engine seriously. The resultant property damage and delay cost the contractor several thousands of dollars over and above the medical cost of treating the employee's bruised leg.

*Accident-cost in the aggregate, as measured by compensation and medical payments,

is made up of the greater volume of low-cost minor injuries, rather than the lesser volume of high-cost fatalities and serious injuries.

Were it fair to do so I could build up an apparently stronger defense for this four-to-one ratio by citing cases such as the following:

1. A premature quarry blast, set off inadvertently by an employee who became startled because of a slight injury, resulted in serious damage to six drill rigs and a steam shovel. This equipment was buried under tons of rock and the total loss was over \$10,000.

2. Flooding of a tunnel occurred directly as the result of a minor accident. The loss amounted to over \$25,000.

3. A slight injury to a lineman caused him to drop a coil of wire, resulting in a short circuit. This led to claims against the power company and a loss of several thousand dollars.

4. An injury to an engineer, who was adjusting the stuffing box of a large steam engine while it was in operation, caused him to drop a wrench into the path of the moving crosshead. The cylinder head was broken, the engine was thrown out of alignment and badly wrecked.

5. An explosion of a japanning oven (loss \$17,000) was the result of an error on the part of a workman whose attention was diverted by a minor accident.

The original estimate of incidental cost was published in 1926. I refer you to *The Travelers Standard*, December, 1926, issue, to the proceedings of the Tenth Annual Industrial Congress, New York State Department of Labor, page 244 to 257 inclusive and to *Manufacturing Industries*, January, 1927, number.

A Tendency Toward a Higher Rate of Incidental Cost

From further research we draw the following conclusions:

1. There is a tendency towards a still higher ratio of *incidental* cost to *direct* cost.

2. For every accident involving compensation or professional medical cost there are approximately thirty minor accidents that receive merely first-aid treatment.

3. The cause of fatalities is the same cause that predominates in the minor injuries, from which we conclude that if we prevent minor accidents the fatalities will take care of themselves.

4. The "incidental" cost of non-compensable accidents is equal to the total direct cost of all compensable accidents. On the basis of "incidental" versus "direct" cost these non-compensable accidents in themselves establish a one-to-one loss ratio. These are the type of accidents that are not usually reported either to State Compensation Boards or to insurance companies. Example No. 3 in this paper well illustrates this point.

5. For every actual injury that occurs there are several "near" accidents resulting in property damage, spoilage, lost time, and other cost difficult to calculate with exactness.

6. Physical hazards are playing an ever decreasing part in the occurrence of accidents. This is well demonstrated by the many cases where plants with unguarded machines but with careful workers have fewer accidents than well guarded plants with careless employees.

Although my subject is not that of how to prevent accidents, it may not be out of place to say that prevention depends upon two essential elements:

First: An analysis by a trained safety engineer.

Second: The will to take action on the part of the employer.

The first of these conditions exists today; the second is in vital need of additional strength.

The employer must be awakened. He must realize that the prevention of accidents is good business. He must so endorse it, give it his backing, and must place

it in his plant on a par with production and sales. To do this he needs a newer and stronger incentive than he has heretofore had.

Let us continue our educational activities, let us continue our work on safety codes, bulletins, and safety literature, let us continue to work with the children at school and the workers in the plants; but above all let us recognize that this problem of ours can be best and most speedily solved through and only through the active and enthusiastic cooperation of the employer-executive.

Believing that it will assist in the attainment of such cooperation, I respectfully submit the "Incidental Cost of Accidents" for your consideration.

CHAIRMAN PEAK: We will take a few minutes now for discussion on this important paper rather than wait until the end.

At the time this study was originally published in the NATIONAL SAFETY NEWS the interests which I represent sent out to all of the managers of the various units and asked for reflections from them as to what they thought of the findings on the incidental cost of accidents, and I was much interested in the replies.

They ranged all the way from statements that they were way out of line to the assertion that they were not nearly enough. That perhaps is a reflection of the opinions that are going on inside the various heads in this room this afternoon. Let's quiz Mr. Heinrich on some of his findings, because we are all practically agreed that there are such costs. I know there will be plenty of discussion of this question when you get out in the corridor, but the best place to discuss it is right here.

Not Less Than Eleven Factors Are Counted

MR. HEINRICH: You have a list of factors, as I say, eleven of them. Sometimes you will have one hundred if you go into the fine points. I will be glad to give you a copy of the form used by the foreman in setting down the data. It is pretty hard to get on that card the whole number of men who stop work at the same time.

If somebody starts to ask questions at the time of the accident you will find that two, three, four or five men looking over the jig found it was smashed to pieces. As soon as that man went to the first aid station, two or three men gathered around the lathe to view the wreckage. They wanted to see what happened, and another man made a sign to take it off the machine and throw it into the scrap heap. Another man went to look up the old pattern to see if they could get another casting made. All these things should be set down on paper.

You will know the value of the jig that was ruined. Set that down. You know the property damage. Ask all those questions when the accident happens. Set them down on a form and then compute the total cost. This cost and the compensation and medical costs should be compared to get the incidental cost of accidents.

There is in every plant an item of expenditure that is called overhead cost. It includes light and rent and heat and other things like taxes and incidentals. These are made for the purpose of permitting men to earn money for the employer. If that light and rent and heat expense continues while the employee is not there you have a partial man-hour overhead cost that is lost, that is not productive, it being an expense without a commensurate return. Whenever a minute or an hour or a day is lost which is due to an employee's injury, a certain percentage of overhead cost must be charged to the accident. That applies to the man-hour profit as well as to overhead cost.

If your concern makes ten thousand or a million dollars a year and you have some thousands of man-hours working in that plant, then the total number of man-hours divided into the total profit indicates a man-hour profit; and if any one man, whether he is a piece worker or a day worker or a salaried man, is not producing because of an accident, you are not earning that man-hour profit, and that is also a logical and reasonable charge to the accident itself.

The question that might arise as to cost due to refusal of a machine operator to let some other workman use his machine, due to labor differences, may be a bit away from this particular subject. Such difficulties will not arise if the plant is run properly by supervisors who know what proper supervision is. The supervisors in a properly run plant are men who know how to convey orders to the employees in such fashion that they will get results. The question of skilled and unskilled labor, which will not permit of rebuke or reprimand or discipline, enters into the question. The point can be made and the results can be secured if proper understanding of supervisory duties exists in the personnel. You might find it necessary to grab a man by the shoulder. You can do that in some cases. You can't do it in others. You may have to persuade a man. You may have to reason with him and explain how the profits of the company are neglected, but however you go about it, there is a method in any kind of a plant and in any kind of a situation to convince a man why he must follow the orders of his plant superintendent or foreman.

CHAIRMAN PEAKE: We are very much indebted to Mr. Heinrich for presenting this subject and also for his added remarks.

Three times within the last twenty-four hours I have participated in a very lively discussion on the question raised in connection with discipline and accident prevention.

The next speaker is going to speak on the subject of discipline. He is Mr. G. H. McClain, safety engineer, Jones & Laughlin Steel Corporation, Pittsburgh, Pennsylvania. I have great pleasure in introducing Mr. McClain.

How Should Men Responsible for Accidents Be Disciplined?

**G. H. McClain, Safety Engineer, Jones & Laughlin Steel Company,
Pittsburgh, Pa.**

My subject framed as a question infers that discipline would naturally follow when responsibility had been determined, yet we find after making some investigation that the application of discipline for accident responsibility is not as general as it might be, or ought to be, in industry at large.

Discipline, within itself, is a fundamental social necessity. Most of us can remember our childhood days and the occasional proverbial trips to the woodshed with father. At the time this discipline was applied we were not wholly in sympathy with it, but as time goes on and our judgment becomes more mature, we are more or less convinced that father was right. These stringent methods of discipline not only applied to our home life but to our school life, as well.

Perhaps one of the best illustrations of the application of discipline is found in any well organized army. Those of us who had occasion to serve in any military capacity during the late unpleasantness, can vouch for the truth of this statement. Any well trained, well organized army will soon degenerate into an ungovernable mass, without respect for rules, orders or officers, if discipline is relaxed or removed.

Another example of applied discipline is in our well organized railroads. Employees know that infraction of certain rules carries with it certain measures of discipline. In fact, our whole social structure is founded upon discipline. Every law in our city, state and federal codes pertaining to the protection of the rights and properties of the people carries with it certain penalties or disciplinary measures. We believe you will agree with us that it is absolutely essential and necessary to have discipline in any industry or business organization. If a man does not properly use his time for the benefit of his employer he may rightfully expect discipline. If he persists in reporting late to work or

violates any one of many other well established rules he knows that he may expect to be punished for it in some way.

The subject of the application of discipline for accident responsibility has many angles. For instance, the determination of this responsibility, the application of discipline when the man responsible for the accident has been injured or when through his negligence someone else has been injured, and so on.

It is the hope and dream of every safety engineer to be able continually to reduce the number and severity of accidents to the men for whom he is responsible. To gain this end he uses various plans and methods. He strives to improve working conditions, to reduce or eliminate mechanical hazards and so to educate the men that they will know the right way and do the right way. But no safety engineer can truthfully say that all of his men do the right thing or the right way all the time. It so happens that human nature has many variations. Men differ as to temperament, intelligence, ambition, etc., all of which complicates the situation. It would seem that a man would always think enough of his own physical welfare and those depending upon him not to take the chances that lead to accidents, or not to do something through his own negligence and carelessness, or fail to do something, which would contribute injury to his fellow workmen. Yet this is not the case. The accident records are full of cases in which men have done things or failed to do things which directly resulted in injury to themselves or to their fellow workmen. It is principally on this phase of the situation that discipline plays its part.

Industry Progresses by Definite Rules and Regulations

It is needless to say that no industry can get very far without a definite set of rules and regulations. This pertains to accident prevention as well as production, conduct and other things. It is fortunate that a large majority of men do things the right way and it is not necessary to discipline them. It is fortunate for all of us that an extremely small percentage of people ever attempt murder. This also applies to our highways. A vast majority of drivers of automobiles recognize the necessity of carefulness and observe traffic rules and laws and are repaid by keeping their names in the city directory and off of the tombstone. Yet there is enough violation of rules and laws by a very small percentage of wrong doers that it is necessary to maintain a vast organization of peace officers, judges, etc. The same applies to the violators of safety rules and regulations in industry.

Before discipline can be applied, in event of an accident or a near accident, it is necessary to determine the responsibility. In some cases this is apparent and easily determined and in others it becomes more complex and difficult. Extreme care must be used when placing responsibility, or discipline is likely to do more harm than good. I recall an instance where a fatal accident occurred in a large industry employing several thousand men. The department in which this man worked held an investigation and fixed the responsibility on his foreman. The safety engineer did not agree with this. He wrote his report on the accident, took certain correspondence with him and went into the office of the superintendent. In his report he placed the responsibility upon the superintendent. Naturally when he read this report, to use a trite expression, he hit the ceiling and demanded immediate explanation. The safety engineer then placed in front of him certain correspondence, including recommendations for mechanical improvements, dated about two years previously which would have prevented the fatal accident. Of course this is an extreme case and it is a long way in responsibility from the superintendent to the fore-

man, but it is no uncommon thing to encounter an attempt to throw a smoke screen by placing responsibility on some subordinate or some workman.

In most cases, however, we find that the responsibility for an accident can be placed upon the foreman, the injured man himself or a fellow workman. The foreman sometimes allows working conditions to exist which he knows are unsafe but under the pressure of getting his work done he lets it go by. Again we find that a foreman is compelled to accept the responsibility of an accident due to the fact that he has not properly instructed or trained his men. I am sure you will agree with me that one of the most important, if not the most important thing, that a foreman can do to prevent accidents in his department is to give specific instructions as to the way the work shall be done in order that it may be done safely, as well as to point out to them in a definite way the hazards that they may encounter which are not directly connected with their work. It is indeed difficult to place the responsibility of an accident upon a workman or fellow workman when he has not been specifically instructed as to the right and wrong way to do work.

Carelessness Is a General Characteristic

Then again we frequently encounter the man who is inherently careless and does not take the trouble or the time to do his work safely. We believe that is largely a characteristic of the human race. We are prone to follow the course of least resistance. We may walk within ten feet of a nail sticking up in a board and because it requires a few steps out of our way, we are inclined to pass it up. We may observe an unsafe condition but because it requires a little time and effort to have it corrected, we may pass it up and say or do nothing about it. We may be working with a hammer or chisel that has a burred end, but since it requires us to walk to the blacksmith shop and back, we may continue to use it, even though we know it is unsafe. Therefore, we say that there are, without doubt, a number of men who know the right way and yet fail to put into practice what they know. Thus, as we have said before, the placing of the responsibility for an accident is an important and at times a very difficult proposition. But when the responsibility has been placed, we are confronted with the necessity of applying the proper discipline.

In the dictionary we find the word "Discipline" defined as follows: Chastisement: to train to obedience or efficiency; to regulate; to chastise.

As applied to the discussion in hand, we would say that the prime function of discipline is to train to obedience and efficiency with reference to doing work safely. We do not believe that the idea of chastisement enters into this to any great extent. Discipline by its very nature inflicts some sort of unpleasantness upon the one being disciplined. If it did not do this it would not be discipline. To the most of us, three or four months of confinement in the county workhouse would be rather severe discipline, yet we all know it to be a fact that a certain class of men commit crimes in the early part of winter in order that they may be certain of food and shelter during the rigorous winter months. To these men confinement in the workhouse or jail is not physical or mental hardship at all. What may be discipline to one, may not be to another.

Industrial discipline may range all the way from a reprimand to discharge from the company's employ. The man responsible for the accident may be a foreman or a workman who has spent many years in the service of his company and in most respects has been entirely satisfactory. His knowledge of his work is an asset to his employer and discharge in his case might be unwise. He may be of such intelligence and temperament that a reprimand from the proper person would be most effective. And again it might be wise not

only to reprimand him but to suspend him from employment for some time. The suspension of employment is a thing that must be considered in the life of a man's dependents. If he has a large family and he finds difficulty in keeping abreast with his rent, grocer's bills, etc., a few days would be sufficient. We have known instances where a department head, after thoroughly informing a man as to why he was being disciplined and his relation to the accident or near accident, sent the man away with instructions that he was to go home and stay there until he was sent for. The uncertainty of this proposition makes the discipline more effective.

Again it may be that the man responsible for the accident is what we usually speak of as a "floater" and his services can be dispensed with without much difficulty. In a case of this kind it is sometimes a practice to suspend the man for a week. The idea in this procedure is that if he were discharged immediately he would have a right to expect his money and would probably go on his merry careless way to be injured or cause injury some place else.

Should the Injured Man Be Further Disciplined?

The question arises as to whether or not a man who has received an injury which was caused by his own carelessness, has been sufficiently disciplined by the injury itself. In some cases this may be true and in some cases it may not. A case recently came to our attention of a man who, in a fit of temper, dropped a plank from his shoulder to the ground without any attempt to let it down in a safe manner. The plank rebounded, striking him on the foot and causing a slight fracture of one of the instep bones. The man's conduct previous to this accident had not been satisfactory and it was the opinion of those interested that the injury itself was not sufficient discipline. When the man was discharged from the medical department and reported for work he was then sent home by his foreman for two weeks longer. The man was an old employee and had begun to act as though the foreman's orders and instructions were not for him. However, since this occurrence his attitude has changed and he is a much better employee in every respect.

Another phase of the application of discipline is, what should be done with the man who is directly responsible for the injury of another? A method that we have tried out and find to be quite effective is to suspend the responsible party from employment as long as the injury prevents the other man from returning to work. Of course there are occasional exceptions to this method, but in a general way it is quite effective.

In concluding, let me again point out what we consider the essentials of applying discipline. First, that great care be exercised in determining the responsibility for an accident; and second, that equally great care be used in applying discipline. It must be done only after the man himself understands clearly and thoroughly why he is being disciplined and then not in any heated or argumentative way, but it should carry a certain amount of dignity and finality that will impress the man that there is a law and a justice that is greater and more powerful than he and that it will operate at all times for the benefit of the largest number of men.

CHAIRMAN PEAKE: If the discussion and questions that have been raised at previous sessions are any indication, we have some strong comebacks to the previous speaker.

MR. McCLAIN: I should like to ask some of these fellows how they would discipline that foreman who failed to protect his track? There was no accident. How would they do it? I would send him home for a couple of weeks and somebody else would do something else with him.

EDWARD A. WORD (National Carbon Company, Fremont, Ohio) : Discipline applied to a man for disobeying the safety rule could not get as good results as by educating the man to work safely. New York City has been called the melting pot, and I want to cite one instance that I have dealt with personally.

Three years ago one of our departments, the tamping department, similar to a punch-press department, had an abnormal amount of lost-time accidents. It was one of the worst departments in the service of some fourteen plants belonging to the National Carbon Company.

In an endeavor to clear up and correct the lost-time accidents, we started by firing the men who received these injuries. We fired six men, but we didn't stop the accidents until the foreman himself was sold to safety. Now, it is over two years since we have had a loss in that department and I want to state that about 90 per cent are of foreign extraction in that department and about 70 per cent are foreign born. Some of them speak very little English.

A foreman must talk plainly to his men in dealing with anything that has to do with safety and I believe by this method we can get across the message of playing and working in a safe America.

R. S. BONSB (Standard Oil Company of New Jersey, New York, N. Y.) : I should like to know who is to determine whether the man was neglectful or responsible for the accident? Should a group of foremen pass on it or should the safety committee pass on it or should the man injured pass on it? In your opinion, which is the most efficient and definite means of determining the man's neglectfulness or his responsibility?

Determining the Man's Responsibility

MR. McCLAINS : There is more than one way to do it. I may practice one method and I don't necessarily recommend that it be used. I think if it was up to me I would have a little case in court perhaps, down in the superintendent's office. I wouldn't pass up the department heads where that man was working, because according to the organization blueprints, that superintendent is the boss, and I would go down to him and say, "Harry, you know what happened last night. Are you going to pass it up?" I have asked that man to stay over and investigate it. We hear everybody's side of the story. It is probably the safety engineer's job to ask suggestive questions that will lead on to the probable cause without showing his hand or anything of that kind.

I don't mean to try to evade your answer. I have gotten our department heads where they want me in on it, but I wouldn't do it without them. It is primarily their job. I am apparently unconcerned about the whole thing and try to act like I am over in the corner. I ask them how they are going to discipline him and they can't pass it up that way.

MR. BONSB : It is a tender subject, but you can't be tender. What is the best way to determine whether that man is responsible? Who is in the best position? That is what I am trying to find out. Who is in the best position to determine whether that man is responsible? And if he is responsible, it is very easy for the man to whom that man is directly responsible to apply the disciplinary measures. Have I made my question clear? It is a question of fixing the responsibility, because the responsibility must be fixed before the effective disciplinary measures can be applied.

E. F. BLANK (Jones & Laughlin Steel Corporation, Pittsburgh Pennsylvania) : I think probably Mr. McClain's modesty prevents him from explaining it any more fully. He explained that when a serious accident occurred they would hold the little courts of inquiry, at which all the witnesses are present and the man who is responsible for the accident. The safety engineer in that case, more or less, cross-examines the witnesses to the accident and the matter is probably brought up in the talk with

the injured party. After the questions have all been answered it is pretty clear in the mind of the superintendent or the safety engineer where the responsibility lies. Mr. McClain leaves that up to the department heads and the thing is probably decided by the department heads, but cooperating with the safety engineer on the job. Does that answer the question?

MR. BONSB: Yes, sir.

CHAIRMAN PEAKE: I would like to ask Mr. McClain what particular benefit is derived in applying a penalty in case of a fellow who is given six or eight days' lay-off, the purpose being to dismiss him when he returns. It is taking an unfair advantage of a man. Why not do it right away and get over with?

MR. MCCLAIN: In the steel industry we have all grades of men. I don't know that it is any different from anything else, but it is not uncommon for a man who is wanting to get out and start on his way, to go slamming away without a pair of goggles on because he knows he will be fired. Just to fool him, we don't fire him, see?

There is a certain amount of unfairness about that, as I said in my paper, but if this bird says to the other in danger, "I want to leave this place and I am going to take a slam at somebody," he starts a fight and he will be discharged. You know how that is. Many times during the war fellows would start smoking in powder plants to get discharged. Lots of time they did get discharged too. We have the system; if you violate the rules you will not be fired, but you will be laid off. You are not fired; you are suspended. It is 100 per cent right. We don't discharge a man out-and-out unless his conduct has been something that we can't stand for, or if we find him in the dressing station time after time and I think he is going to land finally in the morgue. I will begin to think about his wife and baby and he will be sent out because he wants to be killed. If that is so, I would rather have him outside the company's property.

CHAIRMAN PEAKE: We have for this afternoon a playlet entitled "The New Way" which is staged by the employees of the American Car & Foundry Company, of Chicago. I am told the play will occupy about 20 minutes. I would suggest to those who expect to leave before the 20 minutes are up that they go now, but I would rather have you all stay as this is well worth staying for.

The New Way

A Safety First Playlet in One Act

Given by Employees of the American Car Foundry Company, Chicago

CAST OF CHARACTERS

Superintendent	Mr. Franklin
Michael Kiley, Foreman Lumber Yard	
Chief Clerk	Willie McGee
William Chyla, Wheel Foundry	
General Foreman	Mr. Bill Speeder
(Whose motto is "Hurry Up")	
J. F. Considine, Jr., Asst. Foreman Wood Erect.	
Jack Jones	Alias "The Creeper"
(Too lazy to keep out of danger)	
Thos. Smith	Alias "Crabby"
(Always complaining)	
Manuel Camden, Asst. Foreman Wood Erect.	
Joe Poleski	Alias "Hunky Joe"
(Hard worker, but careless)	
Harry Johnson, Gang Leader Steel Erect.	

Charley Pepper....."The Boss"
 (Who carries out Mr. Speeder's Orders)
 F. M. Robinson, Safety Inspector

Pete Martini.....Alias "Red Eye Pete"
 (Always half soused, maker of "Moon")
 Anton Spano, Punch, Shear & Press Dept.

George Brown.....Alias "Doc"
 (The Plant Eye Doctor)

Alex Swanson.....Called "Honest Aleck"
 (Always on the job)
 Paul Robinson, Wood Mill

Frank White.....Alias "Joblots"
 (Maintenance and General Safety Man)
 Walter Spangler, Asst. Foreman Wood Erection

TIME

Anytime, 1927

SCENE

Superintendent's Office and General Foreman's Office,
 Anybody's Factory, Inc.

Willie enters and sitting down at his desk starts to work on his typewriter.

MR. FRANKLIN (*enters his office with a cheery*): "Good morning, Willie."

WILLIE: "Good morning, Mr. Franklin."

(*Mr. Franklin sits down at his desk and looks over papers on his desk.*)

SUPT.: Willie.

WILLIE: Yes, Mr. Franklin.

SUPT.: I have been looking over our business report for last year and I find that we show a decrease in profits over the previous year; why is this, when our volume of business was as large?

WILLIE: Well, Mr. Franklin, you know that while we were running that Mud & Co. job, Speeder had two men hurt and had to fill their places with new and inexperienced men, and before these new men were broken in considerable material was spoiled, all of which, of course, was charged against the job, so that we were unable to show any profit on that job. Then, on the Haymarker job the same thing happened when those men were hurt in Department "E". Of course you have seen our accident report for last year and know that we paid out over \$8,000 for compensation, which is also deducted from the profits of the year.

SUPT.: No, I haven't seen it; where is that report? (*Willie brings report.*) (*Supt. glances over report.*)

SUPT.: Well, this is something that must be looked into at once. Call Bill Speeder. (*Willie goes to door and calls, "Oh Speeder; come in here; Mr. Franklin wants to see you." Speeder enters from his office.*)

SUPT.: Bill, sit down there, I want to talk over this matter of accidents with you. Do you know how much we paid out for compensation last year?

BILL: No.

SUPT.: Well, it amounted to over \$8,000.

BILL: That is impossible, Mr. Franklin; we did not have many accidents last year.

SUPT.: Here is a list of the men injured and the amount paid to each. (*Bill takes report and looks it over.*)

BILL: I had no idea that it amounted to that much.

SUPT.: Now, Bill, something must be done to stop this right away, and I want you to go out in the plant and look over the situation, then report to me as soon as possible. (*Bill goes out, enters Charley "The Boss" from Speeder's office.*)

CHARLEY: Oh, I thought Bill was in here; I wanted him in a hurry.

SUPT.: What is the matter, Charley? You look like you were out of breath.

CHARLEY: We had another bad accident just now, Mr. Franklin. Jack Jones got his leg broken, and you know he has a wife and five children and I wanted to know whether to send him home or to a hospital.

SUPT.: What! another bad accident! Send him to the hospital, Charley, and then come back in here. *(Charley sends Jack to the hospital and then returns.)*

SUPT.: Charley, how did the accident happen just now?

CHARLEY: Well, I don't know yet, Mr. Franklin, all I know is that Jones and several others were piling some material and the pile tipped over, and the others got out of the way, but Jones was too slow and got caught.

SUPT.: Charley, you go out and get the men that were working with Jones and bring them in here. I am going to find out about this. *(The boss leaves and returns with the gang.)*

CHARLEY: Mr. Franklin, these are the men that were working with "The Creeper."

SUPT.: What are their names, and how long have they worked here?

CHARLEY: Well, here's Crabby Smith; he has been here about two years, ain't it, Crabby?

SMITH: Yes, two years next month.

CHARLEY: And, Hunky Joe; how long you been here, Joe?

JOE: Twelve years, Mr. Boss.

CHARLEY: And Red Eye Pete; how long for you, Red Eye?

MARTINI: About a year, two months, Meester Bossa.

SUPT.: Smith, how did Jones get hurt?

SMITH: Aw, you know in that darn shop anyone would get hurt.

SUPT.: Yes, yes; now tell me how Jones got hurt.

SMITH: Well, you see, Superintendent, I got something in my eye and had Doc Brown take it out and he hurt my eye something fierce and I couldn't—*(Hunky Joe interrupts)*

HUNKY JOE: I me tell you, Mister Boss, "The Creeper" no good; he too slow me good workman; me work fast; you know me work here twelve years; me good workman; me hurry up good; me no give damn for anybody; me hurry all the time—*(“Red Eye” interrupts)*

RED EYE: Aw, shut up; you don't know nothing; me tella da boss; me see pretta good; Crabby he gotta bada eye from Doc. Doc taka piece a sawdust out Crabby's eye with a file, so I gotta bottle gooda moon and I give Crabby gooda drinka, and Creeper take gooda drink too; everybody worka like hell.

CRABBY *(Aside to Hunky)*: He is a darn fool; the boss will can us now for drinking.

HUNKY JOE: Mister Boss: I me workum good fast; Creeper too much lazy, no pilem fast enough; me pilem high, my pile: Creeper pilem slow little pile, my pile fall down so, I don't know maybe no good floor, maybe no enough cross piece. I don't know.

SUPT.: Is that right, Smith?

SMITH: Aw, I don't think so, that stuff ain't made right you see, every other one must be turned around end for end to pile them so they will lay even, and we didn't do that and I guess that is what made it fall.

SUPT.: You men wait here until I go to see that pile that fell. *(Exit Superintendent.)*

CHARLEY: Pete, you shouldn't tell Mr. Franklin that you had moonshine.

RED EYE: I no gotta much, Mr. Boss, littla bit no hurt.

HUNKY JOE: Me no need moon; me workem alright every time. (*Enter Supt. as Crabby starts, "You're a damn fool."*)

SUPT.: Charley, who is the man who is re-piling the material that fell on Jones?

CHARLEY: Oh, that is Swanson; Honest Aleck they call him.

SUPT.: Did he ever get hurt?

CHARLEY: No, sir; Mr. Franklin, he is always on the job.

SUPT.: I thought so, as I watched him work; that is the kind of men we want on the job. I also noticed that the floor is bad where this pile is. Don't White take care of such conditions?

CHARLEY: Yes, sir, Mr. Franklin, most places he does when we tell him.

SUPT.: You men can go back to work now and Charley I want to see White in my office here. (*Charley, seeing White pass the door, calls, "Oh Joblots, Mr. Franklin wants you."*) (*Bill returns as Joblots enters.*)

SUPT.: Bill, you have had another bad accident this morning.

BILL: Yes, sir, Mr. Franklin; but I don't see how we can avoid it if men will not try to be careful themselves.

SUPT.: Now, Bill, after looking around through the plant, what do you think we should do to stop these accidents? You know this is an awful hardship on the families of these injured men: they say Jones has a wife and five children. Now, who will care for them while he is in the hospital?

BILL: I don't know, Mr. Franklin; I don't see what we can do; all our machines are guarded.

SUPT.: Bill, I have been doing a lot of thinking while you were gone and I agree that all our machines are guarded; but that is as nothing compared to the work we are going to do to make this plant safe; nor will it cost us anywhere near as much as guards have. Our next step is to educate our men to work safe. This can be done by you and your assistants constantly preaching safety to your men. It may be necessary to remove one or two men from the service, if you cannot educate them; and I think I saw a couple this morning that will be damn hard to educate. About Mr. White here, I believe he should be relieved on the job of safety man, taking care of maintenance only, and a new one appointed as Safety Man; and that White be instructed that safety comes first; and that Doc Brown's files for removing particles from men's eyes be taken away from him, so that he may spend all his time working at his trade of machinist hereafter. Do you understand that, Mr. White?

WHITE: Yes, sir.

BILL: All right, Mr. Franklin; who do you want for Safety Man?

SUPT.: How about Swanson?

BILL: That's fine; I will tell him. Aleck is so careful in everything he does that I am sure he can handle our Safety Work for us and get results.

SUPT.: Very likely he can, Bill, but let us go farther. I think Swanson will need some help, so I suggest that you form a safety committee among the workmen, the members of which, along with their other duties, will be constantly on the lookout for unsafe conditions and especially careless and unsafe workmen. You and Charley had better get in on the selection of that committee with Swanson and get the thing started right away, and remember your biggest job is to teach the men the safe way to work.

BILL: All right, Mr. Franklin, may I pick whom I wish on this committee?

SUPT.: Certainly, Bill; that's up to you. (*Bill leaves and enters his own office where he finds Charley waiting.*)

BILL: Gee, Charley, I thought we were both through when Jones broke his leg, but the Old Man just said we must work a new way; we must educate our men to work safe by teaching them, and I think he is right. We are to have Swanson for Safety Man and we are also to pick a safety committee

from our force to help Swanson by always talking safety among the men as well as reporting unsafe conditions and practices.

CHARLEY: That's fine. I feel better now because I know that with Aleck on the job as Safety Man and a committee working we will have a much safer shop; then, too, we have the backing of Mr. Franklin, which is going to be a big help. When do we start with this new arrangement?

BILL: Right now! First get Swanson in here.

CHARLEY: All right, sir. *(Charley leaves.)*

SUPT.: Willie, where is this morning's mail? *(Willie hands mail to Mr. Franklin, who looks over it.) (Charley returns to Speeder's office with Aleck.)*

BILL: Alex, do you know what a Safety Man should do in this plant?

ALEX: Yes, sir, Mr. Speeder, I think I do.

BILL: Well, we are going to make you Safety Man and your duties now will be to find unsafe conditions and practices around the plant and have them corrected; also help to educate the men how to work safe. In this latter part, you will have the help of a safety committee, whom we shall select, as well as Charley and myself.

ALEX: All of this is agreeable to me, Mr. Speeder; whom do you think you will select on the safety committee?

BILL: I haven't decided as yet.

CHARLEY: Often the worst offenders make the best boosters, Mr. Speeder. Why not take the three men we had in Mr. Franklin's office this morning? If we make them work safe, it surely will be an object lesson for the others.

BILL: Alex, do you know who Charley is referring to?

ALEX: No, I do not, Mr. Speeder.

BILL: Well, it is the three men that were working with the Creeper this morning: Crabby, Hunky Joe and Red Eye Pete. What do you think of them?

ALEX: They are all right. I am sure I can get them to work safe. Will you tell them about their appointment on the committee?

BILL: Certainly, and the sooner the better. Suppose we get that matter settled right now. I would like to talk to those men about their duties as Safety Committee Men.

CHARLEY: Shall I bring them in here, Mr. Speeder?

BILL: Yes, Charley; and you stay here, Alex, until we get this committee arranged. *(Charley leaves.)*

BILL: Alex, here is a sample safety badge. We will get some more of them and have the committee wear them.

ALEX: That is very good Mr. Speeder. *(Charley returns with the three men.)*

CHARLEY: Here are the men, Mr. Speeder.

BILL: Pete, you saw the Creeper get hurt this morning, didn't you?

PETE: Yes, sir, Mr. Speeder; I see him.

BILL: Suppose you had broken your leg instead of the Creeper and had to go to the hospital, what would you think of that?

PETE: I donta know, Meester Boss. I gota biga family, wife and six kids, pretty bad, big rent, I musta work, Mr. Boss; hospital no gooda for me.

BILL: Yes, Pete, I know that, but if you was over there in the hospital in place of Jones now, what would your family do?

PETE: I donta know, Meester Boss; maybe kids get nothing to eat.

BILL: That's right, Pete, maybe the kids get nothing to eat. Now, Pete, don't you think you and your family would be much better off if you would leave the moon alone and try to work in such a manner that neither you nor your partners would get hurt?

PETE: You mean I work gooda safety first, Meester Boss, then I never go to hospital?

- BILL: That's it, Pete.
- PETE: All right, Meester Boss. I worka safe alla time now; never hurta anybody; maybe Creeper come back, he no hurta anybody either.
- BILL: That's very good, Pete; I think you will be of some help to us in the future. Crabby, what would you think if you were in Jones' place now?
- CRABBY: Aw, I don't know, Bill. I never get hurt. Why don't everybody look out for themselves like I do; then they wouldn't get hurt either.
- BILL: Would you like to spend a month or six weeks in a hospital while your family were at home with no one to provide for them?
- CRABBY: I don't think I will ever get hurt, Mr. Speeder.
- BILL: You're almost hopeless, Crabby. Now, Joe, you have heard all this talk, what do you think about it?
- HUNKY JOE: Boss, I me no wanta go to hospital, me got pretty good family. Me like plenty work so kids go to good American school. Me feel pretty bad for Jones; me work safe every time now.
- BILL: That's good, Joe.
- CRABBY: Mr. Speeder, I guess I was wrong about getting hurt; maybe I would get it some day and I would like to go along with the rest of the boys, play the game as they do, if I can, and you say it will keep me and my buddies out of the hospital.
- BILL: It surely will do that, Crabby, and I am glad to hear you say that you want to go along with the rest of the boys. Alex has been made Safety man and I want you three men to assist him by reporting unsafe conditions around the plant that you may see in your regular course of work, also careless men, to either Alex or Charley or myself. You will also warn men when they are working in an unsafe way. Understand that you are to continue with your work as before but always keep in mind that you are a safety man now and must help the other men to work safe. Alex will give you all the help in this that he can.
- HUNKY JOE: Boss, you mean we must tell everybody the right way how to work safe?
- BILL: Yes, Joe. When you see someone who is not working safe you stop them and show them how to do their work in a safe manner.
- (The three in unison) All right, Mr. Speeder, we will.
- BILL: Alex, is this O. K. with you?
- ALEX: It certainly is, Mr. Speeder.
- (Mr. Franklin enters.)
- SUPT: Bill, oh, you have got these men up here again.
- BILL: Yes, Mr. Franklin, these men are on our safety committee.
- SUPT.: Fine, Bill. I am glad they are here as I just received a letter from New York announcing a Safety Trophy to be awarded to the plant showing the best safety record for the year 1927, to be known as the "Dickerman Safety Trophy," and I wish you boys would make every effort to bring that Trophy to this plant.
- CRABBY (getting very excited and throwing his hat on the floor yells): Come on, boys; let's go! We are going to get a great big medal or trophy or whatever they calls it now for just working safe.
- CHARLEY (to Bill, as they go out together): Bill, I think we got a good start for safety.
- BILL: I do, too.

EPILOGUE

A word to you of the Chicago Works,
Who have sought aid for your various hurts,
Who have gone to see our good Doc. Powell,
With an ache and a pain and a great big howl;

Sixteenth Safety Congress

To those of you who have been careless men,
And have not cared who got hurt or when,
We wish you to know that this big shop,
Is playing safe and accidents must stop;
Our little playlet shown you here tonight,
Is just a lesson and we hope it might
Be the cause of turning some careless man,
From his unsafe ways to the Safety First plan;
If our message to you here tonight has been
Of any benefit or help at all, why then
We will feel well paid, if we can see
All you men working with us in Safety.

THANK YOU!

ADJOURNMENT

Friday Afternoon, September 30, 1927

W. H. WINANS, Chairman
Industrial Relations Department, Union Carbide and Carbon Corporation,
New York City

The second meeting of the A B C Session was called to order at two-ten o'clock by the chairman, W. H. Winans, Industrial Relations Department, Union Carbide and Carbon Corporation, New York City.

CHAIRMAN WINANS: You, of course, or many of you, have attended previous A B C sessions. You know what their general purpose is. I hope you are getting from them what you want and what you came for. The general idea back of it all is that very frequently by merely exchanging ideas and experiences on some of these problems of accident prevention which confront us, we find that all of us have a great deal in common.

You know the story of the man who upset his boat in the lake in the park quite a distance from shore, splashed around and floundered in the water, calling for help and yelling that he was drowning, that he could not swim. A park policeman who was standing on the shore watched him for a while, and finally yelled out to him, "Let your legs down." The man stood up in four feet of water.

Very frequently we find from these sessions that we are standing in four feet of water and don't realize it. I hope you get some suggestion this afternoon that will enable you to let down and put your feet on the ground.

Our first speaker is to discuss a problem which most, if not all, have found very perplexing at some time. I hope he will tell us whether we can let down or at least which direction we can swim in. Mr. Arkills comes from Seattle, Washington. He is Safety Engineer for the Waterfront Employers of Seattle, safety engineer for the Pacific Coast Steel Company at Seattle, and consulting safety engineer for the Manufacturers' Association of the State of Washington.

How to Secure the Confidence of the Operating Heads

M. E. Arkills, Safety Engineer, the Waterfront Employers of Seattle,
Seattle, Wash.

One of the natural desires of every safety man here is to secure the full cooperation of his management. One of the natural desires of every management is to have each department, including the department of safety, advance such a common-sense program that it can be subscribed to unreservedly.

Early in the title of this paper we find the word *how*. When we use the word *how* in this connection it implies a mode of operation or a process. The treatment here given will, however, be very elementary in its scope, and not a scientific treatise. We furnish no panacea for such minds as choose to worry about this subject. The powers thus wasted would be better directed toward the accomplishments that count for safety and production.

Secure: Se—means "without," cura—meaning "care," then secure means without care. If we secure a thing we may cease to worry about it. Or we are without care. Even if it were possible to furnish a complete solution to this problem we would prefer to leave a healthy incentive to good work.

Confidence: This word when dissected is found to be composed of 1—Faith; 2—Belief; 3—Assurance; 4—Certainty.

Faith: We as a people have been taught for many generations to take certain abstract things on faith, so this is not difficult.

Belief is a result of one's conscientiousness; the strongest impressions at the time in question. Beliefs are shifting things. They are capable of change from without.

Assurance is encouragement, declaration, promise.

Certainty: This can only be founded on fact.

How about a practical application of the foregoing?

Faith: The employer takes the new employee partly on faith. We all feel we would not have been given a chance in our present places had it not been for the element of faith. Faith is a splendid quality in man. We should guard against doing those things that tend to shake anyone's faith in ourselves or any worthy cause whether we are sponsoring it or not.

Belief: Since beliefs are a fertile field we should direct our efforts toward a common understanding of the helpful truths underlying our important work. If we find that one of the operating heads is not in full accord with what has been found to be effective safety engineering in other plants, then he is in need of a few new concepts that will balance his belief in favor of such engineering. Possibly the safety man should strengthen his own belief with the occasional addition of new and workable concepts. When the National Safety Council Congress is in session the golden harvest is on. We may all gather many sheaves of helpful concepts here. They will add to our enthusiasm, and enthusiasm is catching.

Points in Securing Confidence of Management

Assurance: The executive would always like plenty of assurance that what we are doing is sound, logical, workable and is a part of the general scheme for economic advancement. Late accomplishments in the employer's own plant are doubly assuring. The live executive will like to know that a plant similar to his own has made a saving in men and money. This spurs him on to make the same saving in his own plant.

Certainty: Concrete facts and figures as to the savings are always helpful in establishing with certainty the soundness of our safety work. Simple, well-checked, easily understood statistics in small amounts are greatly appreciated by the busy operator. Notice, please, we stress small amounts. Too many, or complicated, statistics defeat their own end.

In summing up hurriedly, let us see what thoughts are here advanced:

1. We have attempted to show *how* improvement may be had.
2. That it would be stultifying for us if too great a sense of security were obtainable.
3. That faith, our starting point in all new fields of endeavor, should be zealously guarded.
4. That beliefs may be improved by proper cultivation. That the concept may become the builder's brick of our building we call "Belief." We cannot give off that which we do not have ourselves.
5. That assurance is ministered to by previous records made by ourselves and others.
6. That the foregoing standing on the sure foundation of facts and figures will do much to secure the confidence of the operating heads.

CHAIRMAN WINANS: Before discussing the points presented to us by Mr. Arkills, it might be well to have a letter which has come to our attention, indicating what happens when the confidence has been secured, as Mr. Arkills has referred to it. I am not going to mention the name of the company with which the gentleman is connected who will present this letter. If he sees fit to mention it himself

later, well and good. I will call on Mr. R. E. Colville, who is assistant manager of the Plant Service Division of a large industrial concern, to present this letter and explain it to you.

R. E. COLVILLE, U. S. Gypsum Company, Chicago: I might supplement the chairman's remarks by saying that the company which I represent has rather extensive operations. We have mines and we have mills, we have railroads, and we operate steamships, so the thing I am putting before you will indicate that it comes from an experience which is rather broad and that this man is a man who can speak on the subject. Incidentally, there are twenty-seven plants which are affected.

The letter was written to all operating heads (plant managers and other operators), after an experience of several years of intensive safety work, that is, selling safety and trying to justify the reasons for our efforts along that line. The letter itself represents a culmination of an idea in this man's mind. His title is vice-president in charge of operations. The letter is dated September 27, 1927.

A Letter That Caused Much Discussion

"Since my letter of August 26 reviewing our safety record for the year, three other employees of the company have lost their lives and our record now stands:

"16 MEN KILLED IN 8 MONTHS"

"I have read the comments made by those who have replied to my letter, and have found them interesting and helpful; but most of the replies indicate the need of a definite program which promotes better things than the one we have been following. Mature consideration has brought the following conclusion:

"We have attempted to reach our men through rules, guards, signs, slogans, committees, safety talks, safety campaigns, competitive ratings, prizes, etc. All of these things, with the exception of safety rules and guards, savor of a sales campaign through which an attempt has been made to win the workmen to safety by selling them an idea. This plan has failed, as evidenced by our record of deaths, increased severity, and increased cost. Abuses of the system have crept in, an instance of which is the placing of men at work when they were but partially recovered, at a direct loss to the company, the aim being to maintain a good safety record in man-hours lost; the real objective, accident prevention, being entirely lost sight of in an attempt to make a mere record.

"We will now about-face. You will discontinue all of the things listed above except that you will maintain safety rules, guards, signs and ratings. From September 1 on, ratings will be on the following basis:

- (1) Deaths
- (2) Number of accidents
- (3) Severity
- (4) Costs"

(Incidentally, we are self-insured in about seventy per cent of our payroll, that is, our largest plants and those which can be are self-insured.)

"The October No-Accident Campaign offers us no more hope of progress than the former campaigns."

(We have had two campaigns each year.)

"We will have a good record and then begin to slide off in the months that follow. You will, therefore, hold no more safety campaigns and you will cancel forthwith all plans made for the October campaign.

"Effective at once, all formal safety talks and appeals are to be discontinued. From this time forward you will require that every employee at your plant be a safe worker. To make this plan effective you will call together your department heads and announce this change in policy. Place the responsibility of selecting and retaining efficient workers upon your managers.

"The subject of accident prevention has been best expressed in the following simple statements:

"The safe factory, in general, is the efficient factory; the efficient factory, in turn, is the safe factory."

"When accident losses have been eliminated or brought down to the irreducible minimum, then, and then only, will the highest production be realized."

"The dynamic force which can obtain this desirable objective has but one source: it resides in management."

"Accident prevention is a responsibility which cannot be evaded. It rests on the managers and executives of industry to make safety of major interest and a continuing care."

"This letter is addressed to all plant managers and will be received by a few who have splendid records. Let me repeat, there is no security in past immunity; therefore, it is my wish that those of you whose plants have a good record act in this matter exactly the same as though your record had been unsatisfactory."

The Keynote of the Plan Is Efficiency

"The keynote of this plan is efficiency. Efficiency comes as a result of good management. One of the tools of good management is discipline. During the past five years, when growth in plant and production required nearly all of our time, discipline was lost sight of to a degree. Many of our young managers know little about it, and I am under the impression that discipline has not been employed in connection with our safety work to any marked degree. When a man fails to give you quality or efficient production, you will quickly decide that he is not fitted for the task and you will either find something else which he can handle efficiently or you will dismiss him. If a man lacks interest in his work and you are unsuccessful in your attempt to make him efficient, then you dismiss him, because if you do not your quality and your cost record suffer. If you do not hesitate to handle men in this fashion when quality or production is at stake, why hesitate when it relates to safety? *Hesitate no longer, but warn your managers that they must be efficient in the selection, the direction, the discipline and the control of their men.* If they will not do this, they must be subject to the same penalty as the workman. Their future with the institution from this time on rests as definitely on their safety record as on their ability to get quality at low cost. This plan requires that when men violate safety rules or they are inefficient, they shall be disciplined in an appropriate fashion, the discipline ranging from a warning to dismissal."

"Your safety organization is to be cut down to a clerical force sufficient to handle the work remaining under this changed plan."

(It may be interesting to note right here that some of our plants have as few as twenty people, while we have other plants, one of which is as large as 1,700 men. Of course, this will be interpreted differently at the various-sized plants, but the large plant will not have even the safety supervisor who now is directly responsible for the carrying out of the safety and accident prevention; but the line of control will come directly down from the vice president to his production manager, to the works manager of the plant, and from the works manager directly to the workmen. In other words, you won't have a safety man who hasn't the authority to discipline the foreman, you won't have that safety man trying to direct. He will be a man who helps the Works Manager carry out his own plans.)

"I now charge you with the responsibility of selecting and maintaining in your organization only such men as are efficient and safe workers."

"Accidents must cease and you must do the things that are necessary to stop them."

"The accident prevention responsibility is now in your hands."

"I have often heard the comment that the men think we are not sincere in our interest in accident prevention, and that our only interest is to save money for the

company. Dispose of this subject, once for all time, by stating firmly that we intend to operate our plants efficiently, and to be efficient, accidents, bringing in their train suffering and death, must cease. Further, we have not the slightest interest in what anyone thinks about our reason for insisting that the plants operate safely.

"I want every manager in the company to become at once absolutely hard-boiled on the subject of accident prevention. We will not ask anybody to work safely any longer; safety is required of every man. It is a rule of the company and it is to be obeyed as all other rules of the company are to be obeyed. Let your treatment of safety offenders be even more severe than of offenders against quality or cost."

"Please let me have an acknowledgement of this letter, and if there is anything about it that is not clear do not hesitate to ask questions. Also, consult your production manager when he visits your plant. The important thing, however, is for you to grasp the underlying idea, make it your own, and begin operating under it at once, for the better selection, direction, discipline and control of your men."

CHAIRMAN WINANS: Thank you, Mr. Colville; that is quite a story. I don't know how many of you have ever received a letter like that. I never did. I don't know what impression it would make on me at this moment if I did receive it. I imagine that has raised some questions in the minds of several of you.

Mr. Arkills presented to us some fundamental principles which from his point of view appear to be essential to secure the confidence of the operating heads in accident prevention work. It impressed me as quite a different method than an order from the general manager. He referred to such fundamental things as faith, which you must not destroy, absolute belief in the principle by the presence of substantiating facts and assurance, those things which come about from a man-to-man relationship rather than which come about through a general order.

We have time for discussion. If you wish to discuss either phase of the matter, you may do so.

Cooperation of the Executive Body Gets Results

G. R. G. FISHER (Illinois Manufacturers' Association, Chicago): This letter is to me a surprise, and I am sure it is to many here, and yet in another sense I am not surprised. For ten years I have been going through factories and mills and shops talking on accident prevention and giving them lessons in first aid, and during the last four and a half years, directly under the auspices of the Illinois Manufacturers' Association and in conjunction with the Illinois Manufacturers' Mutual Casualty Division. I have this to report to you, and it will lend emphasis, if emphasis can be lent, to this letter. Wherever we get the cooperation of the executive body we get results. In other words, accidents come down following our appeals to the man as a matter of personal safety, and everything else, where we have the cooperation of the heads of departments and they interest themselves in helping us to put this thing over. But where we do not get that, we do not get results.

It is very evident that this whole thing, if it is going to be successful in the sense of accident prevention and the eliminating of accidents, must have a whole-souled sympathy on the part of the executives and all the way down. If you don't get that from them, you will never get it from the man.

I tell people I get a better hearing from the preacher, and I do. Why? Because the man responds to what we say. He knows it is for his good, and the results are wonderful. I am a preacher, I know.

The whole subject of safety, as to its success and its maintenance, depends entirely on the attitude of the boss and everyone under him officially.

A. AMRAN (Hamlin & Co.): Perhaps I did not follow as closely as I should the letter this gentleman read. I should like to assure myself that I understood him correctly. Did the vice-president in charge of operations of this company express himself to the effect that he was not in favor of a safety organization in his plants?

I believe it said to eliminate all safety organization matters except the clerical part. It is so out of the ordinary and contrary to all we have heard that I cannot quite grasp it, and I want to know whether I am right or not.

MR. COLVILLE: I expected something of that character. It is true that our plan is to eliminate committees in the plants, committees made up of so many workmen and the foreman, and the joint committees. Instead of that we are placing the same amount of responsibility in the hands of the works manager.

Your safety supervisor can go along and say, "Here, fellows, let's make a committee inspection." Suppose he finds a lot of conditions that are not safe. What can he do? He cannot do anything. He has no power other than the ordinary department head. In this way the vice-president holds each works manager responsible for the safety of his plan, judging by the four things that I mention, the deaths, the number of accidents, the severity and the cost, and, of course, those are the things that count. These works managers at the end of the year have a reckoning day. They are given their quota bonus on the basis of good quality, good cost and good safety, and the thing that this does is take it out of the hands of the committee and place it right where the authority and responsibility are placed. I don't think that we have lost a thing; I think we have gained quite a lot.

Incidentally, we have a safety supervisor who travels from plant to plant, and it is his duty to carry down this same idea. He makes some contact which the vice-president alone could never expect to make.

"Run Your Plant Safely If You Want the Bonus"

E. D. CHAPMAN (R. R. Donnelly & Sons Co., Chicago): Wasn't this new rule put into effect because of the fact that the various plant managers were standing aside and allowing the safety committee to do their work? I should think that if the plant manager was an efficient one he wouldn't allow the responsibility of the accidents to go out of his hands. It would take the plant manager and the safety committee together to cooperate.

MR. COLVILLE: I agree with you, but you know and I know that we are always going to have men who don't take their jobs to heart as much as they should. But I will bet everybody here that we have as efficient works managers as the average, and a little better, maybe. Here is the thing that it does: instead of just saying to you "How run your plant safely"; we say to you as a works manager, "Run your plant safely if you expect to win your bonus at the end of the year"; and that goes right through his pocketbook, because that is what counts with these fellows. We may be humanitarian, but if we can add to it that other point, we have got him.

CHAIRMAN WINANS: You see, our subject is "Securing the Confidence of Operating Heads in Accident Prevention." We are trying to find a way to prevent accidents. It is assumed in the subject that the confidence of the operating heads is necessary. How are you going to get it? Those of us who heard that foreman talk at the Detroit Congress last year, heard him say that as a foreman in the shop he knew that the old slogan "Safety first" was bunk, that when it came up to the top and there was a question between production first or safety first, production came first and safety second. Until that situation was removed, so that the foreman and department heads knew that the manager in charge meant safety first, there was nothing to it.

It is the same proposition as an experience we had in one of our own plants where we have a grinding operation that is very hazardous because of flying chips. We struggled and struggled to get the men to wear their goggles. We continued to have eye accidents. The manager continually talked with the foreman, and the foreman continually talked with the men. One day we lost an eye. The manager said, "That is my fault." He went out into the shop, called the men together, along with the foreman, and said: "Your foreman here has talked with you fellows

and asked you to wear goggles. I have occasionally gone through here and I have seen some of you without them. I have asked you to wear them. From today on nobody is going to be asked to wear goggles in this plant. If you fellows are going to work on these jobs, you are going to wear goggles. I am not going to be responsible as manager of this plant for lost eyes. If you don't want to wear goggles, you will have to get a job somewhere else."

That established confidence all right. That is one way to do it. There is another way to do it. What is the discussion?

C. G. SMITH (N. Y. State Insurance Fund, New York City): I have listened with a great deal of interest to the letter that has just been read. I would be very much surprised if it did not provoke a great deal of discussion. It seems to me that there are a number of things to be noted about the letter. In the first place, it sounds to me like a letter that was dictated but not read. In other words, the vice-president of this company, whoever he may be, got sore about this whole proposition, as I read it from the letter. He dictated a letter out of the fullness of his heart, as evidenced by the many repetitions, and to my mind the poor way in which the letter is constructed. In other words, he hit the ceiling. If I ever dictated a letter like that, I would want to leave it on my desk and reread it before I sent it out, and I would put it through a good deal of editing. I say that because it seems to me the letter was not well considered. The vice-president seems to think that safety is something he can get by ordering it done; and at the same time he orders it done he scraps all the forms of organization which have been set up as a result of long experience for the purposes of producing safety. It is just like ordering the tide not to rise, it seems to me.

It also seems to me to involve the assumption that you can get anything done by firing men who don't do it. That may be all right, but when you fire a man who doesn't do something you have ordered him to do, you have got to get somebody to replace him. How do you know you are not going to get somebody worse than he is? You may get someone who is a lot worse that you have to train. It seems to me the letter represents a distinct step backward in the movement of accident prevention, and it doesn't look constructive at all.

Be Sure You Deserve the Confidence You Ask For

CHAIRMAN WINANS: Mr. Colville very kindly presented this letter because he wanted your opinion as to that method. It is an interesting proposition. Of course, we heard quite a bit about this proposition of securing the confidence of operating heads from Dr. Harry Meyers in the Automotive and Power Press session this morning. He placed the emphasis on whether you deserve the confidence you are trying to get. What are you going to do with it if you get it?

Do you remember that story of Johnny who came home from school with his grade card, not so good? Pa looked it over and said, "Johnny, what is the matter? You are not getting good grades. Don't you know, son, that when George Washington was your age he was the head of his class?"

Johnny looked up and said, "Yes, pop, but when he was your age he was President of the United States."

Let's be sure we deserve the confidence we are trying to get.

E. J. WOLLMAN (Great Lakes Forge Co., Chicago): I think Mr. Arkills' discussion is a good example of elementary safety and Mr. Colville's letter is an example of bad safety.

I notice at the top of this program that the meeting is for junior safety men. I think it is a little out of line here to discuss a letter of that sort. I think it should be presented to a gathering of men who have been in the safety game a good while.

R. S. BONSB (Standard Oil Co. of N. J., New York City): I think it was a good idea to have that letter read. While that might have been polished up a little

bit, yet it came from the fullness of the man's heart and when a man speaks from his heart he usually gets his message across.

We people who have been in safety work a long time know that we never got anywhere until safety ceased to be a matter of welfare and became a production matter. Just as soon as management discovered that the man could not produce in the graveyard or in the hospital, we got somewhere. Therefore, putting it up to the department head, such as he has done, made it a direct part of his job to get results. I think that is a splendid idea. I wish I could get our people to write such a letter. I am happy to say our president has issued a letter in which he says the management, the division heads, the department heads, will be held responsible in the future for serious accidents. I want to say that ever since that letter was sent out, there has been a greater feeling for safety than there ever was in our entire organization throughout the world, because that went all over the world. That letter got results, more results than any of our safety committees ever could have gotten or ever would have gotten, because when you put that up to the man himself, he knows better than anybody else. It is impossible for a safety committee or a safety engineer to go into a plant and tell a man what he can do. I used to think I could do that, but the older I get the more sense I get. I find you cannot do it. But if you can arouse that man's interest and get his confidence, he knows all the different factors and he can do the job better than anybody else if you make him do it.

Occasional Man Failure Is Still to Be Considered

CHAIRMAN WINANS: Mr. Arkills, perhaps you would like to close this discussion.

MR. ARKILLS: I might say just one thing. I believe that this letter is an unbalancing of the complete program, to a certain extent, but it is just the sort of thing that we must have, in a way. I believe that in a full rounded-out program a letter fully as strong as that should go down from the top, and right along that line; but possibly leaving out the curtailment of the safety department. He will only reach a certain percentage of the accidents if he has 100 per cent cooperation through his managers. He still would have the occasional man failure on the job under conditions that the foreman would not be able to reach for a long, long time. The managers and foremen cannot be right there for each identical operation every minute, and some fool blunder will be pulled. If the man himself is thinking on this subject he will overcome it on his own behalf. For that reason, we must carry on all of the branches of our safety work as we are now outlining them. But I do believe that letter is stronger than it should be, possibly, in that one regard.

I carry on practically all of my work through the management, right from the top down, and the foremen have done perhaps 80 or 90 per cent of the accident prevention work in the plants that I have served. We have made splendid records, but it has been the foremen who have got the credit for them. We have foremen's safety meetings. Monthly we have a foremen's safety meeting at the steel plant, and about every six weeks we have a foremen's safety meeting on the waterfront. Those meetings on the waterfront are attended by 60 to 110. At those meetings we try to get over lessons on the things that are of most importance to us, the things that are actually causing the greatest number of accidents. That is the one thing that we must stress in all of our work, to find out first of all what is causing the accidents, and then to prevent them.

MR. COLVILLE: I just want to answer Mr. Smith a little in defense of this thing. There are three points I want to bring up. One is that we expected these different ideas; but if you will notice one point, it says, "The keynote of this plan is efficiency." We go on the idea that to be efficient you have got to be safe. Another point is that you are going to have a safety supervisor there who will perform the operations of the committee.

The third point is that one of our operating heads has mentioned the fact that he has seen the production manager many times with his cost book but never with his safety book. That may give you some idea of how seriously this thing is being taken up.

Mr. Smith, this letter was not intended to be a literary masterpiece, so I think we must plead for indulgence in that regard. We have done the selling; now we are getting a little stiffer with our requirements of our management.

Incidentally, this is the United States Gypsum Company which has taken this action. I thought you might be interested to know it, and we have been very glad to have your thoughts on it.

CHAIRMAN WINANS: May I say that the purpose of these meetings, as I said at the outset, is to bring out different ideas. It wasn't the original intention simply to put over one idea. We want to be clear on these ideas here. Perhaps Mr. Colville next year will present a different letter.

We have the privilege now of witnessing a playlet which is to be presented by five employees of The Palmolive Company, Milwaukee, Wisconsin. This playlet was presented first before the safety engineers in Milwaukee, and then later at the foremen's safety school there. The subject of the playlet is "Responsible." When I looked at the program and saw that word, it made me think of that story of the young college fellow who started out to look for his first job. He had not had any experience, so he went over to a large industrial concern, went into the waiting room, looked around, and nobody paid any attention to him. He sat down and waited, waited, waited. Finally an office boy came over and sat down at a desk and didn't pay any attention to him at all. He waited a little longer, became quite impatient, straightened up, decided certainly his college education should be worth something to him, went up to the office boy and said, "Young man, who is the responsible party around here?"

The boy looked up, "I don't know who is responsible, but if there is anything wrong it's damned certain I'll get blamed for it."

Responsible

Given by Employees of The Palmolive Company, Milwaukee, Wis.

CAST OF CHARACTERS

Max	The Injured Man
Gus	His Foreman
Bob	Committee Man
Paul	Committee Man
Matt	Chairman of Committee

SYNOPSIS

A press operator has suffered the loss of a part of two fingers on his right hand. The safety committee is meeting with him and his foreman to determine the responsibility for the accident.

ACT I

Committee Room: Table in center of room with five chairs properly arranged. Papers on table to represent reports. Hat rack near door.

Enter injured man dressed in street attire. The index and middle fingers of his right hand are properly bandaged. After hanging his hat on rack he seats himself at left hand end of table.

Enter two committee men in conversation with each other. Both of these characters are presumably in supervisory capacities and dressed as such.

- BOB: (*Seeing Max*)—Why, here is Max now! (*Walks up to Max who has stood up and pats him on the shoulder*). How are you?
- MAX: As good as can be expected.
- PAUL: (*Having hung his cap or hat on rack*)—Hello, Max! I was surprised to hear of an old-timer like you having a serious accident. How is the hand?
- MAX: (*Again seating himself*)—These two fingers are partly gone.
- PAUL: (*Seating himself in chair next to Max*)—Gee! That's not so good.
- BOB: (*Having seated himself in chair to the right of center of table*)—And it's your right hand at that. A machine certainly has no regard for human flesh and bone.
- PAUL: How much time will you lose?
- MAX: I have been off two weeks now and the doctor says I will be able to return in about four weeks. (*Both Bob and Paul manifest their sympathy by shaking of head*).
- BOB: (*Taking cigar from pocket*)—Have a smoke, Max?
- MAX: Yes. Thanks.
- PAUL: (*Helping Max Light the cigar*)—Gus and Matt ought to be here pretty soon.
- BOB: Here they are now.
(*Enter Gus and Matt. Gus is attired in a shop coat and wears a cap. Matt, in shirt sleeves, is carrying papers*).
- GUS: (*Going up to Max who remains seated*)—How's the hand?
(*Max holds up the injured hand and shakes his head negatively*).
- GUS: Not so good, eh? (*Shaking head while walking to chair opposite Max*)
How long before you'll be back with me?
- MAX: Oh! About four weeks.
(*Gus seats himself and taking off his cap indifferently places it on the table and lights a cigarette. Other characters may smoke at their convenience.*)
- MATT: (*Being seated at center of table*)—Well boys, you have all heard about and are no doubt interested in the serious crippling accident which so unfortunately happened to our fellow worker, Max. Following our usual procedure we have called this special meeting this morning to ascertain the facts in the case and determine, if possible, the responsibility for the accident.
- The report of this accident shows that on September 6, while operating a press, Max suffered a crushing of the index and middle fingers of his right hand, necessitating the amputation of the first joint of both these members. This certainly is a lamentable accident due to the fact that we have had no mishap of such a serious nature for a long time. I am sure that we all appreciate what this misfortune means to you, Max, for you have surely had some hard luck.
- MAX: Yes, it was too bad. I lost two important members of my right hand.
- MATT: You no doubt realize and appreciate what this loss is going to mean to you in your future life.
- MAX: There is no one that realizes that better than I do. Since the accident about two weeks ago I have had plenty of time to think about this and I can inform you folks that it will mean much to me. Those two fingers played a very important part in my private life as I have always been considered somewhat of a penman and also a musician.
- PAUL: That sure is too bad.
- MATT: Tell us Max, in your own way, how this accident really happened.
- MAX: You all know that I had been operating No. 8 press for the past five years. Due to the speed of our machines and the constant use, the dies sometimes get out of adjustment. This condition forms a shaving which accumulates

to a certain extent and if not removed will cause an imperfect impression on the bar. This accumulation was giving me a lot of trouble and I tried to flick the shaving away with my finger. This is the result. (*Holds up fingers.*) (*Committee men understandingly look at each other.*)

MATT: Did you attempt to do that flicking while the machine was in motion?

MAX: (*Rather downcast*) Yes.

MATT: Tell us whether or not you think you did right in trying to flick the shaving away with your finger.

MAX: I must admit that I did wrong in view of safety practices.

MATT: Since by your own admission, Max, you have apparently disregarded one of the fundamental teachings of our safe practices can you give us any procedure by which this accident could have been prevented?

MAX: You folks all know how fast our machines operate and that to prevent the accident would mean a shutdown. This shutdown in order to adjust the die would mean a loss in my production and would show up on my piece work earnings. My foreman, who is also interested in production knew, of the condition of my machine. (*Committee men register surprised look.*)

BOB: Well Mr. Chairman, I think this puts an entirely different complexion on this whole case. I think . . .

MATT: Wait a minute (*Retarding Bob's sentence*). Gus, you heard what Max had to say in regard to this unfortunate accident in your department. Is his statement right?

GUS: (*Taken off guard*) I guess it is but let me tell . . .

MATT: Now just a minute, Gus. You knew of the condition of this particular machine on this day previous to the accident?

GUS: Yes. I passed this machine shortly before the accident occurred and as is customary I picked up a bar and noticed the imperfect impression. I immediately knew what caused this.

MATT: What procedure would safety measures prescribe that you should follow in a case of this kind?

GUS: Well, just what Max hinted, namely, a shutdown in order to adjust the die.

MATT: I see. Gus, please tell us what you know about this accident.

GUS: All right. I'll tell you just what happened before the accident as far as I am concerned. As I have just remarked, I noticed the imperfection on the bar and called Max's attention to this fact. Max indicated that he knew of this condition. I then continued on my observation of the other machines in the department. I had just arrived at No. 1 press when I heard the commotion resulting from Max's accident.

MATT: Observing the condition of the bar, I'll say you had two procedures which you could follow: Either to do as you did, namely, pass up the condition, or to shut down the machine for adjustment.

GUS: (*Hesitatingly*) Yes.

MATT: You certainly will admit now which procedure you should have followed consistent with safe practice.

GUS: (*Sullenly*) Yes—Shut down the machine.

MATT: (*Forcibly*) Why didn't you do it?

GUS: (*Heatedly*) You folks all know that practically every operation in my department is on a piece work basis. We in industry all know that the primary object of piece work is increased production per man. Our quotas are assigned on the basis of maximum production and therefore the foreman is vitally interested to produce his assignment. Each individual operator is interested only for himself. Therefore we are both primarily concerned about keeping the machines going, going, going, all the time.

- MATT: (*Rising heatedly*) Gus, do you mean to insinuate to this committee that speed in production is indirectly to blame for this accident?
- GUS: (*Forcibly*) Yes, I do, if you want to put it that way.
- MATT: Gus, look at that unfortunate man, one of your own employees. This man will be back in your department as soon as he is able to work and will be with you probably for many years, compelling you every day in your contact with him to look upon his condition. Don't you really feel sorry that this accident occurred?
- GUS: There isn't anybody in the entire plant that feels more badly about this accident than I do.
- BOB: Mr. Chairman, will you permit me to say a few words?
- MATT: Certainly, Bob, go ahead.
- BOB: Gus, in the course of your management of that department did it ever occur to you that the most valuable material in your department is your own men? From what I have heard during the course of discussion it would appear to me that you are stressing too strongly the point of material property and production and that you do not sufficiently consider the fact that every man and the welfare of every man under you is dependent directly upon you for protection while at work. If you had considered this point more seriously there is no question in my mind that this accident could have been avoided by an excusable shutdown.
- MATT: (*Having again seated himself during Bob's discourse*) Yes, speaking of shutdown, isn't every shutdown in your department covered by a report?
- GUS: Yes.
- MATT: (*Turning to other committee man*) Paul, have you any comments to make on what you have heard so far?
- PAUL: Yes. Gus, you have attended the Foremen's Safety School?
- GUS: (*Bored*) Yes, I have been going to the Safety School at the Auditorium for the past three or four years.
- PAUL: One of the principal talks during the course concerns itself about the fact that safe practices can be made consistent with maximum production. Did discussion along this line never interest you? Why did you go?
- GUS: Oh, I've been going to the darn meetings, as I just said, for a couple of years, but went there mostly to get five punches on my ticket so I could attend the banquet free of charge at the end of the course.
- PAUL: (*Shaking head*) There is no question but that he has a lot to learn about safety. (*Chairman and Bob nod admittingly*).
- MATT: (*Turning to Max*) You have been severely punished by this accident for your disregard of safe practices. You have suffered a great loss which we cannot replace, but nevertheless, this discussion is mostly for your benefit and also to prevent by all means a recurrence of this or any other accident. One of the principal functions of this committee is to make our organization the safest place in which to work. You no doubt admit by this time that you took an awful chance and proved to be the loser. I'll wager that you have thought about that fact repeatedly since the accident. We consider you right now one of our best arguments for the observance of safe practices, always regretting that your crippling was necessary to do so. You may go now and when you come back to work carry these thoughts to your fellow employees.
- MAX: (*Rising*) I appreciate your attitude toward me. (*Exit*).
- MATT: (*Turning to Bob*) Have you any further comments to make?
- BOB: (*Shakes head negatively*).
- MATT: (*Turning to Paul*) How about you Paul?
- PAUL: No.

MATT: Now Gus, without going further into this case it appears that in running your department you take a peculiar attitude toward safety. Off hand, I'd say that you are responsible for this lamentable accident. I base this statement on several reasons. This particular machine was producing goods of inferior quality. This is absolutely inconsistent with the policy of our company and any other company. If nothing else, that was sufficient reason for shutting down that machine to make the adjustment.

You maintain and stress the factor of speed. I will venture to say that the necessary shut down in this case would have meant about thirty minutes. Isn't that right?

GUS: (*Shakes head*)—Yes.

MATT: Presuming that you could not pick up that lost production in the course of a day, or week, or maybe the entire month, you could nevertheless protect yourself, as we have pointed out to you and as you have admitted, by means of a shutdown report. In fact, I would say that this is the principal reason for having this form in effect. Then again, you have expressed an indifference toward the Foremen's Safety School. This has been an annual affair for seven years in this city and has been maintained at no small expense by local industries. The mutual understanding which you and Max seemed to have had on the quality of the product would indicate that this sentiment prevails throughout your entire department.

I am almost willing to discount these various points in your disfavor if you will just let me impress this fact on your mind: In the future Max will always be a living example of your superficial interest in your fellow worker. Don't you realize that in this day and age you are your "Brother's Keeper" in industry? In my mind you are liable for this preventable accident. Have you anything to say for yourself?

GUS: (*Dejectedly*) Gentlemen, I am now convinced that I have been wrong in my attitude. There is no question but that I was at fault but I have learned my lesson and I can promise that in the future I will cooperate with you to make our plant the safest.

MATT: We appreciate your change of attitude, Gus, but nevertheless we will take all the facts under advisement and in a few days we will inform you as to our decision relative to imposing a justifiable penalty.

TO COMMITTEE MEN: That will be all for this morning boys, and I wish to thank you for the interest and sentiment expressed toward this case.

(CURTAIN)

CHAIRMAN WINANS: We thank you very much, gentlemen, for telling us that story.

Our next subject should be "First Aid Training and Its Relation to the Prevention of Accidents." For many years Mr. Titus was connected with the telephone company in the installation work. All of us know the remarkable work along the lines of first aid training that has been done in that wonderful organization. It is no wonder that he believes as he will tell you he does.

First Aid Training and Its Relation to the Prevention of Accidents

W. A. Titus, Western Electric Company, Hawthorne Works, Chicago, Ill.

I take it that the acceptance of my subject constitutes a challenge to me to prove that training and first aid really mean something in accident prevention.

I want to make this thing clear to you. We have at the Hawthorne Works a very adequate hospital. We have a large staff of physicians and nurses. We do not encourage or permit lay first aid on the premises. That means literally this: that first aid training as we do it is not for the purpose of preparing our people to handle accident emergencies within the plant at all. It is solely for educational value in the safety picture. That makes the problem just a little harder to prove, I think.

I imagine that in most industrial plants first aid training is being given where there is some idea that lay first aid work will be done in handling the emergencies of the industry. I may say that I have yet to hear of an industry in which first aid training is being done (except our own) where that condition of not permitting lay first aid in the plant prevails. If there are others represented here, I should be interested to hear from them.

Perhaps in order to understand clearly what we are getting out of first aid training and in order that you may take away any values there may be in our methods of approach, I should tell you briefly how we carry on our training program. I hope to get over to you this one idea in that explanation—that the organization and administration of a first aid training plan, either on a large or a small scale, is both simple and economical. I imagine that many people who would like to go in for this thing hesitate to do so because they are afraid either of the course or of the problem of finding adequate features.

Organizing a Program Among 28,000 Employees

We have been doing first aid training in the Bell System, of which the Western Electric Company is a part, for a number of years now, but by and large, prior to the time that we started it at Hawthorne in June, 1926, I don't think any training had been done strictly for educational purposes.

In the operating companies they have problems in which lay first aid plays an important part; that is the telephone companies proper, because their organizations, particularly the exposed personnel, work in the field pretty largely, and and many times out of contact with adequate surgical or medical facilities. They need that sort of thing. We are so equipped that we don't. As least we haven't discovered the need for it yet.

A year ago last June I was told to go ahead and organize the program. Up there at Hawthorne at that time we had some 28,000 people. The project was to teach those 28,000 people what they ought to know about first aid. I submit that that is a mass production problem, and we tackled it on a mass production basis.

The first thing we did was to select 300 supervisors. You will get presently the reason for that. We selected 300 supervisors on the theory that their supervising position implied that they already knew enough about handling men to put over a simple idea, to maintain a reasonable degree of classroom discipline to command a proper hearing.

We divided those 300 men into 15 groups of 20 men each. We assigned each of those groups to one of our staff doctors. That may suggest right away to you: "My Lord! If they have got 15 staff doctors out there, what kind of a place are they running? They must be killing them right and left."

Let me explain so you don't get a wrong impression that there is only one man on surgery; the others are health men. We used those 15 doctors as instructors. We got those fellows together with the American Red Cross for special technique in first aid. We turned them out in the summer of 1926. We had 201 men that summer who on the basis of their instruction, we were convinced, could go ahead and teach a class. Naturally these men had never

taught before, at least they didn't know they were teaching. Some of them were pretty much scared at the prospect of getting up on their hindlegs and talking before a group of people. They bucked under the saddle like unbroken colts. They brought me all sorts of stories why they ought to be excused from this teaching problem. So I worked a mean trick on them. I told each class that one week subsequent to that date we were going to have a first aid contest and that it was up to that class to produce a five-man team, that I expected at a certain time and place to find 15 five-men teams lined up for a contest.

Then I got hold of Dr. Gentles, the head of the first aid division of the American Red Cross in Chicago, and persuaded him to come and act as referee. He was good enough to get Dr. Orr, who is head of the medical organization of the state militia, as a judge, and three or four other doctors. We added a few from our hospital as judges.

We brought those instructors together in our main rescue building, gave them a little feed, let some of our visitors talk to them, and then wound up with a good peppy talk from one of our works officials who has a reputation for just that sort of thing. When he asked me what to say, all I said was, "I want these boys to get clearly that this thing they are getting ready to do is something that the management believes in and is squarely behind." He did the job to the queen's taste.

A Remarkable Demonstration by New Men

Considering the fact that for the week previous a very considerable percentage of those team men had had wives sick in bed, children on the verge of death, and grandmothers to be buried, and all the stuff that goes with baseball games, as you well know, I was a little bit surprised that every single one of them showed up. When we got up from the table, they went out on the floor and went after those first aid problems, presented under Red Cross conditions, like terriers after rats. It was the most remarkable thing I ever saw. Our visiting doctors commented upon it. The poorest team score on that floor, under those conditions (and remember they had had no time to organize the teams, they were simply demonstrating before a select audience how much they had learned), was 78, which incidentally gave me a chance through that medium to prove to the management that we had some fellows who knew their first aid, and that we had not wasted their good money in that summer training.

Their audience that night was made up of staff people pretty generally. It was limited to about 200 folks, because I didn't want them worried by having a big wild audience to work in front of the first time.

I got them together the afternoon after that contest just to see what their reaction was. They were all enthused and warmed up. I said to them, "Fellows, I wonder if one thing struck you as it struck me; that is, that you individually learned more first aid in that brief hour of contest than you had learned in 15 hours of intensive instruction through the summer." And they just came right up like that: "You're darned tootin', we did."

"That being the case, maybe the way to teach this first aid thing is to make it a succession of first aid problems."

"We guess you're right."

We threw away all the teaching outlines that we had used on the teachers' training course, and we wrote a succession of ten practical first aid problems covering the field of the thing we were trying to put over, pretty largely with their own suggestions; practical problems, not industrial problems, but problems of the highway and the home, beginning with the simple and ending with the complex.

The class was given the problem and the specific text-book references through which they could read up the solution. They came into the class and a certain number of them were invited to demonstrate the correct procedure. They tried their hand. The rest of the class sat back and criticized. If Bill Jones didn't like the way it was done, Bill Jones was invited to do it better. Every lesson was a practical first aid contest.

We enroll our classes entirely on a voluntary basis. We simply get out the necessary publicity announcing that at such a date we will start first aid training. We did start in September of last year. Simple little enrollment forms were passed out to all the supervisors in the plant. Anyone who wanted one filled it out and turned it in.

We organized the class on a first-come, first-served basis. Each branch, on the basis of its total personnel, was allotted a quota of a maximum, based on what we thought we could handle with our available teaching staff and our classroom facilities. We organized a maximum of 85 classes, assigning 20 men to a class. On that basis we put over three semesters before warm weather started this year. We had graduated, under Red Cross standard requirements for examination, 3,001 men under that plan up to that time. We now have in our fourth semester of training a little better than 1,600 men at work.

There are some tricks in the handling of the examination on a mass production basis that may be of interest to you, and while they perhaps mean nothing in my subject. I am going to tell you how it is worked.

Two Hundred Questions on First Aid

The question came up early in the game whether, examining so many people on so many different points, it was going to be practically impossible to avoid an exchange of examination information between men who had been examined and men who were to be examined. We prepared 200 questions covering the whole field, 25 series of eight questions, balanced on a card, to cover the different departments of first aid training. Then we put that up in a little booklet. The cards were numbered and reproduced in this booklet form for convenience. We handed it out like this: "Here it is. This is what you fellows are going to be asked when you are examined."

"Oh, is *that* going to be it? Oh, that's fine." Then, "Holy Moses, which one am I going to be asked?"

"Lord knows, that's up to you."

They come into the examination room, the examiner sits down behind the desk, shuffles the cards, spreads them out and says, "Come on John, pick yours." The only answer that John has got is that he has to know the answer to 200 questions before he starts. If he knows his 200 he knows his first aid.

It is just a mass production stunt but it is perfectly applicable on a large or small basis. It allows you to do the job quickly and uniformly. It relieves you of the situation which might develop where Bill says, "I fell down because that particular instructor had it in for me anyway and asked me a stump question." The instructor has no option in the matter. John picks his own block of questions.

Before we go any further into the attempt to prove this thing, maybe the question—Why first aid training at all?—should be discussed. I ask that question because we have to break down the resistance of hard-boiled individuals who can't see the sense of taking it.

Primarily, as I see it, this question of first aid training is something that we owe to ourselves, our families, to society at large.

Picture this simple situation, if you please. (I hate to drag in the gruesome, but it helps to make the picture.) You are driving alone on a highway. You run off the road and your car turns over. You wind up in the ditch with a simple fracture of the leg and a splinter of glass through an artery in your upper arm. You have no right to assume that the next car along that road will have a doctor in it. Stop and consider what probably will happen to you. The next outfit along the road may be one or two men; they have got red blood enough in them so that they stop and try to help you. They get out, drag you out of the ditch, pull you into the rear end of the car, and go hunting for a hospital. When you arrive there, what does the surgeon on the job at the hospital find? A shell bled white, a hopeless case. He can't do anything.

Suppose the hospital was around the corner and you got there quick enough so he could plug the hole and save you partly, at least. He commences to strip the clothing away, and what does he find in the leg? A simple fracture compounded, a broken bone piercing the flesh, churning around in an infected wound. It means weeks in bed, with a possible amputation, out of a simple situation that any intelligent man could be taught to handle in one of these elementary first aid courses. Any intelligent man can learn the blood control in one minute.

The Rising Flood of Accident Is Appalling

Let me submit, if you don't like the idea that this is the kind of treatment you are going to get, what are you going to do about it? Have you got any right to expect any better treatment in an emergency like that than you are prepared to give yourself? I say, no. That argument usually gets them.

You can duplicate that type of situation to the queen's taste. Picture it for yourself in a thousand and one different ways. It is always the same darned issue. You have no right to expect any more expert treatment in the emergency than you are prepared to give yourself.

I am a nut on the subject, I admit, but it seems to me that the gradual rise in accidents on the highway and in the home is appalling. With all we have done to educate people both with respect to the home accident and the shop accident, there are 3.22 ways of getting hurt outside the plant to every one in the plant, on the basis of our own figures; and our plant is one in which we have got every hazard that anybody in this room can think of, I'll gamble.

I want to make this prediction, that that rising tide is going to force a popular reaction on this question of first aid that will result in a short time in a situation where no man or woman would confess ignorance of first aid principles any quicker than they would confess illiteracy. That is my guess.

I will tell you what it costs us to do this thing we have been talking about. . . . By the way, this first aid thing is part of the problem of interesting folks. The stationery to be considered—the publicity to be considered, first aid supplies, special furniture for equipping classrooms, service to classrooms, preparation of supplementary text material, teaching outlines, teachers' codes—need not worry you the least bit, because the job has been done and well done. You can have anything we have got, so far as we are concerned. Other people have got good samples of the same thing available if anybody wants to try it.

It costs us \$2.50 a man to put that program over. I hope I can prove to you that it is worth it.

Let's get right down to the challenge of the subject. What does this training thing mean in accident prevention? It means this: I don't have to argue with you over the question of whether or not the keynote of supervision is the ability to teach. The whole success of the supervisor depends upon his ability to

teach. This question of keeping folks safe is not the mysterious thing that I thought it was; it is a matter of finding a sound, whole, intelligent man teaching in his trade and then supervising them to see that they follow his teaching. That is all there is to it. Who in the place can do that teaching job but the foreman? He is the technician, the man who knows the job. Who can supervise it but the foreman? It is when staff organizations attempt to get in between that man and his supervisor that situations arise which produce such letters as you heard here. Our attitude with respect to this staff interference idea is: Don't do your personnel job in such a way that you get between the man and his boss. When you break that line you are headed for trouble.

We have taught our supervisors, at least 300 of them by this process of training, to teach some one thing that is closely allied with safety. We have demonstrated to the man in practice that he teach that thing. He has learned a confidence and a technique with respect to teaching. That is one gain, perhaps intangible, but I think it is there, certainly.

A Safety Consciousness Alive to Carelessness

We have taught the men in the class through the presentation of an infinite variety of practical situations to see eventualities. In other words, we have created mental image after mental image after mental image. Those of you who are psychologically inclined will get my drift in that connection, a safety consciousness by the reiteration of situations which are the result of carelessness and indifference.

The guardable hazard is now down to two per cent or less in our plant. Any further improvement we make must be made through the education of the other 98 per cent.

We teach our first aid with due regard for anatomy. We don't give them rules of thumb which they can forget in six months. We teach them why these things are done. We are teaching them to understand that this body is an intricate machine—not an Ingersoll watch that ticks and keeps time, to be sure—but a wonderful mechanism with jeweled bearings, a thing to be cherished and cared for, a thing which when it gets out of whack should be taken to the expert watchmaker—the doctor—and not tinkered with individually; which reaches back to this question of personal first aid in the face of surgical facilities.

In most things that we do in personnel work we are dealing with a lot of intangibles; they are pretty hard to measure. I have got one little unit here which seems to be a measurement, although it may have to be limited. In the year since we started training these men, the 3,001 men I have named who completed training have yielded four accidents. That is at the rate of 1.3 accidents per 1,000. The remaining personnel have yielded a rate of 5.74 per 1,000.

I will submit right here that in all probability these 3,000—the first to rise when the call came—represent perhaps a superior level of intelligence in the organization. Maybe it is true that those fellows, left to themselves, would not have yielded a 5.74 ratio; I don't know.

On our basis of enrollment, where definite quotas are allowed by branches and departments, we have attempted to provide a homogeneous enrollment with representation from all levels of the organization, all types; and I will submit this one thing, that the chance taker, the fellow you worry the most about, as a rule, is no dumbbell. The devil-may-care type is rarely a dumbbell.

I will just close by saying I am happy to state that my folks tell me that we have cracked all previous records this month by way of celebrating the Safety Congress. We are turning in the month's accidents with a record 26 per cent better than any month in the previous history of the company at Hawthorne.

CHAIRMAN WINANS: Thank you, Mr. Titus. There is one question that I should like to ask Mr. Titus to discuss for a moment. Perhaps it is in the mind of one of you at least. How, in your opinion, Mr. Titus, can this first aid training principle be applied in a small plant, say, of 250 people? I take it from your statement that you feel the principles are possible of application practically anywhere. Can you suggest to those of us who do have such small plants how we might do it economically?

MR. TITUS: It seems to me it is only a question of pyramiding, any way you work it. If you want to start in a small way, with one man, go get a doctor from the Red Cross. They have got plenty of them and they will be glad to serve you. They will put over a whole course for you under their own supervision for \$60. That gives you not only a teacher at the start, but a chance to train 20 teachers, or 25 teachers, as the case may be, right off the bat. Select the best of your available timber as you see it; put them in a class under a Red Cross instructor. In ten weeks' time you have got available as many as that selected group will yield. It may be all of them. From that you can expand as fast as you please. Twenty will yield you 400 enrollments, possibly, right off the bat.

There is nothing at all difficult about it. The Red Cross has worked the thing down now to a point where it works splendidly.

Talking the Conservation of Life and Limb

MR. CHAPMAN (R. R. Donnelley & Sons, Chicago): I want to ask if the training was done on the company's time or on the employees' time.

MR. TITUS: That is the beautiful thing about it. Even the training of the teachers has been done on their own time. Remember this: when we talk about safety to our men, we talk about the conservation of life and limb as a social obligation that we all carry. The circumstance of association with an industry is only an accident. The safety of the individual is something that belongs to me as a man and not as a supervisor, and I am going to handle that job, no matter what it costs me in personal effort and personal time. That is the way these fellows are going at the thing.

After all, this contribution is a social contribution, it is not an industrial contribution. They don't use one hour of that training time within our plant.

CHAIRMAN WINANS: What time of day is it done? In the evening?

MR. TITUS: Immediately after quitting time for an hour and a half. Of course, we have all our people within one fence. A large proportion of them live within two miles of us. That makes it relatively simple from that standpoint. That arrangement, of course, is capable of infinite modification.

H. J. SPOERER (Youngstown Sheet & Tube Co., Evanston, Ill.): What are the working hours?

MR. TITUS: Seven-thirty to five sharp; eight-thirty to five-fifteen, office. We make no differentiation between shop and office people in these classes. They all start together.

IRA V. KEPNER (Pennsylvania Salt Mfg. Co., Philadelphia): I should like to ask Mr. Titus a few questions with reference to why he will not permit first aid inside the plant.

MR. TITUS: What is to be gained, with a first-class hospital, expert surgeons, nurses and good transportation?

MR. KEPNER: What size is your plant? Is it all confined in one large building?

MR. TITUS: Two hundred acres, about 240 buildings.

MR. KEPNER: The Pennsylvania Salt Company plant at Philadelphia is probably that size. We have a great deal of outside work which comes to the plant. Just to illustrate what we do in case of a serious accident: One of our barge captains,

while changing the position of his barge, became foul of one of the towlines and it just snapped off his leg below the knee. If it had been done by a hatchet it could not have been cut off more smoothly. One of the railroad men just inside heard him give a little yell and rushed down there. He was a first aid man. He had nothing about him at all except his belt, which he took off and used for a tourniquet. The man was about six minutes from the hospital, but that first aid that he received there saved his life; there is no question about that.

MR. TITUS: Of course, it is fair to qualify my statement somewhat in this way. It does not make any difference how many prohibitions you put on the giving of first aid in emergency, if there is a red-blooded man on the job first aid of some sort will be given, trained or untrained. What we are trying to do, primarily, is to avoid the big hazard of infection. We don't want people under the encouragement of first aid training to try to take care of themselves and stay away from the hospital. The hospital is perhaps some distance from the average man's work. If he can get away with a dab of iodine and a bit of rag on his own initiative, we don't get the case. We are not satisfied always that that is the best treatment. Certainly the puncture wound never should be allowed to go on that basis. We think it is better to establish the prohibition, accepting the inevitable with respect to the outstanding emergencies. Thank the Lord they are darned rare with us.

CHAIRMAN WINANS: I think we had better stick to our subject, which is not how to administer first aid, but what the value of first aid training is in accident prevention.

The Psychology in First Aid Training

Mr. Titus, will you tell us just why you think that first aid training makes a man safer? What is the underlying psychology? Why is it? You believe it.

MR. TITUS: I tried to make that point in the statement that the deliberate reiteration of pictures of eventualities is the way it is done; and, after all, we are only applying the psychology of the safety poster and the safety film when we do that. We are trying to build a picture by reiteration.

Suppose it were possible for you to assemble all your whole and sound employees and parade them along a platform, a la fashion show, and the same with all your maimed employees, and you pulled that regularly once a week. Do you suppose it would have its effect? We don't want to do that. That is gruesome. That is an offensive way of doing it.

But you say to a man in the class, "All right, we want a problem to work with. You think up one for us." He spreads one out for us, something he read about, something he heard about, something that happened to a friend of his. Everybody hears about that problem. We try to treat it. There is another one and another, ad infinitum. They are all piling up a brain picture of an eventuality behind carelessness.

MR. ARKILLS: I should like to ask Mr. Titus if in his course he mentions that these are the result of carelessness and tries to put over that thought while they are being trained.

MR. TITUS: My answer is that each problem is fully dramatized.

A. C. WALL (Larkin Co., St. Louis): May I ask Mr. Titus if he can read some of the questions that are asked?

MR. TITUS: At random we will pick the question asked by the man who picked Card No 11. I just cut it out of the deck.

"While driving alone in the country you run down a cow on the road. In the collision you are pitched through the windshield and receive cuts on the arms and shoulders, all bleeding dark blood slowly. It is ten miles to town and about a half mile to the nearest farmhouse. Describe your action."

"Willy is bitten on the left lower leg by a stray dog. Wound is lacerated and

bleeding dark blood freely. His mother has fainted away on the kitchen floor. How would you handle the case?"

"While the family is vacationing at the summer cottage Johnny falls out of the tree and receives a compound fracture of the right thigh bone, just above the knee, with a severe sprain of the left wrist. There is considerable bleeding of dark, red blood on the leg. In order to get a doctor you have to drive 13 miles. Describe how you would handle the case."

"You are alone in a car on a side road and pass a farmer with a team of young horses. The horses run away, tipping over the wagon. The farmer suffers severe sprain to the right ankle and dislocation of the hip. How would you proceed in rendering first aid?"

CHAIRMAN TITUS: Do these relate to plant accidents?

MR. TITUS: No, they are all outside accidents. They may happen to any of us under average living conditions.

I will be glad to send you this booklet which details all the examination questions if you will write to W. A. Titus, Hawthorne Works, Western Electric Co., Chicago.

ADJOURNMENT.

*SIXTEENTH ANNUAL SAFETY CONGRESS
NATIONAL SAFETY COUNCIL*

Public Speaking Class

Tuesday, September 27, 1927

C. D. HARDY, Lecturer

Professor, School of Speech, Northwestern University, Evanston, Ill.

The first session of the Public Speaking Class at the Sixteenth Annual Safety Congress was called to order at nine-forty o'clock by Mr. Julien H. Harvey, director, Territorial Councils, National Safety Council, Chicago, Illinois.

Mr. HARVEY: This series of sessions, ladies and gentlemen, is something of an experiment on the part of the National Safety Council. We feel that every man and woman interested in the safety movement is called on, more or less frequently, to deliver safety talks, and we believe that a good many are not just as well satisfied with their efforts as they would like to be. We all haven't the opportunity of attending schools of oratory.

We felt, therefore, if we could bring to you a series of lectures on this subject, giving you some of the fundamental principles, it might be extremely helpful to you in your future work. If we are going to make these safety talks, we want to make them just as effective as possible. I said it was an experiment, but judging from the attendance here this morning I don't believe it was much of an experiment. I feel confident that tomorrow morning we are going to have to have a bigger hall for these meetings because you are going to inform your friends and are going to bring them back with you to the second and third lectures.

I don't want to take any more of the time of the speaker in introducing him, except simply to say that the gentleman who will handle these three lectures is Professor C. D. Hardy of the School of Speech of Northwestern University, who will now take the floor and tell you just how to do it.

Some Guiding Principles for the Speaker

When I was first asked if I could come down here to make some suggestions by way of discussion on general effective oral discussion, I was considerably confused as to what type of people I should meet, how many I should have here, and just what I ought to say. And now that I am here and find, not a class, but an audience, I am even more confused; I am even nonplused as to what I ought to say and just how I ought to say it. I am a bit in "statu quo." I don't mean by that term "in statu quo" what your lawyers mean when you go to seek their advice and they use that legal term.

I have in mind a bit of a story that my father, who was Yankee-born, up in Maine, used to delight to tell. It was about a group of old Mexican war veterans who lived up in Maine, in Aroostook County, who were too old to go to the Civil War but were

nevertheless very patriotic. It was their custom to gather around a stove in a little old country store up in Aroostook County to hear the news from the front. On this particular morning—it was the sixth day of McClellan's seven days' retreat from Richmond—they gathered around the country store and the reader of the group was reading the morning newspaper, and he read across the top of it, in headlines not quite so large and conspicuous as those that are used by certain modern newspapers but nevertheless rather conspicuous, these words: "The Army of the Potomac is in statu quo."

Where the Army of the Potomac Lay

This old fellow had never studied any Latin. He didn't know exactly what those words meant. He took off his spectacles, wiped them, reread the line, "The Army of the Potomac is in statu quo," and said, "Now, then, gentlemen, them thar words be from the Latin and they mean that the Army of the Potomac is in a hell of a fix."

Now, when I, a mere teacher, am asked to talk to a group of practical business folks about a practical matter such as you frequently confront, I am in a bit of statu quo as to what I ought to say and just how I ought to say it.

In this series of discussions (three of them), I am going to try to point out some of the fundamental principles that govern good public speaking, in this first lecture. Second, I am going to discuss some of the principles that govern the development of the speech by way of the selection and application of material, and in the third address or discussion, if you do not want to dignify it by the name of address, I am going to attempt to say some things about the conduct of the man on the platform, his use of voice, his use of body and the emphasis necessary to make his oral discussion effective.

There are, as it seems to me, good and sufficient reasons why a group of folks like yourselves should be interested in oral discussion. You are called upon very frequently, I am sure, to make talks before audiences of one kind or another. Public speaking has always been an important asset in our American democracy. It is much more important, in my judgment, in these days than it has ever been. Our life is no longer simple. Go back 100 years, and we had but very little industry in this country. We were principally an agricultural people. Our business organizations were simple. The business institution did its work in a limited area. Now that same type of institution does business all over the country and perhaps all over the world. That means a complex organization. You multiply that one complex organization by the number of large businesses that we have in the United States, and you get the tremendously complex social and economic business organization.

Ability to Explain Ourselves Important

Well, the moment you get a complex business and social organization, just that moment you get more difficulty in understanding what is going on and understanding how different individuals run their businesses, and the more difficult you find understanding, the more important it is that we get on the basis where we can explain ourselves one to another; explain our businesses, each to the other. That requires considerable development in the way of expressing ourselves, and, for that reason, if for no other, in my humble judgment, men who have occasions to make addresses may do well frequently to look into and to check themselves up on the best methods of making oral discussions.

I read an interesting book not so very long ago in which the author made this

point: That we were developing in science, in invention and in complex social and economic order much more rapidly than we were developing in our ability to make adjustments and to explain ourselves to one another in this complex social and economic organization. And he made the point that in the next 25 or 50 years we must develop much more rapidly in our capacity to express ourselves to one another than we have in the past, else we would not be able to understand our rapid development in economic and social organization.

I think there is some truth in that principle and, for that reason, I think it is well for us to take some interest now and then in this whole matter of discussion of problems.

Three Things to Avoid

First, I want to point out two or three things that in my judgment effective oral discussion is not. In the first place, it is not dogmatism. In a democracy, the last word on any subject can scarcely be said. Recently I heard a man in my own field make a speech in which he was very dogmatic, speaking as though he had the last word in the case. He made a very poor impression upon his audience because he was speaking to people working in the same field, thinking in the same field with about the same body of facts that he had to deal with, and he spoke as though he knew it all. The impression made upon those to whom he was talking, and with whom he was discussing his subject, was unfavorable. There are two types of men who can perhaps speak dogmatically. The man who is a tyrant, who has arbitrary authority, who can make men come and go as per orders, may speak dogmatically. He may speak as though he had the final word in the case. The other type that may speak dogmatically, is the individual who is recognized by everyone, to whom he is speaking, as an authority, as the one man who knows more about that subject than anyone else.

Now, if you recognize yourself, in speaking to a group of people, as a man who has either the arbitrary power to make your suggestions effective, or who has a position of authority, so that you know that everyone to whom you are talking recognizes you as authority, perhaps you can speak dogmatically. I do not mean to suggest that that is the thing for you to do, but, unless you belong to one or the other of those classes, it seems to me you ought not to speak dogmatically. You ought, on the other hand—I will take this up a moment later—to sit down and reason with people, or stand up before people and reason with them, rather than speak dogmatically to them.

I think it is true—I have had a bit of experience in business, not a whole lot, but a little—that the man who develops great power and influence in business has a temptation, when he speaks to an audience, to speak dogmatically. In his business he has developed the habit, the tendency of speaking with a great deal of positiveness. I suggest that when addressing an audience one ought not to speak with too much of that dogmatic attitude. It suggests rather an unfavorable front, if you will permit me to put it in that way.

The second thing I want to say is that public speaking is not demagoguery. What do I mean by demagoguery? I mean the man who makes purely an emotional appeal. I mean the man who makes facts say a great deal more than those facts inherently will say, or a man who takes facts and disguises them so as to make those facts say what he wants them to say, rather than what the facts in and of themselves would say, if presented and left to tell their own story. I am aware that there are a good many public speakers, even in America here, who do speak in terms of the demagogue, and get away with it for a time, but in the long run your misdemeanors on the public platform are going to find you out. In the long run the truth will come to the front and you will be recognized for exactly what you are, namely, a demagogue.

A third thing that effective public discussion is not is, that it is not the grand manner. What do I mean by the grand manner? I mean the delivery of an oration to people, a show, the spread-eagle, grandiloquent type. Fifty years ago you could do something in this respect that you can't do in this mechanical, this practical, this workaday age. Men on the whole are no longer interested in listening to the man who puts on grand gestures, who throws out his chest, who bellows so that you can hear him an entire block, who builds up his periods to make an emotional appeal, or an appeal to the imagination only.

Public Speaking Has Been Greatly Modernized

We have a great deal of bad teaching even in our schools in that respect. In the past we have taught a great deal the type of oratory that was characterized, or the type of speech that was characterized, by a Daniel Webster or a Henry Clay. There are two things to be said about that, the first is that we are not living in the age in which Henry Clay and Daniel Webster lived. We have changed our type of public address very materially. Wendell Phillips taught us how to do it. And the second thing is that unless you are different from the type of fellows that you look to me to be, you aren't Henry Clays and Daniel Websters. If you know yourself to possess the magnificent personality, the sweep of personality, the colorful, the imposing personality of a Daniel Webster, you can speak in the grand manner. If you can command language, as he commanded it, you can speak in the grand manner, otherwise it seems to me that you ought to adopt a different method. Now these are three things that I wanted to suggest, by way of introduction, that I think public speaking is not.

There are several things I want to suggest that I think effective public speaking is. The first one is, that effective public speaking is having something to say. Personally I cannot conceive of a good speech that is made up merely of words and sentences and paragraphs. In our age what men, particularly in business, are demanding is fact, a speech that is built upon fact. There is altogether, I think, too much belief, on the part of many people, that the development of effective speaking, oral expression is a gift, a matter of what nature has done for us. Now I wouldn't say that nature has not done a good deal for many people, but anyone who thinks that effective speaking is purely inspiration, forgets, I think that, after all, effective speaking is perspiration, not inspiration; it is hard work. It is delving into the facts until you get all of them.

You build your speech upon information. That is particularly true, I think, the moment you begin to discuss safety matters. If one is to make (now perhaps I ought not to mention this field but I am going to make this statement) an effective speech on safety matters, I submit to you that he ought to know what has been done in safety, not only in his business, but in other similar businesses, and what has been done in safety matters the country over. He ought to know historically what has been done as well as what is now being done in safety matters. In no other way, in my judgment, can a man make an effective speech.

The first thing, I repeat, that an effective speech is, is having something to say. The second thing that I want to suggest is the development of the power to think in the facts that you have, to analyze those facts into their various parts—divisions we would call them, if I were speaking to a class in public speaking—divide the body of information into its logical parts, presenting one part at a time.

If my experience means anything, friends, I think here is the greatest limitation of public speakers. They may have quite a body of fact, they may know quite a little about a subject, but they do not spend time enough in thinking about that subject until they have thought themselves through from the beginning to the end of the material; discovered what is primary, what is secondary, and then, in the statement of that material, state it so that the primary is first and the secondary is second, so that

the primary is principal, and the subordinate follows in support of the principles. To get that gradation in the organization of one's material, goes back to one's capacity to think into his information, through his information until he has discovered the significant.

The third thing I want to suggest is that public speaking is conversation; elevated conversation, magnified conversation, if you please. Do I mean to suggest that the speaker before an audience converses with an audience? Well, that is exactly what I mean. What is the difference between conversation on the part of a speaker before an audience and conversation between two individuals in a room? The difference is not in kind, but in degree. If you will just imagine the intimate, well done conversation between two individuals, put under a magnifying glass, you get about what I mean.

I mentioned Wendell Phillips a moment ago. He taught public speakers in America a great lesson. He taught them that it was possible for a cultivated, dignified New England gentleman to step upon the platform, before a group of people and talk to those people just as though he were talking intimately with them. I want to give you a striking illustration of how that worked in his case. He went to Cincinnati, according to report, in the days before the Civil War. He was warned not to appear there to deliver that address. He went. When he got there, there was no one that could be found in the city who had the courage, as chairman, to introduce him. The audience was assembled. They waited fifteen minutes for the chairman to introduce the speaker. No one appeared. Then a gentleman appeared upon the platform and began to talk. Everyone thought of course that that was the chairman of the meeting introducing the speaker. The speaker had been going for ten minutes before the audience recognized that it was Wendell Phillips opening his discussion. So conversational was he, so simple was he, so unlike a speech maker, the customary speech maker of that day, that they didn't recognize that he was the lecturer beginning his lecture. Now that is what I mean by a conversation.

Bryan a Master on the Platform

I dare say that practically everybody that I am talking to here has heard William Jennings Bryan make a speech. Now you don't need to have agreed with William Jennings Bryan, in either religious matters or political matters, to recognize that he was a master on the platform. I don't think I ever agreed with William Jennings Bryan on anything, certainly in politics I did not, but I recognize in him the most powerful platform man in our day and generation. What was the secret of his power? Well of course there were several phases to his power, but one of those elements was the fact that he could talk to you. He conversed with an audience. I heard him several times, upon the chautauqua platform out through Iowa and Missouri, talk upon his story of the two conventions. I refer to the two conventions in 1912. And I heard him many times talk for no less than two hours upon that subject. The interesting thing to me was that, as he stood on the platform scarcely moving at all, scarcely making any gestures of any kind, scarcely raising his voice above a conversational level, he just talked to those people. He never for a moment delivered a lecture to them or a speech at them. He conversed with them.

Now that doesn't mean, folks, that you can't put intensity into the speech. That doesn't mean that you can't put force in it. That doesn't mean that you can't put emotional drive into it. You can. But you keep it on the conversational level, and I submit to you that is the way to get hold of the interest of people and to hold the attention of people. Particularly, friends, is this true in the age in which we are making our public addresses.

Then in the fourth place I want to suggest that effective public speaking is getting the intimate approach, the individual approach. Have you ever asked, or attempted to answer this question: Why is it that the man of affairs, the man of a great deal

of influence in his community, the man who has accomplished results, who has standing, when he gets upon the platform before an audience, is quite frequently frightened to death at that group of people? I have in mind at the moment a banker, a bank president, who has no difficulty in saying "no" whenever he wants to say no, who has no difficulty in facing the most imposing individual in the community and saying to him exactly what he wants to say to him, or what he feels, under the exigencies of the occasion, he must say to him; but put that man upon the platform before 50 or 100 people and he shakes like a leaf. He is frightened. I don't think he could say no then at all. What is the matter?

There is one explanation of the situation. I think it is this, as near as I can analyze it: He thinks of that audience in front of him as a great composite, big individual: just as big as there are numbers of individuals, thought of as one, in the room. I suppose there are 250 people in this room this morning. That means there are 250 individuals in the room. All right, if that is true, then what is my mental attitude toward you? Is my attitude toward you the same as though you were one great individual, or as I talk here are you listening as individuals and responding as individuals? On the whole, of course, you are responding as individuals and not as one great big unit. Now, if I didn't recognize that to be true, I should be a great deal more scared of you than I am, and I am scared enough, so far as that part of it is concerned. My approach to you is that of one individual mind to another individual mind. If the speaker on the platform, before an audience, can once get the consciousness of that, it is going to be much less a problem for him to face and to talk to that audience. Just bear in mind that they are individuals listening to you. And bear in mind, further, that they are individuals, on the whole, sympathetic with you. They are individuals, on the whole, who are anxious to see you succeed with your talk. It is only now and then that you will find a mind out in the audience that would like to see you fail, who does everything in his own thinking that he can do to see you fail. The audiences in America are very sympathetic with the speaker, whether they agree with him in policy, or in fact, or not. They are in agreement that they would like to see you, as an individual, make your talk a success.

The Question Provides Individual Approach

Now, if one can just get that individual approach, so that, when he asks a question, those in the audience will feel that question to be theirs, as individuals, he will be more nearly a success. And I mention again here the case of William Jennings Bryan. He asked a great many questions, he used what we pedagogues call the rhetorical question, a good deal. And it was always interesting to me to sit away back in the last rows of the chautauqua tent and listen to him. When he asked a question I was conscious that that question was effective with me. It was my question. He asked that question of the individual, not of the mass. It was to reach the individual in the crowd, that was his purpose.

You will find that speaking is a great deal easier matter if you get the individual approach. That involves two or three things, I think. I am not going into great detail on this but I think it does involve two or three things. It involves, first of all, the capacity to stand on the platform and to look people straight in the eye. The man who does not have the capacity to look people straight in the eye and talk to them as individuals, loses 25 per cent, at least, of his power. The man who stands upon the platform and looks at the corners of the room, while he talks, or the man who stands on the platform and can see nothing but three feet of carpet in front of him, loses, I say, 25 per cent of his effectiveness. Get the ability and the freedom to stand before a group of people and to look directly at them as individuals, and you have taken a persuasive attitude toward them.

The fifth thing that effective public speaking is, is speaking so as to be heard. There

is nothing more irritating surely, as one sits in an audience, than not to be able to hear what the speaker has to say.

There are several items to be emphasized on this point. I can't discuss them all this morning. I may get some of this discussion into the last talk of the series, but there are two or three general things that I want to mention this morning. Being heard, having a voice to be heard, is, as a rule, ladies and gentlemen, not a matter of degrees of loudness. Loudness has something to do with it, but as a rule it is not a matter of loudness primarily; but is a matter of the way one focuses his tone so as to give it carrying power. One may speak in a voice no louder than I am talking now and be heard anywhere in this room, provided the voice comes to a focus at the front part of the mouth. Too many speakers use the throat muscles only; too many speakers use the chest muscles only. Very few speakers use the diaphragmatic, the abdominal muscles correctly. The good speaking voice is produced just exactly as one breathes. If you can catch yourself relaxed, you find that the power that brings the breath into the lungs, the power that gets it out of the lungs is the diaphragmatic muscle, the pear-shaped muscle which crosses the body here (indicating), and abdominal muscles here (indicating). The voice that has carrying power is the voice that is produced here (illustrating), one, one, one, two, three, four, a, e, i, o, u, up, out. Get the force from this point (indicating). Then the column of air comes up through the throat, which should be relaxed, into the front part of the mouth, where it is focused. The important matter is to get the voice up and out.

Illustration of Correct Voice Placement

This suggestion perhaps is the most practical one that I can make on this point. Get the ability if you can, to throw the voice from you to the back part of the room. Just imagine your gathering the tone up into a little ball and throwing it from yourself against the back wall. Now the tone that is produced in that way will carry farther and be more easily heard than the loud, blatant voice. I had a great lesson in that once, when I was a student, back in 1903 and 1904. There was a performance in the Auditorium Hotel, of that great pageant, Ben Hur. There were three speakers in that pageant who interested me specially. One of them played the part of Messala and another played the part of Ben Hur and the third played the part of a minor character. The fellow who played Messala and the man who played Ben Hur were favorably known as actors with splendid voices; strong, full voices. They were conscious of the fact that they had those big voices and they used them with the idea of being emotionally impressive, rather than with the thought that their voices should carry in that auditorium; but the minor character was a little fellow, with a thin voice, but he knew that it was light, and he knew that if he was to be heard, he must make an effort to project the tone.

I sat way up in what was called "nigger heaven" those days. The condition of my exchequer made that necessary. But I remember this very well, that I could hear every word that that minor character spoke and I could hear only half the words that the other two men spoke; and why? Because that minor character recognized that he had vocal limitations and, as he spoke, he turned his voice out over the audience and made a conscious effort to give it a little propulsion, a little projection of that voice up into the gallery, and we heard him without any difficulty. He didn't strain for it, but he did make that effort to project the tone.

The sixth thing I want to say is, that public speaking is speaking so as to be understood. This involves not only, of course, the use of the voice, but it involves also articulation. Remember this, men, if you don't remember anything else, that the outstanding fault of American speakers is indistinctness of articulation, mumbling of words, lapping one word upon the other, dovetailing words, throwing words so closely together that you can't tell where one leaves off and the other begins. That is the outstanding fault. We are what I would call a lip-lazy people.

You who have been born and reared in the Middle-West particularly, have behind you, as I have, about the most difficult environment of any place in the United States to get away from indistinctness. I have fought it all my life. My difficulty has always been that I let loose of the consonantal elements too quickly. Let me give you an illustration. Suppose I should ask each individual in this room to pronounce one word, b-o-l-d. I venture that not half of the people in the room would articulate it correctly. You would pronounce it as though it were spelled b-o-l or b-o-w-l; I wouldn't hear the "d" at all. I wouldn't catch that "d". Now, our difficulty in articulation arises almost entirely, I say *almost* entirely (there are some other factors that enter into that that need not be mentioned here), almost entirely because we fail to bring out the consonants to make ourselves understood. That little word is one illustration. Here is another one. Streams. Now if I should ask the individuals in this room to use a sentence with that word in it, unless I could catch from the context of the sentence whether it was plural, I couldn't tell whether there was an "s" on that word or not. You would pronounce it as though it were stream rather than streams. You wouldn't get that "s".

Laziness Accountable for Faulty Diction

Why don't we? I am condemning myself here just as badly as I am condemning any man or woman. I know what I am talking about on this point. I know what difficulties I have had. The reason that we miss those final consonantal elements is because it takes a little muscular exertion to bring out the end of the word, the final consonant, and we are too lazy physically and from habit to emphasize, to give it that little final stroke.

Let us carry that idea just a little bit farther. Not only do we have difficulty with the ends of words, especially those words ending with double consonants, but we eliminate syllables, whole syllables within words, and for the same reason that I suggested a moment ago. Take a word like "institution" or "constitution." Very frequently, you will hear that word pronounced as though it were "instution" and not "institution." You will hear "constitution" pronounced as though it were "constution," instead of "constitution." The word "multiplication" will be pronounced as though it were "mulplication," rather than "multiplication."

Why do we do that? If you analyze what the lips do in the pronunciation of any one of these words, you will find, when you get through with one syllable, and before you begin the other, the articulative machinery must let loose and then take a quick forward jump in order to give that second syllable. And we are too frequently careless and don't make that extra effort. That makes us indistinct as speakers.

Let me take that one word, multiplication. Mul-ti-pli-cation. We pronounce it very frequently "mul-plication," leaving the "ti" out.

Notice, when you get through with the "mul", where the tip of your tongue is, "mul", it is in exactly the right position to begin the "pl". You don't have to make an extra move. If you put the "ti" in there the tip of the tongue must come back and then come forward with a rapid movement. Rather than do that we cut across lots and get "multiplication."

I have been illustrating. Of course you are not interested in constitution, institution, or multiplication just as words, not at all; but I think you are interested in what makes you speak indistinctly; and you are interested in that proposition because you want to speak more effectively when you are orally expressing yourselves before a group of people.

What is the remedy? There isn't any remedy in the world but work. There isn't any remedy in the world but attention to the elements that are involved. Take such a word as bold, b-o-l-d, enunciate one consonant, then the next, then blend them. Practice that, and when you find any word that is difficult, when you find a word that

you are indistinct upon, go over it again and again, bringing out those final consonants until you develop the habit of speaking distinctly.

This sounds like a pedagogue talking, I know, but it is vital in this matter of public speaking, and there is no country in the world, I think, where it is more vital than in the United States. We are notoriously indistinct speakers.

I said something a moment ago about the carrying power of the voice. I said placement was a primary element. I want to include now this matter of distinctness of enunciation as another element in the carrying power of the voice. You want to be heard, you want to be understood. You cannot be understood, cannot be heard and understood, unless you do those two things, get projection power into the voice and distinctness of enunciation.

I am going to skip one point suggested in the outline in your hands and go to the last one because my time is pretty nearly up.

The Message and Audience Should Be Correlated

Effective speaking in the last place, is putting one's idea in terms of the other man's experience, in terms of the other man's knowledge. I want to set down this as a principle. You cannot form a judgment upon any policy or truth that is uttered by another, unless that utterance is in such form as to make it appeal to what you know, or what you have passed through at one time or another. Notice how that applies. If a banker is going to talk to a group of laboring people, will he talk in terms familiar to bankers? If he does, he fails. He must talk in terms that the man knows about. We do not quote the Bible to a Mohammedan and we don't quote the Koran to a Christian. We get into the experience of those to whom we are talking, and here once more you will find the finest example that I know of, in American speech, in Abraham Lincoln. What gave him his power? Certainly it wasn't his beauty. Certainly it wasn't handsome physique. Certainly it wasn't beautiful voice. Not at all. It was his ability to take a fundamental principle of government or of law and put that principle in language so simple that it appealed to the information and the life experiences of those to whom he was talking. How frequently you hear a man talk to an audience, a man who knows what he is talking about perhaps, but talking over their heads or outside of their experience. He is going to fail when he does that. Hence, the last thing I want to say to you is that a fundamental principle of effective speaking is that the speaker must put his ideas in terms of the other man's experience, if he is going to get the other man to understand him.

What have I been trying to say this morning? Very briefly summarized it is this: I have been trying to point out that there is a very important place for effective oral discussion in this modern world. I have been pointing out that public speaking is not dogmatism. I pointed out that public speaking is not demagoguery, twisting facts so as to suit the speaker, regardless of what the facts say themselves. I have been pointing out that public speaking is not the grand, or the grandiloquent manner. It is not a show-off. I have been saying that public speaking is having something to say; public speaking is clear, clean-cut, well-analyzed thinking in a field of information; it is conversation, a gentleman, an earnest man, a straight-from-the-shoulder, honest to goodness business man talking to a group of people and trying to explain something to them in an earnest, conversational manner. It is getting the individual approach; it is speaking so as to be heard; it is speaking so as to be understood; and lastly, it is an attempt on the part of the speaker to put his ideas in terms of the other man's experience.

ADJOURNMENT.

Selecting Materials For the Speech

The first thing I want this morning, folks, is a show of hands. How many people are here who were not here at the lecture or discussion yesterday morning?

I ask that question for a purpose. I want to find out whether I ought to make a brief statement of what I discussed yesterday, in order that we may proceed a little more intelligently this morning.

In the discussion yesterday I tried to point out why, in these days of complex business and industrial organization, there was a greater demand for executive speech, in order that we might better understand one another in our social order, than there had ever been in the past. I think the presence of as large a group of busy folks as you are at a convention like this to hear academic talks on an academic subject, is sufficient evidence that there is an interest on the part of men of affairs in the practical interest known as public speech. I tried to point out in my first lecture some things that public speaking was not.

I said in the first place that public speaking was not dogmatism; meaning by this that in a democracy, when men talk on and about principles, and with about the same degree of authority in the field of information as the audience possesses, no man has a right to say that he has the final word.

I said in the second place that effective speaking was not demagoguery. By that I mean pure emotional appeal, a misuse of facts, and an attempt on the part of the speaker to make a few facts reach and establish a conclusion altogether unwarranted by the nature and the significance of the facts used.

I said, in the third place, that public speaking was not a show; it was not a demonstration. It was not the attitude of a man who gets upon the platform and virtually says to his group of people, "Now watch me do it and see how well I can do it." From that point I went on to suggest that public speaking was first of all having something to say; knowing one's material. I put considerable emphasis upon that. Secondly, I pointed out that public speaking was the development of the power to think effectively, and to analyze clearly, in a body of information that one was at the moment attempting to use. I said, in the third place, that effective public speaking was just good, earnest, straight-from-the-shoulder conversation, magnified conversation and large conversation to be sure, but nevertheless one man talking to other people, not declaiming at them, not lecturing at them, but talking to them, reasoning with them, appealing to them.

I said, in the fourth place, that good effective public speaking was getting the individual approach. By that I meant presenting one's material so that as he talked he gave the impression that he was talking to each individual in the audience, and talking for his information, for his benefit, and appealing directly to him. I pointed out in the fifth place that effective public speaking was speaking so as to be heard, which involved a voice that had some carrying power, and the development of that kind of an instrument. We do not, unless we stop to think about it, recognize what a vital instrument we have, what a useful instrument we have in the human voice, the most fascinating musical instrument in the world when properly used. And I pointed out also, in the sixth place, that effective speaking was speaking so as to be understood. This involved the whole field of articulation. I pointed out one or two suggestions as to the development of the power to articulate better the words that we use. I think I shall repeat some of that discussion in the last lecture, or the lecture tomorrow, so I will not go into detail on that.

Lastly, yesterday I pointed out the importance, if the speaker is wise and if he is to be effective, of the speaker putting his material in such form that he appeals to

the knowledge and the experience of the group of people to which he is talking. I put considerable emphasis upon the fact that none of us has any capacity to form a conclusion, draw an inference about anything on which we have information, either in the way of knowledge or of experience.

Now that is about what I covered in the talk yesterday, stating it as briefly as I can.

Between that talk of yesterday and today, if I had had the time, I really ought to have put in another discussion which would go over the general ground of the importance and some of the principles involved in the selection of one's point of view. Then if I had had the time I should have given you some discussion on the analysis of the proposition, the organization of material around the proposition, and then a discussion of the relationship or the importance of getting a proper relationship between one's detailed evidence and the original proposition that one was discussing. But in a series of three talks it is necessary to leave out some things; and so that portion of the discussion, which logically belongs in there, I will have to leave out. This leads me to the discussion that I am to present, in the best form I can today, namely, final statement.

After one has gathered all of his facts, after he has analyzed that material into its principal and its subordinate elements, after he has properly graded it with the primary first, and the secondary second, then comes the whole matter of final statement. I want to emphasize the importance of this final statement. I want to emphasize the final statement particularly with people who speak *extemporaneously*. By extemporaneous speaking I do not mean conceiving information on the spur of the moment. Such is purely *impromptu* speaking. But I refer to that type of speaking where the man has gone into his subject, has gathered information and has arranged it so he can deliver it. Then he trusts to the spur of the moment to give him the final statement.

Final Statement the Crux of Your Speech

The point I want to make with you this morning, and I want to make it very definitely, is that this final statement is almost, if not altogether, as important as the facts you use themselves. You know you can spoil a logical argument by a very poor final statement. I have heard it done again and again. That is particularly true, I think, with scientific people. This is not a criticism of scientific people at all. I know why they do it; I can understand their point of view. They are interested in their facts. But I have heard those scientific people. I have in mind for the moment an engineer who is a very able man in his field, but who pays no attention to his final statement. That is all right when he is talking to a group of people familiar with the information in his field, but it makes his presentation very weak when he is talking to a group of people who have but very little, if any, information in his field, and his failure lies at the point of final statement.

Now if you will go into a bit of study of the strength of such men as Abraham Lincoln in his public speaking of William Jennings Bryan in his, of Henry Ward Beecher in his, and all of the rest of them, I think you will agree with me that a large part of their power lies in final statement. In other words, final statement itself is really argument. Daniel Webster's greatest speech before a jury, that of his Capt. White murder trial, when subjected to analysis, shows that the real strength of it lies in the simplicity, the directness, the amplitude and the cumulative power of his statement of the details of evidence.

So much then, for the importance and the significance of this final statement. When we speak extemporaneously we so frequently trust to the spur of the moment for all of the material in that final statement. We would do better if, in our thinking about our material, we thought it through to the last step and got pretty well in mind what this final statement was to be. I won't advocate this with you, but this is what I do with college students. I say to the college student, "You never know

whether or not you are going to be able to say the thing well, until you have said it," and with that in mind I require them to write, I require them to write out completely and in full detail. I don't ask them to memorize, not at all, excepting now and then, but I do ask them to write fully in order that they may test their final statement. But of course you can't do that you are too busy to do that, but you can think your material through far enough so that you know what your final statement is going to be.

There are four ways or four principles that I want to emphasize this morning in getting an adequate final statement, and the first is what we call restatement, a form of support; second, statement in details; third, the use of illustration; and the fourth is the citation of or the use of, authority.

The Value of the Restatement

I don't know whether I will be able to cover all that ground this morning, in the way I would like to, or not. If not, I will cut off the last step and leave it for tomorrow morning. By restatement I mean not necessarily a repetition in the same words that the original proposition is given in, but a statement in other words. What makes a point interesting to a group of people who are listening to a speaker? Well, as nearly as I can analyze, it is this: The speaker makes a general affirmation of what he is advocating. That holds it up to view for a very brief instance. That may be sufficient, but with the popular audience, the ordinary audience, not familiar in detail with the material, it is likely not to be sufficient; he must go one step farther. How will he do it? Imagine, folks, the idea or the proposition as a little globe. You make one statement about it from one point of view; you turn the globe just a little and you make another statement about it in other words; you turn it a third time, make another statement, fourth time, make another statement, a fifth time, make another statement. But all the time you are talking about the same idea.

Teachers of composition in colleges and universities put a good deal of stress upon the value of restatement in writing. Well, certainly if it is important for the individual who writes, it is doubly important for the individual who speaks before an audience. Why?

Remember this, that there is a peculiar relationship between a speaker and an audience that does not obtain between the writer and his reader. The audience hears, hears once only, must hear rapidly, and, if he is to get the idea, he must get it practically instantly, for the speaker has gone on to a second step, and if the speaker has failed to present his material so that his hearer does get it instantly, and the auditor finds it necessary to reflect, that moment he is lost because the speaker has gone on while he reflected on the significance of a statement already made.

Bear that fundamental relationship between the speaker and the audience in mind and you get the significance of this point that I am talking about.

I want to illustrate that just a little this morning. I mentioned Abraham Lincoln a moment ago. One of the fundamental elements of the man's strength was his power to make a statement. I can't illustrate elaborately this morning, we haven't time, but if you will recall your American history for just a moment, you will remember that the Civil War had been going on for about a year when Horace Greeley, who was then editor of the New York Tribune, and a very influential power in American politics, wrote an open letter to Abraham Lincoln in the columns of the New York Tribune stating that the war had been a failure and insisting that Abraham Lincoln do certain things and report to the American people why he did not do certain things. Abraham Lincoln replied to Horace Greeley also in an open letter. That is a famous letter, it is a classic. It is one historical document. It is brief. I can't quote all of the words, and I won't quote the words exactly, but

I will quote them in such a way that I think you will see how it illustrates my point of restatement.

In his reply Abraham Lincoln said, "I would first of all save the Union, I would save the Union under the Constitution." He goes on to say, "I would save the Union in the easiest way possible." Notice that is practically a restatement of his original proposition. Then he goes on to say, "If I could free all of the slaves and save the Union under the Constitution I would do that. If I could free part of the slaves under the Constitution, and let the others go free, I would do that; if I could save the Union under the Constitution without freeing any slave, I would do that. Whatever I do, whatever I may do, I do because I want to save the Union. Do you think otherwise?"

Now, that is a good letter. That is a good statement. To be colloquial about it, it is a corking good one. He has done what? He has just made one statement and then he has talked all around it until, when you get through reading that letter, you will know exactly what Abraham Lincoln's position is. That is what I mean by restatement. Do you have the power to do that? Is it not worth while for one to cultivate the power to do that? Notice how practical it is. It applies to everything that one does, whether he is talking as a salesman, as an executive, as a safety man or as a preacher, Fourth of July orator, or what not.

Now let me keep the same idea in mind and bring it just a little closer home. I have written a little paragraph here. I don't offer this as a classic, by the way, but I thought, in our own field, it might be suggestive.

Driving the Point Home

This is what I have said: "Safety on the streets and highways is more a matter of law observance than it is a matter of law enforcement." You may agree with that proposition or disagree with that proposition as a safety matter, but that is the proposition that I am stating here. Now let me see how we can employ restatement to bring that out a little bit more definitely. Here is the first restatement. Notice as I go through five or six restatements here that I do not leave my pivotal point. The second restatement is this: "Let the laws and ordinances be obeyed as they are written, or are built up by custom, and the accident totals will diminish." Third, "In proportion as every driver of a motor vehicle knows what the traffic regulations are and conducts himself accordingly, in that proportion will he and his vehicle cease to be a hazard on the streets in the cities and on the highways of the country." Fourth, "When the pedestrian learns to keep his mind alert and his eyes open to recognize the regulations, the common sense customs and the ordinances that are provided for his convenience and his protection, his life and limb will be no longer in danger."

Fifth, "Enforcement of traffic laws at all times, and at all points, is not humanly possible, but it is possible for all people, drivers and pedestrians, to learn what the rules are, and to obey them without a police officer at their elbows to compel recognition of the rights of others."

Sixth, "That community is safest where the habit of law observance has become second nature to every man, woman and child that uses the streets and the roads."

Seventh, "Constant vigilance by all alike is the price of safety in modern civilization."

Here you have six restatements of an original proposition. I have used care, I think, not to deviate, and not to change my original statement, but I have stated the same thing seven times and in seven different ways. Now, as a principle of public speaking, what does that amount to? It simply amounts to this, that you are taking a point of view, holding it up before the mind of your hearer, revolving it around several times until you can make an impression with it. Bear in mind what I said a moment ago, that your relationship as a speaker to

your audience is different from the relationship of the writer to his reader. The reader can stop to think about it, the reader can read it twice, he can read it three times; the hearer can do none of those things.

Now I come to my second form of support, I call it, going into details. Any good teacher of writing will, I think, tell you this: That good composition means the use of details and more details and still more details. Now I know I am treading on a bit of dangerous ground here because unquestionably, if you should say, "Can't you become tiresome in the use of details?" I should be compelled to answer, "Yes" in regard to that, under certain circumstances. You become tiresome in the use of details, in the application of a generalization, which do not change the point of view, which do not, by the use of a new detail, add a little to the significance of the proposition. But every time, in the use of details, you add a little to the thought of the proposition you are not tiresome. In other words, when you move the thought forward all of the time you are never tiresome simply because you use details.

I want to illustrate that two or three ways this morning. I want to take you to a classic illustration. You remember, it was in 1896 that William Jennings Bryan, here in Chicago in the Coliseum, nominated himself for the first time for the presidency of the United States. That was a famous speech. It was a famous occasion. He was just thirty-six years of age. The occasion for the debate was this: Whether or not a free silver plank should be included in the Democratic platform of that presidential campaign. The people of the commercial centers of the country, led by David B. Hill of New York, objected. Those from the Central West and the Far West headed by William Jennings Bryan, wanted that plank in the platform. They couldn't decide the matter in the Resolutions Committee. It came out on the floor of the convention. David B. Hill concluded the argument for the gold Democrats. William Jennings Bryan concluded the argument, and I think was the final speaker, I know he was the final speaker for the free silver contenders. That speech is known in history as the Cross of Gold Speech. There was one paragraph in the speech, and only one, that attracted a great deal of attention, and that was William Jennings Bryan's definition of the business man. And I want you to note, after he states his general proposition, which states: "You have made your definition of a business man entirely too limited," how he goes into detail to show what he means, when he says that you have made your definition of the business man entirely too limited.

Expanding the Detail

Now this is what he said of that speech, and I heard Mr. Bryan say this. "That was the only paragraph in the speech that was new." He had used everything else before, and that was the one paragraph in the speech that attracted the most attention and provoked the most discussion, and this is what he said, "We say that you have made the definition of a business man too limited in its application." (Notice the details now): "The man who is employed for wages is as much a business man as his employer. An attorney in a country town is as much a business man as the corporation counsel in a great metropolis. The merchant of the cross roads store is as much a business man as the merchant of New York. The farmer who goes forth in the morning and toils all day, who begins in the spring and toils all summer and who by the application of brain and muscle to the natural resources of the country creates wealth, is as much a business man as the man who goes on the Board of Trade and beats upon the price of wheat. The miners who go down 1,000 feet into the earth or climb 2,000 feet upon the cliffs and bring forth from their hiding places the precious metals to be poured into the channels of trade, are as much business men as the few financial magnets who, in a back room, corner the money market of the world. We come to speak

for this broader type of business men. "Ah! my friends," he goes on to say, "we say not a word about those who live on the Atlantic Coast—but the hardy pioneers who have braved all the dangers of the wilderness, who have made the desert to blossom as a rose, the pioneers who have reared their children near to nature's heart where they can mingle their voices with the voices of birds, out there where they have erected school houses for the education of their young, churches where they praise their Creator, and cemeteries where rest the ashes of their dead. These people, we say, are as deserving of consideration of our party as any people of this country. It is for these, that we speak."

Now, I don't know that you agree with William Jennings Bryan in his definition of a business man. I am not interested in that at all. What I am interested in is pointing out to you how William Jennings Bryan as a public speaker on a great occasion made first his general statement, then in the development of that theme, in the enlarging of that theme, went on into great details; one detail is the wage earner; another detail is the small lawyer; another detail is the small merchant; another detail is the small banker; another detail is the miner—one detail right after another, until he builds up that idea, and he did make a great impression with it.

Comparison Used to Emphasize Detail

Now let's bring our material just a little bit closer home.

I hold here in my hand a little book called "A Manual for Speakers," gotten out by the National Safety Council. It contains about 60 pages of facts and figures in regard to safety material, safety facts. You will find on the left page on the sheet of notes, a full statement in regard to this booklet. It can be procured, and if you are interested in this subject of safety far enough to get information over a wide field, I think you will find considerable of it in this book. I believe it is for sale. I don't know of any place, although I have done some searching, where there is quite so compact a lot of safety facts as there are here. I am not particularly a salesman for this book. I wasn't asked to be a salesman for it. I am simply suggesting that there are some facts here that are interesting. I want to bring out one or two facts that will illustrate the point I am talking about, namely, how to make an idea stand up by going into detail. Let us take the proposition of the total fatality accidents and the economic cost records in the United States in any one year. This record is sufficiently high to challenge the attention of every right-thinking citizen. That is my proposition. Let's see if, by going into a little detail, we can make that proposition stand up a little larger than simply by the mere statement in those general terms.

I turn to page five of this book and I find these facts: that the total accident fatalities in the United States, approximately figured in 1925, is 90,000. There were 46,000 public accidents, 20,000 home accidents and 24,000 industrial accidents, making the total of 90,000.

Now perhaps for many occasions just the presentation of detail, 90,000 fatal accidents in the United States in any one year, is sufficient to make your idea impressive; but supposing that it isn't sufficient, or you think it isn't sufficient, for a given audience; what are you going to do anyway?

I suggest that the thing you need to do there is to explain the significance of that 90,000 and what it amounts to. There might be many ways to do that, but here is one way to go a bit into detail. We had a World War. We were in that World War about two years. We find, in going into the statistics, that we have buried in France something over 45,000 American soldiers. We, here in the United States considered that a great loss. Many homes were deprived of loved ones, many friends lost their friends, and so forth; but note that the total number of buried men in the World War for the United States and that now lie buried in

France, is but little more than one-half of the folks that are killed in the United States in any one year from our total accident fatalities.

All I am trying to do here is to illustrate how you can make the proposition stand up. Let me carry that just one step farther for purposes of illustration and clearness. I turn to page seven and I find this significant figure, that the total economic loss for the United States in any one year is approximately \$3,000,000,000. You are business folks; maybe you can think in terms of billions of dollars. Maybe your minds get around a billion; mine doesn't. It is beyond me.

Can we make that \$3,000,000,000 for an audience any more significant by going just a bit into detail? Perhaps we could help by saying that \$3,000,000,000 loss from accidents in the United States in any one year is approximately one twenty-fifth of the total national income. That may help a little. Go one step farther. That \$3,000,000,000 represents an amount, if I have the figures correctly, that is a little more than one-half of what it costs the United States Government to run its business for one year.

What have I done? I have simply made an attempt to take a generalization, then to apply it and to apply it by going into the details of the facts, leaving not only the general statement standing up there for the mind of hearers, but adding to it a detailed application to make an impression upon the minds of the individuals in the audience.

Illustration Most Effective Medium for Conveying Idea

Now I go on to the third form of support that I want to emphasize, and that is the use of illustration. I think this is the most important thing that I shall say this morning. We catch the significance of ideas through the medium of illustrations much more easily than we can catch the significance of ideas in any other way. What is an illustration? An illustration is simply a description or a narration of a general idea practically applied to human affairs to show how that general idea when practically applied works out.

Why is it that illustrations are so effective when presented to an audience? The answer to that question lies in the psychology of all of us. But few of us can think in terms of generalizations. We have to think in terms of concrete facts. The philosopher thinks in terms of generalizations and he can do that successfully because, as he speaks in abstract terms or generalizations, his mind immediately works that generalization out into the field of practical application. He makes that thought connect up with life as it is lived. It is his business to do that. He is accustomed to doing it.

Most of us are not in that business and are not accustomed to doing it, with the result that we haven't quite the capacity to do it and quite the disposition to do it. But if some speaker will take the generalization, put it in terms of a practical illustration, we can get the significance of that generalization much more easily.

I want to illustrate that because by illustration I think I can impress the idea better. I am going to take an illustration from a very famous lecture. I suppose many of you men, probably not all of you but many of you, have heard at one time or another in your life Russell H. Conwell, of Temple University of Philadelphia, deliver his lecture on "Acres of Diamonds." It is the most famous single lecture ever delivered in the United States. It was delivered over 6,000 times.

Delivering a lecture 6,000 times means that if a man delivered that lecture on every day except Sundays it would take him over 19 years to deliver that lecture 6,000 times. I mention that simply to draw attention to the fact that you have here a classic, a piece of public speaking that is enduring. Why has it endured? That is what I am coming to. What is there about that speech that makes it enduring? There are a number of things about it that make it enduring but the

one outstanding thing, in my judgment, is its use of illustrative material. He speaks very little in abstract generalizations, glittering generalities or glowing periods. He speaks constantly in terms of exact, definite, typical, genuine, human experience. I want to show you how.

I will take just one illustration from the lecture. His general theme is that the secret of success lies in your own neighborhood, or lies at your own doorstep, if you only know it. He develops the idea by the use of illustrative material. This is what he says. The lecture as a whole is just filled with illustrative material very much like this:

He says, "Professor Agassiz, great geologist of Harvard University, that magnificent scholar, told us at the summer school of mineralogy that there once lived in Pennsylvania a man who owned a farm and he did with his farm what I should do if I had a farm in Pennsylvania, he sold it" (I suppose there are some men here from Pennsylvania), but "before he sold it he decided to secure employment connected with coal oil. He wrote to his cousin in Canada that he would like to go into that business. His cousin wrote back to him, 'I cannot engage you because you don't understand the oil business.'

"Said he, 'I will understand it,' and with commendable zeal he set himself at the study of the whole theory of coal oil. He began way back at the second day of God's creation.

"He found that there was once another sun that shown on this world and that then were immense forests of vegetation. He found that the other sun was put out and that this world after a time fell into the wake of the present sun. It was then locked in blocks of ice. Then there arose mighty icebergs that human imagination cannot grasp and those mountains of ice did ride those stormy seas, and they beat down that original vegetation. They planed down the hills, they stormed over the mountains and everywhere buried this original vegetation which has since been turned, by chemical action, into primitive beds of coal and in connection with which only is found coal oil in paying quantities.

"So he found out where oil originated. He studied it until he knew what it looked like, what it smelled like, how to refine it, and where to sell it. 'Now,' said he in a letter to his cousin, 'I know all about the coal oil business from the second day of God's creation to the present time.' His cousin replied to him to come on. So he sold his farm in Pennsylvania for \$833, even money, no cents.

Right at His Door

"After he had gone from the farm" (now get this because this is the most interesting part of the whole illustration), "after he had gone from the farm, the farmer who had purchased the place went out to arrange for watering his cattle and he found that the previous owner had already arranged for that matter. There was a stream running down the hillside back of the barn, and across that stream from bank to bank the previous owner had put a plank edgewise at a right angle, at a slight angle for the purpose of throwing over to one side of the brook a dreadful looking scum through which the cattle would not put their noses, although they would drink on the other side below the plank.

"Thus that man who had gone to Canada and who had studied all about the oil business had been himself damming back for twenty-three years a flood of coal oil which the state geologist in 1870 said was worth to our state \$100,000,000.

"The city of Titusville stands bodily on that farm now, and yet though he knew all about the coal oil theory he sold that farm for \$833, and again I say, no sense."

There are two or three things about that little illustration which I want to emphasize, and the first is that it makes clear and definite and specific the point that he has in mind, which is that the secret of success lies at every man's door; it is next to him.

The second thing I want to say about that illustration is that it is interesting. It is an interesting illustration in and of itself. It is an interesting bit of narrative.

Not only is it important in speech to get an illustration of your general point that actually illustrates, but if you can go one step farther and make it interesting, so much the better. And that is what Mr. Conwell has done.

The third thing I want to say about that illustration is that he has injected into it a very delightful, quiet bit of humor, and that suggests to me in closing that you can use humor by way of illustrative material.

I have, in times past, done some talking before business organizations and have attempted to state the significance of American business, the largeness of it, how it covers enormous territories.

There is probably no better illustration than the story of the Irishman who considered himself very much of a traveled man. As he said himself, he had been all over Ireland. He planned to come over to the United States and travel over it. He planned to land in New York, go through Chicago out to San Francisco, down the Coast to Los Angeles, to El Paso, to Dallas, Fort Worth, Birmingham, Washington, Philadelphia, New York and then home. That was his itinerary.

He landed in New York and, after considerable confusion, he found himself finally on one of the rear coaches of one of those long Pullman trains at the Grand Central Station. If you have ridden in a New York Central train up to Albany (I suppose most all of you have) you know it takes quite a long time for the conductor to get back to take up your ticket, particularly if you happen to be in one of the rear coaches. By the time the conductor, on this occasion, got back to the Irishman he was getting considerably nervous. He pulled out a yard and a half of green paper and said to the conductor, "You won't let me go by?"

The conductor promised him he wouldn't let him go by. The train went north and after two hours and a half of running stopped at Albany. The Irishman got up, picked up his bags and started to get off and was considerably surprised when the porter told him he hadn't reached San Francisco yet.

He settled back in his seat and the train went west through Buffalo, Cleveland, Toledo and into Chicago. Here, as you know, in the nature of things, he has to change trains. He was very much indignant when one of the red caps insisted that his ticket called for another train, but after the use of considerable picturesque language he was persuaded to get on another train.

The train went west across Illinois, Iowa, Nebraska, through Salt Lake City, and after three days and nights of travel he got into San Francisco.

By this time the Irishman was completely subdued and he sat back in his seat in a sort of dazed, semi-comatose state. When the porter came and told him he had reached San Francisco he looked a bit startled, got up, picked up the bags, trudged out through the car, set his bags on the platform and stood there looking out over the Golden Gate; and then he said, "So they say it is a wonderful thing that Columbus discovered America. It is not wonderful at all, at all; how in hell could he have missed it?"

I have used that story in the past simply to illustrate the significance of nationwide, extensive American business and it is possible to use humor in that way by way of illustration.

ADJOURNMENT

Thursday, September 29, 1927

The Speaker on the Platform

In our little study yesterday we were attempting to present the importance and significance of final statement in the speech, and I drew attention to four means of doing it. I had a chance to discuss three of them.

First. What I called restatement or repetition in different words, a varied form of expression of the original proposition.

Second. The amplification and enforcement of that original proposition by way of statement in details.

Three. The development of that proposition by way of use of concrete illustration.

The fourth method of doing it was appeal to authority or the citation of authoritative statements with which to illustrate or to enforce one's point of view. I did not get a chance to discuss that.

Americans Dependent Upon Authority

I think in the opening remarks of this little study this morning, which I am afraid is going to be pretty sketchy as I am going to cover a number of points, I ought to say something about the use of authority. I think here in America, perhaps more than in most public speaking among the nations of the world, we have a faith in authority that most nations do not have. I have spent some time examining and listening what the Englishman does in his public speaking and I do not think he relies upon authority quite as much as we do.

I think there are two reasons in America for authority. The first is, we are a little bit reluctant about making the analysis that is necessary for us to get ourselves informed upon a subject so that we know the facts ourselves. Perhaps, to put it very bluntly, I may say that we are a bit lazy about getting at the facts. I find this to be true with the students that you work with on this subject. I assign them something to work on, and what is the first thing they do? They rush to a library to find out what someone else has said on the subject.

The most important thing for them to do would be consult their own mind, their own thinking on that subject, and their own search for facts and information on the subject. One of the reasons why these students do that is because they are just a little lazy intellectually. But that is a general tendency here with a man in America. He rushes off to find out what some authority has said on the subject and bases his own observations upon what somebody else has said. Now, that is one reason why we are very fond of authority.

Another reason is, we must be dependent on authority. We must rely upon authoritative statements. Very few of us can know much about any one question in a complex civilization such as ours. It is necessary for us to consult those who do know, so that it is perfectly justifiable for us, in building a speech, to find out what others have thought on the subject and what others have said on the subject, and to use that material, providing we use it legitimately and providing we use it wisely.

Now, if you have a copy of the notes that were distributed yesterday, you will find that I outlined there several tests, I think there are eight or nine of them. I don't think I remember them all. I have a note of them here and just as likely will forget half of them and forget I have the notes in my hand.

I applied some tests and while these tests don't apply in every case, most of them, perhaps, ought to be applied with a great deal of care. In general, these tests are well enough for us to observe in the citation of authority, and the first test I have applied there is to ask the question, "Is the citation of authority complete?" Now,

what I mean by that is this. Have we quoted, if we quote, sufficiently so that we satisfy the demands of the address? A sketchy quotation may be of no particular help in the development of one's idea. A sketchy quotation may stand in your way rather than be an asset to you if it be so sketchy, so scattered a quotation or citation, that the hearer in front of you is not impressed by what you say and the way you say it. In the citation of authority then, one needs to bear in mind to get a sufficient quotation, a sufficient citation, to meet the demands of his subject and, at the same time, to meet the demands of his hearers.

Second. Is the reference to authority definite? When one quotes from a government document, let us say, do you, in your quotation, state sufficiently definite as to where you got that information? Now, why do that? You want to make an impression. You want to get those who are listening to you to believe what you say. One of the ways to do that, if one is using authority, is to draw attention to the man you quote and who he is, the document you quote and what it is, and how it comes to be an authority and where that document may be found. In other words, put your information on your proposition in such form that those to whom you are talking will be able to check back and find that authority and perhaps test you and perhaps investigate that subject considerably further.

Now, so far as our intercollegiate debating is concerned, this is one of the cardinal principles that we emphasize because we are sure of the fact that if we quote an authority and do not definitely cite where it comes from, the man who is sitting out in front of us, as a judge, is going to discount the value of that material. That is true in the academic performance, but it is also true from the point of view of the practical use of that material.

Three. Is the authority mere hearsay? I don't think I need to discuss that. The significance of it is at once evident to you.

The fourth test I have suggested here is: "Has the man you quote been in a position to know?" Has he been in a position to learn? That is, has he been in a position where he can get at the information? Has he been in a position where he, through experience, through information, through contact with the facts, has been able, as we think, to learn what the facts actually are? You know, going up and down this country, we have a lot of people who are posing as authorities upon this issue and that issue, who have done what many of us do, a lot of superficial reading, and quotes himself or states himself as an authority.

If we are seeking for authority on commercial matters in the United States foreign trade, for example, we can quote Mr. Hoover or men of his kind. Why? Because those men are spending their lives in the examination of that sort of subject matter. They are in a position to know.

Is Your Authority Prejudiced?

Next, is the authority prejudiced? That perhaps does not need much discussion, but what do I mean by a "prejudiced statement?" I mean by a "prejudiced statement" pretty nearly the same thing that I emphasized the other day in connection with demagogues. A prejudiced statement is a statement of a man who can see but one issue and that issue the one which meets his own self or selfish interests. Try the authority by that test. You know that can go for expert authority just as well as most any other kind of an authority.

Last night, if you were at the banquet, you heard a definition of an expert. Let me give you another. An expert is just an ordinary man a long distance from home. We have a lot of authorities in this country who can qualify under that definition.

Now, I don't mean to suggest that you shouldn't quote from a man who has an interest in the subject in which he is giving information, or about which he is talking, or about which he is writing. He may even be a propagandist for his subject.

But, if he is to be a reliable authority, if he is to be one that you ought to quote, he should so put his material, so thoroughly analyze his material, as to remove the atmosphere of prejudice out of it.

The fifth test I have suggested, "Is there too much reliance placed upon any one authority?" When a speaker before an audience begins to quote or cite authorities, and he cites but one, very soon those who are listening to him become just a bit suspicious that perhaps that one man is the only one who knows anything about that subject, and that that one man may not be from all points of view a competent authority, so that in the use of authority, one would do well in the development of his address to get the opinion of more than one individual to support the proposition that he has for the moment in mind.

Next, is the authority supported by other lines of argument? Now, I want to make a general statement. It doesn't always hold true. Many of the things I am saying won't always hold true in every circumstance, but, as a general rule, authority becomes valuable in explaining a subject, valuable in the argument upon a subject insofar as it is supported by other evidence. What do the lawyers do in the development of their briefs? They state their proposition; they analyze it; they argue it and then they cite their authorities to support the position that they have taken.

Let me repeat that again in other words. The lawyer states his proposition; he states his evidence; he draws his own inferences from the evidence or attempts to show how that evidence points in a given direction, and after he has done all of that, then he cites his authorities, citations from this court judge and that judge, from that state court and from this court. You see, their authority is not used solely for the purpose of argument, but for the purpose of supporting argument.

Good Argument but Applied Common Sense

After all, isn't this true, that good argument, good exposition is nothing more or less than simply applied common sense to a given situation? When we are listening to a speaker who quotes from an authority, who has drawn a conclusion that is all out of balance with the laws of common sense, just that moment those who are listening become a bit suspicious of the strength or the value of that kind of authority.

When citing authority, apply that test to it, and the last suggestion that I want to make is this one. In the authority likely to be impressive for the audience before which you are quoting the authority? A great many mistakes, as I view it, are made upon this point by those who use authority in addresses. This is what most of us do. We have our subject before us for investigation and for analysis. We get at the largest body of fact that we can. We find those who support our contention and without thinking exactly what we are doing for a specific audience and for a specific purpose, we cite our facts and we quote our authorities, because they are ours, failing to bear in mind that we are not quoting the authority, not citing the facts, for our own satisfaction, for the relief, so to speak, of your own expressional facilities. We are quoting that authority for the purpose of reaching hearers in front of us and so it becomes a very important matter to apply this test as to whether the man we quote is an authority for those to whom we are speaking.

If you are discussing a question before a farmers' convention on marketing, let us say, you don't quote a steel magnate, if you are wise. You don't quote a Standard Oil magnate, if you are wise, even though the Standard Oil magnate be ever so informed, the steel magnate be ever so informed. You quote an authority that will be effective for the people to whom you are talking. It will have to be the Secretary of Agriculture or, perhaps, it will even be Senator Capper of Kansas who is supposedly, I think, an authority on all agricultural propositions. If you are talking to a group of laboring people, you are not going to quote, if you are wise, a man who is anti-labor in all of his convictions and all of his sentiments and most of his

utterances. You will quote Samuel Gompers, you will quote the former great labor leader of the miners, Mr. Mitchell, or some such an authority as that. A man who will be accepted as an authority in that particular field by those to whom you are talking.

Now, I have put a good deal of emphasis on that. I have put that emphasis on the point, I think, advisedly, and I have put it there as strongly as I have because I have decided feeling that, in the use of authority, we again and again fail to recognize that fundamental principle. It comes right back to something I said in the first discussion, namely, that if you are going to be effective before a given group of hearers, you must find some way to put your ideas in terms of the information and in terms of the experience of those to whom you are talking, and while that applies, in general discussion, it applies even more importantly, as I view it, in the citation of authority.

Now in our studies, we have gotten this far. We have laid down some general principles that the speaker must obey if he is to be successful. We have discussed the address and how to develop it. Now, we come to getting the man upon the platform.

First Impression of Primary Importance

The first thing that I want to suggest about this is that the first impression that the speaker makes upon an audience is through the eye. The audience sees him. What impression does he make? Is it an effective one or is it an ineffective one? When he gets before that audience, how does he stand? Does he stand like he was scared to death? Does he give the impression of pulling away from an audience? Does he give the impression of a shrinking violet? If he does, he is lost before he begins.

I don't know whether you men have ever done it or not, but it is very interesting to me—I suppose because I am primarily interested in the subject—to study the first impressions that speakers make. Let me suggest this rule or principle. Either you are going to command or you are going to be commanded by an audience, and I don't know of any experience in the world that is more exquisitely painful than to be before an audience and feel that you are commanded by instead of commanding the situation.

Now, it is very difficult to lay down any definite rules on this. I have no dogmatic statements to make about it. I have this suggestion to make, that the individual, when he appears, the individual in the poise of his head, the individual in the set of his jaw, must give the impression of downright earnestness, downright energy.

Now, men do that differently. Some men do that by an imposing front. Some men do it by a quiet, steady, earnestness, but the man who actually succeeds before an audience must, somehow or other, give a first good impression, else he is handicapped. I don't mean to suggest that you can't give a bad first impression and still be effective before you get through. The famous Thomas De Witt Talmage used to do the exact opposite from what I am giving here. He used to give the impression of intentionally shrinking away from the audience. Talking to a group of people, he would back away from them. Before he had even made a statement he would be way back on the platform and all at once an inspiration would seem to seize him and he would move out to the front of the platform enthusiastically.

Now, he took advantage of a little human psychology that is very interesting, the surprise element. He got his audience down, so to speak, then with a jerk, he brought them back. That is all right if you have the personality to do it with. No objection to it that I know about. But, as a rule, that is a difficult thing and a dangerous thing for most people to try. But, whatever you do, let the impression be one of command, one of energy.

Second. I suggest that it is important for the speaker when he first appears (I am speaking now physically and emotionally and intellectually and imaginatively), when he first appears before the audience to give the suggestion of good temper, of good will, of friendliness. How you like to get that first impression from a speaker, that impression that makes you feel he likes you as an individual! How an audience likes to get the impression from a speaker that he is a friendly sort of an individual, that he likes folks. Test it. Test it in history. Test it in your observation to see if this principle is not true.

William Jennings Bryan's—I won't say the greatest—but one of the greatest assets was the ability he had, perhaps unconsciously, to make the audience feel that he liked it, that he was friendly to it. One of the most unfortunate impressions you can make with an audience, when you step before it, is that you are chesty, that you are a very important individual. There are men psychologically made up so that they do not seem to be able to get rid of that and the four-flusher stands out in the front as that kind of an individual.

A skillful student of human nature can, in about seven cases out of ten with the average speaker, be able to spot a four-flusher almost before he begins to speak at all, because of the front which he puts up. You know, if you want friends in the world, I am being a bit philosophical here, but if you want friends in the world, you will have to be friendly. Friendships come out of you rather than from the outside into you. Now, if that is true between individuals, it certainly is true as between the speaker and his audience. William Jennings Bryan liked folks. No question about it. He gave you that impression when he stepped before an audience.

Theodore Roosevelt liked folks and while he was a pugnacious sort of an individual, just the same you felt that Theodore Roosevelt was a good mixer. And if Abraham Lincoln's history means anything at all, it means that one of the things he always impressed upon people when he talked to them was that he was a kindly, sympathetic, whole-souled man and that when he discussed a question, he discussed it from the point of view of the welfare of those to whom he was talking.

So, the first impression is very important and you know it is more than just physical, it is more than just the outside, it comes from way down in the depths of a man.

To develop ability of the kind that I am talking about takes a lot of thought. It takes a lot of growth in bigness of human nature, of mind, of body, of imagination and sentiment and of ideology, if you please.

A Restless Speaker Creates A Restless Audience

All right, we have the man in front of you. He begins to work. His physical action is rather important. Now, there are two or three things I want to suggest here. You have very frequently, I am sure, seen the man get upon the platform before an audience and make peculiar motions as he talked. He took about ten steps to one side and talked; took about ten steps to the other side and talked; and back and forth, back and forth, he went. Now, there are two things to be said about that. The first is that the moment the speaker does that thing, though he may be successful (because men are successful sometimes and do that) he suggests restlessness, uneasiness, nervous tension before an audience and the psychologists have told us some rather important things here.

You are imitative folks. If the man up here is restless, nervous, can't control himself and he fidgets about in his actions, you begin to become confused and restless and intense yourself, as a reflection in imitation of that action. That is the word I want, imitation, in imitation of what he does. Now, of course, you do that unconsciously. You never do any of those things consciously, but there is a principle there for the speaker to bear in mind.

Now, there is another thing I want to say about that. It wouldn't be noticeable

here because I am above you, you can all see me and what I do (that makes it more embarrassing for me too) but if you are standing on the level, for example, with an audience and in speaking you speak a little while in this position and then you move over and speak a little while in that position and you just get nicely settled and those in front of you get you in line through the heads of those in the audience, you step over again and what happens out here? Nine out of every ten people will have to move in order to get you in line for the next few sentences that you are going to utter. All right, you get them in the line the second time and everybody is settled and everybody is comfortable, and away you go again. You get over here in this third position, everybody moves, you settle them again, and then off you go again. I have seen that happen with audiences until you pretty nearly had a pendulum swing. Now, as I say, it wouldn't happen with a platform like this where the speaker is above you, but it will happen where you are on anything like a level with your audience. It is a little item, but something that ought to be avoided.

You know, that is something that is so easy to avoid, if you just stop to give it a little thought.

Now, next, I don't usually say anything about gestures in these talks on public speaking, but recently I have made a number of talks on public speaking before various groups of men and nearly every time somebody has expressed their disappointment because I didn't say anything about gesture. They like to get into action. Well, there aren't many things that I am going to say about gesture. One or two fundamental things. Gesture, of course, springs out of the relationship between the speaker and his subject and there ought to be a proper relationship between the kind of physical action you have, to emphasize your thought itself. For example, we do not talk about elevated emotions, sentiment, immortality, beauty, harmony in the world of imagination and in the world of affairs and gesture this way (indicating). Yet, I have seen it done. I have seen ministers stand in the pulpit with the pulpit high in front of them and come down on a long period of immortality and says: "If you are going to see your God, you will have to do so and so." (Indicating.) Knock it into them. Well, you are just a little out of proportion. You aren't doing what Shakespeare said—the best thing that has ever been uttered in English in his play Hamlet, "Suit the action to the word and the word to the action."

Now, this other general suggestion. If one is going to get into physical action, by way of a gesture at all, the strong part of a gesture is the end of it. Now, here (indicating) or here (indicating) or here (indicating). That gesture should come in at the point where the emphatic idea is, the emphatic word is and not somewhere else. And yet, how often I have seen that simple principle violated. Let me illustrate.

If You Must Gesticulate Use Discretion

I know a very distinguished clergyman (who, by the way, has stopped this type of gesture I am talking about now), and his preparation for his gesture would be long and steady and strong. He would build up his period and get up here (indicating) with his hand all quivering with intensity of his emotion, and then as his chest would swell up and he would wind up his period, this (indicating) is what he did. Now, notice the absurdity of that. A long preparation for a gesture, all kinds of force behind that gesture and then that sort of a dishrag finish.

Again and again have I seen eccentricities of that kind in gesture. Now, if you are going to gesture and you know you can talk very effectively without gesturing at all (I don't know whether I could, I always fly into action, some of it I know is absurd, violating the very things that I am talking about) you don't need to gesture at all; but if you are going to gesture, give a little attention to proportion so that your gesture corresponds, your physical action corresponds to the thought, and

that you get the gesture and physical action in at the point where the emphasis should be.

Now, one or two other things. We get in a lot of action sometimes that ought not to be there. This general principle should always be remembered. Any physical action that begins to attract attention to itself as a physical action is wrong and is in your way. Let me illustrate that just a little. Here's one. (Indicating) I remember as a college boy, a very distinguished man coming to our college chapel to talk to us. He made a very good talk, but this is what he did. (Indicating) He stood upon the platform and talked to this group of people out here and he was examining the floor down in front all the time. I was wondering if he was studying the nail heads down there, or what it was. He did that to such an extent that as a college youngster, sitting out there in front, I didn't do anything but watch him to see what he was going to do next.

I also saw a very able speaker doing this (indicating). He would talk a little while and then he would do this (indicating). He would get off another half dozen sentences and then this (indicating). Now, I suppose the thing which started him doing that was wearing tight collars. But, do you know, that got in his way until really he couldn't make an effective address. I have used this illustration before. I have used it before in connection with the name of the man. I am not going to name the man this morning, but he is one of the famous orators of this country.

Beware of Mannerisms

On a dignified occasion, by the way, on a Sunday afternoon, a certain speaker made a very effective address, but about every ten or fifteen sentences, and the more earnest he was the more often he did it, he had this gesture. He would get to going and he would get his arm up here and about to make a gesture, when he would do this. Well, now, that done once or twice wouldn't attract any attention, but that done as a mannerism, as an eccentricity, makes the speaker look very absurd, and he made a very absurd impression. I want to give you an illustration of just how far this goes sometimes. At the Chautauqua, about ten or twelve years ago, there was a very distinguished clergyman from the East lecturing. He had a very peculiar habit. Every time he would get interested in his subject he would hitch his trousers, and he would go along a dozen sentences and then he would hitch his trousers again. He had his coat and vest off on this particular occasion. He was wearing a belt and suspenders. He was doing what I think most men in these days do not do, he was wearing two-piece underwear. When he began his lecture, he talked for about fifteen minutes, then he made his first hitch. Then he went on and made a second hitch. Then he missed the belt and grabbed the tip of his trousers on the third one and on the fourth or fifth one he missed his trousers and grabbed the underwear. Now, before he got through he had six inches of his underwear, pretty nearly, in view.

That of course, is an extreme case. I haven't stated it extremely at all; I have simply stated the case as it was. Well, the thing that interested me was when he began his hitching. I didn't pay much attention until he did it a number of times. A number of the young folks began to notice that hitch and before he got through, I don't think there was anyone in that audience under 35 years of age who heard a word he said. They were watching the hitch.

This is interesting to me. I heard that same man this last winter and I don't know whether somebody told him about it or not, but his hitch is all gone. He has ceased that eccentricity.

Now, in the use of the hand, for example, in physical action, get that hand in the best position you can. Learn to open the hand. Can you open it? Can you put your hand up here and bring it down and let it come open? Most people who make that gesture make it that way (indicating). Let it come open, that's the way to be emphatic. Let it come down there (indicating) and come open. Or, if you are going

to gesture with the finger, let it be the index finger, with the other fingers closed. I want you to note this bit of an illustration. I take this out of my observation and experience with an old college friend of mine who was a college debater and an able man. He afterwards became a law student in Chicago, and he is now a practicing attorney in Arizona and a mighty able fellow. He wanted to be emphatic in his debate; he wanted to use what we called the intellectual gesture, and this is what he did (indicating). Instead of using this (indicating) this is what he did (indicating). Now, I defy you to put your hand in a more awkward position than that. It can't be done. I have tried it.

Now, all he needed to do was that (indicating) and he would get grace, proportion and ease in his gesture. He wanted to be easy, but he did exactly the thing that he ought not to have done.

Now, the only thing that I am trying to illustrate here, friends, is that in this whole matter of physical action before an audience, don't do things that attract attention to themselves as such. Now, I want to make one observation, one reservation there. There are people who have eccentricities, who use those eccentricities as an asset, but there is this difficulty; the eccentricity, the manner, that I am talking about is purely a physiological, an outside, an external one. A man who has a mannerism, a peculiar characteristic which is a part of his character, a part of his whole being, perhaps can use that eccentricity without getting himself into a great deal of trouble. But aside from that kind of an individual, look out for the eccentricity, the mannerism, that attracts attention to itself.

Variety the Spice of the Speech

Now, there is one other proposition that I want to talk about from the point of view of the oral address. Get in it variety, variety of emphasis. You will note on those outlines I have named six things. I can't take time to discuss them in detail this morning. I have named six items. First is slide, then there is force, then there is pitch, then there is rate, then there is pause. The last one for this occasion is of no particular significance because it belongs more to the actor's art than it does to the plain public speaker's art. Now, get this principle: emphasis is contrast and when you get contrast between sentences, I mean your oral utterance of sentences, you begin to have the stroke of the voice upon the emphatic word. Every time my finger falls, I drive the word home. Let me illustrate. I will quote, if I can, a passage from memory with which you are familiar.

"Fourscore and seven years ago our fathers brought forth on this continent a new nation, conceived in liberty and dedicated to the proposition that all men are created equal. Now we are engaged in a great civil war, testing whether that nation, or any nation so conceived and so dedicated, can long endure. We are met on a great battlefield of that war. We have come to dedicate a portion of that field as a final resting-place for those who here gave their lives that that nation might live. It is altogether fitting and proper that we should do this. But in a larger sense we cannot dedicate, we cannot consecrate, we cannot hallow this ground. The brave men, living and dead, who struggled here have consecrated it far above our power to add or detract. The world will little note nor long remember what we say here, but it can never forget what they did here."

Take that last sentence. Notice how you can make the thought stand out there by the use of slide, emphasis of slide. "The world will little note nor long remember what we say (indicating) here, but it can never forget what they did (indicating) here." Two slides, to make the saying stand off, over against the doing with emphasis of slide.

Most of you, I suppose, know something about music. I don't. I don't pretend to know anything about it. I just pretend to know this general principle about music, that you have great variety in it. You have rapid movement: then you have

slow movement; have volume, then you have quiet notes; you have harsh notes, then you have mellow notes. They are all written on the musical score. The musician follows them up and down. Now, why is music written that way? Well, there is a psychological reason for it. You are a sensitive organization, nervously speaking; you can't stand to listen to the strain of the same note the same rate, for any great length of time. Just imagine a violinist who would strike the same note for three minutes, never changing it for three minutes, before an audience! How long would you stay? Well, just long enough to get out the back door.

Now, the interesting thing is that that same principle holds with oral utterances, your voice is a musical instrument, you are playing with it. The difference between you and the musician is that the music is made for him and you have to make your music while you talk. You are sensitive, I say, as hearers. There must be variety, change.

One of the ways to get it is through the use of slide.

Force. When you want to be emphatic, when the ordinary public speaker wants to be emphatic, how does he do it? Making more noise. If he wants to be still more emphatic, how does he do it? Making more noise. He just builds it up, builds it up and builds it up. That is all right. No objection to that within certain limits, but the interesting thing is, he could get his contrast just as well, and therefore, variety, by going down in force as well as up in force.

One other thing I want to say about that, you can get your contrast sharp when you go up quickly in force and then drop it until you can just be heard; you get the low degrees of force and the high degrees of force, so to speak, right together, one right up against the other. The man in speaking throws out a word with a great deal of volume and the next words come quietly spoken and the man who is skillful can pretty nearly awaken the dead by that sharp contrast. I have tried it. I don't see anybody sleeping here or I would try it on you. I have had fellows in front who seemed to be not interested at all, half asleep. As I have stood upon the platform, I have thrust a note at them as hard as I could, then the next one just as soft as I could and it is very interesting to see them perk up. Now, I did that mechanically, but the skillful speaker, of course, accommodates his change in force to the change in thought. He does it unconsciously. But, if we are students of the subject, we learn to do it by attempting to practice it.

Well, now, folks, I simply must stop here. There are one or two things I want to say. I was asked about one or two months ago to come down here and talk to you on public speaking. I said, "Why, these business men won't be interested in a discussion on Public Speaking." "Well, come down anyhow." And so I consented to come down and I expected we would have perhaps 25 or 50 stray souls who had wandered in. I didn't expect that I would be talking to a theater two-thirds full of men on the third of these lectures. Please be assured that I appreciate the hearing you have given me.

ADJOURNMENT.

SIXTEENTH ANNUAL SAFETY CONGRESS
NATIONAL SAFETY COUNCIL

A. S. S. E.—Engineering Section

New Section Officers

Chairman, R. MCA. KEOWN, Industrial Commission of Wisconsin, Madison, Wis.

Vice-Chairman, J. I. BANASH, Consulting Engineer, Chicago, Ill.

Vice-Chairman, W. GRAHAM COLE, Metropolitan Life Insurance Company, New York City.

Secretary, W. DEAN KEEFER, National Safety Council, Chicago, Ill.

Assistant Secretary, GENE S. WOOD, 29 W. 39th Street, New York City.

Executive Committee—THE OFFICERS AND—

R. M. ALTMAN, Marathon Paper Mills Company, Rothschild, Wis. (Paper and Pulp Section.)

A. L. ARMSTRONG, Eastman Kodak Company, Rochester, N. Y. (Chemical Section.)

C. B. AUEL, Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa.

E. W. BECK, United States Rubber Company, New York City.

J. M. CARMODY, Coal Age, New York City. (Mining Section.)

R. E. COLVILLE, United States Gypsum Company, Chicago, Ill. (Quarry Section.)

G. W. COOK, The Travelers Insurance Company, Hartford, Conn. (Textile Section)

F. A. DAVIDSON, Chesebro, Whitman Company, Inc., Long Island City, N. Y. (Construction Section.)

E. ROSS FARRA, Grand Rapids Safety Council, Grand Rapids, Mich.

J. B. GIBSON, Western Electric Company, Chicago, Ill.

W. F. HANNA, United Railways and Electric Company, Baltimore, Md. (Electric Railway Section.)

ERNEST HARTFORD, American Society of Mechanical Engineers, New York City.

H. W. HEINRICH, The Travelers Insurance Company, Hartford, Conn. (Hartford Chapter.)

THOMAS B. HOWE, Aetna Life Insurance Company, Cleveland, Ohio. (Taxicab and Fleet-Owners Section.)

F. L. HURLBRUTT, Patent Scaffolding Company, Chicago, Ill.

S. R. JENSEN, Armour and Company, Chicago, Ill. (Packers and Tanners Section.)

M. G. LLOYD, U. S. Bureau of Standards, Washington, D. C.

- T. O. MEISNER, American Can Company, Maywood, Ill. (Power Press Section.)
 H. W. MOWERY, American Abrasive Metals Company, New York City.
 G. A. ORTH, American Car and Foundry Company, New York City. (Woodworking and Lumber Manufacturers' Section.)
 R. E. PROUTY, Aetna Life Insurance Company, New York City. (Marine Section.)
 A. D. RISTEEN, The Travelers Insurance Company, Hartford, Conn.
 W. L. ROLLER, The Hocking Valley Railway Company, Columbus, Ohio. (Steam Railroad Section.)
 R. C. STRATTON, The Travelers Insurance Company, Philadelphia, Pa.
 C. W. SMITH, Standard Oil Company (Ind.), Chicago, Ill. (Petroleum Section.)
 G. E. SANFORD, General Electric Company, Schenectady, N. Y.
 THOMAS S. STROBBER, Wagner-Taylor Company, Philadelphia, Pa. (Food Section.)
 R. F. THALNER, Buick Motor Company, Flint, Mich. (Automotive Section.)
 A. J. VAN BRUNT, Public Service Corporation of New Jersey, Newark, N. J. (Newark Chapter.)
 T. A. WALSH, American Optical Company, New York City. (Metropolitan Chapter.)
 THOMAS J. WHELAN, The Travelers Insurance Company, Boston, Mass. (Boston Chapter.)
 S. E. WHITING, Liberty Mutual Insurance Company, Boston, Mass.
 W. H. WINANS, Union Carbide Company, New York City. (Metals Section.)

Retiring Officers

Chairman, E. W. BECK, U. S. Rubber Co., New York City; *Vice-Chairman*, R. C. STRATTON, The Travelers Insurance Co., Newark, N. J.; *Vice-Chairman*, R. A. MCA. KEOWN, Industrial Commission of Wisconsin, Madison, Wis.; *Secretary*, W. DEAN KEEFER, National Safety Council, Chicago; *Assistant-Secretary*, MRS. GENE S. WOOD, New York City; *Executive Committee*, The OFFICERS and C. B. AUDEL, Westinghouse Electric and Mfg. Co., East Pittsburgh, Pa.; J. R. BANASH, Consulting Engineer, Chicago; C. R. Tuesday, September 27, 1927

ERNEST W. BECK, Chairman
Supervisor of Safety United States Rubber Company, New York City

The first session of the American Society of Safety Engineers, Engineering Section, of the National Safety Council, was called to order at two-thirty o'clock by the chairman, Ernest W. Beck, supervisor of safety, United States Rubber Company, New York City.

CHAIRMAN BECK: I am sorry Mr. Singleton is not here. In his absence, I will call on Mr. Owen of the Council staff, who is secretary of the committee on Static Electricity, to present the report of this committee and to lead the discussion.

Progress Report of A. S. S. E.—Engineering Section **Research Committee on Static Electricity**

F. C. Singleton, Safety Director, Standard Oil Company, (Indiana), Chicago.

History and Scope of Committee

In 1922, the National Safety Council formed a committee to study static electricity. Several meetings were held at which static electricity and the National Safety Council's Safe Practices Pamphlet No. 52 "Static Electricity" were discussed to a great extent. That pamphlet has been of value to many in the study of static electricity hazards and their elimination.

Upon the consolidation in 1924 of the American Society of Safety Engineers with the National Safety Council, the American Society of Safety Engineers became the Engineering Section of the National Safety Council. That section organized a committee now known as the A.S.S.E.—Engineering Section Research Committee on Static Electricity.

The primary purpose of the committee last mentioned was to study the generation of static electricity on motor vehicles and to recommend practical methods of eliminating static electricity as a cause of motor vehicle fires. A report of that committee was made at the Fourteenth Annual Safety Congress.

In order that the personnel of the Committee would be representative of the various activities most interested in a study of the static electricity problem, the following persons have agreed to serve as members of the A.S.S.E.—Engineering Section Research Committee on Static Electricity.

Chairman. Frank C. Singleton, Standard Oil Company (Indiana), Chicago, Ill.
Secretary. Stewart J. Owen, Jr., National Safety Council, Chicago, Ill.
 Thomas W. Butler, Standard Oil Company (Indiana), Chicago, Ill.
 L. A. DeBlois, National Bureau of Casualty and Surety Underwriters, New York City.
 Frank A. Epps, Tidewater Oil Company, New York City.
 E. E. Follin, Standard Oil Company (Indiana), Chicago, Ill.
 Dr. C. F. Hagenow, Washington University, St. Louis, Mo.
 Dr. Frank B. Silsbee, United States Bureau of Standards, Washington, D. C.
 E. J. Smith, Underwriters' Laboratories, Chicago, Ill.
 Roger T. Waite, Aetna Life Insurance Company, Hartford, Conn.

The scope of the committee has now been increased to include static hazards and their elimination in all industrial activities. A brief summary of the more important studies made by the committee is given below.

Tank Trucks and Static

At the Fourteenth Annual Congress, the committee reported that several assumptions may be made as to the possible source of the static charge which could ignite gasoline.

- A. The vehicle may arrive at the filling station charged from such causes as:
 1. Air friction against the body of the car.
 2. Tire friction on the road.
 3. The splashing of gasoline within the tank.
- B. The static may be generated at time of filling as from:
 1. The flow of gasoline through a hose, either grounded or ungrounded.
 2. The breaking up of the gasoline stream into small drops after it leaves the hose nozzle and before it reaches the bottom of the tank.
 3. The flow of gasoline through a strainer as, for example, a piece of chamois skin.

Air Friction Against the Body of the Car. Experiments made at the U. S. Bureau of standards show that static electricity charges may be generated on an insulated metal plate by blowing air currents with a slight dust content against the plate. So far as we know, no experiments have been made to prove or disprove the theory that tank trucks traveling over a road at a fairly good rate of speed, especially where the air is dusty, will become charged with static electricity because of the friction of dust particles against the sides of the tank trucks. However, since an insulated metal plate may become charged because of air currents mixed with slight dust being blown against it, it seems reasonable that a tank truck in transit may become charged with static because of the friction of the dust particles being blown against the tank truck.

Tire Friction on the Road. Experiments made at the U. S. Bureau of Standards show that a motor vehicle may become charged with static apparently because of tire friction with the road. A sedan with disc wheels and balloon tires was driven over a dry concrete road at low speed (not over 12 miles per hour). A metal rod connected to the chassis projected to one side so that as the car passed a certain point, the rod made momentary contact with a fixed wire connected to an electrometer. Under these conditions the instruments indicated a potential of about 3,000 volts. The potential was not much affected by changes in car speed or in the distance which the car had gone before contact was made, provided this distance exceeded 50 feet. The experiments were made on a cool day in the spring, but the electrical resistance of the tires was so low that the car discharged in a few seconds. A person touching the car could detect no charge and no spark was visible in the

daylight. The effect was substantially the same when the engine was stopped and the car coasted down a slight incline past the electric testing instruments. No material difference was observed when the brakes were dragging.

Splashing of Gasoline within the Tank. This theory is based on the knowledge that water falling through the air at a velocity exceeding 25 feet per second will often break into spray and that these small spray particles will carry a static charge. Since gasoline has a surface tension less than that of water it may be assumed that the gasoline will break into spray when poured or thrown through the air at velocities less than 25 feet per second and thus develop static charges on the spray particles. Since gasoline is not a good conductor of electricity, the charges generated do not at once find their way to the sides of the tank and a considerable charge may thus accumulate in the body of the gasoline.

Static Generated at Time of Filling. The experiences of various oil companies show that static developed while filling or discharging a tank truck may be due to the friction between the hose or strainer and the flowing gasoline.

The theory of the development of a static charge because of the breaking up of the gasoline stream into spray after it leaves the hose and before it reaches the bottom of the tank is similar to that given for the development of a static charge by the swishing of the gasoline in a moving tank truck.

Methods of Elimination of Static Hazards on Motor Vehicles

A. While Truck is in Motion. It is the general practice to equip tank trucks with chains long enough to drag on the ground in order to "bleed off" such static charges as may be generated in any manner while the tank truck is in transit.

While the drag chain will not discharge to ground at all times any static that may be on a tank truck, particularly when the truck is passing over dry pavements, etc., the chain will act as a conductor to ground when the truck drags the chain over conducting objects such as man hole covers in the street, railroad rails, damp earth, etc.

The use of drag chains is not approved by some persons who state that a drag chain is dangerous because it may catch on some obstruction in the street with damage to the tank truck. This objection may be overcome by inserting a soft link in the drag chain so that the chain will easily part if it is caught on an obstruction.

Some persons who object to the use of drag chains as dangerous agree that bonding while loading and unloading is to be recommended. The recommendation of such bonding is an admission that static may exist on the tank truck, and if the providing of a drag chain will but partially help to discharge the static to ground, it is a precaution well worth installing.

B. At Filling Stations. Various methods are used to eliminate the static hazards while filling or discharging tank trucks at supply stations. One company has installed a metal ball on top of each tank truck. At each loading platform there is a handle known as a "contact" handle which is permanently connected to the grounding line of the filling station. This handle hangs directly over the truck when it is standing at the loading platform. On this handle is a sign "Ground your trucks before loading." The men are required, before loading, to attach this handle to the metal ball on the tank truck, thus equalizing the potential between the filling line and the truck.

Another company has devised a mechanism by which the loading cap is locked in the closed position. Before the tank truck can be filled, it is necessary for the man to unlock the loading cap of the truck by using a plug which is attached to one end of a grounding line of the filling pipe.

Where a funnel is used, it should be provided with a metal bail with spring straps on the side to insure metallic contact with both the filling pipe and the tank truck. The hose used should be metal lined and directly connected to the ground at one end, and having the nozzle on the other end in direct contact with the container being filled and the metal lining of the hose.

The generation of static by the breaking up of the gasoline stream into spray after it leaves the hose may be avoided by using a hose long enough to reach within a very short distance of the bottom of the tank being filled.

Experiments. Various oil companies have been approached in regard to making experiments to prove or disprove whether a gasoline tank truck may become charged with static because of one or more of the three reasons given under A. above. The companies have been reluctant to make the experiments because of the cost of the necessary tests and because of the fact that since the grounding methods now used on gasoline tank trucks and filling lines at supply stations have been employed practically all of the hazards from static have been eliminated. Therefore, while it may be of advantage to know exactly why a gasoline tank truck may become charged with static, unless funds are provided for making the necessary tests, it is very doubtful if such tests will be made.

Gasoline Tank Cars

The generation of static charges while filling or emptying tank cars is generally due to the friction between the flowing gasoline and the gasoline lines.

It may be that static charges are developed on tank cars while the cars are in motion, for the same reasons given for the charging of a tank truck while in motion, but since the tank car is in direct contact to ground through the rails over which it passes, it is not believed much trouble will be caused by static charges so developed.

Static hazards encountered in handling tank cars may be protected against by a permanent bond between the rail and the gasoline lines and also a temporary bond between the filling stem and the car. As a further protection against static as well as a protection against stray electric currents from sources foreign to the tank car or gasoline lines, such as street car tracks, etc., the tracks upon which the car rests while being filled or emptied are generally insulated from the remainder of the tracks and a grounding bond established between the different rails of the insulated portion of the tracks and the filling or discharging lines.

Dry Cleaning Establishments

Static charges in dry cleaning establishments may possibly be caused by:

- (a) Splashing of the cleaning solvent in the machines.
- (b) Friction between the cleaning solvent and the supply lines.
- (c) Friction between the cleaning solvent and the articles being cleaned.
- (d) Friction between the parts of the articles being cleaned.

Possible remedies for the elimination of or protection against static hazards in dry cleaning plants are:

- (a) Use of cleaning solvent with high ignition point.
- (b) Use of certain soaps in the cleaning solvent.
- (c) Avoidance of alcohol and ammonia in the cleaning solvent.
- (d) Moistening of silks before cleaning.
- (e) Humidifying atmosphere.
- (f) Bagging of goods in nets.
- (g) Grounding of machines, etc.
- (h) Closed cleaning system.

A. *Dry Cleaning Solvents.* The dry cleaning solvents now generally used are prepared in accordance with what is known as "Stoddard's" formula and have an ignition point of from about 100 to 105 degrees F. The use of such solvents has done much to lessen the fire hazards in dry cleaning establishments.

B. *Certain Soaps.* The use of certain soaps with the cleaning solvents is said by some authorities to be of great value in decreasing the fire hazards. A desirable soap is one which, when mixed with the cleaning solvent, will not lower the ignition point of the solvent. Many soaps, because of their low flammable bases, are said to be a factor in the causes of many fires in dry cleaning establishments.

C. *Alcohol and Ammonia.* The use of alcohol and ammonia is claimed, by some dry cleaning authorities, to be poor practice. Alcohol, if an appreciable amount is used, will lower the ignition point of the solvent because alcohol has a lower ignition point than the cleaning solvent. Ammonia is said to be objectionable because it sets the spots that may be in the goods being cleaned because of the water in the ammonia.

D. *Moistening of Silks.* It has been found that moistening silk articles before cleaning helps to prevent the accumulation of static charges. Many substances, such as silk, are non-conductors when dry, but they may become conductors at least on their surfaces, when wet or moist with water. It is, therefore, important to have the goods stand in a humid atmosphere some appreciable time before they are cleaned.

E. *Humidifying Atmosphere.* It has been found that a high humidity helps to prevent the accumulation of static charges. High humidity tends to make insulating materials conductors, at least on their surfaces.

Moisture Content of the Air Has a Marked Effect

The average moisture content of the air which prevails in the summer months is sufficient to produce a marked difference in the capacity of bodies to build up charges. It is, therefore, generally more difficult to get a static spark in summer when the air is humid than in winter when the air is drier.

In damp weather, all objects carry a slight film of moisture containing some impurities (such as carbon dioxide) from the air. This film of moisture is a fairly good electro-static conductor and serves to connect every object with the ground, thus preventing the accumulation of static charges.

It will thus be seen that the fundamental effect of high humidity in reducing static trouble is the result of the moisture film which it produces on the surfaces of most solid materials. As an appreciable time is required for this film to form, it is important to have the material stand in a moist atmosphere some time as well as it is to have the air humid during the operation.

It is said a relative humidity of not less than 40 per cent should be maintained in dry cleaning rooms at all times. Humidity may be easily maintained by allowing steam to discharge at a low constant rate from a pipe connected to the exhaust steam line of the plant.

F. *Bagging of Goods.* Bagging of all goods in a net bag, particularly silks, rayons, etc., has been found to help in the prevention of static charges while such goods are being cleaned. Such a practice tends to keep the parts of the goods from rubbing against each other, thus limiting the possibility of static being generated by friction between the surfaces of the goods.

G. *Grounding of Machines.* All machines in a dry cleaning establishment should be grounded by means of copper wires soldered or otherwise securely fastened to the machines and to pipes or iron rods buried in a moist earth. Ordinarily, it is

not sufficient to depend upon the cleaning solvent supply pipes as a ground, as these pipes do not always form a direct ground connection.

H. *Closed Cleaning System.* Apparently, at least one manufacture of equipment for dry cleaning has solved the problem in a way that has much that would seem valuable in connection with other dangerous operations. The scheme is simple. The naphtha or other volatile solvent to be used as a cleaning medium is kept in a closed system, out of contact with air. The washing machines are arranged to be closed air tight. The basket in which the goods to be washed are placed is constructed of tubes expanded into headers to form a skeleton tumbling barrel inside the washing machine. This basket can have steam circulated through the tubes and headers to heat it. The basket also can be rotated at either a high or low speed.

The process of cleaning is about as follows: Goods are placed in the basket of the washing machine and the door is tightly closed. Then a vacuum pump is connected to the machine and the air is exhausted. When a sufficient vacuum is obtained, the valve to the gasoline storage tank is opened and the gasoline flows in under the suction of the vacuum pump. Suction is continued until there is no appreciable air in the washing machine, only gasoline and its vapor. Then the washing operation proceeds as usual, except that it is possible to turn steam into the tubes of which the basket is made and heat the gasoline so that a more effective cleaning than usual is had. When the goods have run the allotted time, the machine is not opened, but the suction connection is again opened and the gasoline is drawn off leaving a rather good vacuum in the machine. The heat is turned on the tubes of the basket to evaporate the solvent, the vacuum being maintained, and finally the basket is rotated at its highest speed. In all the process of washing and drying, the machine at no time contains air, and when the goods are finally removed they are both clean and dry so that if a spark should be drawn from them no special danger is present. In addition to the safety feature, the process is said to develop a marked saving in volatile solvent, as all the vapor is condensed and recovered.

Belts and Pulleys

Drive belts generate static electricity probably by—

- (a) Contact between and separation of the belt and pulley and
- (b) Friction between the belt and the air.

As to static charges being generated by the contact and separation of the belt and pulley, it appears that a static charge may be developed in such a manner, particularly when the friction of the belt and pulley is taken into consideration.

Most persons are familiar with the display of a static "glow" when a roll of friction tape is unrolled in a dim light. Since it is possible that static may be generated by contact and separation in such cases, it appears reasonable to assume that the friction caused by the contact and separation of a belt and pulley revolving at a fairly high speed may also generate static.

Some doubt has been expressed that friction between a rapidly moving belt and the air may generate a static charge. When it is remembered that some belts travel at high speed, that some dust may be present in the air, and that a stream of air with a slight dust content blown against an insulated metal plate will generate static charges, it seems possible that the friction between the dust particles of the air and the rapidly moving belt may generate, at least, small static charges.

Static accumulation on belts and pulleys may be eliminated or at least protected against in one or more of the following ways:

- (a) By grounding wire combs.
- (b) By grounding the hangers or shafting.
- (c) By the use of various belt preparations.

A. *Grounded Wire Combs.* The U. S. Department of Agriculture, after a thorough study, recommends the use of either two grounded wire combs which rub

the belt at the points where it leaves the pulley or a net work of grounded wires stretched parallel and close to the belt on both sides. Sag and whipping of the belt must be taken into consideration in the arrangement of these combs or net work of grounded wires. Satisfactory results are reported where a grounded metallic comb has been placed close to, but not touching, the surface of the belt where it runs off the driven pulley.

In grounding belts in a dry cleaning establishment or other places where an explosive vapor is present, the combs, if used, must be either in contact with belt or very close to it, so that there will be only a brush discharge of the static. If the combs are placed too far away, there will be "hot" sparks between the belt and the combs which may ignite the vapor. It has been recommended that a wire cable with the end frayed, paint brush fashion, be used in dry cleaning establishments in place of the metallic comb, the cable being grounded in the same manner as the comb.

B. Grounding of Hangers and Shafting. Where metal pulleys are used, the static charges may be removed by grounding the hangers on the shafting. Some say that the grounding of the hangers is not sufficient as the oil in the bearings of the shafting acts as an insulator and it is, therefore, necessary to ground the pulley or the shafting or both.

Where the shafting is grounded, metallic brushes similar to those used on electroplating dynamos may be used. Similar brushes may also be used to ground the metal pulleys.

C. Use of Belt Preparations. Various preparations have been used with success by some companies to eliminate or prevent static charges on belts.

One company reports that the use of an emulsion of one-half glycerine and one-half water applied periodically to the outer surface of the belt was successful in eliminating static charges on its belts. The effect of this emulsion was to form a film of moisture which conducted the static charges to the pulleys, the shaft bearings being grounded.

Another company reports success when castor oil is well worked in on both sides of the belt and a coating of graphite grease is applied to the outside of the belt.

Powdered Materials

Causes. Friction between powdered materials and various objects, or possibly friction between the particles themselves, may generate static in one or more of the following manners:

- (a) Materials falling through the air.
- (b) Materials being blown through a pipe.
- (c) Ejection of the materials from small nozzles or orifices.
- (d) Materials sliding down chutes.
- (e) Handling of materials in various ways.

Static charges in the presence of powdered materials are particularly dangerous where the powdered material itself forms an explosive dust mixture with the air, thus furnishing fuel for a static spark to ignite. Powdered materials which will form explosive dust mixtures with the air include not only black powder, certain chemicals and the dust of coal, grain, flour, starch and other grain products, but also those of sugar, wood, aluminum, celluloid, cork, cotton, fertilizer, powdered milk, phonograph records, rubber shoddy, soap, shellac, sulphur, and other combustible substances.

One experimenter states that static may be found on rust particles escaping through the needle valve of a compressed gas tank. Experiments have shown, it is said, that hydrogen gas escaping from such a tank rusted on the interior, may be thus ignited.

One company reports that granular or pulverized non-conducting materials, if dry, easily become charged with static electricity when they are moved. The motion of the materials need not be violent. A bag of thoroughly dry materials, sensitive to the formation of static, may, on a dry day, accumulate quite a charge if merely lifted from the floor and set down again.

Dry materials become charged when allowed to slide down a metal or wooden chute. The charge is distributed over the individual particles and cannot be readily discharged. There is a tendency, however, for a spark to occur at the moment that the last of the material leaves the chute. Static sparks five or six inches long are said to have been produced by emptying a single tray of dry smokeless powder. This does not occur if the air is damp or the powder is "green."

Possible Remedies. Dust of powdered materials should not be allowed to accumulate in such manner as to form explosive mixtures with the air. In some instances, however, there will be unavoidable dust accumulations.

Machinery or equipment in which material is ground, or through which powdered or finely divided materials pass, should be grounded at a sufficient number of points to insure the collection of all charges. This may often be accomplished by means of copper wires securely fastened at various points to the machines, etc., and connected to pipes or other suitable conductors buried in moist earth.

One company manufacturing a food product had trouble with static where the finely ground grain was blown through cloth screens. This was eliminated by the use of fine copper wires woven into the screens and connected to the ground.

Serious troubles in connection with collection of sulphur dust in a filter type collector has been eliminated by grounding the collector bags. Another company, however, reports that after repeated experiments, it was unable to remove, by grounding of apparatus, the static charges which occurred on wood pulp in the process of drying and sifting.

Humidity may also be employed if the dampness in the air does not affect the process. Where humidity is used the articles must stand long enough in a humid atmosphere to become slightly damp and the atmosphere of the rooms in which the operations are carried on must also have a high relative humidity.

One company which experienced considerable trouble because of explosions due to the generation of static while the sulphur was being unloaded into storage bins, overcame the trouble by water sprays from sprinkler heads placed over the storage bins.

Further Studies and Tests

It is the intention of the committee to take up the static problems found in other industries and to make a study of their causes and remedies. However, it will be guided by the advice of the various Council members, who are urged to submit their problems to this committee together with test and experience data.

The committee recently completed the revision of Safe Practices Pamphlet No. 52, "Static Electricity," copies of which are now available.

A. L. ARMSTRONG (Eastman Kodak Co., Rochester, N. Y.): Are the static charges which are built up on tires carried up into the tank?

MR. OWEN: From the talk that I had with the physicist who performed that experiment, I would say yes.

MR. ARMSTRONG: Your charge is first on a non-conducting surface, the tire. You would have to have at least 300 volts to break down the resistance to get to the housing, and then, your connection between housing, springs or chassis and frame, would not be very good conductors to carry static charges.

My reason for not believing that static generated by the tires accumulates on the tank is because any static charge on a non-conducting surface must come in contact

with a collector to be taken off. For instance, you take a sheet of cloth. It is a non-conductor, but it will build up static charges in passing over a roll or by pulling it off the roll. The collector must touch that cloth along its entire width in order to take off those charges. If that were not true, you would not have static charges. Reasonably, too, if your tire were a conductor, you would not have static charges, because they would be carried to ground.

Why should static charges pass through the tire onto the wheel, onto the axle, from there to the chassis and up onto the tank and into the solvent inside of the tank. I don't believe it.

Consider static on transmission belts. You can remove the static from the belt, but the static will continue to build up on the pulley and the shafting. It won't pass from the shafting to the hanger. If you ground the hanger, you still have charges on the shafting. These charges must be built up to a potential and they have built up to a sufficient or about 300 volts to break down the resistance caused by the oil in the bearing.

Removing Static From a Non-Conducting Surface

To remove static from any non-conducting surface you usually use a collector, say needle points, as nearly in contact with the non-conducting surface as possible, and carry your static charges to ground. On the shaft and pulley, if you do not ground the shaft, you build up potentials around 300 volts. The potential on a tire would have to be about 220 volts to break down the resistance of an ordinary concrete road. I am just wondering why static charges on a tire should not pass off to the road at 220 volts and not to the tank at 300 volts?

The Standard Oil Company has removed all chains from its wagons. It is claimed all static is removed by running a chain from the running pipe down into the tank.

MR. OWEN: Have they made any tests to determine whether they have any static there or not?

MR. ARMSTRONG: I don't know.

FRANKLIN L. NEWCOMB (Standard Oil Co., New Jersey, Elizabeth, N. J.): For the past two years I have had a man riding tank trucks every week or two over long trips and short ones, under all conditions of weather, over all conditions of road, loaded fully, partly loaded and unloaded, and we have never found a single, solitary trace of static electricity on a tank truck.

We have found traces of static electricity on trailers, truck trailers. We are just as convinced as ever that negative evidence is no evidence at all; your chances of getting it are mighty slim. We do not use any drag chains on our tank trucks, and we have never had an accident due to that cause.

I think it is just as logical to put drag chains on your automobile that is carrying passengers as it is to put drag chains on your tank trucks.

MR. OWEN: How about the different climatic conditions?

MR. NEWCOMB: It seems to make no difference.

I wrote and asked Mr. Singleton where he got the dope that he had, and he said the Atlantic Refinery gave it to him. I wrote and asked them; they said that in a couple of cases running through crowded areas with lots of other motor vehicles on the street they had found slight traces of static electricity on their tank trucks. They don't know to what extent, but they did find traces of it. They laid it strictly to the exhaust of other cars.

We think that is true, because we have had the same trouble with our trailers, probably caused by the exhaust from the truck in front. They seem to be the only cases under which we have found static on these trucks.

MR. OWEN: Would you mind sending that data on for the benefit of the committee?

MR. NEWCOMB: I will if the company will permit me to.

THOMAS W. BUTLER (Standard Oil Company, Indiana, Chicago, Ill.): What instrument did you use?

MR. NEWCOMB: Electroscopes.

M. E. ARKILL (Waterfront Employers of Seattle, Seattle, Wash.): I had a peculiar happening in the purchase of an automobile a few years ago. It developed static, and would pull a spark of about three-quarters of an inch from the door knob of the coach, and you only had to drive around one city block to get it. We chased down every conceivable thing. I went to the best electrical experts I could find. I finally decided it was in the tires. When I put on the first new tire, I eliminated the static in my car. It was so bad that I was scared to pull up to a gas station without calling the gas man to me before he reached for the gas filling plug, because I felt if he ever got there before I got hold of him, he would probably blow me up.

MR. HOMER (Youngstown Sheet & Metal Co., Youngstown, Ohio): I was just going to tell of a similar instance I had with a new car. It had just been out half an hour. A man was taking his wife out. As she got out of the car she got a shock from the handle. They tried to find the trouble. It was located in the tires. They changed the tires and it was gone. They found on experimenting with the tires, that they had used cord tires that were very loosely woven, and apparently the friction of the cord in the tires had produced the static. Upon removal of the tires, the static was gone.

MR. OWEN: The instance you cite reminds me of a condition that existed here on the motor buses in Chicago. A number of people reported that they had received shocks when they stepped off the buses to the ground. The company overcame that condition in a rather ingenious manner. A piece of quarter inch cable with one end frayed, paint brush fashion, is connected to the brake lever in such a manner that when the driver throws his brake on, this paint brush end of the cable touches the ground. It apparently removes any static on the vehicles, because since the company has put those cables on, no complaint has been made of any passenger receiving a shock while getting off a bus.

One Objection to the Grounding Chain

MR. NEWCOMB: My main objection to the grounding chain on a tank truck is that your man who is operating the truck may get careless and not use the grounding devices that are provided for him when he comes back to load, or he may not be careful in making his ground when he unloads.

We do know that during the unloading and loading operation, we must ground the tank truck. We have had cases where we had trouble and even had tank truck explosions. We had one not long ago that was caused by the grounding device being allowed to get in poor condition.

MR. OWEN: Before you start to discharge, do you always ground your tanks?

MR. NEWCOMB: Before we start to discharge, the man must bring the unloading hose in contact with the customer's tank so as to equalize the potential. He inserts the nozzle in the fill pipe, and it has got to make contact with the fill pipe. The hose is metal lined with the lining connected to both the coupling and the discharge nozzle.

When filling a tank truck we have a grounding chain which we lay across the faucets of the tank; this chain is also connected to the fill pipe. Then, we always keep the fill pipe in contact with the dome of the tank truck. We use a cup-shaped affair that just fits right in there, and we have a seal or closing valve on the fill pipe, which has enough resistance so the operator must hold that pipe in contact to keep the valve open.

MR. OWEN: If your company is willing we would like to get full details of all that information for the committee.

W. F. ROONEY (Tide Water Oil Co., New York City): I have known for some time that the Standard Oil Company has done away with drag chains, but we continue to use them, because we have no good reason yet for discontinuing their use. When the end of the chain wears off, we attach a short length by means of a harness snap.

We also use grounding clamps in unloading our tanks. I inspect all of our bulk stations twice a year and occasionally I find that the grounding connections at the loading places are in pretty poor shape. I found on some of our older trucks that the tanks themselves were insulated from the metal chassis by wood sills. On such tanks, where we ground at the loading platform and at the unloading process we never experienced any trouble at all. That helps to support Mr. Newcomb's statement that the tank truck in operation does not generate static electricity. We do use the ground chain as an extra precaution, however.

Static on Gasoline Tank Cars

MR. OWEN: On gasoline tank cars static is generally due to the friction between the flowing gasoline and the gasoline lines.

It may be that static charges are developed on tank cars while the cars are in motion, for the same reasons given for the charging of a tank truck while in motion, but since the tank car is in direct contact to ground through the rails over which it passes, it is not believed much trouble will be caused by static charges so developed.

Static hazards encountered in handling tank cars may be eliminated by establishing a permanent bond between the rail and the gasoline lines and also a temporary bond between the filling stem and the car. As a further protection against static as well as a protection against stray electric currents from sources foreign to the tank car or gasoline lines, such as street car tracks, etc., the tracks upon which the car rests while being filled or emptied are generally insulated from the remainder of the tracks and a grounding bond established between the different rails of the insulated portion of the tracks and the filling or discharging lines.

THOMAS W. BUTLER (Standard Oil Company of Indiana, Chicago, Ill.): That is purely a protection against electric current, and should be treated as such. My personal opinion is that static electricity is not a vital factor in handling tank cars.

MR. NEWCOMB: The Standard of New Jersey goes so far that we bond our rails and we directly connect our fill pipes to our rails and then our fill pipe which we clip onto the flange at the top of the tank before we allow them to put the pipe in contact with it.

MR. BUTLER: Is that done in all stations, large and small?

MR. NEWCOMB: Most of it is done in the small stations.

MR. BUTLER: Our practice is to use overhead unloading at all our stations.

MR. NEWCOMB: Even then, I think I would do it. We don't unload overhead.

A Hazard in the Unloading of Tank Cars

MR. BUTLER: This proposition has been brought up by a number of railway companies. They bring it up as a hazard in the unloading of tank cars. We have something like 4,000 or more stations scattered over the ten states of the Middle West, and we have no record of tank car fires that could possibly be caused by static electricity. We have checked up and have found that it is stray electric current that is causing all the trouble. Stray electric current is a different proposition from static electricity. I object to spending a lot of money equipping 4,000 or more stations with protection against static electricity when actually there is very little danger.

MR. NEWCOMB: I think you have very little danger, because when you open up the tank car to make your connection, you have vapors that are so rich that they won't explode anyhow.

I am more afraid of the large volume of explosive mixture at the loading operation than I am of the car full of gasoline. You could probably throw something over it to close it up.

A. L. ARMSTRONG (Eastman Kodak Co., Rochester, N. Y.): We operated for a good many years on that same theory and thought we were all right, but we did have some grief. After we had run experiments and proved that you can get an explosion with a tank car half or three-quarters full of flammable solvents, we went ahead.

Various Additional Points Are Brought Out

MR. OWEN: If there is no more discussion on tank cars, let's turn to dry cleaning.

MR. ARMSTRONG: Why is it bad to add alcohol to the cleaning fluid?

MR. OWEN: Alcohol in considerable quantities lowers the ignition point of the solvent.

R. J. CROSBY (Travelers Insurance Co., Hartford, Conn.): Why take it for granted that these things occur? Why don't we have tests made?

MR. OWEN: For the simple reason that we have no funds to pay for them. The committee's report contains numerous theories, some proved, others not proved.

MR. ARMSTRONG: I think the report should explain the method of introducing steam into the air to give the right humidity.

MR. OWEN: There is a suggestion here in the last paragraph of part "E" which reads: "Humidity may be easily maintained by allowing steam to discharge at a low constant rate from a pipe connected to the exhaust steam line of the plant."

MR. ARMSTRONG: That doesn't go far enough. It is better to introduce moisture through your ventilating system.

THOMAS W. BUTLER (Standard Oil Company of Indiana, Chicago, Ill.): I think that a constructive suggestion which should be included in the committee's report.

CHAIRMAN BECK: I was in a cement spreader house where periodically a steam hose with a one-inch nozzle was played into that room.

MR. BUTLER: That is dangerous if you use high pressure steam, for that in itself may generate static as high as 10,000 to 15,000 volts. On low pressure steam it would not apply.

An Experience in An Old Plant

MR. ARMSTRONG: You don't say anything in here about hydrometers. They should be of the wet and dry bulb type.

About humidity, we had an old plant where we were trying out explosive processes and we had continual explosions. They were daily occurrences. Realizing that it was impracticable to put in a complete humidifying equipment on a modern basis, we simply put in small circulating fans with a circular pipe through which a fine spray of water was going all the time. The idea was to raise the humidity well above the safe point, and we stopped the explosions from that day on.

D. C. WRIGHT (Western Shade Cloth Co., Chicago, Ill.): We have a man who makes an hourly inspection throughout the plant tabulating the humidity readings. Explosions were almost a daily occurrence for a period of years before we started that.

MR. OWEN: Are you ready to proceed with belts and pulleys now?

MR. ARMSTRONG: We cannot put enough humidity in the air with a six-inch belt

that is traveling at a high speed to keep that belt from building static charges. The only way to take off the static is with a collector. We use a new type of collector that was designed and built in our own plant. It is a one-inch angle iron that can't be knocked out of adjustment. We ground this collector with a number 6 wire. We drive pins through the angle iron to come within $\frac{1}{8}$ inch of the belt. The pins are $\frac{1}{8}$ -inch in diameter and are made for us by the Stainless Steel people, so they will not corrode or rust. These pins discharge with what we call a glow discharge, which is a blue flame that is not hot enough to ignite solvent vapors.

I would like to comment on the use of various belt preparations. I have been able to run experiments on all these so-called belt preparations for the last five years. I have never been able to find anything that would last more than three or four hours. We went to the Rochester Belt Company and had belts made up which were impregnated with different materials to keep them moist, and we even went so far as to have belts made with copper inserts and copper wire in them. That was going to be a beautiful patent, but it didn't work out.

Number of Collectors Depends on Size of Belt

The only logical collector is the needle point collector. That is the way we feel about it. They should never be installed so they are farther away than $\frac{1}{2}$ inch from the belt. If you don't get farther than $\frac{1}{2}$ inch, you will never get a spark discharge.

MR. MILLMAN: Do you have a particular place to put them?

MR. ARMSTRONG: There is no particular place to put a collector in relation to the belt and pulley. In dry cleaning plants and in all places where they handle solvents, it is a good stunt to steer away from wooden pulleys. You will find if you use iron or steel you will have less trouble.

MR. MILLMAN: How many collectors do you put on the belt?

MR. ARMSTRONG: That depends entirely on the size of the belt, and the load it has to pull. On most of our belts, we never have over two. With a cross belt, it is rather difficult to put them on, but it can be done. Where you have shift belts, you may have to install long collectors so the belt rides across them and at different angles.

R. J. CROSBY (Travelers Insurance Co., Hartford, Conn.): Have you made any tests in connection with the use of wire collectors or wire fastenings on belts? Do you consider the use of wire fastenings dangerous?

MR. ARMSTRONG: I don't think it has any bearing on static electricity. I don't think that a wire fastening in a belt has any bearing on the potential of static that will build on a belt.

Experience of Council Members Used

W. L. SCHNEIDER (B. F. Goodrich Rubber Co., Akron, O.): Has there been any research work made as to the type of material that belting is made of?

MR. OWEN: Not by the Committee. We have been guided by the statements made by certain members of the Council in which they have stated that belts of this construction or belts of that construction did so-and-so according to the tests they made.

MR. SCHNEIDER: I have never seen anything mentioned about the "V" belt.

MR. OWEN: No, because the "V" belt is comparatively new. Are we ready to proceed with powdered materials now?

MR. ARMSTRONG: I would suggest that the Committee write Arthur Schoen, Research Laboratory, Eastman Kodak Company, Kodak Park, Rochester, New York. I would be glad to ask Mr. Schoen to criticize the report.

MR. F. J. O'CONNOR (Du Pont Co., Wilmington, Del.): Is there anybody present who of himself has actually been present and has seen a fire or an explosion start from static electricity? I have seen in the past twelve years the reports of about 35 fires in newspapers, not engineering journals, ending with some such statement as this: "The cause of this fire is not definitely known, but undoubtedly it was due to static electricity." I think probably different persons have seen static fires in dry cleaning establishments, but I would like to ask if anybody has seen an actual fire start from static electricity outside of laboratory experiments.

A Peculiar Circumstance Causes a Fire

MR. HUNGERFORD (Firestone Tire & Rubber Co.): In our cement house early this spring, I happened to be checking up on a few rules we had issued to operators. One of the rules is that operators should not wear rubber soled shoes, due to the fact that the human body may become a fine container for static charges. It was at the end of the shift, and the operator of the spreader had gone down and changed his clothes and put on a nice pair of heavy rubber soled shoes. He came back upstairs again and stood talking to one of the other operators. As he stood there talking, a spark jumped from his finger and started a fire under the hood. Of course, we have hoods over the horizontal spreaders. There were three of us who saw the same thing. We didn't do much after it started; it didn't take us long to get out through the three big doors. (Laughter.) I guess I tried to go through two at once.

CHAIRMAN BECK: I would like to supplement what has just been said. We had a man who carried an unusual amount of static; some people do. This fellow was constantly setting fire to our spreaders. We installed a hose line alongside of his station. Then we grounded the man by requiring him to stand on a grounded metal plate and thereafter we had no trouble with his starting fires.

MR. ARMSTRONG: One of the largest dry cleaning plants in the State of New York is in our city. The owner, not thinking what he was doing, installed rubber tired wheels on his trucks carrying the clothing. He had about six fires in one day. Whenever an employee would walk near one of the trucks, a fire would start.

In *Chemicals* about six months ago appeared an article in regard to static electricity. Two men were filling a barrel with a certain chemical. The barrel was set on a scale that was set on wood. They had grounded their pipe but had forgotten to ground the funnel. When they removed the funnel, a static spark was formed and both men were killed. That was actually seen by two other men.

CHAIRMAN BECK: Mr. Armstrong, do you think, on booster tanks they would be better with metal rim wheels?

MR. ARMSTRONG: Yes. We use the bronze wheel.

M. E. ARKILLS (Waterfront Employers of Seattle, Seattle, Wash.): Would not the static be discharged anyway when you let your handle down, because on the feet there is metal on the booster tank and just two rubber tires?

CHAIRMAN BECK: Yes, I think that is so.

Example of An Accident to a Tank Car

G. R. G. FISHER (Ill. Manufacturers Association, Chicago, Ill.): Is there anybody in the room familiar with the type of hose to be used when steaming tank cars to eliminate or minimize the possibility of building up static charges?

THOMAS W. BUTLER (Standard Oil Company of Ind., Chicago, Ill.): I have no personal experience, and I am not familiar with refinery practice. I would say off-hand that a metal lined hose permanently connected to the tank car would eliminate any danger.

MR. FISHER: I might give the instance which prompted the question. Two months ago we had a tank car come in for repair, and it blew up. I pronounced it static electricity. One of the men said it couldn't be that because they had used a rubber hose.

Two years before on a similar case two experts on static electricity recommended the elimination of metal connections on the rubber hose. They said, "If you eliminate the metal and use the rubber hose entirely, you will eliminate static. We ran some extensive experiments at the refinery on static electricity. We have spent a lot of money in putting in metal wrapped hoses. We also have grounded the steam line.

MR. OWEN: Is there any further discussion? Understand, please, that this is only a progress report. Various ideas have been presented for you to discuss. Any data or information that you can give the committee will be much appreciated. We are trying to help you solve your static electricity problems. The more cooperation you give the committee, the sooner we are going to find the answers to your problems.

CHAIRMAN BECK: I would urge our members to submit to this committee the data developed by their research laboratories. It wouldn't be possible for us to begin to do what some of you are doing in your own laboratories, but if we pool our data we will accumulate a vast fund of valuable information for the benefit of all. We have been fortunate in getting a man like Mr. Owen to serve as the secretary of our committee. You have seen a sample of some of the work that he is doing this afternoon.

We have one other progress report to be presented by the Committee on Wire Rope Attachments and Connections. In Mr. Sunderland's absence I am going to ask Mr. James to lead the discussion.

Progress Report of A. S. S. E.—Engineering Section Research Committee on Wire Rope Attachments and Connections

Charles C. Sunderland. John A. Roebling Sons Company, Trenton, N. J.

History and Scope of Committee

In January, 1926, in order that an impartial study of wire rope fastenings might be made and because of the importance of the problem to industry and the Safety Movement in general, the A. S. S. E.—Engineering Section of the National Safety Council formed a committee known as the Committee on Cable Splices and Clamps, to make a study and report on the efficiency of the various wire rope fastenings in use. Since the title of the committee did not clearly indicate the purpose for which the committee was formed, its title was afterward changed to Research Committee on Wire Rope Attachments and Connections. The personnel of the committee consists of representatives from interested manufacturing firms, associations, etc., and is as follows:

Chairman, Charles C. Sunderland, John A. Roebling's Sons Company, Trenton, N. J.

Secretary, Stewart J. Owen, Jr., National Safety Council, Chicago, Ill.

C. B. Auel, Westinghouse Electric and Manufacturing Company, East Pittsburgh, Pa.

K. M. Bradley, General Electric Company, Lynn, Mass.

Sidney V. James, Underwriters' Laboratories, Chicago, Ill.

E. O. Keator, Dayton, Ohio.

Harry J. Leschen, A. Leschen and Sons Rope Company, St. Louis, Mo.
N. O. Lindstrom, A. B. See Elevator Company, Jersey City, N. J.
Homer J. Weeks, American Steel and Wire Company, Cleveland, Ohio.
Eli Weyhenmeyer, Hazard Manufacturing Company, Wilkes Barre, Pa.
S. E. Whiting, Liberty Mutual Insurance Company, Boston, Mass.

Suggested Plan of Procedure

There is a difference of opinion as to the efficiency of many wire rope fastenings now on the market, particularly those of the clip or clamp types. In order that the actual facts might be determined in a systematic manner, the following plan of procedure has been prepared.

The principal wire rope attachments and connections can be listed as follows:

- Socket Attachments Using Zinc Method.
- Socket Attachments Using Babbitt
- Wedge Sockets.
- Swedged Attachments.
- Thimble and Clip Connection.
- Thimble and Clamp Connection.
- Sheave with Clip or Clamp Connection.
- Combined Thimble and Clamp Connection.
- Spliced Eye and Thimble Connection.
- The Contractor's Stand-by.

Socket Attachments Using Zinc Method

In regard to these attachments, it will be necessary to investigate the strength of this connection with various degrees of poor workmanship, and this investigation might show that with a socket of liberal design, even poor workmanship will not affect the strength of the connection to a serious extent. It will also be advisable to investigate the strength of the socket attachment using the zinc method, but making the attachment with babbitt instead of zinc. The results will be sufficiently striking to show the user how dangerous it will be when using such a combination.

Socket Attachments Using Babbitt

The National Safety Code for Elevators, specifies the method of making socket attachments with babbitt, and states that these attachments must develop 80 per cent of the ultimate strength of the rope, and this is possible on elevator ropes which can be considered medium strength ropes, but it is not possible to secure 80 per cent efficiency when using this method for high strength ropes. An investigation of this method in connection with high strength ropes, should be made, so that the user can be fully informed as to the actual strength of this attachment in connection with high strength ropes.

Efficiency Depends on Design of the Socket

Wedge Sockets

It is stated that a wedge socket connection will develop from 70 to 90 per cent of the ultimate strength of the rope. This efficiency, however, is dependent on the design of the wedge socket, the diameter of rope, and whether or not rope is low or high strength rope. Tests should be made so that proper values could be quoted for the conditions specified.

Swedged Attachments

Swedged attachments for wire rope are being offered to the trade as 100 per cent attachments, but we find that the efficiency is variable depending upon the rope diameter, therefore, this matter should be investigated and results tabulated to give full light on the subject.

Thimble and Clip Connection

Although considerable investigation has been made in regard to the efficiency of clip connections, there is still further work to be done, to eliminate the confusion now existing in the mind of the consumer as to the actual number of clips required (of various designs) to develop the maximum efficiency of the connection. For example, *four* clips on a Plow Steel Rope may be sufficient to develop the maximum efficiency for this rope's strength, but if four clips were used on a Blue Center Rope, it would be possible to attach these clips with sufficient pressure to break the rope, but if *six* clips were used with lighter pressure, the efficiency of this connection would be at least 10 per cent higher than if *four* clips were used.

Thimble and Clamp Connection

The design of a clamp has great bearing upon the efficiency of this connection, therefore, a series of tests should be made with *three* bolt clamps having straight grooves in comparison with *three* bolt clamps having one set of grooves corrugated to fit the rope lay. The comparison of these tests, would strikingly show the necessity of the later design.

Sheave with Clip or Clamp Connection

Sometimes a moderate diameter sheave is used instead of thimbles in connection with clips or clamps, but in this case the snubbing action of the rope around the thimble being absent, requires the use of more clips or clamps than when used in connection with the thimble.

Combined Thimble and Clamp Connection

There are various designs of combined thimble and clamp connections, some of which are very efficient, and others that have very little merit. It might be advisable to make tests and point out the differences, so that the user will be fully informed as to the safety of this connection.

Spliced Eye with Thimble

There are at least *five* different methods of making spliced eyes, some being more efficient than others. A series of tests should be made to determine the relative strength of the different methods of splicing eyes.

The Contractor's Stand-by

A series of tests should be made to show how dangerous this type of connection can be. These tests can be used as basis for a definite recommendation advising against the use of this connection.

Clip or Clamp Connection without Thimble

This is very bad practice, and tests will show the danger of this combination.

Studies and Tests

It is the intention of the committee to study all of the wire rope fastenings now in use.

In some cases tests have been made, the data of which will be used by the committee. However, in many cases it will be necessary for tests to be made, in order to learn the true facts in an impartial way in regard to some fastenings now on the market.

The various members of the Council are urged to submit their wire rope attachments and connections problems to the committee together with test and experience data.

The committee has recently completed the revision of Safe Practices Pamphlet No. 26 "Manila and Wire Rope," copies of which are now available. In the revision of that pamphlet the committee has given considerable time and study to that part dealing with wire rope fastenings.

The Committee Asks For Test Data

SIDNEY V. JAMES (Underwriters' Laboratories, Chicago, Ill.): In the absence of Mr. Sunderland, who is the chairman of this committee, I have undertaken to present the committee's progress report.

You will note that the report classifies the various methods of attaching and connecting cables and then discusses each one separately in a general way, pointing out its limitations and outlining what information is available on that subject. In most cases you will find the committee recommends that tests be made on which sound conclusions can be based. Perhaps some of this test data is already available. If so, the committee will appreciate your bringing it to their attention.

The first item mentioned in the report is the zinc socket. Has anyone anything to say on this subject? The report outlines the limitations and the principal features to be kept in mind handling this method. Is there anyone here who would care to discuss this method, outlining their own experiences with it, and giving any thoughts that they might have to convey to the meeting on the use of this method of attachment in fittings?

M. E. ARKILLS (Waterfront Employers of Seattle, Seattle, Wash.): In setting a socket with zinc, it is customary, I believe, first to pickle the ends of the wire with an acid to remove the grease. Is there any way known to overcome the continued action of the acid?

MR. JAMES: I believe it is generally recommended practice to neutralize the acid after cleaning the wires. Any alkaline solution such as soda is suitable for this purpose. Of course, in the use of rope having a hemp core, the core is cut off at a point beyond which the wires are not cleaned. It is best not to let acid touch the hemp core; otherwise capillary action may cause premature deterioration of the rope.

If there are no further comments on this subject, let us turn to babbitted sockets and wedge sockets.

C. D. MEALS (American Cable Co., New York City): Regarding wedge sockets, I doubt your ability to get an efficiency of 70 to 90 per cent of the rope strength under operating conditions. In a measure the efficiency is increased as you would increase the diameter of the wedge.

Discussion About Babbitted Sockets

In the wedge sockets they use on shovel ropes, however, they naturally try to keep the weight of the fitting down and they make the wedges too small for the rope diameter.

In traveling around the mining country, I find they invariably use babbitt for the sole reason that they have it around for other mechanical purposes. They don't keep zinc around the plant. The Hudson Coal Company, however, didn't like the idea of bending the strands back so they had a special socket designed that was possibly three times the length of the standard socket. They had no trouble with it.

MR. JAMES: Is any special precaution taken to clear them before the babbitting?

MR. MEALS: They simply clean them with boric acid and water.

MR. ARKILLS: I believe the wedge socket is lower in efficiency than the zinc because you can't get equal pressure on all wires.

The local branch of the Roebling Company out in Seattle tells us that zinc is the only thing they recommend because of its nearly one hundred per cent bending ability. They don't recommend turning back the end of the wire.

I will send the committee a paper that was written by our safety committee. We are printing a thousand copies for distribution to friends that have been asking for it. We have sent out over two thousand mimeographed copies of it already.

Experience of the Pacific Coast Logging Industry

MR. JAMES: The committee will be very glad to get it.

H. SLEERE-CLARK (British Columbia Loggers Assn., Van Couver, B. C.): The logging industry on the Pacific Coast is using the strand back in the sockets. They break chokers to the extent of four or five per day in every operation.

MR. MEALS: They could break the cable and still be at one hundred per cent efficiency.

MR. CLARK: The breaking of the cable occurs from any place up to the choker hook.

MR. MEALS: It is unusual to break six strands of a rope.

CHAIRMAN BECK: Some inspectors of insurance companies are asking that elevator cables be resocketed each year. How often do they need to be resocketed?

MR. JAMES: I don't believe that there is enough information available at the present time to answer that question.

MR. MEALS: Our laboratories made some tests a few months ago with the ordinary method of socketing elevator ropes and then with the new method which we have developed. We rigged up a trimming press and fixed the stroke so that we would vary the load from zero to 25,000 pounds. That was on a five-eighths elevator rope breaking at 1,000 pounds. We found that with the babbitt connection after, I think, about one-quarter of a million cycles of operation of this press that the wire started to break at the entrance to the socket. Upon further investigation under a microscope, we found it was really due to a side brittleness.

CHAIRMAN BECK: Is there any twisting of the cable?

MR. MEALS: We had relieved that.

The Fitting Is in the Form of a Cylindrical Sleeve

CHAIRMAN BECK: I am wondering if that is not a factor in a great many cases.

MR. MEALS: I think it would be.

MR. JAMES: The next is the swaged attachment.

MR. MEALS: I think our company is the only one that makes them. The report says the efficiency is variable depending upon the rope diameter. We have swedges which are essentially a cold flowing of steel on steel, and in doing that you swedge the material around your strands and around the component parts of your wires. It is merely a matter of getting enough wire surface in contact to get one hundred per cent efficiency.

This fitting is in the form of a cylindrical sleeve squeezed on to the rope. We know in a general way that a fitting whose length is five rope diameters will give us one hundred per cent.

LLOYD A. BALLENTINE (American Cable Co., New York City): We are beginning to put out another fitting made of aluminum, which is lighter than steel. We

squeeze it on with a hydraulic press, and we are able to develop between 95 and 100 per cent of the rope strength. Aluminum, of course, flows easier than the hard steel. The tests are more uniform than with other attachments.

MR. JAMES: I witnessed some of the tests that were run at the Underwriters' Laboratories. It is an outstanding feature thus far that the uniformity runs extremely high.

Now, we come to the various types of clip and clamp connections. There seems to be no conclusive test data available at the present time and the committee is considering the advisability of having special tests made.

ADJOURNMENT

Wednesday, September 28, 1927

The second session of the American Society of Safety Engineers—Engineering Section of the National Safety Council was called to order at two-ten o'clock by the chairman, Ernest W. Beck, United States Rubber Company, New York City.

CHAIRMAN BECK: In order for me to speak of the activities of the A. S. S. E. during the last year, it is necessary to mention the good work which has been done by the various committee chairmen.

One new chapter has been organized as a branch of the Metropolitan Chapter and is known as the Northern New Jersey Branch of the Metropolitan Chapter.

Six engineering clubs have also been organized, operating in most cases with local safety councils.

During the last few months, the A. S. S. E.—Engineering Section, has devoted considerable time to organizing a large body of engineers, members of this section who are serving as representatives of the A. S. S. E. in their particular field; with the object in mind of bringing about a closer cooperation with various local branches and chapters of engineering societies. They are encouraging the holding of regional conferences, suggesting topics and speakers for their programs and cooperating with them on safe practice pamphlets and code work.

We have received an excellent response from our members selected to work with the various branches and chapters of engineering societies, and we look forward to a better understanding of purpose than ever before.

Our Committee on Research, Standards and Codes has many problems which it is working on.

About 14 engineering problems are under way, and we are represented on about 30 other codes. This committee is a very important one, as it serves as the engineering clearing house for the council.

Our membership has continued to increase, and we now have nearly 1,000 members. In order to do research work on an outstanding accident hazard, our headquarters office has arranged for an appropriation to take care of doing research work on the subject of circular saws.

The problem of annealing chains is also being considered as reported by the chairman of this committee.

Regional Safety Conferences have been held in 18 cities. In each case, we have cooperated with all the safety and engineering bodies located in the particular vicinity. This work should be increased and I believe more meetings should be held. It is possible for our different sections in the Council to hold regional conferences.

We have been fortunate in securing the assistance of Mr. S. J. Owen, who is a member of the headquarters staff and serves as secretary of the research committees.

Before bringing my few remarks to a close and calling upon the various chairmen for a report of their committees, I would like to state at this time that I believe the A. S. S. E.—Engineering Section should serve as a clearing house for all safety industrial codes on which the National Safety Council may act as sponsors. There are so many codes and safety standards being drawn up today that it is difficult for any one person to keep track of them all. Some of these have been drawn up without the proper representation on the sub-committees. It is very important that the A. S. S. E.—Engineering Section should know the progress made by every code which the Council is sponsoring, and also be in a position to follow up such codes that the Council is sponsoring during the period which they are being drafted.

CHAIRMAN BECK: We are extremely fortunate today in having with us the man of whom I always think when the word "code" is mentioned, Dr. P. G. Agnew, secretary of the American Engineering Standards Committee, New York City.

Safety Codes as Company Tools

Dr. P. G. Agnew, Secretary, American Engineering Standards Committee,
New York City

One of the favorite bones of contention in safety meetings is, shall the subject be approached as a personnel or as a problem of equipment? Does the path of safety lie through the development of the correct attitude of mind on the part of the individual or does it lie through administrative organization and physical equipment?

Today most of us will agree that these two points of view are not antagonistic, but that they are complementary. We might as well ask which is most important in a building, the bricks or the mortar? Manifestly both the bricks and mortar are essential, and we cannot manage without either. No matter how fine the physical equipment, nor how perfect the organization, accidents are sure to arise if we do not have the right attitude on the part of the individual worker. In the same way, no matter how fine the attitude of the individual worker may be, hazards and resulting accidents are sure to follow unless there be proper administrative organization and proper physical equipment.

In the first place, it is essential that the individual develop the right thought habit; it is equally essential to develop the right kind of organization routine, that is to say, habit.

One of my teachers frequently made use of an expression that has been of great value to me: "the thing must be beaten into the habit of the mind." Just so, the thing must be beaten into the habit of the company's mind.

What has all this to do with safety codes? Everything. When the safe and efficient way of carrying out an operation has been beaten into the habits of the minds of the individuals concerned in the operation, and when it has also been beaten into the habit of the organization's mind, we have merely codified the matter.

Take as an example the safety code for abrasive wheels. In a long industrial experience with grinding wheels, a large body of information has been developed in regard to the nature of the hazards and great progress has been made in finding solutions for all of the more important hazards; limiting speeds to keep the centrifugal forces within proper factors of safety; the strength and range of protecting hoods; proper limiting angles of exposure; methods of operation and inspection. The most practical solution of each of these and a score of other questions have been codified as a simple set of rules and suggestions covering the use, care and protection of abrasive wheels. These features are becoming beaten into the habit of mind of those industries in which the abrasive wheel is an important tool.

When a manufacturer has need of a turret lathe, he does not start out to re-invent and build such a machine. He buys the lathe as a complete tool, installs it in his shop, and after making any necessary adjustments to fit it to his particular task, puts it to work as a part of his tool equipment.

Why should he not do precisely the same thing with a safety code pertaining to his business? It is not necessary for him to await a series of accidents in his shop to teach him wherein the hazards lie. He may take over as a part of his capital equipment the experience of the whole industry, not merely in discovering where the hazards lie, but may also have the benefit of the solutions which have been reached as a result of many years of painstaking study and work. The code, in fact, combines the experience not of one industry alone, but of many diversified industries.

Why a National Code? The wider and longer the experience on which a

code is based, the more valuable does it become as a ready-made tool for the use of the whole industry.

So complex has modern industry become that in seemingly simple matters the number of groups with experience in a subject of this kind, and therefore with a real contribution to make, is surprisingly large. Consequently each of the national codes is developed through a joint technical committee made up of the accredited representatives of all such interested groups; manufacturers through their national trade associations; state commissions having regulatory authority over safety matters in the industries, or charged with the administration of accident compensation, through their national association; employing groups using the equipment in question, through their respective trade associations; casualty insurance companies through their two national organizations; the workmen whom the code is designed to protect, by representation arranged through the U. S. Department of Labor upon nomination by the workers' organizations concerned; national engineering societies; technical bureaus of the federal government interested in the subject; and independent specialists. In all seventeen national organizations were represented on the joint committee for grinding wheels, which had thirty members. After two years of careful and persistent work, unanimous agreement upon a complete code was reached, and it was issued as an American standard code, in accordance with the regular procedure of the American Engineering Standards Committee, the national clearing house for standardization work.

Thirty Thousand Copies of Code Distributed

In order to place the results of all this experience and work at the service of their customers, to be used by them as a tool in the prevention of accidents in their shops, manufacturers have distributed 30,000 copies of this particular code among the firms using grinding wheels.

When one considers the interstate character of most of our industries, and the inconvenience and unnecessary loss in the manufacture, distribution and use of apparatus, resulting from conflicting requirements in the various states, no detailed argument is necessary.

The national safety code program which has been outlined, was launched as a result of prolonged consideration on the part of all interested groups, and after two large and thoroughly representative conferences held at the Bureau of Standards in 1919, at the last of which unanimous agreement was reached upon the general plan which has been followed.

In the important investigation of the relation of safety to management efficiency which has been carried out by the American Engineering Council and which has already been reported to you, a fundamental thesis was established, namely, that there is a most intimate relation between the efficiency of management and the accident record of a company. As stated by L. P. Alford: "The safe factory in general is the efficient factory; the efficient factory in turn is the safe factory."

The following statement is made by Albert W. Whitney and Sydney J. Williams:

"Suppose a box falls off a loaded truck and kills a man: For every such case which results in a physical injury there will be perhaps a hundred cases where a box falls off without injuring anyone. But in every one of these hundred cases either the box will be broken or in any case the truck will have to be stopped and the load repiled. While, therefore, there will be only one case of physical injury, there will be a hundred and one cases of inefficiency. An accident is something gone wrong and it can result only from causes which have their effect over a far wider field than that of the immediate accident itself.

The physical injury is only the spectacular evidence of some underlying mal-adjustment in the same way that a headache is only an alarm bell that calls attention to something that is wrong within."

In other words, if we do each job in a sound engineering way, which means the industrially efficient way, using these words in their broadest sense, we shall be taking steps to reduce accidents to a minimum. This ties up directly with the fundamental principle of industrial standardization. Mr. Whitney has elsewhere stated that standardization is the habit-forming process of industry.

The efficient plant is one which has standardized its products and reduced its operation to a systematic, effective routine. As an industry, it has formed sound, efficient habits.

In bringing this about, the plant will have saved itself much trouble and expense, and will have saved its employees from unnecessary injuries, if it has used as tools the codes available on this special subject dealing with the machinery and processes involved.

American Engineering Council Findings

The findings of the American Engineering Council show that "quality and thoroughness of management which secure consistently high efficiency of production as a major objective, will also attain a high safety record as an accompanying major objective." They also show that "maximum productivity is dependent upon the reduction of accidents to an irreducible minimum. There is such a close relationship between safety and production that it is impossible for a plant to have continued increases in productivity unless it reduces at the same time its accident rates."

A plant that will take its place in the forefront of the industry will do well to make a careful study of each of the national safety codes dealing with its work, and put into use those parts of them which are applicable to its operations.

No plant can afford to overlook new developments in the equipment and tools relating to its business. In precisely the same way, it cannot afford to do otherwise than make use of the National codes which are applicable to its work as these codes are developed. The representative sectional committee in charge of each code is a continuing body which stands ready to serve in interpreting and clarifying questions with which the code deals and in keeping the code abreast of developments. These committees are always glad to be of assistance to companies interested in the use of the codes.

Just a final word in regard to the voluntary use of codes in industry and their administration by state commissions. In the opinion of the American Engineering Standards Committee and of the men who are taking part in the development of some fifty national codes, the voluntary adoption of the codes by firms concerned is even more important than the legal adoption by the several states. Those companies to which industry looks as leaders in the development of the industry in economical and efficient operation, in personnel policies, and in safety work, are the ones which are least affected by the regulations of state commissions. They lead rather than follow the commissions and are the ones who are in the forefront in the development of the national safety code program.

CHAIRMAN BECK: I am very much impressed with the way Dr. Agnew emphasizes the word "tool." So many of us have felt that codes are abstract. You have given me the thought that codes can be used as tools to promote safety and to increase production. Each of us should study the codes applying to our specific industries.

Copies can be secured by writing the National Safety Council Headquarters in Chicago.

C. B. AUEL (Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa.): I think we are apt to dismiss Dr. Agnew's remarks with insufficient thought as to what he has intended to convey. There is no question in my own mind as to the value of his remarks. From my standpoint they permit of no discussion. The only unfortunate thing about the work that Dr. Agnew is engaged in is that it is not sufficiently well known, and apparently the American Engineering Standards Committee at present lacks a publicity department. We should one and all endeavor to advertise the work of the Engineering Standards Committee along three lines: First, among the users of such codes like ourselves; second, among the various states, some of whom even yet apparently (I say apparently, and I can only judge by appearances) have never heard of the American Engineering Standards Committee, and are consequently too apt to change state laws from year to year so that it is almost impossible for those of us doing an interstate business to keep up with them. The third line of advertising we should give these codes is amongst the manufacturers of machine tools, and, again, some of those as yet do not know of these codes. Each one of you should take it upon himself and not leave it to anyone else to do his share towards making known the work being done by the American Engineering Standards Committee, and the fact that you are heartily in accord with it.

CHAIRMAN BECK: The next subject will be "Annealing Chains." Mr. R. F. Thalner, of the Buick Motor Company, Flint, Michigan, chairman of our research committee appointed to study the subject, will present a brief summary of his committee's report.

Brief Summaries of Reports Presented

(Mr. Thalner presented a resume of the Progress Report of the Committee on Annealing of Chains. This report is presented in full elsewhere in these Transactions.)

CHAIRMAN BECK: Our next subject will be the question of "Noise—a Factor in Accident Causation." We are fortunate in having with us Dr. H. Clyde Snook of New York City, who, as chairman of our special research committee, will present a resume of this report.

(Mr. Snook presented a resume of the Progress Report of the Committee on Elimination of Harmful Noise. This report is presented in full elsewhere in these Transactions.)

MR. AUEL: May I ask if Dr. Snook's committee is to study industrial noises? We would be pleased to have something on the reduction of noise in screw machine departments.

DR. SNOOK: We are quite convinced that we haven't enough facts to enable us to outline a proper method of attack upon any phase of the problem at the present time. We do not know how noise affects the individual. We have available a large body of knowledge that tells us how noise originates, and how with some engineering effort noise may be suppressed or reduced. Noise reduction or suppression requires skillful engineering. It is done with some difficulty at the present time. Each such job of noise reduction is an original research job, but how far noise reduction should be carried, to what noise level, to what energy level the noise should be reduced, is not now known. Because of this fundamental weakness in our position the committee believes that its greatest opportunity to render service in connection with the noise problem is to determine what the effects of noise are upon the human organism, psychologically, physically, or physiologically, and that involves hearing. That brings in the otologist who studies the science of how we hear and what we hear. The psychological reactions of human beings to noise brings in

the psychologist. Possibly there are physical reactions to noise other than those that come through the sense of hearing. Many of us believe there are nervous reactions to noise, and that brings in the neurologist. As I said before, the physicist has his job well in hand and is proceeding rapidly with it. On that account we feel these other scientists should become interested and enable us to assert a sufficiently clear, definite and large body of facts that we may know what noise does to the human being, and thereby be in position to define how harmful it may be to any and all of us.

We look upon noise elimination in industry at the present time as a specific problem to be considered by the individual manufacturer. We are not yet in a position to help him. He has available at the present time just as much information in the literature as we have regarding the methods of eliminating noise, and, as the report says, the committee does not now know whether the principal attack should be upon the suppression of the sources of noise or whether it should be upon the protection to the individual against existing noise, or whether both things should be done. We are not now in position to say, but we do believe that when, let us say, the medical profession, exclusive of all these scientists that will study the reactions and effects of noise upon the human organism, have given us sufficient information and enough facts about what noise does to the human being, we then will be in a position to make a definition of harmful noise, and we then will be of some help to our friends who now wish to eliminate noise.

Work to Eliminate Noise On Screw Machines

MR. AUEL: Perhaps some of our membership have already made certain investigations and are able to give us a little help without waiting for the committee. We have done considerable work in screw machines, and we get some curious results where we can pretty nearly eliminate noise with the round bar, we can't do it quite so well with the hex bar, and even less with the square bar, but, generally speaking, the best results we have gotten so far have been with the use of two tubes, one inside the other and the intermediate space filled with oil. We set up these tubes at the tail end of our screw machine and allow our stock to rotate inside the tubes. That is not wholly satisfactory, but it is better than anything we have run across. Maybe some of our people have worked along different lines and have gotten some really worth while results. Unless the committee has accumulated such data there might be something that is available for the membership right now simply for the asking.

H. W. MOWERY (American Abrasive Metal Co., New York City): In conjunction with the annual report of the Noise Committee last year, which I had the pleasure of presenting, there was considerable data given as to ways and means of eliminating a variety of noises. In ice cream plants, in various types of machinery through insulation and otherwise, we gave considerable data on how to eliminate noises.

But to my mind, at present, one of the principal problems of the committee is this: We have absolutely no data to show that noise is resulting in casualties in industry. We believe there are numerous cases where accidents are caused by noise preventing employees from hearing warning signals, for instance. But it was with the idea that we find out first whether noise really was harmful to the individual before we went any further in the campaign to determine what noises should be eliminated. It is possible that the noises in the screw machines are very unpleasant. Does the prevalence of such noise result in accidents? Does that noise result in undermining the physical resistance of the employees? These are some of the questions that we felt should be answered before we started a direct effort to eliminate such noises.

MR. COMPLIN (Ford Motor Company of Canada): I remember about two weeks

ago reading an article in a newspaper. They found by actual test that stenographers on silent machines were turning out more work and better work than those using the noisy machines. Surely the workman, by doing away with noise, will probably get more and safer production.

CHAIRMAN BECK: In my own office our people seem to work more efficiently when the noiseless machines are operating.

DR. SNOOK: There has been some investigation made with respect to the point raised by the last two speakers. Fortunately, one of the members of the committee was the first to make some study of the effect of noise upon the efficiency of the worker and the rate of speed of the worker. Professor John B. Morgan, Northwestern University, in 1916, then at Columbia University, published a booklet giving the results of a two years' investigation of the effect of noise upon the speed of workers, upon the reactions of a large number of individuals, and he found that at first, generally, there is a reduction in the efficiency of the individual, and a little later on, while the noise still continues, the individual attempts to compensate for the handicap of the noise, and in many instances over-compensates and speeds up beyond the normal speed that existed without noise being present. Individuals vary in this respect, and the matter of fatigue was not thoroughly investigated, but it was this work that is the basis of our understanding at the present time that noise causes the individual to consume more oxygen, breathe more rapidly, exhale more carbon dioxide and use up his energy more rapidly. The subject is not thoroughly studied and on that account the committee does not at this time wish to commit itself to anything further than that which is contained in the report. The subject needs investigation. We need more facts. We all think we see certain results of noise. What we see influences us very greatly, and they may be only individual variations. Generalizations are very dangerous at this stage of our incomplete knowledge of the effects of noise upon the human being.

Accident Prevention in Engineering Colleges

MR. CONNER (The U. G. I. Contracting Company, Philadelphia, Pa.): We have one shop in which there are several noisy machines, but we have not noted any ill effects. I think it is, in a measure, getting one's self accustomed to the situation. I know myself when I go into that shop, that the noise annoys me until I am there for about a half hour, then I get accustomed to it. So far as the men in that shop are concerned, I don't think noise affects them whatever. Possibly it might affect them when they go home, missing that noise.

CHAIRMAN BECK: I think there is a great deal in accustoming yourself to the noise. After you live with a noise for a time, it becomes a part of the rhythm.

At this time I am going to call upon Mr. R. McA. Keown, Industrial Commission of Wisconsin, Madison, Wisconsin, to present the report of the committee of which he is chairman, on "Accident Prevention in Engineering Colleges."

R. McA. KEOWN: The report of this committee is to be very brief. We had hoped that our work would be complete and in operation by this time, but there have been some unavoidable delays. Ten men have agreed to write eleven illustrated lectures on various phases of accident. Eight of these eleven lectures have been drafted and we are now awaiting authorization by the executive committee of the Council to have them published in pamphlet form for distribution to engineering colleges where they will be presented to students as a lecture course, either in connection with regular classes or at meetings of the student branches of the founder engineering societies.

MR. GEORGE SANFORD: As a representative of the American Society of Mechanical Engineers and American Institute of Electrical Engineers, I was recently called upon by both organizations to assist them in their end of the job of promoting accident prevention in engineering colleges. Accordingly we are asking a competent safety

engineer, or a representative of some member of the Council near each technical college or university to help the professors and student branch officers in that college to give accident prevention the consideration it deserves. This is just a starter. It has the backing of the A. S. M. E. and A. I. E. E., so the plan cannot fail to accomplish a lot of good.

CHAIRMAN BECK: Mr. Sanford will now present the report of the nominating committee.

Report of the Nominating Committee

The Nominating Committee, including W. S. Paine, H. W. Mowery, C. P. Tolman and myself, after considerable study and obtaining advice from a number of the members, decided on the following slate:

ASSISTANT SECRETARY: MRS. G. S. WOOD, New York City.

SECRETARY: MR. W. DEAN KEEFER, National Safety Council.

FOR EXECUTIVE COMMITTEE FOR THREE YEARS:

DR. M. G. LLOYD, U. S. Bureau of Standards.

MR. R. C. STRATTON, Travelers Insurance Co., Philadelphia.

MR. J. B. GIBSON, Western Electric Co., Chicago.

VICE-CHAIRMEN: MR. W. GRAHAM COLE, Metropolitan Life Insurance Co., New York, and our old friend, JIM BANASH of Chicago.

And for chairman, a man who needs no introduction. I believe you all know him, Mr. R. McA. Keown, engineer, State Industrial Commission, Madison, Wisconsin.

CHAIRMAN BECK: You have heard the report of the Nominating Committee.

H. W. MOWERY (American Abrasive Metal Co., New York City): I move that the secretary be empowered to cast a unanimous ballot in favor of the slate as submitted.

MR. KEPNER: I second the motion.

(The motion was carried.)

CHAIRMAN BECK: The secretary has cast such a ballot. We would like to hear from Mr. Keown, our new chairman.

MR. MCA. KEOWN: Mr. Chairman and Members of the Section: I thank you most heartily for this honor that you have given me. I hope that I may measure up to it; and that this section, which I think ought to be, and is, the backbone of all of the sections of the National Safety Council work, may continue to advance and grow, and I hope that with the cooperation of the other officers, the Executive Committee and the membership we may make that possible during the coming year.

CHAIRMAN BECK: This will be an appropriate time for us to take action on the suggested changes in the Constitution. I will ask Mr. Keefer to say a few words on that subject.

W. DEAN KEEFER (National Safety Council): These suggested changes in the Constitution and By-Laws were published in a recent issue of the NATIONAL SAFETY NEWS, as required by our Constitution, and I imagine a great many present have already read and studied them. Mr. Chairman, I move the adoption of the following amendments:

Article IV. Officers and Executive Committee.

1. The officers of the society shall be a chairman, two or more vice-chairmen, and a secretary. There shall be an executive committee consisting of the officers, nine committeemen at large, all past chairmen of the ASSE-Engineering Section, one committeeman representing and appointed yearly by each chapter of the ASSE-

Engineering Section, and one committeeman representing and appointed yearly by each of the industrial sections of the National Safety Council. All such officers and committeemen shall be chosen from the corporate membership.

Article III. New York district.

There shall be an assistant secretary of the ASSE-Engineering Section with headquarters in New York City, who, with the regularly elected officers of the Metropolitan (New York City) chapter if such a chapter is functioning, shall conduct the activities of that chapter, including monthly meetings.

MR. AUEL: I second the motion.

(The motion was carried.)

CHAIRMAN BECK: Our next subject for discussion this afternoon, gentlemen, will be "Wire Rope Attachments and Connections." In the absence of Mr. Sunderland, chairman of the committee, I will ask Mr. Owen to present a summary of the report.

(Mr. Owen presented a resume of the Progress Report of the Committee on Wire Rope Attachments. This report is presented in full elsewhere in these Transactions.)

DR. LLOYD: What I am about to say is already covered in that report, but the speaker has referred to the use of zinc and of babbitt in cable fastenings. I think there is some information on that. That ought to be known by the members of the section. The manufacturers are not working at all in the dark when they claim a higher strength of fastening by the use of the spelter in cable connections. Tests have been carried out on that subject at the Bureau of Standards and very definite results obtained showing that a stronger, better fastening can be obtained by using spelter. However, the job must be done by an experienced man. It is quite possible that the ordinary man working under other than ideal conditions won't make as good a fastening on the job with spelter as he might with babbitt. It has been mentioned that the elevator manufacturer prefers babbitt, and I think probably that is the reason; that under the conditions customarily met with out on the job, they know from experience they actually get a better job with babbitt than they do with spelter. Now, recognizing those conditions, the committee on the elevator safety code has in that code given definite recognition to the use of babbitt for making cable connections. This point should be generally understood.

CHAIRMAN BECK: We will now hear the report of the steering committee on regional conferences. Mr. F. L. Hurlbutt, chairman of the committee, is not here, so I will ask Mr. W. Graham Cole to present the report.

Report of Steering Committee on Regional Safety Conferences

**F. L. Hurlbutt, Chairman, Patent Scaffolding Company,
Chicago, Ill.**

Through the whole-hearted support and cooperation of various local councils, industrial sections, council members and outside organizations, your committee has the pleasure of reporting that 19 successful regional safety conferences were organized and held during the past year. While this number is slightly less than the total reported for the previous year, it is most gratifying to note that the total attendance exceeded all previous years. In addition, it is thought that a better geographical distribution offsets the difference in the number of conferences held.

Thanks to the cooperating bodies, 7 of the 19 conferences were miniature Safety Congresses and were held in the cities of Worcester, Mass.; Grand Rapids, Mich.; Kansas City, Mo.; Newark, N. J.; Ann Arbor, Mich.; Sheboygan, Wis.; and

Los Angeles, Cal. Here several sectional meetings were in session at the same time and those that attended emphasized the fact that their individual problems were more intimately discussed.

Other conferences of the year were held in Chicago, Ill.; Duluth, Minn.; Erie, Pa.; Toledo, Ohio.; Philadelphia, Pa.; Pittsburgh, Pa.; Portland, Oregon; Birmingham, Ala.; South Bend, Ind.; and LaSalle, Ill.

So great has been the interest shown in these regional safety conferences that in several instances the demand for tickets for the evening dinner meetings exceeded the available accommodations. Many companies sent their entire supervisory staff, particularly to the evening meetings.

The free exchange of ideas and experience has brought about the success of these conferences and those attending stressed the fact that their superintendents, foremen and others get the spirit of the safety movement more forcefully than in any other way.

Encouragement has thus been given to your committee to proceed with tentative plans for other conferences to be held the coming year, and on behalf of our new committee on conferences, I beseech your full assistance and support. If any of our members want regional safety conferences in their communities, just make your wishes known to your committee and an immediate response and offer of complete cooperation will be forthcoming.

F. L. Hurlbutt, Chairman
W. A. Chowen
M. E. Arkills
E. B. Lefferts
A. J. Van Brunt
M. C. Goodspeed
G. E. Burns

Friction Caused by the Automobile Tire

CHAIRMAN BECK: Let me emphasize the last statement and urge anyone wishing a conference held in his territory to notify the committee at once. I think there is a great deal to be gained by a greater distribution of the cities in which these conferences are held.

In the absence of Mr. Singleton, chairman of the Committee on Static Electric, I will ask Mr. Owen to present a resume of the next report.

(Mr. Owen presented a resume of this report, which is published in full elsewhere in these transactions.)

DR. H. CLYDE SNOOK: Mr. Owen referred to the idea that probably the friction of an automobile tire against the road surface is the cause of electrification of the vehicle. I am inclined to think that the mere act of rolling the rubber tire over any kind of a road, neglecting the frictional effects, is sufficient to cause a tremendous electrification of the vehicle. Some of my reasons for so believing are these: A few years ago, I had occasion to investigate the effect of static electricity upon the printing of magazines in the plant of the Curtis Publishing Company. We found that the mere act of unrolling the large rolls of print paper, or lifting them, or carrying them about, was sufficient to electrify the entire roll. We found that merely bending the paper around a corner, or folding it, or the act of making the printed impression upon it was sufficient to electrify the paper. Paper, when dry, is an excellent dielectric, and I believe this is one of the examples in that long series of examples that may be cited to illustrate the fact that any dielectric when handled mechanically or when deformed in any way is caused to become electrified.

Another reason for believing in this general saying and for believing that the act of rolling tires over the pavement will electrify the vehicle is the fact that in

rubber mills where the rubber is worked mechanically in the rolls, it becomes so intensely electrified that continually in the dark, electric sparks are seen at certain places in the rubber molding or rolling process. So it seems to me it may be found that any kind of pavement may be found to be quite sufficient to account for all the electrification that an automobile or bus may acquire.

CHAIRMAN BECK: Our next report will be that of one of the most important committees we have; the Steering Committee on Research, Standards and Codes. I will call at this time on Mr. R. C. Stratton of the Traveler's Insurance Company, Philadelphia, chairman of this committee.

Report of the Steering Committee on Research, Standards and Codes

The work of your Steering Committee on Research, Standards and Codes, during the past year, has been along research lines similar to the work of past years. This work has included:

1. Giving advice to the Executive Committee of the National Safety Council upon subjects proposed for codes or research.
2. Appointing Research Committees.
3. A general check-up of research, standards and code work, which was in progress by members or representatives of the A. S. S. E.-Engineering Section.

At the present time there are the following six Research Committees:

1. The Effects of Annealing on Chains, R. F. Thalner, chairman.
2. Electrical Hazards, S. E. Whiting, chairman.
3. Elimination of Harmful Noise, H. Clyde Snook, chairman.
4. Exhaust Systems, W. J. Graves, chairman.
5. Static Electricity, Thomas W. Butler, chairman.
6. Wire Rope Attachments and Connections, Charles C. Sunderland, chairman.

Progress reports of these six Research Committees will be presented at this Congress.

In order that all of our Research Committees may be given the necessary assistance, the National Safety Council has employed a safety engineer, Mr. Stewart J. Owen, Jr., to assist all of the Research Committees with their technical problems and preparation of reports.

All members of the ASSE-Engineering Section are urged to cooperate to the fullest extent with our Research Committees in the various studies they have under way. Any information which any member believes will be of value to these Research Committees should be sent to the various chairmen in care of National Safety Council headquarters, Chicago, Illinois.

The ASSE-Engineering Section is sponsor or joint sponsor for 15 safety codes, five of which have been approved and published:

Forging and Hot Metal Stamping.
Ladders.
Paper and Pulp Mills.
Power Presses and Hand and Foot Presses.
Rubber Machinery.

The following 10 safety codes are not as yet completed nor published:

Colors for Traffic Signals—The draft for this code is under consideration and it is understood that it will soon be submitted to the American Engineering Standards Committee for approval.

Compressed Air Machinery—The standardization of the work of this code is well under way.

Construction—Work on this code has been delayed because of the recent start made in safety work by various construction associations.

Floor and Wall Openings—Considerable work has been done on this code and a final draft is under consideration.

Identification of Gas Mask Canisters—The Sectional Committee for this code has been organized and standardization work will soon be started.

Identification of Piping Systems—Considerable work has been done on this code and its final draft is now under consideration.

Standardization of Methods of Recording and Compiling Accident Statistics—The Sectional Committee for this code is now being organized.

Textiles—The work on this code is quite well advanced. The sections on "Cotton Mills" and "Bleaching, Mercerizing, Dyeing, Printing and Finishing" have been under consideration for some time and are about ready for final approval.

Walk Way Surfaces—A draft of this code is under consideration and some progress has been made in its consideration.

Window Washing—The Sectional Committee for this code is now being organized.

Committees on Fifty-eight Safety Codes

The American Engineering Standards Committee has Committees on 58 safety codes. Of these 58 safety codes the following 24 have been approved and published:

1. Abrasive Wheels, Safety Code for the Use, Care and Protection of.
2. Aeronautics, Safety Code for.
3. Automobile Head Lighting Specifications—Laboratory Tests for Approval of Electric Head Lighting Devices for Motor Vehicles.
4. Dust Explosion, Safety Code for the Prevention of.
5. Electric Wiring and Apparatus in Relation to Fire Hazards.
6. Electric Equipment in Coal Mines, Safety Rules for Installing and Using.
7. Electrical Safety Code (National Electrical Safety Code).
8. Elevators and Escalators, Safety Code for.
9. Explosions, Permissible Specifications for the Testing and Use of.
10. Foundries, Safety Code for the Protection of Industrial Workers in.
11. Forging and Hot Metal Stamping, Safety Code for.
12. Gas Safety Code.
13. Head and Eyes of Industrial Workers, Safety Code for the Protection of.
14. Ladders, Safety Code for.
15. Laundries, Safety Code for.
16. Lighting Factories, Mills and Other Work Places, Code for.
17. Lighting of School Buildings, Code for.
18. Logging and Saw Mill Machinery, Safety Code for.
19. Paper and Pulp Mills, Safety Code for.
20. Rock Dusting of Coal Mines, Recommended Practice for.
21. Power Presses and Foot and Hand Presses, Safety Code for.
22. Power Transmission Apparatus, Mechanical, Safety Code for.
23. Rubber Mill Machinery, Safety Code for.
24. Woodworking Plants, Safety Code for.

Copies of the above mentioned codes may be obtained from the National Safety Council.

The 34 incomplete codes are as follows:

1. Amusement Parks.
2. Automobile Brakes and Brake Testing.
3. Building Exits.
4. Colors for Traffic Signals.
5. Compressed Air Machinery.
6. Construction Work.
7. Conveyors and Conveying Machinery.
8. Cranes, Derricks and Hoists.

9. Electrical Fire and Safety Code.
10. Elevators.
11. Exhaust Systems.
12. Explosives.
13. Explosives, Mine.
14. Fire Fighting Equipment in Metal Mines.
15. Floor and Wall Openings, Railings and Toe Boards.
16. Gas Mask Canisters, Code on Colors of.
17. Identification of Piping Systems.
18. Illumination, Coal Mines.
19. Lightning, Code on Protection Against.
20. Meters, Electrical Rules for.
21. Piping, High Pressure.
22. Plate and Sheet Metal Working.
23. Power Control, Electrical.
24. Power Control, Mechanical.
25. Refrigeration, Mechanical.
26. Sanitation, Industrial.
27. Standardization of Methods of Recording and Compiling Accident Statistics.
28. Tanneries.
29. Textiles.
30. Tools, Machine.
31. Transportation, Coal Mine.
32. Ventilation.
33. Walkway Surfaces.
34. Window Washing.

ASSE Represented on Forty Codes

The ASSE-Engineering Section is represented on 40 of the above 58 codes. The following is a list of the names of our representatives on these 40 projects.

1. Abrasive Wheels—W. D. Keefer, G. E. Sanford.
2. Aeronautics—G. E. Peterson, G. A. L. Beaudoin.
3. Auto Brakes—J. H. Truett.
4. Building Exits—S. J. Williams.
5. Colors for Traffic Signals—S. J. Williams.
6. Compressed Air Machinery—Dr. A. D. Risteen, A. S. Johnson.
7. Construction Work—W. D. Keefer, Leo D. Woedtke, W. F. Austin, T. J. Whelan, E. W. Bush, F. L. Hurlbutt.
8. Conveyors—R. F. Thalner.
9. Cranes, Derricks and Hoists—J. F. Connor, C. W. Hines.
10. Electrical Power Control—The Committee on this code at the meeting on June 15, 1927, decided to discontinue work on this code.
11. Electrical Safety Code—G. E. Sanford, S. E. Whiting, R. W. Moore.
12. Elevators and Escalators—W. E. Crippen, W. D. Keefer.

40. Woodworking—A. R. Regula.

It must be remembered that the work of a Code Committee is difficult and exacting. Many of the meetings are held in widely scattered places. Much of the work must be done by correspondence. All of our representatives on the various safety codes have given freely of their time and advice in order that our section may be properly represented on the code, a work worth while. Too much stress cannot be laid on the importance of the work in the formulation and adoption of the various safety codes. All members of the ASSE-Engineering Section should cooperate with our representatives in any manner that will be a help to them. It is only through such cooperation that the desired ends will be obtained. All that has been said in previous reports of your committee in regard to this work still applies.

R. C. Stratton, Chairman
 C. B. Auel
 L. A. DeBlois
 D. L. Royer
 A. L. Watson
 C. E. Pettibone
 S. J. Owen, Jr.

CHAIRMAN BECK: As Mr. Stratton has stated, the National Safety Council does not maintain a research laboratory. They depend almost exclusively on those of us who already have or can obtain the data that is necessary to make our ASSE work successful.

We have but three more subjects to bring up this afternoon. First, I am going to call on Mr. H. W. Mowery of the American Abrasive Metal Company to report for the Membership Committee.

The Report of Membership Committee

1926 Annual Safety Congress—567. Members
 320 Associate Members
 ———
 886 Total

Today there are 596 Members and 402 Associate Members. Total—998.

42 Cancellations during the past year.

154 New Members during the past year.

S. V. JAMES, Chairman.

CHAIRMAN BECK: Our Committee on Chapter Organization and Activities has as its chairman Mr. Ernest Hartford, of the American Society of Mechanical Engineers. In the absence of Mr. Hartford, Mr. John Sandel will report on chapter organization and activities.

Report of Committee on Chapter Organization and Activities

Three local organizations are functioning as chapters of the ASSE-Engineering Section: the Metropolitan (New York City) Chapter, the Boston Chapter, and the Northern New Jersey Chapter. The Northern New Jersey Chapter was organized during the past year.

It is unfortunate that during the past year the Hartford Chapter has ceased to function. The reasons for this have been carefully investigated by your Committee and discussed by the Executive Committee. There are numerous reasons for the failure of this chapter, chief of which seems to be lack of cooperation on the part of the local industries. It is recommended that your newly appointed committee on Chapters and Chapter Activities continue the efforts already started to revive the Hartford Chapter.

During the past twelve months engineering clubs have been organized by six community safety councils of the National Safety Council—in Detroit, Birmingham, Worcester, Atlanta, Kansas City and Cleveland. We have negotiated with these groups to bring their affiliations as chapters of the ASSE-Engineering Section, and it is recommended that your newly appointed committee continue these negotiations.

Several months ago, the ASSE-Engineering Section cooperated with the Pennsylvania Society of Safety Engineers in holding a regional conference at Philadelphia also the A.S.M.E. Local Section. We are also cooperating with the California Society of Safety Engineers and the Society of Safety Engineers of Southern California in organizing the Fourth Annual Pacific Coast Safety Conference to be held in Los Angeles during the latter part of November. Efforts have been made to secure the affiliations of these three societies as chapters of the ASSE-Engineering Section, but thus far these efforts have been unsuccessful. All three of these societies—particularly the two in California—are live organizations and your committee is strongly of the opinion that we should continue our efforts to secure their affiliations as ASSE chapters.

Liaison Members of National Safety Council to Cooperate with Locals of the A.S.M.E.

It may be of interest to note that liaison members of the ASSE E. S. NSC have been appointed and invited to cooperate with the local sections of the 4 founding societies in programs for meetings, speakers, etc. One particular safety engineer has been selected in each locality where there is a local branch of each organization and this member has been invited to attend executive meetings of the particular local section designated. It is expected that this cooperation will result in increased interest in the safety movement and bring greater coordination between the two organizations.

We heartily congratulate our three chapters whose activities have been so successful during the year which is just coming to a close. We are indeed fortunate in having such excellent leaders in these chapters as L. E. MacBrayne, Ralph W. Pendleton,

Alexander Lackey, J. E. Wolters, E. W. Beck, T. A. Walsh, Mrs. Gene S. Wood, F. M. Rosseland, A. J. Van Brunt, S. F. Larchar, etc.

Earnest Hartford, Chairman

Herman Behr

J. M. Sandel

L. W. Ferguson

CHAIRMAN BECK: Our last subject this afternoon, gentlemen, is the one of electrical hazards. In the absence of Mr. Whiting, chairman, I am going to ask Mr. C. B. Auel of the Westinghouse Electric & Manufacturing Company, to report for this Committee on Electrical Hazards.

MR. AUDEL: I didn't expect to say anything, so my remarks will be brief and more or less haphazard.

The committee spent the entire afternoon yesterday discussing this subject. It is hard to make a good start, but we at last decided to study the hazards of circuits operating at or below 750 volts. Among other things there were three fairly definite recommendations made on which we seemed to be in general agreement. One is the more general teaching of the prone pressure method so that when an accident does occur, it perhaps could be made less serious than is usually the case.

As mentioned by Mr. Sanford, we hope to promote the discussion of accident prevention in engineering colleges so that we will not eternally be in the position of bailing out a leaky boat. We feel that as the colleges turn out more engineers with a knowledge of the fundamentals of industrial safety, our problem will become easier with the passing of the years.

The third definite recommendation was to advocate a physical examination at least yearly of all employees handling hot wires, absolutely regardless of voltage. It has been felt there is no small number of instances in which the prone pressure method failed to operate successfully because of the poor physical condition of the victims, and that had the victims been in normal condition many would be alive today.

The Engineer Is the Natural Safety Leader

CHAIRMAN BECK: Thank you, Mr. Auel.

We have heard reference made a great many times this afternoon and throughout the week to the American Society of Mechanical Engineers. We are extremely fortunate in having with us the official representative of that organization. I take great pleasure in calling on Colonel John Price Jackson for a few remarks.

COLONEL JACKSON: I am glad to have this opportunity to commend the work of the National Safety Council and the A.S.S.E. in particular in helping to create a more uniform and active safety consciousness among engineers.

I am a member of two of the founder societies and really represent the A.I.E.E. as well as the A.S.M.E. I have been over the transactions of both organizations quite fully. If safety in this country were dependent upon the accident prevention data of these societies, we would have a terrible death list. That is a serious charge against the engineers of the United States. The officers of these societies feel this situation should be improved. I see only one way, gentlemen, of rectifying it, and that is for the engineers of this country who do have the safety consciousness (most of whom, I presume, at least the best of whom, are in the A.S.S.E.) to cooperate in transmitting it somehow to the entire engineering profession. You cannot talk to any really successful man who doesn't say that the engineer, not the lawyer nor anyone else, but the engineer, should be the leader in the safety movement. If that is true I think we have a very heavy responsibility, we A.S.S.E. people, in "teaching" safety to the engineering world, and all of us should give our very best endeavor during this coming year to establish a very definite program of cooperation between the National Safety Council and the four founding engineering societies.

CHAIRMAN BECK: Thank you, Colonel Jackson. I hope we all will do our best to bring about that closer cooperation. It has been referred to before this afternoon, and I feel men like Colonel Jackson, George Sanford, Mr. Auel and others are bringing about this new spirit of safety among engineers.

M. E. ARKILLS (Waterfront Employees' Association, Seattle, Washington): I happen to be chairman of the Western Washington Section of the A.S.M.E. and our programs for the coming year are all designed to take in the element of safety.

ADJOURNMENT.

Thursday, September 29, 1927

The final session was called to order at two-thirty o'clock by the chairman, Ernest W. Beck.

CHAIRMAN BECK: At this time I would like to turn the meeting over to our new chairman. It gives me great pleasure at this time to present the chair to Mr. R. McA. Keown, Engineer, Industrial Commission of Wisconsin, Madison, Wisconsin, who will be your chairman for the coming year.

(Mr. R. McA. Keown took the chair.)

CHAIRMAN KEOWN: Gentlemen, I feel we have plenty of chairmen this afternoon. I don't know of any reason for calling upon me at this time.

However, we have two items to take up this afternoon. We will receive and discuss the reports of two research committees. First I will call upon Mr. R. F. Thalner, Chairman of the Committee on "Annealing Chains."

(Mr. R. F. Thalner, Buick Motor Co., Flint, Mich., took the chair.)

Progress Report, A.S.S.E.—Engineering Section Research Committee on the Effects of Annealing on Chains

R. F. Thalner, Safety Director, Buick Motor Company, Flint, Mich.

History and Scope of Committee

At one of the executive committee meetings of the Automotive Section of the National Safety Council several years ago, the question of the proper annealing temperature for chains was brought up for discussion, and due to the fact that there were so many varied opinions on the subject, not only in the meeting, but among most all Safety Engineers, it was suggested by W. Dean Keefer of the National Safety Council that some thought be given to the possibility of determining through research work, the effect of annealing on hoist chains. The work was started and at another meeting, on discussing the matter, the question came up as to the advisability of having this work sponsored by the A. S. S. E.—Engineering Section of the Council because other sections as well as the Automotive were vitally interested in the same subject. It was therefore decided to organize this committee under the auspices of the A. S. S. E.—Engineering Section on account of the importance of the problem to industry and the safety movement in general. Various organizations interested in such a study were asked to appoint representatives to serve on the committee, and up to the present time, the following have accepted:

Chairman, R. F. Thalner, Safety Director, Buick Motor Company, Flint, Michigan, representing Automotive Section, National Safety Council.

Secretary, Stewart J. Owen, Jr., Safety Engineer, representing National Safety Council.

E. F. Blank, Safety Director, Jones & Laughlin Steel Corporation, Pittsburgh, Pa., representing Metals Section, National Safety Council.

L. E. Frazier, Metallurgical Engineer, representing American Chain Company, Inc., Bridgeport, Conn.

R. H. White, Engineer of Construction, American Locomotive Company,

Schenectady, New York, representing American Society of Mechanical Engineers.

W. J. Merten, Westinghouse Electric & Mfg. Co., East Pittsburgh, Pa., representing American Society for Steel Treating.

F. M. Waring, Engineer of Tests, The Pennsylvania Railroad, Operating Department, Altoona, Pa., representing American Society for Testing Materials.

Carnegie Institute of Technology, represented by: Professor James Aston, Head of Department of Mining and Metallurgy; Professor F. M. McCullough, Head of Department of Civil Engineering; Professor H. A. Thomas, Associate Professor of Civil Engineering; Professor L. R. Van Wert, Assistant Professor of Mining and Metallurgy; Professor J. M. Daniels, Instructor, Civil Engineering Department.

Frank A. Bond, Vice-President, U. S. Chain & Forging Company, Pittsburgh, Pa., representing Chain Manufacturers' Institute.

A. R. Markel, Assistant to President, representing The Columbus McKinnon Chain Company, Columbus, Ohio.

M. H. Christopherson, State Insurance Fund, New York State Department of Labor, 432 Fourth Ave., New York City, representing International Association of Industrial Accident Boards and Commissions.

George C. Ramsdell, Engineer, The Travelers Insurance Company, Chamber of Commerce Bldg., Pittsburgh, Pa., representing National Bureau of Casualty and Surety Underwriters.

Horace H. Thayer, Naval Architect & Marine Engineer, Witherspoon Bldg., Philadelphia, Pa., representing Society of Naval Architects & Marine Engineers.

David Arnott, Chief Surveyor, American Bureau of Shipping, New York City.

Sydney V. James, Engineer, Casualty & Automotive Departments, representing Underwriters Laboratories, Chicago, Illinois.

Frank A. Bond, Vice-President, representing U. S. Chain & Forging Company, Pittsburgh, Pa.

Lieut. Com. H. N. Wallin, Construction Corps, U. S. N., Bureau of Construction and Repair, representing the Navy Department, Washington, D. C.

There has always been a difference of opinion as to the effects of annealing hoisting chains. Some persons are of the opinion that annealing is beneficial to hoisting chains under certain conditions, while others believe that annealing of chains is not of much value. Among those who believe in the annealing of hoisting chains, there are wide differences of opinion as to the proper methods and temperatures to be used. Some will heat their chains for short periods at low temperatures. Others use higher temperatures with longer heating and cooling periods. Still others use a combination of these two practices.

It was soon realized that among other things it would be necessary to determine the effect of annealing at various temperatures from about 1,000 to 1,700 degrees Fahrenheit; what effect annealing has if any on yield points, ultimate strength, type of fracture, etc., and to devise some laboratory methods to subject each chain to a repeated load test.

Plan of Procedure

Two universities were approached as to the proper procedure to be followed and the making of such laboratory tests as may be necessary. After considerable study a preliminary plan of procedure was prepared by Professor J. M. Daniels and his associates at Carnegie Institute of Technology, which is as follows:

Preliminary Outline—Investigation of the Effect of Annealing on Chains

In the preliminary study, it has been found advisable to use commercial chains of but one size, namely: one-half ($\frac{1}{2}$) inch; but to use two types of chains, one of wrought iron, the other of steel.

These chains are to be furnished by the National Safety Council in lengths of not less than twelve (12) feet or multiples thereof and they will then be investigated in accordance with the following outline:

1. Analysis of chain stock as received.
2. Tension proof load test and tension test to destruction of chain as received.
3. Impact test of chain stock as received.
4. Chain as received to be subjected to a repeated stress test.
5. Tension proof load test and tension test to destruction of chain after being subjected to a repeated stress.
6. Impact test of chain stock after being subjected to a repeated stress test.
7. Anneal chain at various temperatures.
8. Cool chain in air and in furnace after being heated for annealing.
9. Tension proof load test and tension test to destruction of chain after each annealing and cooling operation has been completed.
10. Impact test of chain stock after each annealing and cooling operation has been completed.
11. Study of the effect of low temperature heating, following the same procedure as given above.
12. Metallographic studies of chain under the various conditions outlined above.

Explanation of Items 1 to 12 for Steel Chain*1. Analysis of Chain Stock As Received.*

The analysis of the chain stock can be submitted with the samples of chain or the analysis can be determined after the chain has been received at the Carnegie Institute of Technology. It is suggested that the analysis be submitted with the chain as this routine work can be performed more economically in this manner.

2. Tension Tests of Chain As Received.

A Proof tension test load of the amount prescribed by the committee for one-half ($\frac{1}{2}$) inch chain is to be placed on the specimen, then removed and "permanent set" recorded. The chain is to be then tested to destruction and the ultimate load and type of fracture recorded.

It is suggested that a second sample of this chain be tested in tension using a strain gauge and recording the loads and corresponding elongations. Curves of this type will show the behavior of the samples more clearly than by any other means.

The yield point in chain, especially overstrained material, is a very doubtful figure. An arbitrary elongation can be used, the load being recorded when this arbitrary elongation has been reached. This load would be designated as the yield point of the material which will give comparative results. In the chains tested to date, while studying the methods of performing this work, no yield point was evident by the drop of the beam. There are a series of drops which do not indicate a definite yield point. It is recommended that stress-strain diagrams be obtained which will give the accurate behavior of the chain under load.

The elongation after failure is also a doubtful figure due to the non-uniform

elongation of the various parts of the link, the closing of the links and the manner in which the breaking link is deformed.

For tension test of one-half ($\frac{1}{2}$) inch chain the sample should contain seven links.

3. *Impact Tests of Chain As Received.*

One link will furnish two impact specimens which will be tested in a Charpy Type Pendulum Impact Machine. The specimen will be round, cut to half its diameter and tested in the regular manner. Four impact tests are considered sufficient for an average correct value.

Data from the Impact Tests will give comparative results as to the ability of the material to withstand shock.

4. *Chain As Received to Be Subjected to Repeated Stress.*

A machine will be designed and built at the Carnegie Institute of Technology which will subject the chain to a repeated load of four thousand (4,000) pounds, equal to the safe working load for one-half inch chain. The object of this repeated stress is to place the samples in such a strained condition that they will be representative of material which has been subjected to six months actual service. It is estimated that thirty thousand (30,000) repetitions of a four-thousand (4,000) pound load placed on the specimen in such a manner that the chain is not subjected to sudden impact will approximate this condition.

A sketch of this proposed machine accompanies this report.

5. *Tension Proof Load Test and Tension Test to Destruction of Chain After Being Subjected to a Repeated Stress.*

The same procedure is to be followed as outlined in item number two (2) of this report.

6. *Impact Test of Chain Stock After Being Subjected to a Repeated Stress.*

The same procedure is to be followed as outlined in item number three (3) of this report.

7 and 8. *Anneal Chain at Various Temperatures and Cool Chain in Air and in Furnace.*

The chain is to be annealed at temperatures of 1,000°, 1,150°, 1,300°, 1,450°, 1,600°, and 1,750°. After the chain is heated to the proper temperature and held at that heat for thirty minutes the chain shall be air cooled and furnace cooled. This study will give six temperature conditions, and two cooling conditions. Electric or gas furnaces will be used with pyrometers to determine temperatures.

9. *Tension Tests After Each Annealing and Cooling Operation.*

The same procedure is to be followed as outlined in item number two (2) of this report.

10. *Impact Tests After Each Annealing and Cooling Operation.*

The same procedure is to be followed as outlined in item number three (3) of this report.

11. *Study of the Effect of Low Temperature Heating.*

If it is the desire of the committee to study the effect of low temperatures on chain, where low carbon chain might be subjected to low temperatures in handling hot material, the same procedure will be followed as outlined in items one to ten inclusive of this report, using the temperatures recommended by the committee. The object of this study would be to determine if the low temperatures cause undue brittleness in chain.

12. *Metallographic Studies of Chain.*

Nothing definite has been decided on the amount of work that will be necessary or desired along these lines. Metallographic studies of the chain, after the various operations, are very desirable for a complete investigation

of this subject. The amount of work to be done is to be decided by the committee appointed by the National Safety Council. If it is the desire of the committee, Professors Aston and Van Wert can decide on the amount of investigation necessary for this phase of the work and its approximate cost.

Explanation of Items 1 to 12 for Wrought Iron Chain

The same procedure would be followed using Wrought Iron Chain in place of the Steel Chain. The recommendations for the Annealing Temperatures and Cooling as set down by the Committee appointed by the National Safety Council would be followed.

Approximation of Cost for Testing One Half ($\frac{1}{2}$) Inch Chain

(Only items 1 to 10 inclusive considered)

Cost of designing, building, and installing repeated stress machine for operation.....	\$250 to \$400
Cost of U-bolt grips for holding chain in tension test.....	\$10
Cost of physical tests (16 tension tests, 64 impact tests, reduction of data, curves, etc.) 30 hours @ \$2.50.....	\$75
Cost of annealing operations 5 hrs. @ \$2.50.....	\$12.50
Total Cost of One Cycle.....	\$350 to \$500

The variable cost in this investigation is the repeated stress machine. This machine must be developed in such a way that the chain is not subjected to a shock. After being built, considerable time will no doubt be required to adjust this machine so that the specimens will all be under the same stress.

The cost of the annealing and physical tests will be approximately ninety (\$90) dollars per cycle, a cycle being designated as a complete investigation of the chain from the time it is received until all curves and data are prepared following the steps designated as items 1 to 10 inclusive of this report.

As this work progresses, the time required would no doubt be materially decreased due to the organization of the mechanical operations.

The hourly prices of \$2.50 include the time of one student assistant.

No recommendation is made as to the number of cycles to be completed in this investigation. The committee would no doubt be in a better position to state how extensive this study should be.

The cost of a study of chains larger than one-half ($\frac{1}{2}$) inch ($\frac{3}{4}$ " and 1") would be proportionately higher due to the larger loads involved. No estimate has been submitted for a repeated stress machine to use in over-straining one inch chain. The cost of such a machine would be necessarily large.

Respectfully submitted,

J. M. DANIELS.

Through the courtesy of several members of the National Safety Council, enough new steel and wrought iron chains have been contributed to start this test. Other members have agreed to supply such additional new chain as may be needed.

In order that tests may be made of chains which have failed in service, a number of members of the Council have forwarded to the Carnegie Institute of Technology Laboratory links of chain which have failed in service together with six to eight feet of the chains and descriptions of the conditions, under which the chains failed. Other members have agreed to forward such samples and descriptions of conditions when they have chain failures.

Comment on Plan of Procedure

Professor Daniels' plan of procedure was submitted to the members of the committee as well as to a group of British engineers for consideration. (This group of British engineers is studying the causes of chain failure at the National Physical Laboratory at Teddington, England).

In general the suggested plan of procedure was approved by the committee members. It was questioned, however, whether a new chain submitted to the repeated load test would then be equivalent to a chain which had been in service for approximately six months. The British engineers particularly call attention to the fact that this repeated load test would be sufficient if all chains in service were used properly at all times. They state, however, that in an ordinary shop, a hoisting chain is often subjected to unusual stresses such as when the load is picked up quickly or snatched from the ground. They suggest, therefore, that each new chain should be subjected not only to a repeated load test, but to an impact test before annealing. These impact tests are intended to approximate some of the conditions of the chain in service and should not be confused with the impact tests proposed in the preliminary plan of procedure. These two preliminary tests will then bring each new chain into the same condition in which it would be if it were used in a normal shop for approximately six months.

This objection is being considered by the committee and it is possible that before Professor Daniels starts actual laboratory work, he will amend his plans accordingly.

Causes of Chain Failure

The group of British engineers is studying the entire subject of chain failure, whereas our committee is simply interested in one particular phase of this larger question. The British studies to date indicate that many chain failures can be ascribed at once to one or more of the following causes:

(1) *Gross overloading* due to severe loads or snatches. The reason for the failure is usually obvious from the condition of the fractured link.

(2) *Defects in manufacture.*

(a) Composition defects, such as excessive sulphur or phosphorous or by admixture of steel scrap.

(b) "Laminated rod," caused by incomplete welding in rolling down the pile.

(c) "Burning" of the complete link.

(d) Presence of "burnt" piles in the chain iron. This defect occurs in the iron works and is caused by overheating in the puddling or bath furnaces. As all the strips do not usually come from the same heat or furnace, a bar may contain several of the burnt zones, the remainder being normal.

(e) "Dirty" welds, also incompletely closed welds.

All of the above possible causes of failure are, probably, well known and can usually be identified after failure has occurred. They are important and cannot be remedied by heat treatment.

(3) *Crystallization.*

The British engineers found that under working conditions which are quite normal a chain may suddenly fail. The fractured link shows no total deformation or local deformation at the fracture, the face of which exhibits a brittle "crystalline" appearance. Investigations show that none of the above

mentioned defects are present. Moreover, specimens cut from the link and subjected to the ordinary tests—tensile, impact, bending, microstructure, chemical analysis—show that the material conforms to the requirements of best quality wrought iron. As a result of lengthy experiments, they found that the cause of this type of failure was a very brittle skin on the surface of the link. The skin is very thin, penetrating to a depth of only a few crystals, and is extremely difficult to detect microscopically as in many cases the individual crystals are undeformed. The material at a short depth below the surface was found to be normal by experiments in which the skin was removed mechanically. They were able to produce a brittle skin on the surface of chain links by light surface impacts. They further showed by producing a hard brittle skin—by carbonization—that given such a skin in which a crack can be started by the expenditure of quite a small amount of energy, the crack is propagated throughout the ductile core owing to the stress concentrations produced at the base of the crack and, owing to the conditions of constraint, the ductility of the core crystals cannot be utilized.

The British engineers believe there is no reason to doubt that the brittle fracture to which chain links are liable after service is due primarily to the defects of small impacts to which the surface becomes subjected. If such an impact-hardened link be annealed or normalized, a very marked re-crystallization takes place in the outside crystals and their ductility, and thus the apparent ductility of the core (which has never really been disturbed) is restored. This is simply due to the fact that the re-crystallization temperature of impact-hardened iron is an inverse function of the degree of impact-hardening.

Tests and Studies in the United States

It has been found by some large concerns in this country that surface impacts will produce the brittle skin effects observed by the British engineers and that this condition may be overcome by proper annealing.

The committee appreciates the comment from the British Engineers and will take advantage of the suggestions offered by them. There is, of course, a difference in the scope of their work and ours which must be taken into consideration and inasmuch as our problem is to study the effect of annealing on hoist chains, and, if annealing is found to be beneficial to obtain the proper temperatures and methods to be used, it is believed to be best for the committee to concentrate its study, at least for the present, on that question.

In conclusion, permit me in behalf of the National Safety Council to extend thanks to all members of the committee who have signified their intention to serve in this work, to the Carnegie Institute of Technology for their share of the work and to the concerns which have willingly donated sample chain for the experiment. Through this committee composed of organization representatives and men of high standing in our country, and with the aid of their many valuable suggestions, the report which is made at the completion of the research should be extremely beneficial to American industry.

CHAIRMAN THALNER: At this time I would like to present Professor H. A. Thomas of the Carnegie Institute of Technology who will start the discussion on this report.

PROFESSOR H. A. THOMAS (Carnegie Institute of Technology, Pittsburgh, Pa.): I am coming here representing Professor Daniels, who is really in direct charge of this work at the Carnegie Institute of Technology, but I have been helping him out to a certain extent. He was not able to come so I came in his place.

Since getting out this preliminary outline of what is to be done in the test, we re-

ceived a great many samples of chains that have failed in service. We have made certain preliminary tests and, as a result of these tests, it seemed wise to make a few minor changes in the plan of procedure.

We also received comments on the plan from various men on the committee. We have combined some of these ideas in our plan.

I have here a few broken chain links. This is from the Central Alloy Steel Company at Massillon, Ohio. It is a typical crystalline fracture. That is very different from the ordinary straight tension fracture we get in a direct pull. It seems to me one of the purposes of this investigation is to learn how such fractures are caused and whether annealing can cure them. From reports we get, it seems that links of this kind may often fail with a much lighter load than they are frequently called upon to carry. The load may ordinarily be twenty thousand pounds yet, apparently, the chain may fail at five thousand pounds.

There are several theories as to why chains fail. One theory is fatigue failure. The metal may simply become worn out by a great many repetitions of the stress, but it seems improbable that this is such a break because that requires millions of repetitions as in the case of an automobile crank shaft.

The Theory of British Engineers

Another theory is that it is due to the hardening of the surface of the chain. It is the theory of British engineers that the surface of the chain link receives a great many impacts from ordinary service and that these impacts produce a hard, brittle skin on the outside; and then tiny cracks show up in that brittle skin which gradually work in and cause the fracture.

Another theory is that brittleness is due to overheating of the metal at the time of welding.

Another theory is that that fracture might be due to impact, the load being jerked instead of being picked up gradually.

I have rewritten our outline of tests to try to cover all of these theories.

In carrying out this revised program, we have decided to change the repeated load testing machine. It doesn't seem necessary now to use a machine which will test a chain twelve feet long. It seems better to use a machine which takes a shorter length of chain and which can be run at a high speed.

We also have been looking into the question of developing an impact testing machine. We have a Charpy impact machine, but it is much too small. We can use it for stock only up to three-eighths inch in diameter. So we have designed a new machine which consists of a pendulum swinging through an arc and striking the specimen. We hope the funds will be available so we can make that type of machine and make these impact tests.

It seems quite probable that impact may be an important factor in chain failure. We have made some preliminary tests to try to confirm what British engineers have told us about the surface hardening effect and the results are rather confused so far.

Here is a piece of straight bar, which we put between supports four inches apart and subjected to blows with the hammer, hoping in that way to harden the surface. It took three thousand blows to break it.

We are anxious to make an investigation that will be convincing and that will cover every aspect of the subject that ought to be covered.

CHAIRMAN THALNER: What are the loads to which you will subject chains of various sizes on the repeated load testing machine?

PROFESSOR H. A. THOMAS (Carnegie Institute of Technology, Pittsburgh, Pa.): We will have to make some preliminary runs to determine that. I believe we will get negative results as far as reducing the strength of the chain by repeated loads is concerned. We undoubtedly will show that repeating a safe load doesn't reduce

the chain strength very much. In formulating our plan, we have included certain tests, the results of which we are already sure, but we must have authentic data to convince even the skeptics.

I am not positive as to this surface impacting suggested by the British engineers. I have here a few bars which we have hammered; we then bent them back and forth a few times and then pulled them in tension. Such bars are thus made stronger than they were originally.

The study of annealing steels it is not a yes or no proposition. If there were any one simple test, it would have been done years ago. It seems strange in this advanced age of engineering that there is so much chaos and misunderstanding, but I am sure that we are on the right track to answer many troublesome questions.

H. W. HEINRICH (The Travelers Insurance Co., Hartford, Conn.): It seems to me it is advisable for you to have an impact testing machine that will repeatedly raise and lower your load with a jerk.

PROFESSOR THOMAS: We did have in mind such a machine, but the pendulum machine will give a blow that can be measured, so it should yield a more precise test than you could get from a simple falling weight test.

CHAIRMAN THALNER: In this impact test, will you use bars or chain links?

Experience in Bridge Construction Is Cited

PROFESSOR THOMAS: I think it will be necessary to use the bar. It is quite a problem to support a single chain link in a position where you can get a fair impact test.

JOHN G. SPONSEL (American Bridge Co., Gary, Ind.): I understand that your impact test in the foundry rattler is to be with balls. I think rather than balls you should use weights with sharp edges; cubes for instances, or miscellaneous shapes of iron. In our work, where we revolve bridge members on skids, the members fall over and cut right into the chain; that is typical service.

PROFESSOR THOMAS: I suggested using steel balls because we need something which will remain constant over a period of weeks and months, and it seems to me that a round ball is more apt to give the right impact after it is worn than something with sharp edges.

M. E. ARKILLS (The Waterfront Employers of Seattle, Seattle, Wash): With your repeated load test, it seems to me you will get nothing out of it unless you use a load to stress the metal beyond the critical yield point. When I was with the Pullman Company, I tested six chain links, after which I held three and annealed the other three. I found that by annealing the chain returned to its original condition, but the unannealed links seemed even stronger than before the repeated load test. For instance, a $\frac{7}{8}$ -in. chain carried 6,000 to 10,000 pounds more before breaking than it did before the repeated load test, showing that the cold working that it had gotten during the time it was in use had built up a hardness that raised the ultimate tensile strength.

As far as this outside impact is concerned, I know we had chains that were much abused. If abuse were to cause tiny fractures in the chain, would you not find rust in the cracks when you came to test the chain? I have never seen anything of that kind.

Poor welding is another cause of chain failure. In running seventeen tests one afternoon out at the McCormick Shops, five chains failed in the weld. That is about 30 per cent. That seems to be due to the gas pocket that forms when a little bit of coal gets into the welding heat.

There is a welding process now used where the scarfing is formed like the shape of your thumb, rounded on the outside. This forces out any coal which might be in there and eliminates the gas pocket. They close the first portion in the first heat, then when going back for the second heat, they close it down still farther, first knocking out the scale or oxidized metal to get rid of that in the weld, and then they

finally close the edge down solid. That reduces failures at the weld from 30 per cent to about 3 per cent.

J. A. NORTHWOOD (Bethlehem Steel Co., Johnstown, Pa.): We have had a number of chain breakages which the chain manufacturers tell us are probably caused by the rough usage given the chains by the men in pulling them out from under loads. In other words, the inside of the link wasn't worn, but the outside of the chain was badly worn very shortly after the chain was put into service. Perhaps the separators between the piles are not high enough.

PROFESSOR THOMAS: That was the idea which the British engineers brought out. I am not sure that is the real cause. We made some preliminary tests and I am doubtful. When a chain is carrying a load, the greatest stress does not come where the surface wear is the greatest.

H. A. McDONALD (Eric Forge Co., Erie, Pa.): It seems to me it would be a mistake to use cubes instead of balls when putting a chain in a rattler.

The Question of Impact Presents Two Problems

E. F. BLANK (Jones & Laughlin Steel Corp., Pittsburgh, Pa.): As I see this question of impact, you have two entirely different problems; you have surface impact from wear and tear on the chain; then you have special impact when the chain jerks its load.

I agree somewhat with Mr. Heinrich in thinking we should use both the impact and repeated load tests. The impact you get in your Charpy impact machine doesn't really give you the same kind of an impact that you get in service because in service you get a combination of both impact and repeated load. Every time you pick up a load you pull the slack out of the chain and get a certain amount of impact in addition to the load actually hoisted.

PROF. H. A. THOMAS (Carnegie Institute of Technology, Pittsburgh, Pa.): I think we could adjust our repeated load test machine to get both effects at the same time, by having quite a bit of slack in the chain. It might be more noisy in running and it might impose more wear and tear on the machine, but I think it can be arranged.

H. W. HEINRICH: The British engineers do not state where that impact hardening occurs, whether it is due to rough handling of the chain or to the jerking of the load. I believe that most chains in service receive most of the impact between the ends of the links as one link hits the other and, therefore, that your combination repeated impact load test will show us what we want to know.

M. E. ARKILLS: Might I suggest that the committee ask big users of chain to donate pieces of chain that have been in service so our committee can compare used chains with chains put through various laboratory tests?

E. F. BLANK: I agree that we should learn all we can from every possible source but our conclusions must be based on laboratory tests that have been conducted with a fair degree of uniformity.

PROFESSOR H. A. THOMAS: I have made some tests in the last few weeks to see if surface hardening due to abuse of the chain would weaken the chain. Some of the samples that were sent in to us were broken at the point where the link was bent rather sharply across the link. I took two rods. I surface hardened one with a hammer. Then with a hand device I bent both rods back and forth. It took approximately the same number of bends to break both rods.

R. JENKINS (Inland Steel Co., South Chicago, Ill.): I was wondering how long a chain has to be in use before it should be re-annealed. How long does it take to change a chain link from a fibre structure to a crystalline structure?

PROF. THOMAS: My own opinion is, that crystal structure was due to overheating

and not to crystallization in use. There are only three things that can produce that kind of fracture, one is overheating in the first place, another is fatigue, and the third is impact. We know that in testing.

Now, there haven't been enough repetitions of load to produce ordinary fatigue; the break doesn't look as if it were an impact break, it turns out right at the end of the link; so it must have been overheated in the first place.

It is only superstition to say the steel crystallizes. If it is good steel in the first place, it will stay good. If it is crystalline in the first place, it will remain crystalline. If it were not overheated in the first place, it would not develop that kind of a fracture.

CHAIRMAN THALNER: I know there is quite a difference of opinion on crystallization of chains. Of course, metallurgists will tell you that it is in the material when you buy it; but in practical experience, it seems to show up otherwise; that is, an average chain that has been in use for some time is very apt to become crystallized.

JOHN G. SPONSEL: Why do chains often fail during the first cold snap in fall weather?

The Chain Stretched Like So Much Molasses

M. E. ARKILLS: I think the reason for that is because the cooling of any material tends to bring the molecules closer together and increases the internal stresses. But that is only slight, comparatively speaking, and I don't believe that that is a very big factor, although we do have failure. Sudden impact, or jerking the load, is a more important factor.

I would like to take issue with you, Professor, on your statement, "if the metal is good to start with, it will always be good" because tests I have run don't always bear that out.

I must tell the story of an incident that happened in our plant. One morning I got a telephone call to go to a certain part of the plant at once because a chain had failed. They were trying to lift a punch press out of a hole into which it had fallen the day before. It was still in the blue clay about three inches and it had frozen over night. They lifted on it with the chain and stretched the chain out just like so much molasses. Of course, they blamed me for annealing it too much. I told them that if the chain had been brittle instead of ductile, someone would have been injured, but it just stretched out and gave them plenty of warning so they could get out of the way.

E. F. BLANK: The plan of procedure says that the chain will be annealed at temperatures ranging from 1000 to 1750 degrees. The iron and steel mills are interested in low temperature annealing. We pick up loads of hot metal anywhere from 450 degrees, say to 1200 degrees, and we leave our chains wrapped around these loads when they are set down in the yard to cool. Those chains are brought to a temperature that I suspect is somewhere near the said brittleness temperature and I believe that our research ought to cover low temperature annealing, perhaps from 800 degrees up through 1750 and 1800 degrees.

CHAIRMAN THALNER: We will close the discussion on the chain annealing proposition. I assure you that we have appreciated your attendance and interest.

(Mr. Keown resumed the chair.)

CHAIRMAN KEOWN: I am sorry we must stop this discussion.

We now come to have the report of progress of the research committee on "Noise—a Factor in Accident Causation," and I would like to call upon Dr. H. Clyde Snook as chairman of that committee to take charge of that discussion.

(Dr. H. Clyde Snook, Consulting Engineer, New York City, took the chair.)

Progress of Report of A.S.S.E.-Engineering Section Research Committee on Elimination of Harmful Noise.

H. Clyde Snook, Consulting Engineer, New York City.

It is worth while to recall just what noise is. To this end the following definition of noise is quoted from last year's report of this committee.

"Noise is considered by the physicist to be sound or a mixture of sounds to which no definite pitch can be assigned. In general, noise is understood to be sound that lacks agreeable musical quality. Since pitch is the quality whereby it can be designated as having a certain frequency of vibration, pitch is the assignment of the sound to a certain position in an accepted series of sounds constituting a musical scale. Their comparatively even flow, their regularity and repetition of wave form are the things that characterize musical sounds. Noises have an irregularity and an absence of repetition in their wave forms.

"It is to be noted, however, that this line of demarcation between musical sound and noise can not be sharply drawn, since very few musical sounds are entirely free from attendant noises that, to some extent, modify their smoothness and regularity; and since also musical sounds can be perceived more or less plainly through some noises."

Interest in noise elimination is wide spread. Magazine articles, newspaper items and editorials relating to it have appeared frequently throughout the country during the past year. Information and views thus given to the public has been reasonably accurate and authoritative. No small part of the material thus given publicity was obtained from the members of the Committee, who have used this means to help maintain public interest in noise elimination.

Notable in this work have been the efforts of Dr. E. E. Free, one of our Committee members, who made a noise survey of the city of New York. A similar noise survey was made of portions of the city of Chicago by Mr. R. F. Norris, of the Burgess Laboratories. These surveys have informed the public of the feasibility of noise surveys and noise measurements. Apparatus for such quantitative measurements is readily available as the result of developments made in the Bell Telephone Laboratories.

We are confronted, however, by inability to utilize such surveys as any basis for determining which noises should be eliminated or which may be tolerated. No existing data enable us to draw any line.

Physicians know, in general, that people who are very ill can tolerate only a minimum of noise. But what noises are harmful or how much noise is harmful to people who are not ill, physicians do not know. There is authority for the statement that noise may cause certain disorders of the ear. Deafness from this cause is stated to exist, for example, among spinners, loom-tenders and railway engineers. But it is not known to what intensity noise must be reduced to make it no longer a possible cause of such deafness.

Among effects which noise is known to have upon the human organism there is but one besides the perception of loudness that appears to have been measured quantitatively or studied in detail. This is the so-called "masking effect," an account of which is contained in last year's report and which has been investigated extensively by the Bell Telephone Laboratories. This effect is a temporary deafness caused by noise or any audible sound, lasting only while the noise is heard and

depending in degree upon the loudness of the noise. This transient deafness, due to masking probably is a prolific cause of accidents really due to noise, because of the hearer's inability to apprehend warnings or to detect other sounds while the noise lasts.

Another effect of noise upon the human organism, reported by Dr. John J. B. Morgan in 1916, is a possible increase in the rate of oxidation in the body when noise is heard. This is deduced from indirect evidence, such as an increase in muscular tones, vocalization and changes in breathing. This implies an increased activity of the bodily tissues and an increased consumption of energy. It may account, in part, for the necessity of shielding the sick from noise.

The Committee's Chief Opportunity for Service

There are not now available sufficient data to formulate a definition of "Harmful Noise." It is difficult, indeed, to find reliable proof that noise is harmful at all, except possibly to the sick. We believe that some noises are harmful, even to everybody, but this is unproved. There is no doubt that noise is disagreeable to great numbers of people, who want it eliminated; but there certainly is not enough scientific information to permit reliable estimates of its harmfulness or of the money value of its economic waste for any group of people.

Since information about the effects of noise upon the human organisms is so meager that we do not even know how to define the amounts or kinds of noise that ought to be eliminated, it is believed this Committee has its chief opportunity for service in endeavoring to interest competent scientists in investigating the real effects of noise upon the human body. It is believed that physiologists, neurologists, otologists, psychologists and physicists should be enlisted in fundamental studies of this kind. The various phases of the body's physiological functions, fatigue, nervousness, hearing and the processes of the mind, all are involved continually in the body's reaction to noise.

Several Investigators Interested In the Work

During the past year the Committee has endeavored, with some success, to interest investigators in this work. Among these investigators are Professor John J. B. Morgan, psychologist of Northwestern University, already known as a student of the subject. Under the auspices of the Committee, Professor Morgan has made a preliminary study in an attempt to find a test useful as an index of the effects of noise upon the human organisms. Electrocardiograph records were taken of subjects both as free from noise as possible and again when noises were introduced. The noises were produced by Western Electric audiometers, the sounds of which were amplified and this purpose having been loaned the Laboratory of Physiology of the New York University Medical School and Bellevue Hospital School by the Bell Telephone Laboratories. The work was carried on in the Laboratory of Physiology of the New York University Medical School, which institution loaned the electrocardiograph and recording apparatus.

Dr. Morgan's tentative conclusions are:

1. The heart action is modified by noises.

2. The effect seems to be more apparent in the irregularity of the action, rather than in the average rate.
3. Subjects vary in the way in which they respond to the sounds given.
4. Different sounds have different effects. The most effective seems to be an intermittent sound.
5. The suggestion of a "horrible din" to a hypnotized subject quickens the pulse, indicating that the emotional attitude of the subject toward the sounds may be of greater significance than the quality of the sound itself.

Careful Work Necessary Through Several Years

Although the work is regarded by Dr. Morgan as merely of an exploratory nature, with none of the results to be taken as conclusive, it is believed to be indicative of methods of attack that may be used to attain a reliable definition of harmful noise. The work necessary for this will not be a matter of weeks but of years. The project presupposes persistent and patient devotion to unremitting work that will yield results slowly, almost painfully. It will require, also, the interest and support of persons willing to aid in defraying expense for supplies and apparatus. The Committee hopes to obtain both scientific and financial support for this kind of attack on its problem.

One question has been raised and will be raised again. After all, critics ask, what can be done to eliminate noise? When all the information is at hand how will it help to eliminate noise? A final answer to this pertinent question is not possible now but the Committee is confident that when a definition of harmful noise is at hand it will indicate ways to reduce this noise.

In the meantime acoustic engineers will continue to work out solutions for the most flagrant noise problems. Civic bodies will continue to insist upon the suppression of preventable noise near hospitals. Whether, in the future, we shall prefer to protect the hearer from existing noise, or whether we shall try to eliminate such noise at its source, or whether we shall do both things, remains to be worked out.

CHAIRMAN SNOOK: Yesterday, Mr. Auel of the Westinghouse Company asked a specific question with respect to the method of eliminating noise emitted by screw cutting machines. I avoided attempting to point out a specific suggestion for this definite problem because I wished to confine the discussion to the general phases of the problem.

Three Methods of Eliminating Noise

A reduction in noise emitted from apparatus of the kind that he described can be accomplished and since it is specific in nature, it seems to me that a definite reply to that question is not in order at this time. I should be glad to discuss the matter with him privately if he should care to take it up with me. However, I am using this as an example of the difficulties that lie in the way of a generalized discussion of this subject. The specific question that was raised can be solved by the application of one or more methods of noise reduction.

Noise may be reduced by eliminating or reducing the original mechanical disturbance.

Second, noise may be reduced by absorbing the sounds that are emitted, and

Third, noise may be reduced by shifting the frequency spectrum of the surfaces that couple with the air so that their natural periods of vibration will be shifted to

a less audible range of the frequency spectrum. It is this third method of attack for this specific problem which has to be studied.

Fortunately, apparatus of this kind can have placed around emitting surfaces, materials whose sound transmission becomes quite inaudible. Light weight metal alloys of magnesium and aluminum, make it quite difficult to produce audible tones when these materials are cast in the form of bells because the sounds that these bells emit are in a less audible frequency range.

Dr. Morgan has made an attempt to find some method of attack whereby an index might be found that would indicate the effects of noise upon the human organism. I should like to call upon Dr. Morgan to describe to you briefly the experiments he conducted this summer.

What Does Noise Do to the Human Organism?

DR. JOHN J. B. MORGAN (Northwestern University, Chicago): My problem was to see if we could discover what noise did to the human organism. We always assume that it is harmful, but before we can decide whether it is harmful or not, we have to find out what it actually does and, to date, we have no way to know whether there is any definite effect.

The research referred to that I did in 1926 assumed what most people think, that noises did something to an individual, and I started off with the assumption that noises will distract attention. I had the subject working at a very definite object which I thought occupied all the interest and attention he could muster, and while he was working, I held myself in readiness to keep a very definite record of any move which he made, and I did not report any. Then, I introduced the most powerful, ghastly noise I could, disturbing the whole universe almost with my performance. This noise was introduced suddenly, and then I discovered something that quite surprised me. The first effect of the noise was a retardation in speed, but it wasn't for more than a few seconds and then I found he worked better during the noise than he did before. I removed the noise, whereupon he did slower work than when the noise was there.

The first conclusion you might get from this is, let's make a lot of noise and increase efficiency, but I didn't quite agree with that. I thought something might be happening to the individual in spite of the fact that he was working rapidly.

One of the first things I did was to put a spring under the keys which he had to operate, to ascertain the amount of pressure, and I found very definitely that he pressed the keys with greater vigor when the noise was on and there was also an increase in muscular energy.

Investigating Noise as a Stimulant

I took the breathing record in which there was quite a remarkable change.

You have noticed people who will be articulating with their lips in order to keep certain numbers in their minds. It shows that the individual is adapting himself to noise by doing something else.

I didn't do any more of this work until this summer when your committee encouraged me to go ahead. We talked the thing over and decided what we wanted was a measure that would indicate the heart action, a very complex thing which could be modified by individual attention. We got access to the Medical School of Bellevue Hospital and took some heart records of individuals under noise and then in quiet positions.

This electrocardiograph, as you may know, is a delicate instrument. All you need do is connect the electrocardiograph to the wrists of the subject and you get a complete record on a photographic film of his heart action, both aptitude and rapidity.

We had about twelve to fifteen subjects and we found out the effect varied. In some cases, we had a slowing down of the heart, while in others it took quite the opposite direction. We had a subject under hypnosis and I suggested to her a horrible din and her heart action went to 120 beats a minute with just simply a suggested noise. In some cases an actual physical noise will produce this effect. The heart responds very definitely to what we call the emotional.

There is another thing I want to bring in here bearing on this hypothesis. You can take a new born baby and it will be more quickly frightened by a loud noise than an adult. As we grow up, we are not so easily frightened by noise. This is fragmentary evidence of what we call the harmful effect of noises.

There are other experiments which have been suggested by the committee and one is the carbon dioxide output. I think any way in which we can measure the effect of noise on the system should be followed out. I am particularly interested in the psychological approach.

The Committee Needs More Facts

CHAIRMAN SNOOK: I think this brief discussion by Dr. Morgan certainly substantiates the stand which the committee has taken; we need more facts.

Mr. Mowery, you were chairman of this committee last year, and you must have some ideas regarding what to do. May we hear from you.

H. W. MOWERY (American Abrasive Metals Co., New York City): There is one thing which occurred to me yesterday during the course of our discussion of the abstract of this paper. We have no data to show that industrial plants have accidents traceable to noise. So would it not be a good thing if several of the large industrial organizations, such as the General Electric, Westinghouse Electric, etc., were to study their accidents for a year or two to determine whether or not noise seems to be a direct or indirect cause of accidents. That will be extremely valuable data.

Another thought came to me as Professor Morgan was completing his remarks. One of the main reasons why the committee of last year turned the future work of this committee over to more able hands was because of the feeling that was growing in the minds of some of us that perhaps noise was not really harmful to the human system to the extent that accidents were the result, and that the human body perhaps was capable of compensating by its natural resistance for the reduction in vitality due to noises. That is why it is so essential to proceed with this research to determine definitely if noise has any harmful effects on the human system. If we find there is no harmful effect, then there is no further need to proceed with the work because we have nothing that is of particular interest to the Council to eliminate.

The Intermittent Noise More Harmful

M. E. ARKILLS (The Waterfront Employers of Seattle, Seattle, Wash.): I would like to ask the Doctor if any tests have been made in studying noise and its relation to health.

DR. MORGAN: You may assume that because I said the thing is emotional that it isn't harmful. Psychologically, it is the most harmful thing that can happen to the human being. In our tests, we got a noise as intense and as harmful as we could get and we kept that noise going for thirty minutes and as far as we could make out, it is less harmful than an intermittent noise.

MR. M. E. ARKILLS: From the fact that more pressure was put on the keys, it suggests to me that people working under those conditions might over-exert themselves and thus produce fatigue earlier in the day than without the noise.

I remember an incident when I was working in a drafting room one time right near a shaft which had a wood pulley that squeaked until you couldn't hear yourself think. One afternoon, somebody took the pulley down and we could hardly work the rest of the afternoon after having worked that way for several months.

JOHN G. SPONSEL (American Bridge Co., Gary, Ind.): How many noises are repulsive?

CHAIRMAN SNOOK: A question like that is altogether too general and I am sure that Dr. Morgan can give us some idea as to the difficulties that are involved in answering such a broad and general question.

STEWART J. OWEN, JR. (National Safety Council, Chicago): There are several classes of normal persons. Doesn't noise affect some persons of the same class differently?

DR. MORGAN: That is one of the problems. I am pretty certain that there are not only two classes but that there are many classes which we haven't distinguished as yet. There is no doubt about it at all that noises affect people differently.

CHAIRMAN SNOOK: We have another member of the committee with us, Professor Watson from the University of Illinois. It will be of interest to you to know that Professor Watson has done work upon this very hotel building in the matter of noise elimination. I am sure we will all be glad to hear from Professor Watson.

PROFESSOR F. R. WATSON: First of all, I should like to express my appreciation to Dr. Morgan. I think his work and definite information will be a step forward in the final solution of the problem.

I would like to say two or three words about the beneficial effect of quiet in rooms. This particular room, for instance, is quieted by the carpet and these chairs to such an extent that you can understand what I say, which is not true in a good many rooms.

In regard to the question asked a few minutes ago, I should like to say that some work was done in New York City in connection with the Federal Reserve Bank where they have a large number of employees. What they did there was to count the number of mistakes made by employees in noisy rooms compared with the number of mistakes made in the rooms which had been quieted and it was found there were more mistakes in the noisy rooms than in the rooms which were quiet. This shows that fatigue does make the employee less efficient.

MR. ARKILLS: Would that be a question of fatigue or distraction?

Why the Automobile Runs Into the Train Side

PROFESSOR WATSON: The employees would work on the same kind of work the same length of time, in both quiet and noisy rooms. There were more mistakes in a noisy room than in a quiet room.

This whole question of the quieting of buildings is, to some extent, in its infancy, but progress is being made in a number of different directions and it seems quite certain that within ten or fifteen years, quiet rooms and auditoriums will be more numerous than they are at the present time.

I should like to add one other comment which is in a considerably different direction, but which I think comes up in the matter of safety. I have been interested in hearing that many automobiles run into trains instead of being hit by trains. I rather thought that the tremendous noise and rumble of the train must prove very confusing to an automobilist. Under the pressure of noise, I find that I have to rivet my attention very decidedly upon what I am going to do with a machine. It seems likely that the rumble of the train is explainable for the fact that so many automobilists run squarely into the middle of the train.

CHAIRMAN SNOOK: I am sure many of us know that noise arrests our attention and causes us to hesitate and take time in order to decide what we are going to do. I know that that is the reaction I have towards noise and I dislike noise so much that I am sure something of that is in my own reaction to noise.

MR. MOWERY: With reference to Mr. Arkill's question about fatigue. When I first came to New York City, I got a room on West Twenty-third Street near the corner of Ninth Avenue. There are twelve lines of crosstown surface cars, there are two more lines of north and south surface cars on Ninth Avenue and there is the elevated line on Ninth Avenue. The first week I was there I didn't sleep a wink. I am quite sure that by the end of that week I was considerably fatigued. If I had been engaged in some dangerous or hazardous occupation, I am sure that my reactions would not have been safe in all cases.

A short time ago, I had occasion to go to Asbury Park. I was seeking a rest. I got into a hotel and had a room near the elevator shaft. I believe the elevator machinery must have been bolted fast to the roof members, because the noise from that elevator spread over the entire building. I didn't get much rest. I think unquestionably that noise must cause fatigue. But, after my week's residence there, the effects of the noise diminished and I was able to sleep soundly. No doubt, if I had remained a few days longer, I would have been able to rest even under those noisy conditions. So I am wondering whether or not a human being isn't able to compensate some way or other and after a time become immune to noise. And when can we say whether a noise is permanently harmful or not?

MR. ARKILL: I think the more things we have to compensate for the less resistance we have for other outside influences.

A Campaign to Eliminate Unnecessary Noise

CHAIRMAN SNOOK: The planning of the work for the committee has proved to be tremendously fascinating because there is at the present time such a pronounced fight against unnecessary noise. People are annoyed by it and the differences of opinion regarding the effects of noise upon humans are tremendously great and we need facts. We need a solid foundation of information and that the committee is proposing to set about obtaining.

The physiological reactions to noise that are involuntary may be larger in number than the single one that Dr. Morgan has detected, namely this change in heart ratings, either slowing it up or accelerating it, as the case may be with that particular individual. There may be others, and I am happy to say that Dr. Morgan, Dr. Watson and others of the committee have been discussing and eliciting the support of other investigators so we have great hopes that within a few years we shall be able to know something about the ill effects of noise upon human beings.

C. L. YORK (General Electric Co., Schenectady, N. Y.): You know we manufacture radios and part of the process is testing loud speakers. We notice among the girls that the noise certainly increases mass production. Even the old fellows around fifty-five years of age seem to have a lot of pep.

CHAIRMAN SNOOK: This effect has long been known to the cigar manufacturers in Cuba where they regularly employ a reader who reads to the men making cigars. He entertains them. He reads magazine articles and anything that will hold their interest. Thus mass production is increased.

PROFESSOR MORGAN: It is automotive response. You get a sound which affects your automotive nervous system that causes a change in respiration, in pulse rate, and in secretion of certain glands. That keeps up this acceleration of the heart, and so on, so each change is just one part of the whole.

MR. YORK: When a new building was being constructed at our plant where we had a lot of colored men working, one of the first things done by the contractor was to get a song leader, to keep things moving.

JOHN G. SPONSEL (American Bridge Co., Gary, Ind.): I have heard of the same thing in loading cars of lumber, having a song leader for the colored laboring crew.

CHAIRMAN SNOOK: We will endeavor to maintain a strictly open attitude of mind and the books must not be closed for a long time until we have accumulated information over a period of years in order that we may know the real effect of noise upon the human organism.

MR. OWEN: If anyone has any information or test data that they believe will be helpful to the committee, of course, we are more than anxious to get hold of it.

ADJOURNMENT.

SIXTEENTH ANNUAL SAFETY CONGRESS NATIONAL SAFETY COUNCIL

Automotive Section

New Section Officers

Chairman, A. M. WILLIAMS, Chrysler Corporation, Detroit, Mich.
Vice-Chairman, E. H. COTCHER, The Murray Corporation of America, Detroit, Mich.
Secretary, H. L. SAIN, Delco-Light Company, Dayton, Ohio.
Poster and Slide Committee Chairman, H. L. BUNTING, Olds Motor Works, Lansing, Mich.
Membership Committee Chairman, L. J. PARRISH, A. O. Smith Corporation, Milwaukee, Wis.
Publicity Committee Chairman, H. L. FRACHER, Detroit Steel Products Company, Detroit, Mich.
Program Committee Chairman, O. J. OLSEN, Fisher Body Corporation, Detroit, Mich.
Engineering Representative, R. F. THALNER, Buick Motor Company, Flint, Mich.
Statistics Committee Chairman, W. S. SMITH, Ford Motor Company, Detroit, Mich.
News Letter Editor, E. R. COMPLIN, Ford Motor Company of Canada, Ltd., Ford, Ont., Canada.

Executive Committee, THE OFFICERS AND—

H. J. MELLUM, The Nash Motors Company, Kenosha, Wisconsin.
CHARLES J. KOLB, The Pierce-Arrow Motor Car Company, Buffalo, N. Y.
A. F. DUNNEBACK, General Motors Corporation, Detroit, Mich.
G. A. KUECHENMEISTER, Dominion Forge and Stamping Company, Walkerville, Ont., Canada.
F. J. GORBETT, Chandler Motor Car Company, Cleveland, Ohio.

Retiring Officers

Chairman, A. F. DUNNEBACK, General Motors Corp., Detroit, Mich.; *Vice-Chairman*, A. M. WILLIAMS, Chrysler Corp., Detroit, Mich.; *Secretary*, E. H. COTCHER, Murray Body Corp., Detroit, Mich. *Committee Chairman: Poster*, J. B. GIBSON, Western Electric Co., New York City; *Membership*, C. H. CHAPMAN, Briggs Manufacturing Co., Detroit, Mich.; *Statistical*, G. S. THOMPSON, Detroit Insurance Agency, Detroit, Mich.; *Engineering Representative*, R. F. THALNER, Buick Motor Co., Detroit, Mich.; *Executive Committee*, THE OFFICERS and G. A. KUECHENMEISTER, Dominion Forge & Stamping Co., Ltd., Walkerville, Ont., Canada; L. E. AVERILL, Packard Motor Car Co., Detroit, Mich.; R. A. SHAW, Fisher Body Corporation, Detroit, Mich.; L. L. JUDGES, Ford Motor Co. of Canada, Ltd., Ford, Ont., Canada; D. C. HUNTER, National Cash Register Co., Dayton, O.

Tuesday, September 27, 1927

A. F. DUNNEBACKE, Chairman

Safety Director, General Motors Corporation, Detroit, Mich.

The first session of the Automotive Section of the National Safety Council was called to order at nine-forty-five o'clock, by the chairman, Mr. A. F. Dunnebacke, safety director, General Motors Corporation, Detroit, Michigan.

CHAIRMAN DUNNEBACKE: Gentlemen, this is the opening session of the Automotive Section of the National Safety Council, at the Sixteenth Annual Safety Congress.

You will find, on each chair, registration cards. The purpose of those cards is very definite, and they have been of great help to the Congress in its work. In the first place, it gives us a list of everybody who attends the Congress; the officers go through these lists and find out who come to these meetings; naturally, then, we can distribute our papers and pick out the men who are interested enough in the session to attend the Congress.

Then again, when a person gets up to make a remark or enters into the discussion, if there is any doubt of his identity, it is much easier for the reporter to get his correct name and address. Also, these cards help in tabulating and keeping track of the attendance at the Congress. So, the first thing, this morning, you will each take the card you find on your seat, write your name, the company you represent and your address; later on in the meeting, somebody will take up those cards.

Reports of the Various Committees

Under the regular order of business, the first thing, this morning, will be reports. We will have no long reports from your officers: whatever may be said in the way of a report will be a short, condensed general report that I will give you.

Your officers have met this year in session four different times, in which we discussed the interest of the Section, activities of the Section, and the development of a program for this year. The attendance was always satisfactory. In fact, there was only one meeting in which there were less than five in attendance, and at the other three meetings there was almost a complete attendance. This was very gratifying, indeed, because it is one of the serious and hard things in the conduct of the Section, to get officers to attend these meetings. Where the homes of the officers are widespread, it necessarily means considerable travel, considerable sacrifice of time and money to attend these meetings, and it was very gratifying to note that most of the officers attended all the meetings this year; so there has been the best of cooperation among the officers, and we hope and feel that we have, as a result of that, developed a program which will be interesting to the delegates.

That is the only thing I wish to say in the way of a report. There is one report, that of the Statistical Committee, which I am going to have Secretary Cotcher read. I think this committee has done the best work of the Section. Those of you who received the annual report of the National Safety Council, showing the vital statistics, were surprised to see how many automotive companies, this year, reported their accident experience. It was the most complete, largest and best report on accident statistics that the National Safety Council has issued; and it was largely due to the work of the Statistical Committees of the various sections. That is the reason why they are anxious to have every company in the Council report its experience. Mr. Cotcher will read the report.

Report of the Statistics Committee

Your Committee on Statistics is pleased to report that signal progress has been made during the past year, and you have been presented with a most complete report which I would suggest be given careful consideration by each one individually. It has taken considerable effort on the part of the National Safety Council to present this report and your committee men would certainly urge their respective request that all concerns, whether members of the National Safety Council or not, file their reports so that we can have a complete chart and the actual standing of the group.

I wish to thank you for the confidence you have placed in your committee men and also for the hearty cooperation that I have received. I sincerely hope that the effort made by the National Safety Council to provide these charts will prove an inspiration for greater progress in the future than has been accomplished in the past.

CHAIRMAN DUNNEBACKE: The next thing I wish to announce is the appointment of a Nominating Committee, to select a set of officers for next year. This is always an important step and calls for a good deal of thought. I have selected for the Nominating Committee, this year, three past chairmen of the Section. These gentlemen have all been hard workers in the activities of the Section, they have a wide acquaintance among the members. They are men who can pick out a good set of officers for next year. That committee consists of Messrs. G. A. Kuechenmeister, personnel director, Dominion Forge and Stamping Company, Walkerville, Ontario; R. F. Thalner, safety director, the Buick Motor Company, Flint, Michigan, and L. E. Averill, safety engineer, The Packard Motor Company, Detroit. These gentlemen will meet between now and tomorrow morning. At the opening of the session, tomorrow morning, they will present their slate for your consideration.

Now, we will enter into the program proper. It was quite difficult for your officers to decide just what form of a program to have this year. The meetings of this section have been numerous, and it is always a little difficult to decide what is the best form of program, and how to develop one that will be of interest to everybody.

New Plan Followed in 1927 Program

If you recall, last year, the officers built their program around the hazards of material here. We took materials from the time received, until put up in the machine to be operated on; then we took the materials from the time they were placed at the machine and carried through process until ready for assembly. Then again, we took the materials from the time they entered into the assembling until they were ready for shipment.

This year, the committee decided they would adopt another definite scheme; that is, we would analyze, digest and review the accident experience of several millions of hours of work in the automotive industry, and, studying those, we would know what was causing our accidents. Knowing what causes our accidents, as a rule, we can set up some remedy for their prevention. So the program has been built around that idea, to know what is happening, where the accident is happening, what parts of the body are being affected, what are the rates of severity. Then, when we know what is happening and what is costing us the most money and the most suffering, succeeding speakers will take up different injuries, show what is causing them, and tell us what to do to prevent them.

For the opening of this morning's program, the officers have been very fortunate in having a gentleman from Ontario to give the first paper. This gentleman is

chief statistician for the Ontario Compensation Board; he is a man who, perhaps more than anybody else, has a complete picture of what is going on in the Dominion of Canada, also an extensive knowledge of what is going on in the States. I take pleasure in introducing Mr. T. N. Dean, who is going to tell us what is happening, and where it is happening.

Where the Accidents Happen

T. Norman Dean, M.A., M.S., Statistician, The Workmen's Compensation Board, Ontario, Toronto, Canada

Any examination, no matter how casual and superficial, of the profound mass of industrial accident statistics promulgated on this and the European continent precludes a general statistical survey of any particular classification. This is due in part to the rather fragmentary and chaotic character of much of the published material and partly due to endogenous factors complicating clear cut definition and understanding of basic principles of classification. It is certainly in a measure also due to failure of conscious recognition that reliable statistics are compilations of facts themselves rather than records of someone's interpretation of those facts.

Two limitations on any set of statistics under analysis appear. First: erudite premises and pedantic conclusions are often the result of hastily constructed and carelessly defined columns of figures labelled "statistics." Syllogistic process may be perfect, but if premises are assumptions conclusions are apt to be fallacious. Indeed it would seem that considerable of the popular distrust of statistical presentation has been engendered in just this way and fostered by the orthodox method to obtain argumentative supremacy of bolstering up preconceived notions by arrays of figures calculated or in self deception to present a similitude of mathematical preciseness where only misinformation and confusion may result. Second: general misconception of the nature and function of the average is productive of much misunderstanding. Without technical elaboration, let it be simply stated that it is rarely, and then only coincidentally, that the average is encountered as a real quantity and that the use of averages in comparison without full statement of original data, with all attendant limitations and qualifications, is a hazardous proceeding.

New York Compared With Ontario

An example of these generalized principles is presented herein with a twofold hope: first, that it indicates some hitherto unconsidered aspects of statistical presentation in accident prevention work; and, second, that it may make some more or less technical matters less complicated and thus serve as a guide-post for the future.

The following comparison has been made. In New York State accidents compensated are divided as follows: Temporary disability, 77.5 per cent; permanent disability, 21.1 per cent; death, 1.4 per cent. In Ontario the figures are 91.4 per cent temporary disability cases, 7.8 per cent permanent disability cases, and .8 per cent death cases. The conclusions are easily made that deaths are more frequent in New York than in Ontario and that permanent partial disabilities in New York are nearly three times what they are in Ontario. The former may be due to the more hazardous nature of industry in New York and the latter may occur from a more inclusive interpretation in New York of the condition designated "permanent disability." Ontario, however, is a pioneer prov-

ince, rich in mine and forest resources, while New York is an old established community abundant in light manufactures and commercial pursuits. In the New York records are figures of non-hazardous industries; these are excluded from the Ontario data. It might also be fair to conclude that administrative interpretation of the term "permanent disability" results in a more extensive application in Ontario than restriction necessitated by the construction of a legislative schedule in New York.

Thus is presented a series of conclusions totally different and diametrically opposite to conclusions drawn from the same data. Yet in neither is the explanation wholly patent. The New York figures include temporary disabilities of two weeks or more duration while the Ontario figures include disabilities of more than one week's duration. Translation into similar terms discloses this comparison: temporary disability: New York 77.5 per cent of cases, Ontario 84.6 per cent; permanent disability: New York 21.01 per cent; Ontario, 14 per cent; deaths: New York 1.4 per cent, Ontario 1.4 per cent.

Plausible Deductions From the Statistics

To assemble reliable figures showing anatomical classification of injuries from any widely distributed field is impossible; even to combine records of two plants without definition of bases and full recognition of all qualifying factors is distasteful. Nor does it appear that any useful purpose will be served by so doing. Herein therefore generalities and deductions must serve for those usually used and generally confusing numerical statements commonly designated statistical bases.

First: The trade risk is of less importance than is the general risk.

Second: The part of the body most used in operations peculiar to the trade is most often injured by the causation agency of trade risk and less frequently injured by the causation agency of the general risk.

Third: Mental hazard is a greater causative factor in industrial accidents than either trade or general risk.

Fourth: Injury, disability and money loss are all definite results of accident.

Fifth: The function of accident prevention work is to eliminate trade risk, mitigate general risk, check mental hazard, prevent injury, minimize disability and reduce money loss.

The trade risk is the risk present by reason of the production of some specific article; the general risk is that hazard more or less common to all employments and certainly not peculiar to any one. In stamping shop risks involved through punch press operation is a trade hazard, while dangers involved from unlighted stairs or alleyways, careless handling of objects and upturned nails belong to the category of general risk. The mental hazard, more difficult to separate and analyze, consists in the attitude of mind of employer and manager as well as worker that permits preventable accidents to happen and unfortunately in many cases even induces accidents.

The pathos of the workmen's side of industrial accidents has been so often, so ably and so differently presented that one conceives accident prevention work as a social duty almost to the exclusion of all others. It is pictured as it were a challenge spark flung down by the high gods for white-shield crusaders to snatch, lay upon the heart, nurture and coax till the flaming torch of high-minded, self-effacing and self-sacrificing duty shines forth refulgently to the whole world. It is perhaps somewhat anomalous to look upon accident pre-

vention work from the purely humanitarian side when engaged in production of that which is as death dealing as some of the most deadly diseases. If the prime purpose of accident prevention work is the prevention of all accidents in industry the problem could easily be solved by the application of a four-word formula—"close down all industry." However, as production is necessary to our economy it might be suggested that safety is not first but production is and safety is a necessary concomitant of most efficient production.

Accident prevention work hence becomes at least in part an engineering function of production. From the standpoint of the entrepreneur the application is to the individual plant. The social viewpoint, that of general safety, is necessarily wider. It includes besides general safety, safety in the mass of industry within the confines of the society.

Accident prevention work is, or should be, physical and educative. In the physical sense is the application of protective devices and shop housekeeping. From the educative side it consists of not only the education of the workmen to an appreciation of possible and potential danger, but the education of the general mass of society to the suffering and cost of unnecessary accidents as well as training in first aid and appreciation of rehabilitatory methods to reduce disability.

The Harmfulness of Minor Accidents Is Serious

It can be emphatically stated without fear of successful contradiction that no single cause of accident may be listed without matching it with the complementary death found somewhere in the literature of industrial accidents. Perhaps too much importance has been placed upon the harmlessness of accidents resulting from certain specified causes. Herein enters the problem of infections. No matter how innocuous the agency, no matter how seemingly trivial the wound each and every accident is a potential death bringer. Indeed, about one-eighth of lost time accidents and one-quarter the compensation cost is caused by infection, either concurrent or subsequent, where but for the infection the agency causing the wound is comparatively harmless.

The loss to plant morale and production organization which is the direct end of every lost time accident, is perhaps more serious than the cost of compensation, although the latter is a heavy charge on industry. The removal of a hazard is a potential saving, the prevention of an accident a direct one. The minimizing of costs in reduction of lost time, confusing to organization and resultant in compensation costs, is equally saving. Prevention of infection, efficient first aid, early convalescence, reduction of disability and speedy return to employment are equally as valuable as accident prevention and for the same reasons. Concentration on accident prevention alone is conservation, but in industry as elsewhere with conservation runs its twin-brother reclamation. The scrap heap of industry is combed for reclaimable materials but the waste piles of humanity are not even turned over.

The advances made in accident prevention by individual plants is most heartening but accident frequencies are not being decreased in the main, at least as far as Ontario is concerned. Compensable accident frequency for 1917 was 6.57 each 100 full time worker; for 1923 it was 6.58; for 1924, 6.68; for 1922 it was 6.40, and for 1925, 6.50. For 1920 the average time loss in temporary disability cases was 19.62 days; for 1925, 20.68 days. For 1920 in permanent disability cases it was 74.53 days and for 1925, 92.92 days. The average medical costs per case in 1920 were \$18.20; in 1925, \$20.16. This experience is not peculiar to Ontario, but is nearly if not absolutely universal. In Ontario, as elsewhere, accident prevention propaganda has gone a long way. inspection is

frequent and careful, protective devices and appliances are well known and used, and concrete rewards are held out under a merit rating system. Nevertheless accidents generally speaking are not decreasing in frequency or severity.

That this is not a hopeless condition is evidenced by mortality rates. In spite of the strides made in preventive medicine and prophylaxis mortality rates have remained practically stationary. The great reduction in deaths from typhoid fever to use one instance has been more than balanced by deaths in automobile accidents. The number of death by rabies, cholera and bubonic plague are less than the number of deaths through air craft accidents. It is as idle to deny the efficacy of preventive medicine as it is to deny the use of accident prevention work. However, the one central idea may be left that accident prevention work is not enough. The problem must be tackled from the standpoint of reducing waste and reclaiming salvage. False sentimental appeals, tumult and shouting will not cure the disease. Study and education, a general application of safety principles in a widespread way, study of the individual problems, education of the mass to appreciation of danger, training of the sub-conscious, efficient first aid, prevention of infection, reduction of disability check up of medical services, supervision of convalescence are some suggested avenues of profitable endeavor.

To outline specific ways and means is to carry coals to Newcastle and would be presumption. The central dominating thought may be left. Strip off the artifice of statistical self-glorification, look at the situation squarely in the face. Orthodox methods of safety endeavor have not produced tangible results and from the financial point of view have not paid their way. Appreciate the application to your individual plant and to the society to which you belong, but remember safety is not first—safe production is.

CHAIRMAN DUNNEBACKE: Mr. Dean, I was afraid, when you started to talk, that you would give us a lot of dry statistics, and I want to compliment you on the way you got away from them. While I do not want to encourage too much general discussion now, because we have reserved Thursday morning for discussion, I want you to know that Mr. Dean has told me he will welcome discussion of this paper.

As I look over accident and safety work, I think perhaps some of the greatest tragedies that come to us in our work come because of eye accidents. I think, really, that 80 to 90 per cent of the pleasures, happiness and joys we get out of life and, likewise, the tragedies that come to us in life, come through the sense of sight. The officers felt that a paper in this program, dealing with eye accidents and methods of prevention would be very welcome, and we are fortunate in having Mr. J. C. Campbell, of the Union Switch and Signal Company, of Swissvale, Pennsylvania, handle this subject.

Prevention of Eye Injuries

**J. C. Campbell, Safety Director, Union Switch & Signal Company,
Swissvale, Pa.**

The prevention of eye injuries is a great task to any individual or company. Thousands of eyes are being saved from injury by the scientific application of the theory of artificial lighting, developed in electrical laboratories within the last two decades. Practically the entire science of lighting has been written since the first big experimental institution of this kind was established 20 years ago. Prior to that time little was known about a properly designed lighting fixture. The improvements in lighting in the past 26 years exceed those of all ages that went before, although the beginning of modern illumination was in 1879, when Edison

gave the first practical electrical lamp to the world. Modern homes and factory lighting have done much to save eye strain and help people to preserve sight.

According to recent surveys, of the 42 million men and women employed in America, 25 million have defective eye sight, which, added to poor lighting, is causing at least 100,000 of them to lose their positions each year. Insurance statistics traced 90,000 accidents to poor light and bad eyes in the year 1924, with a loss to the worker of three million productive days. Investigators have also discovered that a poor lighting condition is as often the result of too much light as of too little—a condition made possible through an electric light of too high candlepower. The chief source of poor lighting is the use of unshaded electric globes, causing a direct glare into the eyes of the workers. Of the two million industrial accidents occurring annually, the number of eye injuries is put down as 200,000.

The eye is about the most sensitive and delicate organ of the body and yet it is probably the most abused. In educational institutions and in industrial plants every effort is being made to protect and preserve the eye sight of the public. Yet this same public, on whom the suffering will fall, is often shamefully careless. There is little excuse nowadays for poor lighting in the plant, in the schools or in the home. The fault lies with the individual, be he the manager of industry, the professor of the school, or the head of the home. The question of adequately distributed electric light is one that should be carefully gone into by all people for the benefit of all in preventing eye injuries.

Prevention of Eye Injuries by Foreign Bodies

Now regarding the prevention of injuries to the eyes by foreign bodies. In reading the report of the National Commission for the Prevention of Blindness, it states there is no such thing as a non-hazardous industry. The loss of 82 eyes in 1925 in the practically safe occupations of merchandizing, farming and textile manufacturing is further proof that serious eye accidents are likely to occur wherever men, women and children are employed. While there may be some occupations which have not to date contributed to eye accidents, yet we find with the proper combination of circumstances they could occur. There is no such thing as a non-hazardous occupation.

The Committee also found that from a national point of view, the metal manufacturing industries are a source of the greatest number of serious eye injuries. In Pennsylvania the coal mining industry ranks first as the cause of industrial blindness. In Wisconsin it was found that hand-tools constitute by far the greatest single cause of eye injuries—being responsible for 44 per cent of their total. As an example of the important part that eye injuries play in the whole problem of industrial accidents, the report cites the experience of a large ship building company in whose dispensary 38 per cent of all injuries treated were eye cases—more than 4,300 eye injuries being treated in this dispensary in one year.

In our plant at Swissvale we have realized that eyes with foreign bodies are always dangerous, as they are likely to break out in inflammation at any time. There is no more serious injury to the eye ball than that of penetration by a foreign body, and often vision is not only lost, but the eye ball must be taken out to avoid sympathetic inflammation. We learn from this that the minor eye injury may become serious. In every industrial plant there is always some workman who thinks he is skilled in removing foreign bodies from the eye and who does not, in his ignorance of the serious consequence, hesitate to pick out the imbedded particle with a match or dirty handkerchief without thinking of the danger to his fellow employee from ulcers of the eye following such treatment. We believe this practice is at about the irreducible minimum in our plant. We attribute this to ever-

lasting personal preaching; the employees seem to have realized their eyes are one of the most vital and valuable organs of the body.

Now, I am no doctor and I am not going to give you a lecture on eyes, but how are we going to stop accidents? We sometimes don't like facts. We hate to think that we are safety men and still have eye injuries occurring daily. But what are we going to do about it? Gentlemen, I am not ashamed of the Gospel of Safety. The word, gospel, you know, means "glad news." I want you to take that as my text for the rest of my talk. Industry is saving men's eyes. Managements are getting the best of lighting in their plants. Schools are thinking first of the vision of the children, GLAD NEWS!

Four years ago it was my duty to take a fellow employee to the hospital. He had been pouring metal and putting the chill back into the chill box; it flew back on to his face and eyes. He was not wearing goggles, nor did any one else in the foundry at that time. I got into the car with him and talked to him while we were driving to the hospital. After we arrived and before the doctor came he gave me the best going-over a man ever got. He blamed the company for carelessness in allowing employees to throw garbage into the chill box. In fact he had me scared, but one thing he made me do and that was to go home and think.

The Accident Was a Stimulant to Preventive Work

That man was fixed up in a couple of days and I thank him for all the success we have had in eliminating eye accidents in our plant. We have a plant employing about 3,000 and operating a forge shop of about 40 board and steam drop hammers, a foundry with 400, a machine shop of over 1,000, and a storage battery plant with over 300. At the present time, every man in our chipping room is wearing his goggles. Every moulder when he is pouring off wears his goggles and incidentally his leggings and moulding shoes, and no "maybe's" about it. Every man working on a drop hammer wears his goggles, and I tell you, gentlemen, I feel a very small individual when I stand alongside of a 6,000 pound steam hammer and see the men pounding the steel, wearing their goggles.

Here is a list of our serious accidents sent to specialists this year so far:

One man working in the shipping department cutting wood with a hatchet had a piece fly up and strike him on the eyebrow. No injury to the eye and no time lost.

One man in the assembling room came to the doctor as he was going home and stated he had gotten a foreign body in his eye. His eye being red and inflamed, the doctor sent him immediately to the specialist. It was found he was injured at home. No time lost as well as no compensation.

A man working in the die room reported to the doctor with ulcer on the cornea of the eye. Did not know where he got it. No company case.

Foreman struck on jaw with a piece of wood reported to the relief department a few days later had the eye inflamed. Sent to specialist who diagnosed his case as cold in the eye. Loss of time—3 days.

Now, how does this come about? There are no banners flying at our gates and we have had no brass bands playing. But gentlemen, here is a good idea of our success.

The wife of an inventor once said, she never dared to tell her husband that there was anything he could not do for he would never rest until he had done it. There are not many people of this kind but when you do find one he is hard at work on the impossible. He relishes the thing that can't be done. The employees have lots of fun when they see you going around asking one here, coaxing another there to wear goggles. The whole thing seems ridiculous. But doing the impossible is not always as it seems; the only thing worth working for is the satisfaction that the men wear the goggles. The safety engineer or director must be like the

farmer who in the spring anticipates that in the fall he will have a bumper crop. He spends his days and nights working in the shop planning here, encouraging there so that the seed of safety may blossom into a real plant. It is due to the constant unselfishness of the management and the safety committee, who day in and day out are working for the benefit of their fellow employees that there is finally an abundant crop of employees wearing goggles.

Sometimes we get discouraged trying to accomplish the prevention of accidents. Human nature is feeble, but the safety man who plans to save eyes must realize that "something accomplished, something done" is worth striving for. He must always be on his toes, always looking out for the most difficult employees—the old employee who does not believe in the new fangled ideas of safety and never was used to them, the fellow that knows it all, the young lad or lass who needs a helping hand. He must always be looking for the unattained. It may be like Edison trying to light our streets, or Marconi struggling to speak to us from thousands of miles away, or the Wright brothers striving to navigate the air. There must always be present a feeling urging us onward to get our fellow men to take all precautions to save their eyes and prevent blindness. The man who does that which looks impossible to others is the man who is on his toes, ready, willing to meet all emergencies and to make himself useful. His willing alertness, enthusiasm, courage and indomitable spirit fit him for the prevention of eye injuries.

Employees Fall Into Various Classes

Employees as well as all other living things can be put into different classes. Some act one way, some another. But all in accordance with their own philosophy of life. "As a man thinketh, so is he" is one of the most dependable laws of rational living. If he refuses to think or does not have the will to think, he is at the mercy of his own limitations—unless he is looked after by some friend—and this is where the safety engineer has his chance in industry for the prevention of injury. Every man is in a class of his own. Some go ahead and others are slow and do not make a very good job of coming. It is our job to make this class of employee feel that he is a part of a great organization, where all are working for the good of each other and the good of all.

I read where Roger W. Babson has investigated industrial plants and other business concerns to find out why so many men miss the mark of success in life, and it is his opinion that they do not get hold of an idea in their early years. Getting an idea is like sitting down on a chestnut burr—it should make you jump up and make you feel like doing something. Eastman got the idea that he would like pictures of where he traveled. The result—the kodak. Edison got the idea that the human voice of great speakers and singers could be heard in the homes of the people—what great joy that would bring?—and he invented the talking machine. All progress comes from ideas. Some have better ideas than others.

Now, safety engineers, you have your problems in your plant. Sit down, think, and get an idea of your own. The start of getting men to wear goggles in our foundry was made by the man whom I had taken to the hospital. Safety men, get an idea of what can be done and when you get that idea the most important thing is to hold on to it. Holding on to it is not the easiest thing in the world when you have managers, superintendents, foremen and employees not wanting to protect themselves. At times life becomes so monotonous and commonplace you almost lose your grip—and lose all. These are my personal ideas and inspiration for action.

Some men can be won by fear, for fear is an instinctive inheritance given to human nature for the protection of life. Fear and lack of courage have been man's deadly enemies. Fear is found in the life of everyone and interferes in business. There are quite a number of men in industry who can be won by fear. They are

afraid of darkness although fear is always groundless and unreasonable. This then is one way you can preach the gospel of safety. Getting the employee to choose for himself is another idea. Some men want to reason it out. Encourage them in their thoughts. The safety engineer must be a man who is willing to give all for safety. You cannot be a safety engineer unless you believe in it. You will never get results in your plant by being a lukewarm, halfhearted, go slow safety man. Benedict Arnold had it within his power to become one of America's greatest patriots and he missed the halo of a great man in American history. Why? Because he was *just almost a loyal general*. Two parts hydrogen, one part oxygen when united under the proper conditions form the water we drink. They always combine. There are no accidents in nature's laws and the safety engineer who is not fully convinced that he has the greatest job in saving human lives should get out of it for he will never stop eye accidents until he can go up to a man and tell him of his danger from the depths of his being. A real safety man will accomplish what he wants by keeping after the employee.

No Employee is Penalized or Discharged

Now I realize that a safety engineer talks a great deal about discipline. Gentlemen, we have never in our safety work asked the discharge or penalizing of our employees for not wearing goggles. There has never been an employee brought before his superintendent or foreman and been reprimanded. Discipline is a great word but men are only children grown tall. Hearts don't change much, after all. All my fellow-workmen are like myself; we are only human beings, with our faults and failings; and for the safety engineer to set himself up to be able to judge when and where an employee should be punished is not safety work. A man or woman is only the product of what they were taught in childhood. You cannot discipline a man who has had no discipline when a child. We all realize we want to do what we please. Yes, but if we teach the habit of concentration, that our bodies are only on loan to us and that our eyes are the mirrors of the soul we will get results. We don't preach discipline. We sing "author of liberty;" that is a glorious thought.

When each man realizes his success is tied up with the success of others, discipline has to be taught at the mother's knee. Safety engineers, it's your job and mine to build men, not fire them. If a man is not playing square, you are not his judge. What we want in America today is the development of our national thought toward the value of the human body. I'll tell you why so many men and women are injured in America. They spell that glorious word "liberty," L-I-C-E-N-S-E. That's what you have to watch—when a man thinks he can do what he pleases and spoil all the good that is done in the plant by the safety committees. But for a safety man to talk about discipline to me is all foolishness.

O gently scan your brother man,
And gentler sister woman,
Easy it is to go awrong,
To err is but human.

Business is a two-fold process. Something produced, then sold. The farmer grows a crop of wheat, then sells it to the grain dealer. Ford makes cars, then sells them to local agents distributed throughout the country. There are two processes, one independent of the other, advertising and salesmanship. We have our bulletin boards in our plant, but salesmanship is the most important part of selling eye protection. There are all kinds of salesmen in the world. What are you offering for sale? It is a question you must answer. Labor and capital spend the time fussing with each other, cities are destroyed and fields are devastated by war because the people of nations have the wrong ideas of human rights. Are you selling the safety idea? We need more safety men, eager to sell the idea of

fair play, good character and honesty to their fellow workers. A safety man must be honest and fair with his fellow men with them and away from them.

We find great success in our work is attained by getting the young employee lined up for safety. We make it a point to see the young fellows wear goggles and I just want to pay tribute to our young employees that they are the folks to work with. With the old veteran and the foreman who think that they know all about eye protection, it is slower going. The enthusiasm of the young folks soon tells our veterans and foremen "Get your goggles on." Lindbergh crossed the Atlantic—YOUTH! So you will get your eye accidents settled if you can get the young folks with you. They will solve the problem of wearing goggles in any plant.

We use only the posters supplied to us by the National Safety Council in our plant.

The safety man who is planning for success in preventing eye accidents and all other kinds of accidents must be just as enthusiastic about the success of his young employees as of his old. Successful safety men are always interested in the achievements inside and outside the plant of young employees.

In closing, why do we try? Have you ever put that question to yourself? You will be helped if you do. You will find out a lot of things about yourself that you never have thought of before. You know, a mule pulls the plow because he is hitched to it. People, like the mule, wear goggles because they are afraid of the boss. There are more ways of making a person wear goggles than I have mentioned. It is not always the person that drives another to do something that accomplishes his object. There are people like you who try for reasons quite different than that of the mule. Their drive is on the inside where no one can see. They alone know that it is there. They themselves cannot see it with the eyes that they use in looking at flowers and reading books.

Most Men Are Willing to Display Reasonable Faith

I call it faith. It makes no difference by what name it is called. It is always the same and it causes people to try. Suppose you have never seen Niagara Falls. How then, do you know there is such a place? You never saw George Washington. How do you know there ever was such an individual who led the army at Valley Forge? You say you are certain because you have been told by friends and read it in your histories. The thing that we call faith which makes you try to reach out for the unattained is nothing more or less than your own conviction that you will be successful in preventing eye accidents. Faith in our fellow employees acts like radium—radiates many different wave lengths of force. It gives us our ideas, ambition, the spirit of courage, self sacrifice and a glorious outlook that something better is just ahead. We have our electric lights and victrolas because of the faith of Edison. We would not be flying if it were not for the faith of the Wright brothers. It is because of hope and faith we are meeting today in this room, and because of it we will go back encouraged to our plant and work harder for prevention of all accidents.

Hold steadfast in your faith in God and in your fellow-man. A man is lost when he loses his faith. I have read that a circle is the emblem of eternity. When Fawcett ran for the nomination as Mayor of New York, he took off his coat—the place being warm—and the people were insulted. He lost the nomination. When Premier Baldwin was in Montreal lately he took off his coat and made quite a hit with the people. Gentlemen, if the circle is the emblem of eternity, let us all take off our coats when we get back to our plants, and get all our employees into the circle—that circle which you and I are working for when there will be every man working for his brother's good. The circle of love, truth and fellowship. That is my idea of how industrial plants will get their employees to take care of their

bodies and prevent accidents. My philosophy may not suit you, but it works in our plant where we are all working for the best that is yet to be.

CHAIRMAN DUNNEBACKE: Mr. Campbell, that was certainly very fine, and I wish every one of the fellows in this room, including myself, could feel as happy and content as you are about conditions back home. You are certainly to be congratulated on your record of this year.

This question of prevention of eye injuries is too serious not to be discussed. I think you will agree with me that Mr. Campbell is a better talker than reader, and if any of you have any questions, you will find him only too willing to answer your questions.

MR. FOUAGY (Willys Motor Company): Mr. Campbell remarked that all the hammer operators in his drop forge department wear goggles, notwithstanding the fact that they sweat a great deal and, perhaps, have a great deal of difficulty wearing them. I would like to have him tell us how he is successful in getting these hammer men to wear goggles under the condition they have to work.

Essential to Have Personal Interest in the Worker

MR. CAMPBELL: Gentlemen, it is like everything else, you have to have a personal interest in the workers. I know every worker in the Union Switch and Signal Company, and there are seven or eight hundred.

In the forge shop, when they are working with the drop hammer, I have a little band to put across their foreheads, and that stops the sweat from coming down. Then, we put a little soap on the goggles, and between the heats, they dry these goggles off and have a couple of head-bands they put beside the furnace, which they use each time. That is how they wear the goggles in the forge shop, a little band across the forehead under the hat will stop the sweat from going into the glasses. Then, too, they have the habit, and they know that the eyes are the most valuable things they have. I have not had an eye accident in the forge shop this year.

CHAIRMAN DUNNEBACKE: The question of sweat has bothered all of us. Somebody else may have something different, to get away from that sweating condition, and we would be glad to hear of anything specific which you have tried and found useful.

MR. NEWCOMB (Tichenor Corporation, Cortlandt, N. Y.): I would like to ask Mr. Campbell if he fits each man's eyes with a prescription lens?

MR. CAMPBELL: No, sir; we do not fit anybody. Our company has the frames. If a man's vision is poor and he cannot work in the forge shop, we give him a set of frames, send him down to a physician, he makes a prescription out and the man pays for his own prescription. We do not supply an individual with glasses, that is, a prescription lens.

MR. NEWCOMB: One other thing, you spoke of spectacles: Do you furnish ordinary protective spectacles, without the side screen, in some cases?

MR. CAMPBELL: Yes, I use all these without the rim or side on shapers. I have a big glass, big spectacle, that I ask every man to wear on a shaper, in the tool room and every department.

CHAIRMAN DUNNEBACKE: In that connection with prescription lens, while I do not want to do any advertising, I noticed in the exhibit, yesterday, a new goggle which takes care of prescription lenses. Any of you interested, might stop at that booth and look at it.

MR. THALMER (Buick Motor Company): I was very much interested in what Mr. Campbell had to say regarding discipline. I would like to have Mr. Campbell tell us how he handles a man who refuses to wear goggles on any job.

MR. CAMPBELL: Gentlemen, we are not bothered with that now.

CHAIRMAN DUNNEBACKE: What did you do with them when you had them?

MR. CAMPBELL: As I said, keep eternally after them. I do not believe in running to the boss. I think the great success in my work is that I visit the hospital and visit the sick, and I get in touch with the family and, in that way, you get to know the family condition, and the man knows you are interested.

I had difficulty at the start, when the men did not want to wear goggles, but if you get an injury, let them all know about it. Take that fellow in the foundry, four years ago, he got an injury to his eye and we had to take him to the hospital. When he came back, we made a great advertisement of it. The fellow went around and told how he had to go to the hospital, and they got the goggles on and everybody was tickled to death, because they did not want the same injury as the other fellow got. Every man wears goggles and I have no trouble with them.

Just keep after them and give them a pat on the back. As I said, it seems ridiculous to start to tell men to wear goggles; you have to coax one here and encourage one there, and you have to tell them that blindness is a terrible thing. That is what I meant when I said "Fear"; if a man is afraid, you can talk fear.

I find in my work that the Italian is a fatalist, and he is the only man I have to watch, but I have them so they wear their goggles, although they don't understand why they wear them, sometimes. They have just got the habit now; come down, and you will see every man wearing goggles.

MR. THALNER: This man might not have been injured in the foundry, if a little discipline had been put into effect. Why let that man work until he loses an eye and then use that as publicity to put your goggle rule into effect?

Effect of the Accident Was Far Reaching

MR. CAMPBELL: I said, four years ago. There was a piece of orange in the chill box. The hot metal flew up and struck him in the face. Why discipline that man? He could not help that, he was the one who suffered. What we want to do is clear our chill box and get new ones and take care of the chill boxes. When they saw that injury to that man, and we bought the goggles, everybody wore them because they did not want the same thing. The discipline was to see that the chill box was kept clean; that is where the discipline was necessary, not for the man who was hurt.

MR. THALNER: There is an element of discipline enters into the problem some place, in having men wear goggles.

MR. CAMPBELL: It may be as you say. In my work, I do not look for discipline, that is not my job; my job is to encourage men to wear goggles and start them when they come in the gate. There is no use giving a man a job and then, seven or eight weeks later, bringing the goggles to him.

The great success in the Union Switch and Signal is in the young people. I have about 600 boys and girls, from the age of 16 up to 21, and everyone of these young folks is starting to wear their goggles. You know, as the years go around, we have a better standard of people wearing goggles.

It is a great question, Mr. Thalner. I am not orthodox in my way of getting the men to wear goggles. I do not believe in discipline. I never go to a foreman. If a man starts to "skin" on me, I go to him, myself, and have a talk with him. I keep it to myself, in a good humor. I never let them get away with murder, but they can give me all the stories they want about the Scotch.

That is my record there, this year, 11 lost days and there were 3 of them we did not need to count. All we did was to keep eternally after them.

CHAIRMAN DUNNEBACKE: I heard a good one last week. A fellow in Detroit gets results in this way: He got the wife of one of the workmen to go through the plant, and, in the last three or four weeks, he has had six or seven wives, of

workmen wanting to go through. Take the wives to the first aid room and show them the goggle, and when the workman gets home, he gets it from his wife.

G. A. KUECHENMEISTER (Dominion Forge and Stamping Company): When he takes the women through, does he put goggles on them?

CHAIRMAN DUNNEBACKE: Yes, every person, regardless of who it is, the minute they pass the office door, puts on a pair of goggles. Has anyone else a question?

MR. BURNS (Reo Motor Car Company): I would like to ask, if an employee wears glasses and puts them inside the goggles, how do you prevent fogging?

MR. CAMPBELL: There is a special goggle you can get to fit over the glasses.

MR. BURNS: It does not give them the vision.

MR. CAMPBELL: He can put his own lens inside the goggle.

MR. BURNS: We tried putting the glasses inside the goggles, but had trouble with a substance leaking down on the lens. How do you get away from that?

MR. CAMPBELL: To what substance do you refer?

MR. BURNS: I don't know. In the heat treating department. We don't furnish glasses now, we send the men uptown, where they are charged one dollar and seventy-five cents, and two dollars and twenty-five cents, for bi-focal lens, to set into the goggle.

Problem of the Fogging of Goggles

MR. CAMPBELL: Do you have a medical examination of your men?

MR. BURNS: The optician does.

MR. CAMPBELL: When you hire a man, do you give a medical examination?

MR. BURNS: We do not.

MR. CAMPBELL: We do, and if they are not fit to work in the forge shop, we do not put them there. It is all right to put one man on a grinder and give him goggles, but you cannot put a man with a fourteen-sixteen vision in the forge shop.

MR. BURNS: You have that all through your shop?

MR. CAMPBELL: The men who wear spectacles have that other goggle that fits the lens. I have had no trouble.

CHAIRMAN DUNNEBACKE: How many have a condition more or less similar to Mr. Burns', fogging between the two lenses?

MR. CAMPBELL: You must have heat there.

MR. MILLER (Chevrolet Motor Company): I believe, by analyzing your welding goggle and comparing it with the regular goggle with a lens set in, you will find the way to get away from your fogging. In a welding goggle, as you know, with the protective lens, you put a washer, fiber washer or something of that nature, which separates the two lenses; there is an air chamber and you get away from any fogging between the lens. The same thing should be true with the clear vision lens, with the protective lens on top.

GEORGE S. THOMPSON (Detroit Insurance Agency): It seems to me that we often, in our goggle problem, deviate entirely from basic principles. Now, there is a reason why you obtain a film between a slip-on goggle and a pair of glasses. I know that, because I wear glasses, and if I put on a pair of goggles and go down into a heat treating plant or forge shop or some place that is warm, it is only a matter of time before I get a film in between there. But why allow the film to remain there? Why not drill a couple of holes in the top and bottom and let the air take it out? That is merely a basic principle.

You would not expect a chimney to draw, if you put a board on top of it, because the smoke would come out through the house, and you can create a ventilation through your goggles as easily as you can by taking the board off the chimney and letting the smoke go out. It got in there, and it got in through the perforation, and if you want to let it out, make the perforation large enough to allow a circulation of air to pass through the two glasses, and I do not think you will have any trouble.

MR. BURNS: The goggles are already vented. If you put too many vents, you are going to have small particles flying from the lathe coming in. It would not keep them from fogging, because they are already ventilated. They would not fog if you remove the lens, but then you have your eye uncovered.

MR. THOMPSON: I do not think the gentleman gets my idea perfectly, because of the fact that the ventilation of the goggle is on the side, and you will find little ventilation on top and bottom. Heat rises and so does smoke, and if you want to get it out, you are going to get it out from the top, and the amount of perforations you have to put in there, are so small and so few that you will not get any chips in, and you will not get any weakening of the lens.

CHAIRMAN DUNNEBACKE: Gentlemen, I am going to close the discussion now, but this is the spirit I want to develop in these meetings. The program is pretty heavy this morning, and I do not want to have too much discussion, but, tomorrow, I want as much of this spirit as possible. If we come here and get into discussion, we are going to get some good out of these meetings.

We are told in our safety meetings that we can only prevent 10 per cent of our mechanical accidents through mechanical guards and the balance have to be prevented through education. If that is true, it means we have to spend 80 or 90 per cent of our energy on educational lines, and I do not know of any more powerful factor than the use of employee publications. Companies are more and more interested in house journals, and I think one of the biggest weaknesses in America, in safety, today, is that these house journals are not being used as they should, for the elimination of accidents.

There is, however, one company that has made an outstanding success of it, that is the Buick Motor Company. They have done some wonderful work through their house journal in eliminating accidents, and we are fortunate in having, this morning, Mr. Forrest W. Boswell, who is chairman of the Plant Publication Section. He has left his section to give us his paper.

The Employees' Publication in Accident Prevention

Forrest W. Boswell, Director, Personal Service Department, Buick Motor Company, Flint, Mich.

The employees' publication is recognized more and more as a potential factor in accident prevention. Editors of employee publications who have failed in this regard are missing a great opportunity. The same also can be said with reference to safety engineers who have access to employee publications and have neglected to use them.

It is not my purpose to make a long dissertation upon this subject. I expect to let a few pictures tell the story more effectively and conclusively than mere words.

The value of the printed word and illustration is recognized today more than ever before in the history of the world. A very common expression which is heard today as we meet folks in one place or another is—"I see by the paper"—that this thing or that thing has happened. There is a certain amount of weight attached to what appears in print, especially the daily newspapers and particularly so if the story is illustrated.

The employee publications are the newspapers in industry. Sometimes I am led to conclude that the copy which appears in employees' publications carries more weight than that in the daily newspapers. My reason for such a deduction is due to the fact that the men of the shop know the personnel of the employees' publication. They are about as close to the personnel as members in the same family. It is in reality a big family. Consequently the

publication is known as "The Family Paper." We have formed the habit of referring to the employees of the Buick Motor Company as "The Big Buick Family" and of our employees' publication, the Buick News, as our "Family Paper." This makes for closer intimacy and consequently greater confidence on the part of all concerned.

Hence, stories and illustrations whether they be on the subject of accident prevention or otherwise, are accepted for their face value and the opportunity of driving home a real message is of incalculable worth.

Any stories or illustrations that are used in accident prevention must be prepared from the standpoint of news if they are to be of any particular value.

Buick Radiator Shells to Carry Safety Messages Into the Plant

Plain Bulletin Boards Replaced by Newer
and More Attractive Ones

By R. F. Thayer

AMONG the many types of automobiles being sold today to the public, there is not one that is built with more consideration for safety than the Buick, which is being built in this shop. Every precaution has been taken, by the Buick engineering department, to make motoring in our product as safe as it can possibly be made. Four-wheel brakes give the driver a feeling of security that comes from knowing that when the occasion requires he can make an unusually quick stop; and the strong, sturdy construction of the car throughout, together with the added advantage of controllable headlights, makes riding both safe and comfortable.

Not only is safety embodied in the operation of the car but it is also practiced in the manufacture of this product. Mechanical hazards are being done away with and an

(Continued on page four)

Clever type of home-made bulletin board.

Frank Crane, in his syndicated material in the public press, said that news means something remarkable or something that attracts attention. He says a story in the newspaper—that a dog bites a man—is no news, but if a man bites a dog, that is news. This illustration, of course, refers to the curiosities of news stories. Great care must be exercised to avoid the prosaic and the platitudinous. As much thought and care must be given to the dress-up of the article as to the subject matter itself.

The term "Safety First" has lost much of its real significance because it has become so commonplace. The same is true of the word "Health." The medical profession has recognized this and are therefore resorting to other terms to attract the reader to matters of interest regarding his health. They couch it under such terms as diet, hygiene, what to eat, the value of play, exercise, et cetera, et cetera. The editors and safety engineers must be as adroit and clever in employing the proper captions as are the moulders of thought and opinion in the American Medical Association.

It is generally conceded that by far the great majority of accidents are pre-

Buick Makes Perfect Score in 10-Day Run Over Western Road

The Buick was the only car of its class to set a perfect score in the 10 Day Road test endurance and economy run which was finished recently. This run which attracted national attention was open to all owners of Buick, Oldsmobile, and Pontiac, and Buick's outstanding record was achieved in the important factor made the start.

This run was conducted under the auspices and rules of the American Automobile Association.

(Continued on page 25)

Praising the factory with a good record.

ventable, which means an involvement of the human element. It is therefore a natural inference that if the right approach and appeal is made to the minds of the workers, there will be a reduction in the number of accidents. Educating the worker to work and think safely is the biggest job of the safety engineer. The employees' publication should and can be the most valuable aid in this educational propaganda. At least, these are the conclusions which we have reached at the Buick Motor Company, and I am going to present to you some pictures in support of our contentions. Some of these I will dwell upon more than others.

My first picture shows the new form we use in displaying the posters of the National Safety Council. We use the radiator shell of the car—some are a little

Chart Showing Accident Causes

A chart that every man can understand.

old or may be a little imperfect—and we have four or more of those placed throughout the shop. In this connection, you will notice that R. F. Thalner is the editor, particularly of these safety stories, and he is a member of our staff. Right here, I would like to impress that every industrial concern, whether you are industrial or what not, if you have an employees' section, make your safety engineer a member of your staff. I want to say very frankly that, when Mr. Thalner started out, he was far more crude than he is now after a few years in editing articles along this line, and that is something that you can well afford to do, in your program of accident prevention.

The next picture shows that Factory No. 4—which is a wood-working factory, with all the machinery that naturally would be placed in such a factory—worked an entire month for the third time in a half year, without a single lost time accident.

Negative—yes, but it gets across the message.

The next picture is a chart. Our first speaker spoke about hand labor, hand tools and so forth. I think he said 43 per cent; we showed 46.7 per cent, and all around, as you cut pieces in a pie, you can see the number of accidents on other jobs. I will not take more time on this picture. The safety experience of the past month shows need of all-round improvement.

The next picture is one of a negative type. Perhaps there are very few here who would understand it. We all know that a full hand beats three of a kind or two pair, and so, in the story, it will show the man the importance of keeping his full hand rather than trying to work with two or three fingers.

The next picture really speaks for itself, and I understand that you, in your section, have been giving a great deal of stress to the importance of the strength of chains and so on. One of our inspectors saw a chain piled up and his eye accidentally happened to see those two links as they were exposed, badly worn, and immediately the thing was repaired.

The next picture makes us think of the talk you heard on the importance of wearing goggles. In the story, of course, we call attention to the importance of having two good eyes rather than one good eye and one glass eye. The glass eye may look good, but a man cannot see with it. This picture illustrates how six eyes were saved

Chain Inspection in Fact. 31 Reveals Weak Links and Prevents Accident

*Precaution Prevents Two Mishaps of
Serious Nature in Plant in Few Weeks*

By R. F. Thaler

The August 7 issue of Buick News carried an article regarding a chain which was found in defective condition in Factory 28. Due to the alertness of the man who was going to use that chain a discovery was made showing that this chain had been filed or worn. Last week in Factory 31 a similar incident took place. One of the foremen went into the tool crib to get a chain to hoist a fly-wheel which weighed approximately three or four hundred pounds. In an endeavor to make sure that the chain would carry the

LINKS OF CHAIN ALMOST SEVERED
Four-fifths of actual size.

Any man can recognize the dangerous point.

as the result of wearing goggles. A lens in each pair has been fractured because of some article flying against the lens, shattering it, and yet, at the same time, protecting the vision of the man.

We have another picture where a man was supposed to wear his goggles, but, like some folks, had them misplaced, had them up on his hat. He did not lose his eye, but he came so near it, because of severe burns from a lead bath, that he was taught a life-long lesson. He had to wear a bandage on his eyes for some time. Of course, publishing this, broadcasting it through the shop, teaches a very effective lesson to all the other men.

The next picture is a full two page spread of safe die construction, excepting down in the center we have some tongs displayed. I wish to say, in this connection, that in every instance where we have had dies changed, sometimes inverted, it has always resulted in increased production and greater safety to the operators concerned. It seems to me that is a very vital factor that everyone should bear in mind.

Showing the goggles that saved workmen's eyes.

We have made a number of studies to determine whether these messages and illustrations have put across the thought in mind. In other words, whether they have produced results. We have quizzed foremen, superintendents and the workmen, and the consensus of opinion is that men have been taught to work and think more safely because of our campaign in using stories and illustrations through the medium of the employees' publication, the Buick News.

Before closing, will refer to a test which we made to determine what disposition the employees made of our publication. We had certain persons stationed at the various distributing centers throughout the entire factory. One of these stations was occupied by myself. Everyone was instructed to be on the lookout for two things—

First—What the men did with the papers when they received them.

Second—Whether there were any who refused to accept the papers.

Type of page display that teaches its lesson.

A meeting was held afterwards of all concerned and reports showed that practically every man folded his paper and put it in his pocket, and in some instances in his dinner pail. There were no papers refused by employees.

Another step in this study was to observe what occurred on street cars and busses as the employees were on their way home on the evening of distribution. In practically every instance, every employee aboard these vehicles was perusing intently his copy of the Buick News.

We never find them thrown away on the floor of the shops or along the streets traversed by the men on their way home.

We have, therefore, concluded, and we believe with good evidence, that the great majority of the papers find their way into the homes of the workmen, which serve as an effective impetus in accident prevention because the wife and mother sees and reads what is happening at the shop and intuitively and instinctively admonishes husband or son to think, act and work safely.

CHAIRMAN DUNNEBACKE: We have just five minutes left, before twelve o'clock, so if anybody has any particular question on plant publications, let us have it now, before we adjourn.

MR. MILLER (Chevrolet Motor Company): I do not want to ask a question, but

I want to verify something Mr. Boswell said in his talk, and I will revert back to the Michigan State Conference, a short time ago, and a remark made to Mr. Thamer. I asked him why he did not put me on the mailing list for *The Buick News*. A few days after that, I got a copy and in it was a write-up about selling to the man the idea of safety, and pointing out a picture of a man who had nearly lost his eye, showing a pair of goggles shattered. I took the privilege of clipping that and showing it on a homemade bulletin in our factory.

A few days after that one of our men came into my office with a pair of goggles and said, "If it had not been for that bulletin you had out there, I would have lost my eye. When I saw that, I got a pair of goggles and, this morning, the head of a rivet blew off and hit me in the eye." I think *The Buick News* has helped the Chevrolet Motor Company.

CHAIRMAN DUNNEBACKE: I want to thank you for your attention, and I want to ask you all to come back tomorrow. We have not as long a program, so there will be much more time for discussion.

ADJOURNMENT.

Wednesday, September 28, 1927

The second session of the Automotive Section was called to order at nine-forty-five o'clock, by the chairman, A. F. Dunnebacke, safety director, General Motors Corporation, Detroit, Michigan.

CHAIRMAN DUNNEBAKE: Gentlemen, the first order on the program, this morning, is supposed to be the report of the Nominating Committee, but I guess they are having some battle, selecting a good slate for us, and I do not see that the chairman of the Nominating Committee has come in.

The officers, in arranging the program for this year, saw fit to build a program around the human body. In other words, we divided the body into three or four principal parts and assigned subjects to men who would discuss those parts of the body; how frequently they were being injured, how serious the injuries were, and then, knowing what was causing the accidents, to prescribe the proper methods of eliminating them.

The first paper this morning was assigned to Mr. George W. Starling, of the Harrison Radiator Corporation, Lockport, New York, but Mr. Starling, unfortunately, could not be here, and our friend, Mr. L. E. Averill, who is safety director of the Packard Motor Company, of Detroit, consented to take the subject and handle it for us. Mr. Averill has, perhaps, had the longest experience in safety work of any man I know of; he has been in several units of the General Motors Corporation, he is handling a plant employing 12,000 people, and is chairman of the Engineering Section of the Detroit Industrial Safety Council.

Hand and Arm Injuries

George W. Starling, Harrison Radiator Corporation, Lockport, N. Y.

In going over our accident experience, both minor and major, for the past eighteen months, we find that 69 out of every 100 cases reported to the hospital was a hand or arm injury; 60.2 per cent being hand cases and 9.03 per cent arm cases; and 43.31 per cent of all lost time accidents was a hand or arm case; 37.16 per cent being hand cases and 6.15 per cent arm; 21.34 per cent of the severity was caused by a hand or arm case; 19.04 per cent hand and 2.3 per cent arm.

I think this is one of the most important subjects in accident prevention work, and one that can be greatly eliminated from an engineering standpoint in seeing that your machines are properly tooled, and that your material is easily conveyed to the machine. I am sure that this subject should be given more earnest thought than is the case by most of us. These injuries result primarily from two causes: handling material, and machine operation. I think that you will realize the importance of this in the above figures. Hand and arm injuries are more frequent, due to the fact that the hands and arms are more frequently in the danger zone than any other part of the body.

Punch Press

Picture a punch press operator turning out 300 pieces per hour, 2,500 pieces per day. His hand and fingers enter the danger zone at the point of operation

5,000 times a day or 1,500,000 times per year, in placing and taking out the stock, if he is not using pinchers or a slide feed. In taking our punch press division's experience for the past eighteen months we find that: 86.27 per cent of their cases were hands or arms; 72.93 per cent being hands, and 13.34 per cent being arms. In making a comparison of the first eight months of 1926 with the first eight months of this year, you will note a decided reduction in hand and arm injuries both in frequency and severity. Two hundred and ninety-four in the first eight months of 1926, as compared with 162 in the first eight months of 1927.

In the first eight months of 1926 we had 11 lost time accidents in this division, against five in the first eight months of this year. This was due to the following: Cooperation in designing dies that were safe; installing slide feeds wherever possible, and on the old dies cutting out the upper or lower die where the fingers entered the danger zone; changing the layout of the presses, putting the small presses in a line and tilting them at an angle so the pieces drop into a chute and slide into the container. In case we do not have a slide feed on the die, operators use either a pick, tweezers, or pliers.

Milling Machine

There are several ways to help reduce hand and arm accidents. Take an Ingersoll Mill where you are facing cylinder heads or crank cases and see that your cutters are properly guarded. We have had some bad cuts on the hands and arms on these operations, due to two reasons: First, table of the machine was set to stop when the pieces were too close to the cutters; second, when the operator was loosening up the clamps his hand would hit the cutter, or the wrench he was using slipped and cut his hand against the cutter. We have installed in all of these departments conveyors to carry the stock from one machine to another, and at each machine we have a hoist to lift the stock from the conveyor to the machine or reverse.

Fly-Wheel

Our fly-wheel department is handled in practically the same way as in our crank case and cylinder block department, with the conveyors and hoists allowing one operator to run a battery of four machines.

In our crankshaft department we bring the shafts in trucks which are constructed to set the stock on end. They start in at one end of the route and are taken from the trucks or racks and placed in the machine with the block and tackle and removed the same way. As these trucks become full they are moved to the next machine.

Drill Presses

On our multiple drills we have different kinds of guards. If it is a spot-facing job, we have a guard running around the lower parts of the drills, leaving a clearance of one-half to three-quarters of an inch from the ends of the drills. On others we have a guard on the same principle, except they have hinges working along the same lines of the hinges in some elevator gates. These guards are placed on drill press operations where we have the ends of the drills completely covered, and the ends of the drills penetrate several inches or through the stock. On the others we have an automatic shut-off which, when the drills are raised to a certain point, automatically shuts off your machine. When lowering your drills to the point of operation, your power is automatically turned on. Since installing this device on these machines we have not had an operator's sleeve caught in one of these revolving drills.

Since installing this device, we have not had a hand or arm accident on these multiple presses. We had several of them before, but we have entirely eliminated that by putting those guards on; they are very simple, they are easy to construct and easily operated.

On some of the other machines, we have an automatic shut-off, so that whenever you raise your drills out of the stock, your drill presses automatically shut off; and when you bring it down to a certain point, your drills automatically start, and that has eliminated a lot of bad accidents.

Shaper

We have been experimenting for some time to design a shaper guard that is practical, and at last we are sure we have succeeded. This guard actually works; the operators really like it; it is simple in its construction. I have some still photographs and also a motion picture of the same in operation, which will be shown in the Woodworking Section. Also there are some very good planer and saw guards on the market which can be installed on these machines.

Bear in mind that we do not allow any of our operators to use canvas gloves around any revolving machinery.

Handling Sheet Metal

In the departments handling sheet metal of all descriptions our employees use both the reinforced leather glove and wristlets. Some of our wristlets are leather reinforced, while others we make up of heavy canvas. These wristlets reach from the hand to above the elbow. In some instances where the backs of the hands are not in danger of becoming injured we use the reinforced hand pads.

In the foundry we equip our men who are pouring metal with fireproof canvas gloves, leather faced, with tight wristlets.

In checking over a report received from the Michigan Department of Labor and Industry, covering their compensable accidents in Michigan industries from July 1, 1924, to June 30, 1926, I find the following facts which I think will be of interest:

Injuries resulting from pulleys, chains, cogs, etc., comprised about 1½ per cent of all the accidents reported.

Injuries sustained by carrying or moving heavy, sharp or rough objects, coming under the classification of "Handling Objects" comprised about 25 per cent of the total accidents occurring.

It would appear from the above information, that the matter of guarding belts and pulleys has either been so well taken care of that such accidents are extremely rare, or else these injuries are not particularly common, even though most factories do not completely guard their machinery, as you and I know. I think the latter conclusion is probably closer to the truth.

I also notice that 45 per cent of the injuries occur to the fingers, hands, shoulder, arms and wrists.

I do not believe in having anyone around molten metal using a gauntlet glove or glove loosely fitting around the wrist, because the metal is liable to splash or explode and come down on the inside of the glove.

In our punch press division, before I went there, they were having lost fingers, one, two and three a week, sometimes, and on our small punch presses, we have lost the tip end of only one finger in sixteen months. We have had three fingers lost in our stamping division in the last sixteen months, due to two freak accidents, one of which might be interesting or of benefit to you.

In one of our toggle presses, we have electric motors for lowering or raising the

head, so that when you let your outside die come down on your stock, it is controlled by these two electric motors. In the old type of electric machines, they had holes and used to run them down on a bar. On the side of this press, we had our control buttons, one for raising and one for lowering, and one for the emergency stop.

While we were changing a big die in one of these presses last fall, one of the men reached around the corner of the machine and put his thumb on the button that releases or lowers the head of this press. With the noise in the room, no one heard this motor running, and it takes about six or seven minutes to run this twenty inches down out of the head. One of our men had crawled in under this press and was doing some work in there and just got out, while another one of our boys, helping him, took a one inch eye beam, and, as he shoved it in, the head of the machine dropped down and took three fingers, less than a minute after the man had been under that press.

It was very easy, after this accident happened, to eliminate this hazard. We just went to work and reversed the button, so that as long as you hold your finger or thumb on the button, your motors will raise or lower the head of your machine. If you take the finger off, it automatically stops. That was a simple device, it took about four hours to change all our presses in there, and we have never had any trouble since then.

Education

I think one of the most important phases of our safety work is educating our employees; making the men on the job safety-conscious is the greatest phase of accident prevention. A guard is useless unless the workman is sold on the idea of using it. There are several ways of accomplishing this; by the use of posters, and by posters I mean of a type which will catch the eye of the employee, and be interesting enough whereby he will stop and read and absorb its contents; another way is by using pamphlets with good suggestions covering the hazardous points of the different kinds of operations; but I think the greatest of all is periodical talks in the departments where you are having the most trouble. It is a recognized fact that the foreman on the job must be thoroughly sold on safety, giving constant supervision and cautioning his men to practice safety at all times. The saying, "The best safety device lies above a man's ears," is the truest axiom in safety work. There is another important item which we are apt to overlook: The help we can give each other in exchanging ideas, particularly on new safety devices and safety kinks which we have worked out and proved successful in our own work.

For illustration, a little over a year ago, just before the National Safety Congress in Detroit, we put on a 90-day campaign, and we took the worst departments that we had. By that, I mean, the departments having the most accidents. You would be surprised, as I was, that but one of those departments had a lost time accident during 30 days, after we got into these departments and gave these men and girls a talk. This shows that if you get the confidence of your employees, they are surely willing to listen, if you can show them that you are working to their interest.

In other departments throughout the plant, we have had a great reduction in our hand accidents in the last year, practically the same as in our stamping division, but I just took that as an illustration.

There are so many things that I would like to bring out, because I feel I am talking to a bunch of men who know as much or more about it than I do. We have our own problems. There is one thing I would like to bring to your mind, that I think would be of great help to us. We do not exchange our ideas as we should. We do not give the other fellow the benefit of our experience in accident

prevention work, where we have had some difficult problems and have taken the kinks out of them. If we would only give the other fellow our experience, if we would only exchange ideas with each other, especially when we get some good guard up, would spread the news around to the other fellow we could be a big help in solving the accidents in each plant.

I know I never feel any better in my life than when some fellow calls up and says, "Say, we have something good over here." I always appreciate a fellow who has a bad accident in his plant and who calls me up and says, "We had an accident happen over in such-and-such a department today, in such-and-such a way, and our man lost a hand or arm, and I am just going to tip you off so you can prevent your own employees from becoming injured the same way."

A Peculiar Accident on a Cincinnati Mill

CHAIRMAN DUNNEBACKE: I think you will remember that Mr. Averill stated that between 60 and 70 per cent of their accidents were hand and arm accidents. Personally, I am analyzing the experience of a corporation that is employing over 100,000 men every month; and every quarter of the year I analyze our accidents, setting up about 20 causes of accidents, and it has been my experience, in the corporation that I represent, that about 30 per cent of our severity is accounted for in press accidents. So, you see, if we will get after the hand and arm injuries, I think we will do a great deal to lower the severity and frequency of our accidents.

Now, the chief value of a paper like this lies in its discussion, and I know Mr. Averill will be glad to answer any questions. I am not very keen for long, written papers, or talks, but I am very keen for everybody, in an assembly like this, to get up and contribute something to the subject matter. We came down here to find out something to enlarge our safety experience and to get something that we can take back home with us. I do not think there is a man here who has not something he would like to know more about. This is the place to open up and get your information.

MR. MILLER (Chevrolet-Motor Company): I haven't a question I want to ask, but I do want to call attention to an accident that occurred in our plant this month, and when I left the plant day before yesterday it was the only lost time accident we have had so far. It comes right along the line of accidents that can be eliminated, and we thought we had the cause eliminated sometime ago.

It was on a Cincinnati rigid mill, milling a key-way in a rear axle shaft. We had some accidents, through the fellows getting their hands between the water supply feeding over the cutters on to the point of contact, and, as a consequence, we took the water pipe and moved it up, so there was about three-quarters of an inch clearance between that and the cutter, figuring the fellows had brains enough to keep their fingers out of there.

In this particular accident, due to the slow flow of the water or something, the chips coming up and the water being practically shut off, this man put his hand in to close one side of the pipe, hoping the pressure would bring it out on the other side, with the result he had two fingers amputated.

In analyzing, we found that, by increasing pressures, we would not have any clogging up in the water supply; and by taking the water pump pulley off and increasing the size three times, we increased the pressure of the water coming through the pump to the source, between three and three and a half times over; some did away entirely with the cause of clogging, and there is now no reason for anybody putting his hand in there. You can't guard that point, but there is a condition that you will run into on a milling machine the same way.

Another thing, Mr. Dunnebacke spoke about the majority of accidents coming out of the punch press division. A few years ago, we found the value of meetings,

and last year, the latter part of the year, we went into the punch press division. I want to say, my management has not been so much in favor of letting the men off to hold departmental meetings, and I tried to prove to them it would be of value to hold these "pep" meetings. We went into the punch press division, and for six months we did not have a lost time accident. By meeting down there and peppering the fellows up and telling the story, we went through six months without a lost time accident. Then we discontinued it for four months to see what the accidents were, and butchery began again; so, a little more than five months ago, we started our meetings there. We hold these meetings twice a month, at which time somebody talks to the men; and we have now gone five months without a lost time accident in the punch press division.

CHAIRMAN DUNNEBACKE: Those of you who saw the new film produced by the National Safety Council know that the story hinges around the fact that the man was injured because he left the guard off. In my experience, I find that a lot of injuries to arms are due to the fact that the guards are taken out. Recently, we had a death; one of our engineers lost his life because the guards were taken off a set of gears. I think the question of guards and their removal and not replacing them is very serious. I see Mr. C. B. Auel here. Mr. Auel, what have you in the Westinghouse Company on the question of removing guards? Can any man remove a guard?

Too Much Insistence Upon Mechanical Safeguards

MR. AUDEL: There was a remark made by the speaker and I would like to say a word on that. Of course, we have nothing to prevent a man removing a guard, but our accidents, due to the want of safeguards, are so trifling that we have absolutely ignored them. We do have accidents, but those accidents are accidents away from the machine tools, and that applies to every department of our large works, so that the problem has become a very complex one with us.

Together, eye and foot injuries total about 50 per cent of all we have, but the speaker made a remark which hits me in a very vital spot, and that was this: He did not think it right for the Department of Labor and Industry to continue to insist on the guarding of machine tools, and I feel exactly the same way about it.

My reason is that every industry, or every concern in industry, which has given this subject of accident prevention any attention for a number of years, is in about the same condition as we are. Accidents continue, but they are away from the point of operation. You have a regular program laid out, and it is not right for an outsider to walk into your plant, step around the place, and go out and leave you orders on what to do. Many seem to think that their duty is not fulfilled unless they do leave you some order.

We all have a certain amount of money to spend on accident prevention work, and when we are compelled to spend that money on things that do not prevent accidents, we have less money to spend on educational work where our greatest job lies. So, to the extent that they compel us to spend money on things that do not prevent accidents, they are the cause of a continuance of our accidents.

My suggestion is that every Department of Labor and Industry—and they are constantly complaining of a lack of inspectors to cover their territory—have a preferred list of customers, we will say; when they make an investigation of your plant, you tell them the whole story of what you are doing. I do not mean to say that we should stop guarding machines and tools; by no means; but I say that we should place less emphasis on the guarding of machine tools than we have in the past. When one of their inspectors comes into your plant, let him make a complete round of your department. You tell him the entire story of your safety program, and if he thinks you are measuring up to his idea of a preferred cus-

tomer, let him put you down on the preferred list and go away and leave you alone.

Then, let him come back, if you please, at the end of a year or a year and a half. If you continue to measure up to his idea of a preferred customer, let him put you on the preferred list again, and again go away and leave you alone to carry out your regular program.

Mechanical Safeguards Reduce Accidents 25 Per Cent

Now, it is a fact that if you have not done any work whatsoever in the guarding of a plant and are having 100 accidents a month, and you put in every known mechanical device that you can think of, you will not reduce your accidents more than 25 per cent. In other words, your accidents will drop from 100 to 75, or in that proportion.

The next step in further prevention of your accidents is to form your departmental committees, and they must be real departmental committees, full of pep. I do not mean a paper organization; but if you do that in the way it should be done, you will again simply reduce your accidents another 25 per cent, or say from 75 to 50; and your last 50 can only be eliminated by educational work.

The average Department of Labor and Industry knows nothing beyond the mechanical guarding of machine tools, so they are continuing to force you to spend your money on the lesser phase of this accident prevention movement, and taking away your money from the educational program, along which lines it should be spent in greater proportion than we have been spending heretofore.

CHAIRMAN DUNNEBACKE: Mr. Auel, I certainly admire the frankness of your remarks, and apparently you have the crowd with you. I think you are on the right track. For instance, last June, we had the first Michigan Industrial Safety Congress, sponsored by the Michigan Department of Labor and Industry, at Ann Arbor; and, in the course of those meetings, the chairman of the Bureau of Labor and Industry, frankly told us that one of the objects in calling the Congress was to build up efficiency of his department. He admitted that we, in the factories and industries in Michigan, knew more about safety and accident prevention than his own inspectors, and his idea was to coordinate his department and our industries, in order to build up a more efficient corps of State factory inspectors. I think that bears out your statement.

I notice the chairman of our Nominating Committee is present now, and I am going to ask Mr. R. F. Thalner to submit the report of the Nominating Committee.

Report of the Nominating Committee

I am not the chairman of the Nominating Committee, the chairman was detained at another Section, this morning, so he asked me, as a member of the committee, to submit the report of the Nominating Committee.

We have followed out somewhat the precedent set in the past, and have deemed it advisable to nominate for the officers for the ensuing year the following:

We have advanced the Vice-Chairman, Mr. A. M. Williams, to be nominated as chairman of this Section. Mr. Williams is with the Chrysler Corporation.

The former Secretary, Mr. E. H. Cotcher, we recommend for the vice-chairmanship.

The Secretary's position—which, of course, is the bottom rung of the ladder, in which the new blood is injected—we have given a good deal of thought to. It requires a great deal of concentrated effort and work during the year, on the part of your secretary, and, in casting around, we have decided on the nomination of Mr. H. L. Sain, of the Delco Light Company, of Dayton, Ohio.

In addition to those officers, an Executive Committee consisting of Messrs. L. J.

Parrish, of the A. O. Smith Corporation, Milwaukee; F. J. Corbett, of the Chandler Motor Company; H. J. Mellum, of the Nash Motor Company; Charles J. Kolb, of the Pierce Arrow Company; E. H. Complin, of the Ford Motor Company of Canada; and the two most recent past chairmen as ex-officio members of that committee.

As chairman of your Program Committee for the ensuing year and the next Congress, we wish to nominate Mr. O. J. Olson, of the Fisher Body Company, of Detroit. Engineering Representative, Mr. R. F. Thalner—I do not want this job all my life, but we have this job for the research on annealing of chains, and as soon as that is over, I will ask to be succeeded by someone else. Statistical Committee, Mr. W. S. Smith, of the Ford Motor Company. Posters and Slides, Mr. H. Bunting, of the Olds Motor Works. Membership Chairman, Mr. L. J. Parrish, of the A. O. Smith Corporation. News Letter Editor, Mr. E. H. Complin, of the Ford Motor Company of Canada. Publicity Committee, Mr. H. L. Fracher, of the Detroit Steel Products.

This comprises the complete slate for the Automotive Section, and the nominations are submitted for your approval.

Selection of the New Officers is Unanimous

CHAIRMAN DUNNEBACKE: Gentlemen, what do you wish to do with the report of the Nominating Committee, as to its acceptance?

MR. MILLER, (Chevrolet Motor Company): I move that it be accepted.

(Motion seconded)

CHAIRMAN DUNNEBACKE: It has been moved and supported that the report of the Nominating Committee be accepted. This, however, does not preclude any nominations from the floor, and I want to give you an opportunity to submit further nominations. Are there any nominations for any of these offices, that you care to make from the floor? If not, the chair will entertain a motion that the tellers cast the ballot of the meeting, for the slate as submitted by the Nominating Committee.

E. L. Hewitt (Detroit Industrial Safety Council): I so move, Mr. Chairman.
(Motion seconded.)

CHAIRMAN DUNNEBACKE: It is moved and seconded that the slate submitted by the Nominating Committee be accepted as the officers for the ensuing year? Are you ready for the question? All in favor, signify by saying, "Aye," contrary, "No."

(Motion carried.)

The secretary will report that the tellers report 115 votes cast for the slate submitted by the Nominating Committee.

I am certainly very glad the Nominating Committee has taken the stand they have. I have worked with your new officers for the past year, and some of them for two years, and, in every case, they have been tried and true. They have been very efficient in their work, and have helped out in the program, and I doubt that the program would have worked out as smoothly as it has, without the assistance of these men.

Going down through our analyzing of the human body, as to its danger of injury through accidents, we have set up another subject, that of leg and foot accidents, and in casting about for a man to handle the subject, we have asked Mr. Elmer Hewitt, manager of the Detroit Industry Safety Council, to speak.

I do not know of anything in safety organization that has worked out so efficiently and well as the Detroit Industrial Safety Council. We attempted something a few years ago, which met with some success, but last year it was re-organized. Without going into the details of the organization of the Detroit Industrial Safety Council, I want to say that its great success is due to the untiring efforts of Mr. Hewitt. He has certainly made a success of the job, and is

bringing real safety into the Detroit industries. We will ask Mr. Hewitt to give his paper.

What Price Feet and Legs?

Elmer L. Hewitt, Manager, Detroit Industrial Safety Council, Detroit, Mich.

Do you suppose that your factory manager or superintendent would be interested, if when you return home from this Congress, you could tell him how he could cut his production cost on the average of \$6.02 per car? Do you suppose that he would be willing to spend a dollar or two to accomplish such a reduction?

The automotive and allied businesses are being conducted in a highly competitive field. Many companies have gone to great lengths to effect savings of a few cents per car. And yet some companies have not realized that leg and foot injuries alone have placed a self-imposed burden on the automotive industry which, considered with our newly produced 4-to-1 ratio for the indirect cost of industrial accidents, ran in excess of 27 millions of dollars for the year 1926 alone. This 27 million dollar cost spread over the four million cars produced in 1926 means that every time a car comes off the line an average of approximately \$6 has been added to its cost because of leg and foot injuries. I do not intend to bore you with the arithmetic of that conclusion. (You may refer to the appendix to this paper.)

What part then, of the automotive safety engineer's problem do leg and foot injuries represent? Do they represent 25 per cent of your cost or are they of such minor importance that your principal interest might better be devoted to more fertile fields for reductions?

What type of accidents are causing injury sufficiently serious to legs and feet to make it necessary to classify them in the safety engineer's graveyard—the home of lost time accidents?

What can be done in the way of education and engineering revision that will reduce the number and severity of this type of injury to our workers?

These are the questions which you have probably asked yourself about every type of injury in your plant. They are the three fundamental considerations in the analysis of any accident situation.

I am not going to bore you with statistics, because I know that you would promptly forget 95 per cent of them, as I would. I do, however, want to give you some general conclusions in regard to the relation of this type of injury to the problem as a whole so that you may govern yourselves accordingly in the allotment of your time and interest.

An analysis of the experience of three of our representative automobile companies shows the following:

First—That the frequency rate of lost time leg and foot accidents was 6.7 for the plants considered as compared with a total frequency rate of 19.6 for these same plants for the same period. In other words leg and foot injuries are causing 34 per cent of the lost time accidents in the automotive industry.

Second—That the severity rate of leg and foot injuries was .072 as compared with a total severity rate of .747 for these same plants for the same period. Leg and foot injuries are causing 10 per cent of the lost time in your industry.

Certainly types of accidents involving such a large proportion of frequency and severity are worthy of your earnest consideration.

Next comes the question, "What injuries constitute the major portion of these accidents?" Further analysis of the experience of these same plants shows the following:

First—In relation to frequency of the lost time accidents of this general group of leg and foot injuries:

Foot accidents cause 73% of the lost time cases.

Leg accidents cause 21% of the lost time cases.

Ankle accidents cause 9% of the lost time cases.

Second—In relation to severity:

Foot accidents cause 68% of the lost time.

Leg accidents cause 21% of the lost time.

Ankle accidents cause 11% of the lost time.

The answer to these figures is obvious. Correct the conditions that are causing injuries to the feet of your workmen and you will reduce the frequency rate of lost time accidents in your plant by 26 per cent and the severity by 7 per cent.

How are you going to do it? That question is always the easiest to ask and the hardest to answer. My little survey has indicated to me that the old question of "Falling Objects" represents at least 25 per cent of the answer and that the equally antiquated classification of "Dropping Material" scores a decisive victory for second place. I suppose that we should not be surprised that many of our foot and leg injuries are the result of "trucking" and that running into stationary objects should result in many injuries to the legs of your employees. Burns to the legs and feet caused by both hot metal and hot water have shown themselves to be factors worthy of your consideration. Let me give you briefly, the causes of leg and foot injuries in the order of their importance as determined by my survey of these types of accidents.

- Falling Objects
- Dropping Material
- Trucking
- Metal Burns
- Stepping on Objects
- Collision with Stationary Objects
- Falling
- Mechanical Defects
- Stepping on Nails
- Water Burns

It would seem unwise to attempt to go into all of the details involved in the prevention of accidents of this type, but inasmuch we have diagnosed the case the least we can do is to prescribe some general tonic for the ills.

Engineering Revision Could Correct Many Conditions

There is no question but that engineering revision—and by engineering revision I do not mean mechanical guarding, but the rearrangement of processes to eliminate inherent hazards—could correct many of the conditions now responsible for injuries to the legs and feet of our workers. What I have in mind might be typified in the installation of conveyors and hoisting equipment, obviating the necessity for handling material and trucking operations. Equipping your workmen with foundry shoes, protective leggings and similar equipment is to my mind but one of the revisions which might prove helpful. I personally know of one Detroit plant of about 10,000 employees where a reduction of 20 per cent in foot cases was affected by the promotion of the use of safetoed shoes.

This is the sort of thing that engineering revision means to me—and in it, I believe, is the answer to many of our leg and foot injuries.

I was impressed in looking over some 227 cases of injuries to legs and feet that the cause would be eliminated if the fundamentals of good plant housekeeping had been impressed upon the men through the medium of education.

I realize that it is dangerous to draw conclusions from too little data, but one impression of mine has been strongly confirmed in my little investigation. One of the three plants surveyed had a general experience considerably lower than the

other two plants. This was also true of the types of injuries we are considering. The figures show that the foot and leg injuries in that plant bear about the same relation to the plant's total experience as the foot and leg injuries in the other plants bear to their total experience. My conclusion therefore is this—that aside from the engineering revision which may be obvious in any plant, a strong general program of accident prevention, incorporating in it all of those factors with which you are so familiar, is perhaps the best remedy in our efforts to eliminate leg and foot injuries.

There is really little more that can be said generally about leg and foot injuries in your industry unless we attempted to go into details which would be interesting to but a portion of this group.

All I have hoped to do in these few minutes is to present to you certain high spots of the subject in the hope that I might be able to stimulate some interest which would result in action when you men return to your respective plants. If I have been able to accomplish that much I shall feel well repaid.

In conclusion, I just want to present to you in review the essential points of what I have tried to say.

First—That leg and foot injuries in the automotive industry represent such a considerable part of the experience as a whole that they are worthy of your special attention.

Second—That foot injuries include about seventy per cent of the problem in the class of accidents which we have been discussing.

Third—That "Falling Objects", "Dropping Material" and "Trucking" cause two-thirds of the injuries to legs and feet.

Fourth—That in addition to definite engineering revision such as I have suggested a well-rounded plant program seems to be the best answer to the problem.

The other day I heard a definition of the work "cash" as it pertained to a commercial organization. It appealed very strongly to me and I have attempted to adapt it and interpret it from a safety man's point of view.

To me the "C" stands for Certainty—Certainty in the ultimate success of accident prevention. The "A" means Accuracy—Accuracy of thought and action. The "S" in such a scheme can mean only Sincerity—the Sincerity of purpose. The "H" stands for Humanity—our ability, by virtue of our work, to make this world a better place in which to work and play. I'm sure that the large percentage of safety engineers in this group have a creditable surplus of "cash" in the bank.

APPENDIX A

The 1926 Statistics report of the National Safety Council shows the following figures for the Automotive Section:

No. of Employees.....	1,020,917
Man Hours Worked.....	2,445,341,085
Days Lost	2,860,025

The National Automobile Chamber of Commerce 1927 report shows 3,365,281 persons were employed in the automotive industry in 1926. This, based on the National Safety Council report would mean for the industry in 1926:

Man Hours Worked.....	8,068,500,000
Days Lost	9,438,000

Analysis of the experience of three typical automobile plants indicates a severity rate of .072 for foot and leg injuries, or approximately 907,500 days lost in 1926 due to leg and foot injuries.

Sixteenth Safety Congress

Then with an estimated cost:

\$ 6.00 per day direct cost
\$24.00 per day indirect cost

\$30.00 per day total cost

907,500 (Days) $\times$ \$30.00 (per Day) = \$27,225,000

Total Money Lost due to Leg and Foot
Injuries in 1926.

National Safety Council Reports shows 4,428,286 cars and trucks produced in 1926.
Therefore, cost of leg and foot injuries per car produced was \$6.02.

APPENDIX B

General Experience of Plants Surveyed

Plant	No. Lost Time Accidents	Days Lost	Man Hours Worked	Frequency Rate	Severity Rate
1	421	18,633	17,140,569	24.6	1.087
2	62	1,043	9,634,929	6.4	.108
3	179	5,472	6,870,702	26.1	.796
TOTAL	662	25,148	33,646,200	19.6	.747

Leg and Foot Injury Experience of Above Plants

1	160	1,784	17,140,569	9.3	.104
2	25	230	9,634,929	2.6	.024
3	42	425	6,870,702	6.1	.062
TOTAL	227	2,439	33,646,200	6.7	.072

APPENDIX C

Experience of Three Plants Surveyed by Cause

	No. of Lost Time Accidents				No. of Days Lost			
	Foot	Leg	Ankle	Total	Foot	Leg	Ankle	Total

CHAIRMAN DUNNEBACKE: Detroit being in the heart of the automobile industry, Mr. Hewitt has been able to get some good dope out of Detroit, and what he has given you is based on experience.

Is there anybody here who has any questions on foot and leg injuries?

MR. COMPLIN (Ford Motor Company of Canada): May I revert to the previous speaker's subject? We have a large number of small drill presses in the plant, where the man will take a piece, place it on the fixture, bring down the drill and put it to one side. We are having a great deal of trouble through the backs of the men's hands being burned by flying chips, and I would like to get the experience of

the members as to how they prevent that. Do you put long metal guards along the front of your drills, or what do you do to prevent this?

MR. MILLER (Chevrolet Motor Company): May I answer Mr. Complin by telling about something we have recently adopted? We have had a wide experience along the same line, in using small parts on small drills. Recently after thrashing the thing around and not being able to get anything in from our own head or the foreman, I happened to go into one department. Going past a six spindle drill press, I noticed a guard, home-made, crude, rugged, but the man had taken a piece of sheet metal about three inches long, formed in the shape of a spiral, hooked it to the bed of the fixture, and let it extend around the lower part of the operating point on the drill as it is engaged with the piece, then had cut a piece at the feeding point, so he could slide a piece in under and drop his drill on it.

It gave him a ready view of the piece and operation, kept his hand away from the drill itself, and the piece of sheet metal working around there had the effect of breaking off chips and also kept them from flying out on his hands.

CHAIRMAN DUNNEBACKE: I do not want to forget to speak about this guard that Mr. Averill talked about. We all know that wood-working operations are perhaps the most dangerous in our industry today. Everybody is looking for good shaper guards. A lot have been developed and cast aside, but we believe, in Detroit, we have something now that is all right. They have been built, they have been attached and are running satisfactorily, and many safety engineers in Detroit have gone to the Packard plant to inspect this shaper guard and cannot see anything wrong with it. So, if any of you want a good guard for that, do not fail to see Mr. Averill and get his picture or go into the wood working section and see this one hundred feet of film, showing that guard in operation.

Employee Suggestions Have a Particular Value

H. L. SAIN (Delco Light Company): It has not been my intention to have much to say at these meetings. However, I am wondering if what Mr. Averill said is not true; also, what the gentleman here just illustrated by a safety device for the drill. If you allow the workman to suggest certain things, he is more apt to use them than if you try to put something on the machine, of your own design or from your Engineering Department; although the designs the workmen give you are crude, no doubt you will be able to work out something worth while.

The thing I had in mind was this: If I were to decide from my own conversation and interviews with the different safety engineers present here today, I would be convinced there are no more accidents throughout the country. I will say to a certain fellow, "How are they going at your plant?" "Just fine. Just fine." That is a whole lot of information. My thought is the exchange of ideas by the different safety engineers, as to what their experience has been along the line of certain accidents.

I think every concern, every management of a concern, would be more than glad to pay a man any amount, he could name his own salary, if he could earn what I term as the "W. E. Degree". A lot of us have been to college and we have earned the degree of A. S. S. E., or Mechanical Engineer, or possibly a doctor with the M. D. degree. What do we mean by the "W. E." degree? Possibly it would be right for me to tell you that this "W. E." degree is the "waste eliminator." I think you will all agree that if we could win a title or degree of "W. E." our company would be willing to pay us any price.

We could scrap the entire waste of a department, haul it out on the scrapheap tomorrow morning, and a new work order could be placed in the department and soon replace every piece of that scrap. But I think our greatest work is the elimination of human waste, which cannot be replaced. A man might hop around on a wooden leg, but it is hard to see out of a glass eye, and the thing we should

do is to take up the subject of waste elimination from the standpoint of humanity.

I hear a lot of fellows say, "Well, we take care of that in our plant through education." We do, also, in our plant. We have safety classes of the workmen, right down from the machines, from the assembly benches, we bring them in and have a general discussion. We have the conference type meeting, we allow the men to tell us what is wrong in the department. We do not make any attempt to tell them what to do in the department to make it safer to work in; we allow them to tell us what is wrong and we try to correct it.

One of the greatest things I have in mind is to let a man know what his job is worth to him, and if we had enough time, I might tell you of our plan of trying to tell the men what their job is worth to them; what the labor they sold to our company is worth to them; how they can deposit that labor in our company and draw, in terms of wages, interest on that labor.

I think it is early yet, a good while before lunch; let us have some discussion, and I would be glad to hear from some of you as to how you handle your educational work.

CHAIRMAN DUNNEBACKE: Is there anybody here who is developing a well planned program along educational lines?

A Safety Plan That Convinced the Manager

MR. LIPPINCOTT (Manufacturers Association of Erie): I have had a very interesting experience in one of our large foundries, with the safety engineers. They had a total in lost time accidents for the first six months of 1926, 56 serious ones; this year, they started in early, right after the Congress last year, on an educational plan.

The management had never been interested, he had a safety plan of his own, and I, as an outsider, would come in and he would say, "Bunk!" So, I asked this gentleman if he would take a chance with me and go to the Congress, and he did. He went to the Congress and was there one day; he was in your meeting, he heard the ideas of education; he came back and said, "Now, go to it!"

The plan was for the foreman. First, we had the manager come out and get the foreman, and he hit on him in the usual way, and then he said, "Now, it is up to you Lippincott, go to it!" I didn't know what to do. I took a plan of having the nurse give me every man from every department who came into the hospital, no matter whether it was a scratched finger or a leg off.

On this plan, I worked with the foreman to the extent of, every month, sending them a letter, telling them the number of accidents they had in their department and citing the cases. Where the men were numbered, I would say to this foreman, "Here is Sixty-five, he was in four times this month, what's the idea? Is he tired? Something wrong at home? Just what is the trouble?" It so enthused the workmen that they began to climb aboard immediately. They like to kid me a lot and they did, as I went through the plant; but the whole idea of the educational plan, in my belief and what I have proven this year, is through the foreman. I told you the total last year was 56 accidents; we have lowered it this year to 11, and in the month of March, this plant went the entire month without a lost time accident; which was something they had never done in the history of the company.

I laid these figures before the manager at the end of six months, and now he is working on a bonus plan. If it is a compensation carrying company, explain to that foreman that when the fellow gets hurt, it isn't out of the insurance company, it comes out of him, out of his department. We brought that around with a bonus system, of which there are many plans, but the idea is entirely the education of the foreman.

There is one instance which is outstanding, but it has happened in six different instances in my little town of probably 150,000.

I see Mr. Reamer here, from the Cadillac Motor Company; can't you add something to this discussion?

S. H. REAMER (Cadillac Motor Company): We have gone from September 3, 1926, up to last Saturday morning, when I left, without an accident, on 78 presses.

Supplementing the remarks of the gentleman who just spoke, Cadillac charges every lost time accident back to the department; that loss is charged the same as scrap, it is a cash proposition, it is charged against production. I think that might work out in your case; it seemed to work out very well in ours, and we have cut our accidents in the last year.

Pictures Tell a Story Anybody Can Understand

ALFRED VOX STARR (Corning Glass Works, Corning, N. Y.): The educational literature can be distributed, but very few of the workmen can read English, and a good many of the foreigners cannot read their own language, so even if you translated it, you are blocked there.

We would get a fact picture of stuff like that, where the fellows had a good laugh, street cars running over people, Charlie Chaplin pictures, and we actually thought that was good work; but I do not think it helped very much. Then we put on a show, ourselves, and capitalized on our own accidents, had pictures actually taken of our own accidents. We put up on a bulletin board, "Frank Banten broke a leg." Everybody knew Frank Banten. We even went so far, (and did it under protest of everybody), if a fellow lost his finger, we put that finger up on the bulletin board. There were a few reported losses of appetite for a couple of days, but there was more safety taught than ever before.

CHAIRMAN DUNNIBACK: I think there is too much talk around the country of doing away with the gruesome poster. I know it is pretty hard, but the thing that started me in safety work was a study of four or five gruesome posters. I think it certainly drives it home.

I see Mr. Averill here, who is assistant to the vice-president of the Chrysler Motor Company, and, in Detroit, Chrysler has been doing some fine work along safety lines. I would like him to tell us what is the main point in his safety program.

MR. AVERILL: You are right on the Averill part, but I am with Dodge Brothers, and only indirectly do I know of safety work. Mr. Carson, our safety man, was unable to get here.

The way I get progress in our safety work is through the compensation end. We are self insured, and, of course, are interested in safety, so far as it reduces the compensation loss. I mean in my own department, I was very much interested in hearing the Cadillac man state they charge it back to the foreman and to the department. We have tried that also, and found it very successful.

CHAIRMAN DUNNIBACK: You think the management will respond quicker to safety work when it is up to them in dollars and cents?

MR. AVERILL: Very much, because that is the main objection on the part of the production man, the fact that it is not worth the time it takes the foreman from the job to have their meetings; and if you can show them there is an actual dollars and cents return, they warm up immediately, because they want to get their cost of production down as low as possible.

CHAIRMAN DUNNIBACK: I know, in the General Motors Corporation, up until two years ago, we presented our accident experience according to frequency and severity, but, since then, we have put it up in dollars and cents, and we have gotten more support and cooperation through the management than ever before.

MR. WALTERS (General Electric Company): We are working along both of those

lines. Our employees are on one of the incentive systems, and as you know, that means "hop, skip and jump." The second point of that is that the foreman shares in the incentive. They have got to stand the waste, and he has to stand the human waste. In other words, the cost of accidents is charged back to him. If he can go below his allotted accident cost, it is to his benefit; but if he goes above that, he is out of luck.

We work it another way: We have the employees representing the plant. An employee with a complaint can go to his representative or he can go to his gang leader; he cannot come to the safety committee, direct, unless he has made use of one of these sources.

The foreman is directly responsible for the physical condition of his plant, so that, entering with a complaint of the physical condition of his plant, of an operation which he considers unsafe or any condition not to his liking, will go either to his representative or his gang leader, and, in either case, this report reaches the foreman. We, therefore, concentrate the largest part of our efforts on our foremen, and are securing such cooperation that we have reduced, with 2,400 employees, from 48 accidents last year and up to this date, 34 per cent. In other words, with a severity rate, last year, of two to the hundred, we are now down to 1.4.

Safety Talks During Working Hours Were Permitted

CHAIRMAN DUNNEBACKE: Mrs. Cramer, I am going to ask you to get up and say something. Mrs. Cramer is industrial nurse of the Continental Motors Corporation, and I am going to ask her this question, inasmuch as our program is built on hand and foot injuries: Is there more chance of infection from injuries resulting from the feet and legs than from the hands and arms? Have you noticed anything in your work that would lead you to believe there was more?

MRS. CRAMER: We rarely have an infection from the feet.

CHAIRMAN DUNNEBACKE: The infections from the hands are because the hands are more in contact.

MR. AVERILL: Mr. Dunnebacke, speaking of education on the lines we have carried out, I told you in my talk a few minutes ago about departmental talks. I have heard many fellows say their company would not allow them to go into a department while it was working and take the men off the job and give them a talk. In the 73 talks that we gave, in some of our different departments last year, we went during working hours the "big boss" gave us permission.

We started with the assistant foreman at one end of the building and the foreman at the other, and I told them to pull all the employees off the jobs, and have them meet me in the center of the room, that I would not take them off their work for more than ten or fifteen minutes, and would try and give them a seven or eight minutes' talk.

I went to the majority of the foremen after we got through with these talks—and, by the way, we worked on a bonus system, so you know they do not like to lose very much time—and asked these foremen if they had noticed any reduction in their production, by pulling their whole department off for fifteen minutes. You take a department of 200 or 300 employees, and fifteen minutes means quite a lot of lost time. They said, "No, we have not noticed a bit of reduction in our production;" and, in the majority of cases, they had an increase that day on their schedule. They thought it was because the employees in the plant thought if the company was willing to grant them the fifteen minutes off from their work for this talk, that it meant quite a lot to them and to the company, and they would buckle right into their work when they got back and catch up their schedule before the day was over.

So, if any of you boys have that experience about your manager saying, "We cannot spare the men," you can cite them to this fact; and I am sure if you will

follow it through, you will find you will not lose a bit of production on the ten or fifteen minutes' time.

MR. FOUAGY (Willys Motor Company): I wonder how many of the members here are self insurers?

CHAIRMAN DUNNEBACKE: All those whose companies are not carrying compensation insurance, who pay their insurance claims out of their company finances, raise your hands.

(About twenty hands were raised.)

MR. FOUAGY: As a safety educational program, I think all these men whose concerns are carrying their insurance will testify to the fact that that is the best safety educational plan that they have encountered. I know it is so with our concern. Up to the time we started carrying our own insurance, our accident frequency and severity was very much greater than at the present time. As soon as the effective force of our organization learned the fact that the company was paying the cost, that the management was directly responsible for the expense of accidents, we saw a decided change in the whole attitude of our personnel.

All Employees Realize the Money Cost of Accidents

Probably this is not very encouraging to the insurance company representative, but it, nevertheless, is a fact, that the men in the organization realized that they have a very important part to play in the matter of expense in connection with the company's business, and when accident costs are put back to the operating force in the way they are with the self insuring company, I do not think there is any question about it at all. It is the finest means of getting safety across to your operating force that has ever been encountered. I would like to hear more from some of the companies that are self insurers, to find out if that is not true, and if they have had the same reaction we have had.

CHAIRMAN DUNNEBACKE: I know in our own corporation, the fact that every manager realizes that when he has a compensation loss he has to put his hand in his company funds and this has a very good effect.

C. B. AUEL (Westinghouse Company): Mr. Chairman, you are looking for something novel, you might be interested in a matter we carried out this past year. As perhaps many of you do not know, the United States government, for the past few years, has made an appeal to the country at large, principally through the Chambers of Commerce of the leading cities of the country, to devote the last week in October to the elimination of waste. They call it "Management Waste", and we have used this as our reason for entering into this campaign. But instead of confining it to the last week in October, we have taken the entire month.

We find that our employees have absolutely no conception as to the cost of materials or tools that they are using, day in and day out, and breaking. So, we have put it up to some 25 or 30 departments, in which our East Pittsburgh Works are divided, to prepare traveling exhibits. These exhibits are ten or more feet long and five or six feet high, consisting of inverted "V" shaped boards, mounted on industrial trucks, so that they can be moved about from place to place throughout the various departments. On these boards we put broken drills, broken chisels, hand wrenches, milling cutters, saws, that are ruined in that particular department, together with the productive material with which they work; and alongside of each, we set down the cost to us of those ruined tools and those ruined materials.

We do not quite stop there, but we also put down the consumption of various expense materials, like soap, paper toweling, brooms, a little statement as to the cost of compressed air, and so on throughout the plant.

We immediately follow that exhibition of waste with a "No Accident Cam-

paign", showing that human waste is greater than material waste; and that "No Accident Campaign" covers the month of November.

This month, we are doing something a little further, and I think particularly novel, in that we are adding one more board to these various traveling exhibits, and that board will have on one side of it a statement as to how production has increased in various lines in all of the European countries, among which are, of course, our leading competitors. On the other side, we have collected some 30 or 40 items that can be purchased in the American markets, but which are made in Europe and Asia. I have already collected, for example, paper flowers made in Germany. I have a bottle with cement, showing that our cement industry is being knocked sky high in the Atlantic and Pacific Coast, due to inroads from Belgium and Denmark. I have a big canned ham from Denmark, I have a brick from Germany. I have silk shirts that I had made to order and sent to this country from Japan, which only cost three dollars and six cents. I have hand-wrenches from Germany, electric light bulbs from Japan and Germany, and so on.

A Month Devoted to Campaign to Eliminate Waste

At the top of this exhibit is a sign something like this: "Foreign goods are being imported into this country in ever increasing quantities, made possible because American wages average about four times as high as European wages. Let us keep them there. One way to help do this is to eliminate waste."

As I say, we give the whole month of October to a consideration of the elimination of material waste, and we have the factory in a particularly receptive condition. We follow on through the month of November with the elimination of human waste, the greatest of all wastes.

Getting back to visual education, I think the Westinghouse people are doing a job that we should all appreciate, not only in selling safety, but in value in economic education, and the fact that it is visual puts the thing across in a wonderful way.

But what I wanted to picture is this: in connection with leg and foot injuries, I think our planning department at our Highland Park plant, where we have better than 6,000 men employed, has done one of the greatest jobs in safety that I ever heard of. They are responsible for receiving, transporting and shipping all material; all movement of material comes directly under their supervision. They split the plant a short time ago into eight divisions, split geographically, and it parallels the line of organization.

Each general foreman in the planning department is responsible for the condition of his plant. There is a banner that goes out on a monthly basis to the man who keeps his stock in the best condition. The white lines are now maintained, maintaining aisle-ways, each man is taking care of that automatically, the crates are piled and the skids are shoved back at right angles. We find, instead of a congested condition, we have ample room now that we have the orderly storing of material, the orderly moving of material and the safe piling of material. Instead of having a plant crowded with material and wondering where we would have to build more buildings to make room, we have ample room to carry as heavy an inventory as we carried before.

The general superintendent made this remark, "We are having practically no foot injuries." Why? He had not been through the plant, he was not familiar with the safety job that had been done, and it went back to the orderly, systematic handling and storing of material. Each one of these general foremen had sold the foreman, and each foreman had in turn sold each employee, so that when the "jitney" driver came in and brought his skid and placed it, he took an extra second or two to place that skid squarely. So competition can be worked in plant housekeep-

ing, and I believe that plant housekeeping is one of the big answers to the subject that we have had this morning.

MR. COMPLIN (Ford Motor Company of Canada): I would like to say a word or two about this new thing that has come upon us since the last session, that is the four to one ratio advocated by Mr. Hendrick, of the Travelers Insurance Company. I think that is one of the biggest selling factors we have, if we can put it across right. I found it worked very beneficially.

The theory is this, that the incidental cost of accidents is four times the actual compensation cost. I took the article and read and marked it, cut out some stuff I did not want, made it into a short memo form and shot that to the management for their enlightenment. They had never looked at it that way and it was hard to believe. I was called in to explain if that was so, and we went into the thing very thoroughly, and we decided it was so, and you could notice a remarkably different attitude on the part of the management when they realized that instead of the twenty-odd thousand dollars accidents were costing them, you could really say it was about one hundred thousand dollars.

You can use that on your foreman. I do not know whether you have foremen's meetings or not, but we do, and before you use it, get it into proper shape and do not quote Hendrick's examples. I am not saying they are not right, they are, but you cannot quote a far away example to the men in your own plant. Sit down, get together with the proper men who have the cost of operation, hiring, etc. and figure that thing up for yourself; arrive at your own examples, and then put it up to your foremen. I did that, and I think I opened their eyes. They never thought of it in that light, and I did not go so far as to make the ratio four to one, because I rather suspected they would find it hard to swallow, but three to one was quite within their range.

When I went to the foreman and told him his accident cost in the past as it was on paper, and that if we charged him with five hundred dollars, he could look around somewhere in his department for a production loss of fifteen hundred dollars—that went across big. It made a whole lot of difference in their attitude, and I would recommend that you gentlemen give that serious thought and, in future, give it a try out.

MR. FOUAGY (Willys Motor Company): I wonder if I may say a word in connection with the remarks Mr. Auel made, with regard to the State inspectors and this preferred class of companies.

We, in New York, have the reputation of paying more for compensation insurance than in any State in the Union. I do not believe anybody will contradict me. In connection with that problem, we have as severe inspection rules and regulations as any other State has, but I would like to see something done in connection with the remarks of Mr. Auel, and see if it is not possible for this Section to go on record in connection with some kind of resolution or action, something done in connection with a movement of that sort. I think it would be very valuable to all of us, if it were possible to take the concerns that are doing something in connection with accident prevention and get some consideration with the State Department of Labor, instead of having these orders placed, year after year, on things that are really inconsequential, things that do not mean anything—for instance, guarding belts that, while they are within the code, actually do not prevent accidents. I wish something could be done. I hope this Section will not adjourn until some definite action is taken in connection with that.

CHAIRMAN DUNNEBACKE: If anyone cares to prepare a resolution for presentation tomorrow or Friday, we will be glad to accept it. If not, I will be glad to recommend this as a thought for consideration for your new officers.

ADJOURNMENT

Thursday, September 29, 1927

The third session was called to order at ten o'clock, by the Chairman, A. F. Dunnebacke.

CHAIRMAN DUNNEBACKE: It is always my belief that it is well for the members of the Section to know something about their new officers, that they get a line-up on them and really get acquainted with them. This morning, instead of conducting the meeting, I am going to ask our new vice-chairman to conduct the session. I have pleasure now in introducing Mr. E. H. Cotcher, The Murray Corporation, Detroit, Michigan, who is going to act as chairman.

(Vice-Chairman Cotcher took the chair).

VICE-CHAIRMAN COTCHER: The session this morning is going to consist of one paper that has been prepared, and the balance of the time will be devoted to a round table discussion of any subject brought up in our meetings, or any subject of any importance to the automotive industry. So while you are watching the paper that is being given, that is, watching part of it and listening to part of it, you can be thinking up questions you may want to ask or suggestions you may want to make.

We hope that this discussion will be really the most important and interesting feature of our whole series of meetings this year. As the opening of our program this morning, we are going to be privileged to listen to and see an illustrated paper delivered by a man most eminently fitted. The man who is to address us this morning is not only a distinguished industrial surgeon and one of the most distinguished in the city of Detroit, but he has been recognized and honored by his Fellow M. D.'s, by being elected a Fellow of the American College of Surgeons. If you know very much about the medical profession you know that that honor is not bestowed except for really exceptional and brilliant work. He is not only a good surgeon, as demonstrated by his experience and the honors heaped upon him, but he is what we would describe along about three a. m. as a jolly good fellow—he really is. I think we are going to be given a very interesting talk. It won't be extremely dry, I am sure of that, and I think we will all appreciate very much the honor of hearing the words and seeing the pictures prepared by Dr. T. E. Mullen, Industrial Surgeon of Detroit.

Head and Body Injuries in Industry

T. E. Mullen, M. D., Industrial Surgeon, Detroit, Mich.

Obviously volumes can be and are written on each and every portion of the human body. Each part today has its own field. I will touch only the more superficial portions as they relate to industry, and as they relate to safety, in the estimating of results following injury and the production of economic waste. We are beginning to see light, and hope that in a short time the specialty of industrial surgery will include all measures bearing upon health, social and working ability of employees; and we are witnessing today one of the most important movements for human conservation.

Physical health being man's greatest asset, the capitalizing of it should become a consequential factor in all industries. The success or failure of a health campaign or safety movement depends largely on the personality of the plant surgeon. "Obviously this is not a function which can be measured by instruments of precision nor encompassed by a mathematical formula. Yet personality is a force so powerful and definite that all the world is painfully aware of its distinguishing presence

at every human contact. It is the most difficult quality of man to comprehend and in most descriptions its subtle essence is quickly lost."

The subject of lost time from work on account of illness, injury and other causes is being continually related to the man's productivity and earning capacity and in this way the physician's knowledge of medicine and surgery becomes a factor in economic life. The industrial surgeon is not only concerned with the immediate injury of the man in the plant hospital, but he looks beyond to the hazard of his job, the monotony, even to his home surroundings and he instills into the men the thought that absence on account of preventable accident, through lowered production, is adding to the cost of living.

Consider for a moment the technical work of the industrial surgeon; he is called upon to treat all types of injuries, from minor lacerations of the fingers to depressed fractures of the skull, interspersed between these are the intra-abdominal injuries, such as tears of the intestines, lacerations and puncture wounds of the liver, and he becomes expert in the treatment of fractures of every variety. Infections are his fort.

Injuries to the Worker's Brain Tissues

The subject of "Head Injuries" should really be "Brain Injuries," for it is with brain injuries that we are concerned more than skull or scalp injuries. The mortality resulting from brain injuries is very high. During the period from 1900 to 1910, the mortality figures at three of the large hospitals in New York ranged from 48 to 68 per cent of all cases of brain injuries. The U. S. Department of Labor, Bureau of Labor statistics, reports in 1925 slightly over 1,700,000 accidents, with 10,500 fatalities. These accidents occurred mainly in industries and railroads. Other statistics show a steadily increasing rate of head injuries.

Stewart in 1921 reported 6,135 head injuries with 617 fractured skulls in New York City.

The clinical symptoms and signs are varied and at times were confusing. In many patients the more extensive the fracture of the skull, the less seriously is the brain injured and, on the other hand, the most dangerous of brain injuries are frequently not even associated with a fracture of the skull. As is well known, the fracture in these patients is possibly the least important part to be considered in the treatment; whereas the presence of a marked increase of intra-cranial pressure with and without a fracture of the skull, the advisability of early operative treatment should be seriously considered. For the successful management of symptoms and complications arising from injuries to the brain, either with or without fracture of the skull, there must be a clear understanding of the principles involved, an accurate mental picture of the symptoms following different conditions, such as depressed fracture, meningeal hemorrhage, different phases of intra-cranial pressure and a logical classification from the standpoint of pathological physiology.

The condition of the brain and its coverings are being taken into consideration rather than the obsolete classification of the different forms of fracture of the skull. In cranial injuries, however, and well illustrated in the more severe forms of so-called "concussion" there occurs frequently a mild edema of the brain—that is, there is a slight increase of the intra-cranial pressure. The effect of a prolonged increase of this pressure is an increase of neuroglia connective tissue. This latter tends to prevent normal functioning of the brain cells and causes many of the so-called "post-traumatic neurosis," following brain injuries such as persistent headaches, dizzy spells, indefinite pains in the head, changed personality to one of emotional excitement and irritability or to one of depression, general nervous instability, fainting spells and even epilepsy. Psychoses are at times troublesome, many will eventually clear up but there is that percentage which will show permanent mental impairment. Especially in the cases of compensation settlement the surgeon

finds great difficulty in differentiating between organic and functional disturbances.

The outline of the proper treatment for acute brain injuries has not only served as a general topic for discussions among surgeons but also has more recently assumed an important place from the standpoint of industrial safety.

Our patients are from our shops and the question of the ultimate return to economic and emotional normalcy is a consideration of great importance not alone to the patient and his family but also to his employers, and one can readily imagine the yearly losses sustained by the families of the improperly treated injury, and what burden is placed upon the state, social and other organizations; so the importance of proper treatment of this type of injury becomes more immediate and momentous. The question of saving life is not the all essential one in the treatment of brain injuries, for what benefit is it to the individual if his life be spared if he has not been returned to economic normalcy? The treatment of these cases should be directed towards the return of the pre-injured workman.

Skull fractures are grouped into direct and indirect, linear fractures of the vault, fractures of the base and depressed fractures, each may or may not be associated with common intra-cranial lesions such as hemorrhage, cerebral edema, contusion and laceration. It is important to bear in mind that the fracture itself, excepting the depressed types is of little consequence in the ultimate of the patient. Whether a fracture aside from depressed fracture is present or not, is not of material consideration in the treatment of brain injuries. The presence of a linear fracture, as has been pointed out, is of great benefit to the individual suffering from head injury, in fact it is compensatory to life and is a natural method of decompression and prevents brain compression.

Many Injuries Also to the Abdomen

Sub-temporal decompression operation is indicated where the usual palliative methods have failed and in cases of progressive hemorrhage due the ruptured blood vessels or in cases of subdural clots. Suboccipital decompressions are indicated where fractures exist with rapidly forming compression of the medulla. The two contraindications to operative treatment are shock and medullary compression.

The acute traumatic abdomen is a fairly common injury in the automotive industry. The patient is struck by shaper-blade, a block of wood from a saw, a handle of a machine. He is in extreme shock. We have found that if these cases are operated upon during the first 8-hour period, an extremely large proportion will be saved; the mortality rate rising in a direct proportion to the time elapsing after this period. We have found that most of these cases show very little evidence of injury on the skin of the abdomen, possibly a slight abrasion or even a slight redness of the skin, but operation reveals multiple perforations of the intestines or rupture of the urinary bladder or other abdominal viscera.

Included in this category is rupture or tear of the urethra—which usually occurs by falling from a height and straddling a pipe or wooden frame. Traumatic rupture of the bladder and urethra is relatively rare as compared to injuries in other parts of the body—less than one-half of one per cent of the total number of accidents. However, since the advent of the automotive industry such injuries are more common. Early diagnosis and treatment has reduced the mortality from 88.7 per cent to less than 40 per cent. But like the previous injuries these are productive of economic waste.

Another type of accident that is very common and expensive in the automotive industry is fracture and dislocation of the bones of the wrist. The surgical importance of a well defined knowledge concerning traumatic conditions of the wrist is obvious. An early diagnosis leads to early and appropriate treatment on which cure so much depends.

Injuries about the wrist joint received much more attention in the recent litera-

ture than formerly was the case. Fractures of the radius or the radius and ulna are by far the most common.

Usually they are caused by a fall upon the palmar surface of the hand; a crushing injury to the wrist, or the falling of a weight upon the wrist.

Anatomically, the carpus are arranged in two rows:

(A) Proximal, comprising from without, inwards the scaphoid, semi-lunar, cuneiform and pisiform.

(B) The distal row comprising the trapezium, trapezoid, os'magnum and unsiform.

When the carpal bones are articulated together, they form a bony mass, the dorsal surface of which is convex from side to side, and anteriorly present a concave surface. This is further emphasized by the forward projection on the inner side of the pisiform and back of the unsiform, while externally the tuberosity of the scaphoid and the ridge of the trapezium help to deepen the furrow. To these four points the anterior annular ligament is attached, which stretches across and converts the furrow into a canal through which the flexor tendons, the nerves and blood vessels to the hand pass to reach the fingers.

Various Types of Fractures Discussed

Dislocations of the semilunar never occur without more or less severe trauma to the bones entering into the wrist joint, and it seems impossible to apply sufficient force to luxate this centrally placed bone without serious damage to the ligamentous and bony structures which give the wrist its strength and flexibility. The soft parts are much traumatized and local post-operative reactions will occur.

Damage to the median and ulnar nerves and blood supply to the dislocated bone would seem inevitable. Dissections of the wrist joint in the cadaver prove this danger an ever present one.

It seems reasonable to believe that most dislocations of the semilunar start as dislocations of the os'magnum backward. As the force is continued, the os'magnum drives the semilunar from its pocket in the carpus and itself resumes a more normal position in the wrist.

Dislocations of the semilunar are frequently undiagnosed because of the failure to make a thorough physical examination with proper radiographic interpretation in every suspicious injury to the wrist joint and because of these incomplete examinations, marked disabilities have resulted.

Fracture of the semilunar is a condition of comparative rarity. The ordinary traumatic lesion, generally the result of great violence occurs occasionally, and of fractures of bones of the carpus is second in frequency to those of the scaphoid.

At the hospital of the University of Pennsylvania, there were seven cases in over 10,000 fractures of all bones, or .07 per cent.

In Mullers' Clinic, at Rostock, out of 1393 fractures, there were five cases, or .39 per cent.

Keinboch's disease is the name given to a lesion characterized by a fracture of the semilunar bone. Usually comminuted, the important feature is the absence of history of trauma, violent enough to account for the severity of the lesion; indeed in many cases no history of violent trauma can be elicited. The diagnosis is made with the X-ray. The exact diagnosis obviously is made by the use of roentgen ray. Any injury to the wrist should be examined fluoroscopically, and films made as quickly as possible following the injury, for our prognosis is in a direct ratio to the time elapsing before treatment is instituted.

Relating to the treatment, so much depends upon early reduction, let it be dislocation or fracture, that point is again emphasized. In dislocations of the semilunar, immediate closed reduction under general anesthesia is the ideal method.

Reduction in early cases is not difficult, and gives excellent results. Late reductions are very difficult and sometimes impossible.

A certain amount of disability can be overcome in the young. It would seem that complete fractures of the scaphoid in a majority of cases remain ununited, although fusion of the fragments has been observed, while the incomplete fracture tends to unite without disability.

At Harper Hospital, Detroit, we endeavor to reduce this dislocation under fluoroscopic control.

If the fragments cannot be replaced, they should be removed. A palmar incision is preferable for the semilunar, and a lateral one for the scaphoid.

Cases treated by operative reduction give the poorest end results as to function and power. Late cases treated conservatively or by excision of the fragment give fair results. The after treatment consists of immobilization in moulded plaster dressings for about two to four weeks, with early active motion and early physiotherapy.

Flying Parts of Equipment Cause Skull Fractures

Fractures of the skull in the automotive industry occur largely from falling materials or flying parts of equipment. These may be guarded by the safety engineers' forethought and skill in providing necessary protection to the employees. The spirit of safety for the employee should be in the mind of the layout engineer of the plant, and designer of tools and dies, so that when the machinery for manufacturing is finally released for operation, these executives should confer with the safety engineer to the end that the best possible safeguards be provided before the power is turned on.

Fractures of the wrist may occur from the same cause, but the operator is more responsible in various ways for the wrist accident by lack of "thinking" or exercise of "presence of mind" and by having his hands become engaged. This would apply to the arms and limbs as well. We must bear in mind that in addition to all the forethought possible on the part of mechanical engineers in their designing, plant engineers in their layout, safety engineer in his oversight of these and other installations, there still remains the great necessity of education relative to the responsibility of each individual to himself to care for their fellow employee and society.

One can by taking thought readily grasp the necessity of thinking "safety," as so much is dependent upon the mental alertness. In the process of gaining the desired end and constructing the mind to safe practice, the human tendency is to take the short cut, which is generally destructive because more can be destroyed in a minute than can be constructed in years of patient toil. Therefore, energy of mind, as well as physical energy, is required to safeguard employees from injuries of the head, arms and limbs.

Quoting F. A. Besley, who says relative to "Accidents and Industrial Surgery":

"Progress and advancement in human endeavor and achievement have been accomplished only when the necessity for improvement is recognized and plans devised to bring a change. A survey of the situation in that branch of surgery known as industrial surgery in America would indicate that the circumstances surrounding the care of a large proportion of injured patients, are influenced by the business methods of the insurance companies carrying the financial risks of the various corporations and there has been little or no concerted effort made to improve the method in the care and treatment of the injured.

"It needs no wordy brief of profound argument to justify the conclusion that the methods of caring for the injured are a great economic waste when the increased number of days of immediate disability and the more or less permanent disability that may occur is considered. True, much has already been accomplished and yet the efforts of the few have not been crowned with unqualified success.

"A campaign of education must be inaugurated which will stimulate a broad in-

terest in this important subject, such propaganda for enlightenment must originate in the larger surgical societies, and must reach the industrial insurance companies. The logic must be such as to appeal to their sense of the economic advantage that must necessarily accrue to them in the better care of the injured patient, and in consequence the lessening of the number of days of disability."

VICE-CHAIRMAN COTCHER: It appears to me that we have listened to a very excellent paper. You fellows know what happens when the usual doctor tries to talk. He gets so interested in technique of his profession that he overlooks the application to the safety movement. It strikes me that one important thing that Dr. Mullen did was to ask us a question. He said, here are cases the way they come to me. What are you fellows going to do to keep them from coming to you? He has somewhat elaborated on the remarks Mr. Auel made yesterday when he brought out the fact that we should perhaps educate some of our inspectors to the fact that mechanical safeguards are not the principal function of the safety movement. Perhaps you want to ask Dr. Mullen some questions. Perhaps you would like to offer a suggestion, to answer some of his questions. The meeting will be thrown open for discussion.

H. R. WHITNEY (The General Industries Company, Elyria, Ohio): I should like to know if this tannic acid can be used on all kinds of burns, steam burns or dry burns, or whether it is safe to use on acid burns.

A Case of Psychology Suddenly Developed

DR. MULLEN: In acid burns we have used a base to neutralize the fire, then make the application of tannic acid. We have used it with very gratifying success. It is a very cheap product and very useful. The only expensive thing about it would be your spray. I have used an ordinary little atomizer. A lot of firms have evolved a little pumping station. It isn't poisonous. You can cover the whole body with it. We are turning our burn cases over to Dr. Davidson of Detroit, of the Ford Hospital, in the last few weeks, and the application of tannic acid is made to them.

H. E. MILLER (Chevrolet Motor Company, Detroit): I should like to ask the doctor to go into one part of the talk this morning, particularly the brain injuries, and cite a specific instance, and I ask for his thought as to the cause.

Recently we had a man fall from the top of a machine probably 12 or 14 feet, landing on the forward portion of the head on the base of a ladder and causing a fracture or indentation. The case was diagnosed and disability estimated as a matter of some eight weeks. The man was taken to one of the Detroit hospitals and was apparently on the right road to recovery. A matter of ten days or possibly two weeks had elapsed and the recovery was very pronounced, but in visiting him with the plant surgeon one afternoon the man asked the question, "When will I be able to leave the hospital and go home?" He was advised that he had another two weeks probably in the hospital before it would be safe to leave; realizing the home conditions and so on, the doctor judged it best to keep him there. The following day there was a noticeable relapse or change in the man's condition for the worse, which continued over a period of practically ten days which was only offset by the visit of his own people or family physician who reiterated that it was essential for him to stay there. Following the family physician's say-so the man seemed to be satisfied with it and started to recover again.

I should like to ask the doctor if he can throw any light on the case of that.

DR. MULLEN: Those are what we call psychoses, they are real lesions. I mean they occur in the site of the brain that has to do with the mental conditions, tears in that particular part of the brain. That may be permanent, but it is real injury, a real pathological condition. A man is mentally wrong because he is injured, the association fibers there are damaged. It may take place even in scar forms without any impairment, but you can't tell what percentage will remain permanent or how

much functional impairment we have, and the surgeons in the compensation department have a hard time studying the claim. The old railroad spine accidents are never settled until the money is handed over to the patient and then cure takes place.

J. RUSSELL (Public Service Corporation, Newark, N. J.): I should like to hear something about the use of picric acid.

DR. MULLEN: I have no criticism of picric acid, but we believe it is not quite as good, in recent work I personally have liked tannic better. I can show you men who like picric better. I think they are all coming to the tannic acid. That is the best thing we have at the present time.

A. F. DUNNEBACKE (General Motors Corporation, Detroit): I was interested in your showing so many slides of the fractures of small bones of the wrist. In these were many falls from tracks, slipping on pavement, tripping, just the body falling down and the arm reaching out. Will a glove on the hand minimize the effect of that any? Could you save any of the small bone fractures with a glove on the hand?

DR. MULLEN: I should say offhand, no. It would depend a lot on how well padded the gloves are. I brought out those wrist injuries especially on the oily floor.

Various Suggestions About Slippery Floors

VICE-CHAIRMAN COTCHER: Was it last year somebody told us the best process to use on the floors? If I remember correctly he said to get sal ammoniac, and if that were applied to the steel plates on the floors it would put a surface there that would not take the oil, would not be subject to an oil slip. Isn't that the answer? There are some other rather interesting questions that Dr. Mullen brought out where he asked us a few questions.

R. E. NEWCOMB (Brewer-Tichenor Corporation, Cortland, N. Y.): Does the sal ammoniac work on cement floors?

VICE-CHAIRMAN COTCHER: Metal ones.

MR. NEWCOMB: Has anyone any suggestion for a concrete floor other than dry cement? I mean the sprinkling of dry cement on the oil to absorb it.

H. E. MILLER (Chevrolet Motor Company, Detroit): I saw something on that yesterday; down here in the cafeteria in the Stevens Hotel, I noticed the girl going along with a box of Morton's dry salt, throwing it on the floor to keep it from being slippery.

J. RUSSELL (Public Service Corporation, Newark, N. J.): Muriatic acid on cement floors tends to eat out the cement and leaves a rough sand finish. That will rough up your floor so that the oil lies below the particles of sand.

VICE-CHAIRMAN COTCHER: I notice for instance on the cleaning decks in body plants you never slip on the cement after they have used their cleaning solution a while which is made up of various acids and so forth. We all know that acid will roughen up the cement. Perhaps some of you gentlemen have a question you would like to put in writing and have it discussed. If so, we have a regular question card we use, if you have something which perhaps may take a little digging to settle.

H. R. WHITNEY (The General Industries Company, Elyria, Ohio): I should like to ask him what experience he has in what is termed nickel-itch in the plating room?

DR. MULLEN: I have seen several cases of it. They occur most often on the forearms and wrists. It is a dermatitis, the mere little pimples with pustular heads on them. The only cure for that particular man, (and I sometimes think he is more or less susceptible to that particular thing) is to get him off the job. The same thing applies with regard to oil, and a person who has oil boils and oil in-

fections. Now it comes about that this skin rash, dermatitis, whether in copper or in oil, is due to the pigment; the irritating agent is not the oil, or the nickel, it is the pigment in the oil and the irritation of the nickel. There was quite a paper given to that by the dermatologists not long ago. In my experience they do come up in the forearms.

MR. WHITNEY: What would you suggest as a treatment?

DR. MULLEN: Remove the man. Change him from the job. Certain men in the work never get it and other men step right in and get it.

MR. RUSSELL: One of the plants in Newark is using a bucket of water with about a half pound of alum in it, and the men working around the oil soak their hands and arms in the alum solution, and also at noon and at night before they go home. This seems to toughen up the skin so that it is less susceptible to this trouble.

DR. MULLEN: That gets away from nickel, but oil is our pet subject. Over at the Chrysler plant we are now using a preparation of ointment to put on the men's forearms in the morning and the hands also, which fills in the pores. The oil is irritated by virtue of the pigment in the oil. This is the thing to get across to you.

MR. RUSSELL: Wouldn't the alum close the pores?

DR. MULLEN: I believe it would. We have been using a simple little basic ointment, which prevents the pigment going into the hair follicles. The pigment is what causes the irritation.

MR. DUNNERACK: There seems to be such a large development recently in the application of the chromium process of nickel plating doing away with nickel plating on radiators, lamps and so on, and a lot of the companies are putting in the chromium processes. Have you any alarm about that or do you feel it will be a safe process?

DR. MULLEN: McCord and the Chromium Process Company have it and your firm has it but I haven't had any experience with it. It is too new. I don't think it is any different from nickel, probably. It might be.

Treating the Troublesome Skin Infection

W. H. LINK (West Disinfecting Company, Detroit). In our experience with these oil boils, as well as nickel-itch and dermatitis, we have made quite a research, and we found that the only way to overcome it was to have the workers wash their arms with a soap which was medically treated. The oil boils and also breaking out of a rash from cutting compounds was treated through mixing a very strong disinfectant directly into the compounds in very small quantities. The research work in that has been gone into very deeply and we found that not only our own disinfectant but that any disinfectant, has to have a very high coefficient to be effective. The best one found so far is disinfectant of a coefficient of around seventeen. It can be mixed into the oils and the compounds with the compounds at the rate of 400 to 1, and for oils at the rate of about 200 to 300 to 1; it has worked out very well in the largest plants throughout the country and has cut down the pus infections to a minimum. This research work is still going on and I am very deeply interested in that subject and we are going into it further now, even getting into the grease used on presses, which is made of animal fats which go rancid and affect the men very largely. I am sorry that I am not able to give much on this as we are just getting into it now, but I would be very willing at any time to give information to anybody who wishes to know more, after I get into it further.

L. E. AVERILL (Packard Motor Car Company, Detroit): I think Mr. Link is rather modest in his statement for the past eight years, and I see one of the men over here that I guess is using the same thing, two of them in fact. The disinfectant we have used in our cutting compound has more than paid for itself in life of the compound, extending the life of the cutting compound anywhere from seven to ten days, especially in the hot weather, and cutting our infection cases at least

90 percent. So I think it would be well worth your thought and time to make a little experimental work among cutting compounds and oils, especially in the summer and spring when the infection cases are more numerous.

MR. DUNNEBACKE: I think Mr. Reamer has some good dope along those lines. I think we might hear from him.

S. H. REAMER (Cadillac Motor Car Company, Detroit): We have gone into this disinfectant quite extensively. In the start it was only in the experimental stage and I placed it in a couple of departments and it wasn't long until I found that employees from other departments were coming down and helping themselves to the cutting oils and compounds in these departments. That, of course, certain foremen didn't like, and we extended that to the other departments. At the present time we place this disinfectant in the cutting oils when it is received in the receiving department. A certain percentage of the preparation is put into the barrel. By moving the barrel from the storage department (all our oils are delivered in barrel lots to the department), I think it is thoroughly mixed. At the present time and in fact for the past year, we do not know what an infection case is where we are using cutting oil or cutting compound. I cannot recall an infection case in over a year. In the cutting compound, we treat that every morning in the mixing barrel in the different departments. We are certainly well sold, and I think it would be well to run tests on it; we find that our cutting oil and compound is really in the best of condition and we use it of course twelve months in the year.

By the way, you will notice a very peculiar smell in your compound, especially in the summer time. We have eliminated that completely.

Spraying With Disinfectant Decreased Infections

H. E. MILLER (Chevrolet Motor Company, Detroit): I feel that we will have some real information through the research of the West Disinfecting Company on this subject within a very short time. Recently we went into the subject and through the use of a disinfectant we have eliminated practically all of our troubles. Still we have a case or two crop up here and there that might cause an epidemic. Recently I called on the West Disinfectant Company to make some laboratory experiments for me. Dr. Drake refused to make a long distance diagnosis. He came from Long Island City to go into the situation and requested samples of practically all of the different conditions that were found existing there. I am assured by Dr. Drake that they will have some reports on that in a short time. I think the results of that information will be of value to all of us.

S. H. REAMER (Cadillac Motor Car Company, Detroit): About a year ago in March, if I remember rightly, we had quite an epidemic. In fact, we called in all the specialists we could think of and could not determine the cause. At last it was suggested that we use some disinfectant and we sprayed our plant completely. As we sprayed the plant from day to day, we could see the infections decreased. Now we use this disinfectant in our scrub water. We have a regular scrubbing gang that works every night, and fortunately we haven't had any recurrence. Of course we make our solution very strong for scrubbing, but it is working out fine.

VICE-CHAIRMAN COTCHER: I am told that Fred Steinhilber, of Jackson Steel Products, is here. I have never met the gentleman. I am told if we will ask Mr. Steinhilber how can a personnel director do good safety work, that he will probably give a good answer.

MR. FRED STEINHILBER (Jackson Steel Products Company): I think that if he does it exclusive of everything else he will probably do a good job.

I am not a safety man altogether. I try to watch the thing from a humanitarian standpoint entirely, and with the aid of the foreman we feel that the Jackson Steel Products Company is directly responsible for its men as well as materials. I have been interested to follow the trend of the discussion at this meeting. The foreman

is the man who is, after all, responsible and to substantiate that at a meeting of personnel men, safety men and employment men and executives last week, that same thought was brought out, the responsibility of a foreman for his men as well as for the machinery and product and materials. In looking over the picture I feel that it is the personnel job, and where the personnel director can't give all his time to safety, where he has employment, compensation and first aid, a good deal of the moral supervision, if he looks at this safety problem from a strictly humanitarian standpoint, the suffering entailed, time and money lost—he will do those things. He will be led to do those things which will eliminate this waste and also eliminate the causes of waste and hardships which men suffer.

I was talking with our new secretary a while ago. It is a peculiar thing, just to cite our own experience. We had last month 15 lost time accidents and had 60 days lost, and the month before we had 17 and lost 67 days; and I have been gone the greater part of August and September and I think we have had three lost time accidents with a loss of seven days. I think I had better stay away altogether. I don't understand it. We are just running along as we always do, with the same number of men, the same amount of work, and here we go for a month and have just a few accidents. I wish somebody would explain that. Just why is it? I don't understand it except that I think maybe our present experience is a result of some hard work previous to this time. You can't let up, you have to keep at it all the time.

An Outline of Safety Activities

VICE-CHAIRMAN COTCHER: I think that is a contribution to the discussion. I heard a safety man recently that had an accident in his plant. He said, "What is it? Just as soon as I go away. If I had been there it wouldn't have happened." I am inclined to subscribe to Mr. Steinhilber's remarks that it is the work you did some-time ago in getting foremen and superintendents and others interested. That appeals to me as being pretty much the answer—how much you are able to get the organization to work. I have been given the names of several gentlemen who are here. Is Mr. Dewey of the Delco-Remy Company here? Have you anything to offer? I am told that you have given considerable thought to it, Mr. Dewey.

MR. DEWEY (Delco-Remy Company, Anderson, Indiana): I have been on this thing about a year and a half and have tried stunts of different kinds. When I began our production started to increase, and our force increased from about 3,500 people to right around 6,700. We had five plants. In the first place we put it up to the foremen, which is more or less an easy way. We did a lot of cautioning, don't do it again, and so forth. We are going a little better than we were the previous year. We had no safety department before that. We changed the set-up, got a little more hard boiled with it. We have no definite rules in the platform. Every foreman understands, is supposed to understand, it is put to him in that way, the right way and the wrong way, and it is up to him to tell the men and hold them responsible for what happens the same as in production. We haven't that proposition fully sold, and I don't know whether we ever will have, but we are still trying it. It takes, I find, about two or three months after you start a new scheme to see whether things are going to work or not. I don't mean to say that we are eliminating all the accidents, we are not doing that; and it would be pretty hard to tell you men why I feel we are getting a little better; but knowing the conditions and our increasing production and increase in employment, I feel we are doing some good.

The most interesting thing is a scheme we have started this month. It is not a new idea along the safety line; we may handle it just a little bit differently. In our five plants we had a safety flag. This is a green flag with a white border, and in the large end is a white circle and inside of that is the white cross, similar to the one on the badge except that it hasn't got "Universal Safety" on it. At the large

end it is five feet across. The total length of the flag is ten feet and is in pennant shape. We got up a letter and made it as simple as we could to get it over to the foremen so the workers could understand it. The way we worked it, we started out the twelfth day of this month and ran it in our shop paper. The flags were mounted on the flag poles.

In addition to that each production department had a poster made, I call it a poster, some call it a pennant. It is made out of beaver board one-quarter inch thick that is twelve inches square. It has a black background with white letters and numbers with a white border about one inch wide around the thing. That has the department number. Hanging on the bottom of that is 12x16 inch board, which has a green background with white letters. It hangs in the center of the department. These posters and flags stay up every day and every night. We have quite a night force. Practically 75 percent of the departments run at night. Those stay up all the time and come down only when there is a lost time accident. We consider lost time accidents as those wherein the men didn't finish out the balance of the shift. We don't wait to see whether the injured man comes back the next morning. If he can't finish out the balance of the shift it is up to the foreman. We have assistants to the foremen, as we call them. We have group systems, the premium system, and one man has charge of the men in the group. It is up to the foreman or one of his group leaders to scale the ladder and take down the poster when he knows it is a lost time accident. He also notifies the watchman to pull down the plant flag. They both stay down twenty-four hours, providing no other accident happens in the department.

Last month we had 25 accidents out of 3,625 workers. That doesn't include the whole force, of course. We have around 7,000. But we had 25 accidents, 638 days; one finger was lost in that, and up until last night, including this month, we had ten accidents, and offhand I would say around 100 days. I would say that this had a lot to do with it. How long that is going to last I don't know, but the competition between plants is pretty strong on anything undertaken, in athletics or whatever it may be; we seem to be getting quite a kick out of it.

J. RUSSELL (Public Service Corporation, Newark): Suppose he has a man injured on the machine. If the man can go out and work a broom in the hall does that figure in the accident or not?

Teaching the Foreman the Need of Human Interest

MR. DEWEY: Here is the thing that is done. It has been a hard job for me to get the foremen interested in a man that is injured. If it amounts to anything at all I go out and get him and bring him in. I don't care how busy he is. If I can get hold of the superintendent I bring him in. We have a general superintendent, and in plant one where there are about 3,600 employees, we have another superintendent. We have many departments, and have five superintendents beside the general superintendent. Of course each other plant has the superintendent. I get that fellow. I can't always get him, but I do so where I can. If it is a job we take him to the hospital or to his home and he is there for a few days. I take him out so that I can see the condition of the home, the family, and what he has to go through. If he has to be operated on at the City Hospital, I take him over there, keep him right with me. But here is the thing that is done. The man gets hurt now and the foreman notifies me within just a few minutes and he is right there after me; and the first thing he wants to know is whether he is going to have to go home or not. We don't want anyone kept at work when he is suffering or if it is painful for him to work; but if he is not in any pain and the doctor thinks he can work, we want him to stay. Of course we have a first aid in the plant. It is up to the doctor to say whether that man is able to work. He can go back and do another job; if he is

100 per cent on it we will let him work. If he is not 100 per cent we don't let him work.

VICE-CHAIRMAN COTCHER: Don't think because I started calling on some of these gentlemen that it is the desire of the Chair to shut off spontaneous discussion.

J. R. ANDERSON (Continental Motors, Detroit): I should like to ask Dr. Mullen how far the industrial doctor should go in medicine in the plant? I know the doctor is in a position to answer this question, because I used to work with a doctor twelve or fifteen years ago and we used to have things in common. I sat in a meeting Tuesday with about 50 industrial doctors and that question was argued pro and con and they were divided on how far they should go. I know a doctor who started his practice on the outskirts of Detroit in the industrial district, and some seemed to be of the opinion that the doctors in the plants should be ignored. One of the plants in the city of Detroit doesn't want to get into that condition. Another plant does, and the local doctors say we are trying to corner the market on treating employees for everything.

How Far Should Industrial Medicine Go?

DR. MULLEN: The problem is up in front of us all the time. We can't ignore the neighborhood doctor, and if the plant assumes medical risk, not compensatory, all well and good, we will take care of the sickness cases if the plant has arranged that with the employees. Ordinarily the plant has not arranged that. In the plant that has not arranged such a condition when a man comes in with a cold in his chest and wants a headache pill or physic pill, and says, "Doc, give me a dose of salts," we instruct our nurses never to do that.

We send the man to his family doctor. It keeps me better satisfied. The cheap-skate comes in and wants everything gratis. You men see that every day in your lives. We try to send them to their family doctor. He is pleased, for that is the way he makes his living. The firm is better satisfied. When the nurse comes on and opens up a boil against a surgeon's advice and he isn't there, she slips a knife in. If infection sets in and the man dies, and what are you going to do? It is a non-compensable case, no accident, just a boil. I think a shop should have a suit of liability. If the man dies anyway, no matter what the treatment is, it is a common thing that the wife comes up and says, "You know my husband scratched himself where the boil took place." She wins out. Why? Because the nurse who assumed that responsibility and the surgeon above her are directly responsible, whether they are or not. If she opened the boil and the man died I think the firm can be held for it. I think the best idea is not to treat medical cases in the plant.

They might say, "You can't let the man go out and not give him a pill." It is best not to give medical treatment in a plant. I send them to the family doctor and everybody is satisfied. There is no argument. The medical authorities are better off and the patient is better off.

A. F. DUNNEBACKE (General Motors Corporation, Detroit): Last year, if you will recall, the National Safety Council sent out a questionnaire to all the members asking them to name a number of subjects that they would like to have the National Safety Council sponsor research on, and one of the subjects was the question of annealing of chains. Later on we noticed that the Council did not take any action on it but approved the sponsoring of other things. We passed a resolution in which we asked them to reconsider their decision and see if they could not find ways and means for sponsoring the research of annealing chains. The National Safety Council did reconsider that, and Mr. Thalner, from this Section, is doing considerable work on watching the research development. Inasmuch as he is here I think it would be better to have him speak to us on it.

R. F. THALNER (Buick Motor Company, Flint, Mich.): For the benefit of those who were not in the meeting of the A. S. S. E. Engineering Section yesterday after-

noon, I want to inform you that the progress report which was briefly given in that section yesterday afternoon will be discussed this afternoon at the same sectional meeting.

The work is progressing and rounding into shape. The committee membership has been appointed and we have men on that committee of national reputation. The Carnegie Institute of Technology is doing the actual testing work at Pittsburgh, Pennsylvania. The plan of procedure has been outlined by Professor Daniels of that institution and we hope when the next Congress rolls around we will have something definite to give you as to whether annealing is or is not beneficial to chains. It has been an oft-discussed question as to whether we derive any benefit from this process. Some of us are doing it and some are not, and some of us are heating to one temperature and cooling in a certain way and others are using a higher temperature and using an entirely different process of cooling. The research which is being conducted will endeavor to enlighten all of us on this situation which has been in a sort of muddle for the past ten years.

We would like to have you in there this afternoon if you are interested. We have received comments on the plan of procedure from most members of the committee and they are favorable. We also sent a copy of the plan of procedure to the British engineers of Teddington, England, who are conducting research on the causes of chain failure; and they sent us a very fine letter, extremely instructive, and I think from their experience we are going to be able to benefit in our own work.

Outline of an Accident From Falling Scaffold

H. L. SAIN (Delco Light Company, Dayton, Ohio): I had one experience in our work at the shop which I should like to mention. The doctor spoke of what we are doing to stop certain accidents such as falls, which result in a good many cases in back injuries, or fractures of the skull. We felt sure that the man in charge of our maintenance department had made a good inspection of all scaffold boards. In fact, he kept me informed at all times. In our plant when we are running under normal conditions we have in the neighborhood of 7,500 men and we have three plants in different sections of the city. It is pretty hard to cover the territory with one man, so I must depend on the supervisors of the different divisions. I had questioned the scaffold boards because we were repainting the whole building in plant one, where we have a saw-tooth building, where a man getting on top of that to spray or paint is about 25 feet from the floor. He told me the scaffold boards were all A-1. But about four-thirty in the afternoon on the last day of February, I heard a terrible noise, and I got the chill that runs over the shoulders and the back of your ears. That is a thrill that I don't want very many of. I heard the man carrying on and hollering at the top of his voice, and in they came. You could hear the scrape on that cork linoleum in the medical department. Whenever I heard that scrape coming in I think of the stretchers.

The scaffold board had broken and he fell 25 feet on top of a grinder. We called the ambulance immediately and took him to the hospital and had some specialists come in. Our doctor doesn't care to take all the responsibility himself, so in cases like that he calls in other specialists and we made all the examinations of the man that were necessary. They didn't find any bones broken nor any internal injuries. He was still hollering as loudly as he could at eight o'clock. The minute you would leave him he would start. It seems as though it was a nervous shock.

The man stayed in the hospital two days and they didn't seem to want to release him. He just got up and put on his clothes and walked home. He lost a couple of days from the shock and is back at work now getting along fine. But that was a lesson to us. We stopped all work in all three plants and banded all of our scaffold boards with angle irons and since that time we have had no more injuries

pertaining to our scaffold boards breaking, but up until that time we had had several serious injuries.

H. E. MILLER (Chevrolet Motor Company, Detroit): We have had some jollity, we have had some serious things this morning. We have had some thoughtful messages and so on, but I believe at this time a matter should be called to the attention of this section and some action should be taken. This morning the safety engineer of Chevrolet Forge Co. was notified of the death by drowning of his wife yesterday. I believe, Mr. Chairman, that this section should rightfully express our condolences and for that purpose I make a motion that the chair appoint a committee to draft a resolution of sympathy and condolence to Mr. Kroger.

(The motion was seconded.)

VICE-CHAIRMAN COTCHER: It has been moved and seconded that a committee be appointed by the chair to draft a resolution expressing our sympathy to Mr. Kroger for the accidental drowning of his wife.

(The motion was carried.)

VICE-CHAIRMAN COTCHER: I presume that the committee properly should be appointed by the newly elected chairman, Mr. Williams. But I will appoint Mr. Miller of the Chevrolet Motor Company, Gear and Axle Division; Mr. S. H. Reamer, Cadillac Motor Company; Mr. W. H. Link, West Disinfecting Company, Detroit.

We have five minutes more and if you don't mind I should like to use that to make some announcements unless you have something of consequence. There is a matter that has been brought up in another section. They say, "May I suggest that your Section vote on a resolution addressed to the Executive Committee of the Council as follows:

"Whereas, The National Safety Congress is more efficiently and economically held in its headquarters city, and

"Whereas, the cost of sending delegates is as low as, if not lower when the Congress is held in Chicago, and

"Whereas, the city favored by the Congress when moved from point to point gains only at the expense of the delegates and their employers, be it therefore

"RESOLVED, That this Section is in favor of holding the Congress in Chicago regularly during the last week of September each year."

Respectfully submitted,

GEORGE F. PRUSSING,

The Union Oil Company of California,

Chairman-Elect of the Petroleum Section."

I suggest a motion to refer that to the Executive Committee unless you want to take action.

H. L. FRACHER (Detroit Steel Products Company, Detroit, Mich.): I think that is a matter for the Executive Committee to handle. I make a motion that the resolution be referred to our Executive Committee for action.

(The motion was seconded and carried.)

The meeting adjourned at 12 o'clock.

ADJOURNMENT.

**SIXTEENTH ANNUAL SAFETY CONGRESS
NATIONAL SAFETY COUNCIL**

Power Press and Automotive Joint Session

Friday, September 29, 1927

THEO. O. MEISNER, Chairman Power Press Section
Manager, Central District Safety Division, American Can Company,
Maywood, Ill.

A. F. DUNNEBACKE, Chairman Automotive Section
Safety Director, General Motors Corporation,
Detroit, Mich.

The joint session of the Power Press and Automotive Sections of the National Safety Council was called to order at nine forty-five o'clock, Mr. T. O. Meisner, manager of the Central District Safety Division, American Can Company, Maywood, Illinois, representing the Power Press Section; and Mr. A. F. Dunnebacke, safety director of the General Motors Corporation, Detroit, Michigan, representing the Automotive Section, presiding as joint chairmen.

CHAIRMAN DUNNEBACKE: As you know, this Safety Congress is the first in which there has been a division in certain interests. For years conditions have been working up where it has been thought advisable to separate certain activities connected with the Automotive Section, and last year there was organized a Power Press Section. That the move was advisable is shown by the attendance at the Power Press Section this year. I think we all realize that about 70 per cent of the accidents are caused by punch presses and naturally there are a lot of fellows who wish to know more about punch press accidents.

However, we did not wish to conflict with the interests of the Automotive Section, and with the approval of both sections felt it would be advisable to have a joint session where one might have subject matter in which both are interested. Therefore, I think the program this morning is going to be of a great deal of interest.

When a man gets up to talk he likes to know the type of man he is talking to. It aids so much in what he says and how he says it. So I have been asked this morning to present a little picture of you people who are here.

I am going to ask those men to raise their hands who are strictly safety workers, safety engineers, safety directors, or safety inspectors—the men down in the shop doing actual safety work. (Forty per cent). How many men here have charge as personnel directors of organizations which have safety as a part of their activities? (Fifteen per cent). How many men here are superintendents, foremen or executives, either managers or heads of divisions or heads of departments, but who are actually engaged in the operating and production processes? (Sixty per cent). That is a very fine representation. I am glad to see it.

The first thing I am going to ask this morning is if there are any reports of any

committees or any resolutions to be submitted. Mr. Miller of the Chevrolet Motor Company has some resolutions to present and I am going to ask him to read them.

H. E. MILLER (Chevrolet Motor Car Company, Gear and Axle Division, Detroit, Mich.): Yesterday the committee was appointed to draft a resolution on the death of the wife of one of our Automotive and Power Press members.

"Whereas, While in Congress assembled the Automotive Section of the National Safety Council has been notified of the tragic accidental death of the wife of one of its members, and

"Whereas, God in His infinite mercy has seen fit to remove one who is highly respected," and

"Whereas, We deplore accidents of any kind and particularly those whose results are so tragic;" and

"Whereas, Our heartfelt sympathy goes out to our fellow member in this time of tragedy and sorrow; therefore be it

"RESOLVED, That this Section offer their deepest sympathy and condolence to this member; and be it further

"RESOLVED, That a copy of this resolution be forwarded by our secretary to our bereaved member, Mr. M. A. Kroger, of Detroit, Michigan, and that a copy of same be placed in the minutes of this Section."

CHAIRMAN DUNNEBACKE: This makes us realize that we never know who will be picked for an accident and we never know when it is going to strike. We have a very efficient member of this Section, a member giving his presence to this convention for three days, attending the sessions, and all at once he gets a telegram that an accident has taken his wife.

E. H. COTCHER (Supervisor of Safety, The Murray Corporation, Detroit, Mich.): I move the resolution be passed.

(The motion was seconded and carried).

CHAIRMAN DUNNEBACKE: For our first subject this morning, "Training Foremen in Accident Prevention," we have selected Dr. Harry Myers, of the Delco Light Company and Frigidaire Company, of Dayton, Ohio.

Throughout the whole range of life there are certain fundamentals governing man's every day contract. Dr. Myers has delved in and has grasped a wide range of that activity. He not only knows the philosophy of it, the esthetics of it, but he knows from actual shop operations, from actual work in factories and shops, the different links that connect these steps in our society. As personnel director of the Delco Light Company, he has been doing a very extensive work in foremen training, foremen development, and I know that he is going to give us a very interesting talk.

Training Foremen in Accident Prevention

Harvey Myers, M.D., Personnel Director, Delco Light Company, Dayton, O.

I asked Mr. Dunnebacke to take the census this morning that we might feel a little more acquainted with each other; a little more friendly perhaps; because I think these talks should be very, very practical, very personal; and certainly if we know each other better the result will be better.

I am sorry it has been my misfortune to be absent from the convention during these days. I know you must have had great sessions and I know now as you round out the closing day, you should be having an intense feeling of the need for action of some kind. So if you will allow me, I am going to get onto one of my pet subjects, which is that unless you carry this stuff back to your plants, into your work, and put it in operation, you have been a useless expense to your company. I want you to appreciate the seriousness of that problem. I know you will if you think it all over.

What are you going to do about it? What are you going to do about these things you have heard? Whenever a class leaves any of our rooms I wonder to myself, "What are they going to do about it?" Is this particular thing we are talking about going to show up in the plant in the next half hour, the next day, and so forth? Is this going to show up in your plants soon after you get back? Are your plants going to take on a different aspect because of your being here? That is the practical side of it, and folks, that is where most of us fall down. Some way or another we stop short of doing the necessary thing. One of the favorite questions I like to ask is this: What per cent of the things which you have heard or seen or read, that you have admitted would help you on your job and make you a better success in life, have you really done? I wonder.

Mark you this, of the things that will be said here this morning, the things you admit you can do and should do in the interest of your company and in the interest of yourselves, most of them you will forget. That is one of the reasons why they always take up the collection in church with soft music while you are still sitting, still in the atmosphere. They would never risk it after you get into the hall, because most of the people lose the atmosphere before they get out in the hallway.

How long can you hold an atmosphere? I wonder if you have read Elbert Hubbard? We have asked all our Delco people to read what he says about initiative. You have all seen that the world bestows its big prizes, both in money and honors, for but one thing, and that is initiative. What is initiative? It is doing the right thing without being told; but next to doing the thing without being told is to do it when you are told once. Hubbard divides the world into three classes of people: those who do it without being told at all, and to them go the prizes of life; those who have to be told once; and those who have to be told more than once. The successes of life lie in the first two classes.

The Measure of the Failure Class

When you have to be told more than once you are in the failure class. Is that logical? Watch yourself. Watch yourself in regard to anything that has been said in this convention that has been of new interest, anything in this whole convention about which you have said to yourself, "Yes, I am going to do that." Watch and see if you do it. Check up on yourself.

The first man we have any real record of having checked up on himself was Benjamin Franklin. If you have not read the autobiography of Benjamin Franklin, you should read it. We have sold over a hundred copies of that to our foremen in the Delco Light Company. Benjamin Franklin tells how he checked up on himself and made himself do the things that he should do. I recommend that book most heartily to anybody who, after he gets away from this convention, still finds himself not doing the things he promised himself he would do. You read that autobiography and I believe it will help bring the action that is necessary.

Here is another great big law that ties right in with Elbert Hubbard's talk on initiative, and that is this: My value is governed entirely by the amount of supervision I require. That is why the world bestows its big prizes on the people who don't have to be told at all, who need no supervision. That is why the man who can still do things when told once is a success. It means the least possible supervision. That is why those who have to be told more than once are in the failure class because they require the greatest amount of supervision and it is too costly; they fail. I am saying all this in a fond hope that the things which you promised yourselves you are going to do after this convention, you will do when you get back. Nothing could mean more to your plant, nothing could mean more to your personal success in life.

I am addressing a very mixed audience. I think 40 per cent are safety men. I wish I knew right now what your relation is to the foremen back in your depart-

ments, back in your shops. Then we would have a basis from which to start. I am talking now particularly to the safety engineers. I wish I knew how the foremen regard you. I wonder, because it would be entirely how you are now regarded in your organization as to how we must talk to you about training those foremen in safety work. I wonder if they are now interested in it; I wonder if they now look on you as the man actually helping production; or I wonder if they look upon you as a hindrance and hate to see you come into the department! The general managers who are here know what I am talking about.

I am wondering if the safety man in your organization is very popular. I am wondering if general managers here have an unpopular safety director. If so, he isn't a good one; and what is apt to make safety directors unpopular in their own organization is also apt to keep them from getting along well with the productive forces. You and I produce only indirectly. The employees get the stuff out. The foreman who directs getting the stuff out is making the money that is paying the wages, and I am wondering how you and I are regarded by the productive forces.

If you are not popular in your organization, I will bet I can point out one of the reasons. Did you every stop to analyze the difference between work and play? What is the essential difference? We say in Delco Light we are working on two big fundamental things, trying to make work a pleasure and trying to help people do well in life. One of the things which makes work distasteful, and the deep difference, I think, between men at work and men at play, is the question of authority. And I will say to the safety directors here, if you are not popular in your plant, ten to one you have used your authority unwisely. The very fact that you know you can stop a machine if it isn't fixed up with a safety guard, is a bad thing for you.

An Indication of Solid Character

That is one of the things which will keep you from being unpopular and unworkable in your organization, or wherever else you are. Nothing discloses real character like the use of power. It is easy for the weak to be gentle, but if you want to know what a man really is, give him power. This is the supreme test.

It is to the glory of Lincoln that having almost absolute power he never abused it except on the side of adversity.

Now when you go back and are inclined to talk hard to a foreman, knowing that you have the authority to close his machines down if he doesn't do what you want him to do, if you are going to get hard, nasty and unfriendly, just say those five wonderful words to yourself: "This is the supreme test." Just remember you are not measuring up under the test. How many thousand times I have said that to myself. I was going to lay somebody out because I had the authority to do it, but I caught myself and supervised myself, and I didn't.

What I am trying to say is that this is one of the ways not to teach foremen, by the authority you have. You can't train people by teaching if you don't know the fundamentals of good teaching. Most of the scrap back in your departments today is due to poor teaching, poor instruction. That is absolutely true. I will never forget the first meeting I had in the Delco Light. I was talking about the great need of better instruction; and the boss, Mr. Ketering, came into the room. If you know him you know what a marvelous man he is. The boss listened for a while, then he got up; and he told me more about my own job than I had ever known.

He outlined three fundamentals as only Boss Ketering can. He said, "Instructions degenerate and do not propagate." That is why it is so hard to teach. Instructions run out, they stop. If I tell a man a certain thing and it passes through four hands, you know what happens. Instructions do tend to degenerate, they don't propagate. They don't develop, they run out. That was the first thing Mr. Ketering laid down. Instructions tend to degenerate, they don't propagate, and for that reason you have to be so definite in what you say.

Mark the next, too. He said, "You are poor instructors because you are poor actors. You don't like to do your stuff again and again in an interesting and entertaining way." He said, "Last night I went to see Ed Wynn. He is doing the same damn fool stuff that he did three years ago when I first saw him, and yet I sat there and laughed my fool head off; and then I thought: What has it cost Edwin to still keep doing that in such an interesting and entertaining way at the end of three years? Just the other day I saw his salary is something like \$5,700 a week! Why? Because he can do a thing over and over again and again and for years, and you like it."

Ketering said, "I am positive that most of your men want to do good work if you are smart enough to show them how in an interesting and entertaining way." Do you get that? Not with authority. Although it is true that most of our instruction in our organizations, in our plants, is given in the way of command. But are you interesting and entertaining? Take Ketering's word: "I am positive that 95 per cent of your men want to do good work if you are smart enough to show them how in an interesting and an entertaining way."

I believe that the foremen of your organizations will be interested in the safety movement if you are smart enough to take home the inspiration of this convention and give it to them.

Any Leader Has to Be "Smart Enough"

If you are going back in the same dill pickle state you came away in, if you have been anything but friendly and so forth, anything but pleasant and agreeable and cordial in your organization, and if you can't carry back from this convention this inspiration to your foremen, then you are not as good a safety director as you should be, and Ketering will say you are not smart enough.

Notice, he didn't say how smart; he said, "if you are smart enough." It simply means this, that if you are smart enough, if you can carry away the inspiration of this meeting, then I believe that your foremen are going to be interested in having you come in their departments on this question of safety; but if they are not interested, if they would rather have you out of that department when you come in, then, folks, you are defeating yourself in your project.

There was a third thing that Ketering said: "You are poor instructors because you are apt to teach the last thing you learned and not the first; so that poor devil is learning it from the wrong end." If there is some man in your department who is not as interested in safety as you are, just know that he hasn't the grasp of it that you have. Try to remember how dumb you were, how little you once knew, what first created an impression and interest in you. If you will start there and get that over to your foremen, I honestly believe that you will have interested them, and that is the first thing for you to begin with. If your foremen are not interested in safety I am very, very sorry for you. I believe that you can have interested foremen in this work, this marvelous work, if you will obey those things that Boss Ketering laid out. It is all in the teaching, and to get that started you must first have an interested group of people.

I believe, folks, that we go far afield when we consider safety something apart in itself. I have seen so many people do that, just as they have considered personnel a thing apart by itself. It is all a part of a big work, the development of the healthy, intelligent, interested working force and organization. The fundamentals that go into making safe departments are the fundamentals that go into making good foremanship. Good foremanship means safety and safety means foremanship. What are the fundamentals of good foremanship? When you go into a room do you say to yourself, "There is a good foreman"? When that department is clean and when it is in order, isn't that true? And right now when you go back, start the first thing to have a clean and orderly department and start the biggest thing for safety in your plant that you could ever mention.

The plants that fail are dirty, disorderly plants; the plants that succeed are the clean, orderly plants. Is that true in your experience? Can anybody dispute that? Have you ever seen a safe department that was a dirty department? Did you know that order, absolute order, is the first process of life? We approach the average foreman and the department is dirty and all disorderly. When you ask him about it he says, "I know why; they took one of my janitors away from me." Oh, what a mistaken notion of order. They are thinking in terms of order in janitor work. They don't think of order in the life process. We have all our foremen repeat this and mean it, "Order is the first step in production and if I can't manage the order of my department, I can't manage the department." Do you believe that?

The greatest step in low cost production and good production is order. We firmly believe in Delco Light that unless we can get a foreman interested in the question of order we can't get him interested in any proper question of manufacture. We go to great length. One of the little definitions of order is interesting. Order is a place for everything and everything in its place. In our definition of order we say, "A place is in order when there are no unnecessary things about and those things that are necessary are in their proper place." "No" in that sentence means not any, not even one. There comes the bite. Not even one. If you want to see how this is worked, come down to the Delco Works.

The Safety Movement Inspires Better Foremanship

I just want to make another point in conclusion. The whole safety movement means better foremanship; better foremanship means safety. The best foremen you have in your place are the safest foremen. Why? Because underneath the whole thing we know that the thing which makes for safety and makes for foremanship and makes for the better things of life, is the elimination of carelessness, and that is what is wrong with most of us. That is why we show such a low per cent in accidents. That low per cent most of you would have if you were honest about it. Don't you think that is true? Carelessness in your plants today is not only causing the accidents but is responsible for the poor work that you are sending out.

We know in studying the human side of this question, that the material side is rarely at fault. Most of the things you are sending out now to your customers are right, but not quite all. The big question is why aren't they all right? If most of the things are right it shows that your theories of manufacture, your theories of the fabrication of the articles, are pretty much right. The big question is, why don't they all go out right? Because of the human side—the failures, the frailties of human nature, and the biggest of all is carelessness. We have got a homely little definition for carelessness down there which I want to submit to you. "You are careless if you do not do anything as well as you can." Failure to do your best on anything means carelessness. You think that over, and then just ask yourself this: "How many times am I doing my best on a thing?" Folks, it is not added knowledge we need, it is an added something else that absolutely gets us by the nape of the neck and makes us do our very best.

Here is a little precept of three things that will absolutely eliminate carelessness in your shops and in yourselves: "Be clean, be orderly and have proper working equipment (and by equipment I mean everything that you use) and you can't be careless."

Folks, these things are all tied together. I can't separate them. Safety, accident prevention, is simply good foremanship, good managership, good management all the way through, in shop or in home. I wish we had time for a discussion. I should like to have your ideas. Of course, I am still wondering just as I did when I began to talk to you: What are you going to do about it when you get back?

AUGUST KEMS (Kenosha, Wis): I make a motion that we give this gentleman a rising vote of thanks.

(The motion was seconded and carried.)

CHAIRMAN DUNNEBACKE: While I should like to declare the meeting open for discussion, I hesitate because we have some other interesting talks and we need the time; but I think we will take about five minutes. There may be somebody here who has some particular thing he would like to have Dr. Myers emphasize more.

CAPTAIN FISHER (Illinois Manufacturers' Association): If I am quoting the doctor right, 95 per cent of the men will play the safety game if you are able to put it up to them. I am not asking a question, but I want to say something that will back up that sentiment. I have been doing this work for ten years, talking many times every day, and I get a better hearing in the shops and plants than a preacher does. Why? Because I talk along the lines of the things that interest men and that the men know are for their good; and I am constantly saying to managers, superintendents and foremen, "If you will get enthusiastic along this line the plant will get it." And it is true of my superintendents, like foremen, like workmen. It is amazing how much of the accident problem is due to the lack of enthusiasm among the foremen or the superintendent in putting this safety work up to the men. The men know it is for their good and they catch on and respond.

CHAIRMAN DUNNEBACKE: We will proceed to the next subject. The Fisher Body Corporation has done some wonderful work in safety, and Mr. N. M. Loney is here to tell us how they do it.

Application of a Cash Accident Prevention Bonus

N. M. Loney, Fisher Body Corporation, Detroit, Mich.

Some time ago I was confronted with the desirability of devising some way of bettering the performance in accident prevention in certain rather hazardous departments of the corporation with which I am connected. In order to meet the situation, the existing safety organization was expanded somewhat, the mechanical guarding was considerably improved, and a campaign of education was initiated. A little later, a cash accident prevention bonus system was installed, and as a result of these measures considerable improvement has been shown. I am unable definitely to allocate the improvement in the record to the various measures taken, but I believe that most of it is due to the cash bonus. I do not propose to go very far into the question of the desirability of such a system, but only wish to say that under a given set of conditions it has worked out very well for us.

It is very easy to decide to pay a cash bonus for accident prevention, but I found it quite a difficult task actually to set up the machinery by which this system would be administered. The reason for my appearance here today is that I believe, after considerable effort and experience, we have devised a system which may be of interest to those who may decide that their conditions justify the application of a cash bonus system, and this paper may be of assistance to others who may wish to use such a plan.

The first question which arose was: to whom shall the system be applied? An inspection was made of the records of payments for compensation and medical attention for several years back, and the departments where such payments had exceeded \$5 per year per man were selected as having sufficient expenditures to justify giving a bonus which would be worth while. This \$5, by the way, is the figure which was, more or less, arbitrarily selected as being one which would be large enough to attract the interest of the foremen, and still small enough to leave the possibility of an actual reduction in total cost of compensation and bonus. I might say here that our results have justified us in putting the whole proposition on a cost basis. The humane

side of it has not been overlooked, but we feel that this followed as a matter of course, and we all know that a policy which justifies itself financially is more easily installed and operated than one which has to be placed on an altruistic basis.

As stated above, this figure was adopted more or less arbitrarily after an inspection of the actual experience, but there is no reason why it could not be made considerably less as long as it produces sufficient remuneration to be worth mentioning. Most of the foremen whom we were trying to reach were those in direct contact with the workmen, each supervising on an average of 20 to 30 men, and this figure would produce an average bonus of from \$100 to \$150, which, if earned, would add materially to the foremen's earnings. The department foremen, who supervise the foremen, and who thus, in most cases, are one step removed from direct contact with the workmen, were also considered integral parts of the picture, and their bonus was made dependent upon the earnings of the foremen under them. All rules, of course, require exceptions, so that in order to take care of the exceptions a minimum for any foreman was set at \$20 per year per foreman, and a maximum of \$400 per year per foreman. Between these limits the system, which will be explained later, was allowed to work itself out to whatever it produced.

These limits having been established, the next question that came up was to make sure that the money appropriated was distributed on as equitable a basis as possible. This brought us immediately to the question of the relative hazard exposure of each foreman. Various insurance authorities were consulted, and a study was made of the available hazard ratings. None of these seemed to break down the hazard to fit the individual operations, and all of them were somewhat difficult to explain to foremen who ordinarily are not very well posted on this subject; I therefore conceived the idea of allowing the foremen to set their own hazard ratings.

Pointing Out the Most Hazardous Occupation

It happened that we had five mills doing similar work on the wood parts, and we had two press rooms and two die-making and maintenance shops. All together, these plants employed about 5,000 men, and the operations were quite similar in all of them; generally speaking, the hazard exposure in each was about the same. Small groups of these foremen were called together, and were asked, "What do you consider the most hazardous occupation in your plant?" In the case of the wood mills, the usual reply was that hand jointers, wood shapers and mitre saws were all quite dangerous and equally so. We said, "All right; then, we will tentatively assign to these machines 100 points on our scale of hazards." We then asked, "What do you consider the safest operation?" It was unanimously agreed that bench glueing of wood parts was the least hazardous, and we then set this up at 10 points on our scale of hazards. We then took up each machine or operation as listed on the rating sheet, which will be referred to later, and after considerable discussion fixed a rating on each between the above limits. In cases where helpers were employed, if there was a difference in the hazard exposure between operator and helper, this was fixed in the same manner.

Of course, quite serious differences of opinion as to the degree of hazard developed inside the various groups and between the different groups. In cases where the members of the groups differed, the majority was allowed to prevail; and the differences between groups were settled by a committee of superintendents of the various plants who finally adopted the figures used. These ratings were not entirely inflexible, as the safety department sometimes modified ratings for a particular plant or operation where conditions justified

this. For instance, the difference in the surface over which trucking was to be done might very well justify a change in the hazard ratings for this operation in the various plants. A record is being kept of actual experience, so that as time goes on it is hoped that these hazard ratings may be put on a more scientific basis, but since the whole underlying motive of the accident prevention bonus is psychological, we felt that if the men concerned were allowed to set their own ratings, it would be much easier to overcome the feeling that any individual was being unfairly treated.

As time went on, the system was extended to outlying mills, in one case to a saw mill, and also to take in the departments having to do with the preparation of metal (having first started with the stampings alone), and the hazard ratings for each department developed as described above. Attached in Appendix "A" are the following hazard rating sheets that have been adopted and are now used:

Wood Mill, Press Room, Die Shop, Metal Room.

These sheets are used as follows:

Assigning the Amount of the Bonus

A rating sheet is filled out in duplicate for each foreman by inserting in the proper spaces the average number of operators and helpers expected to be engaged under each foreman during the ensuing quarter. The rating for each operation is then multiplied by the number of workmen engaged on same, and the total extended and carried to a sheet total, which latter is the sum of the ratings of all operations under the foremen's supervision. The ratings for individual foremen are then added to get a total rating for the general foreman having several individual foremen under his supervision.

The next step is to assign the amount of the bonus. The theory here is to make the bonus of sufficient amount to be attractive and at the same time rather difficult to get. Considerable experimenting was done to fix a method by which any severe accident would eliminate the bonus for any individual foreman during the quarter in which it occurred, so that we, at this point, arbitrarily set up an allowance which may be said to express the probable normal percentage of time expected to be lost on account of accidents to the total time worked under each man's supervision. Any foreman exceeding this allowance would lose all of the bonus set up, and any foreman losing only a portion of the allowance set up would lose only a proportionate amount of bonus. You will note that the allowance is proportional to the hazard. The allowance is taken as one-tenth of the rating, and the bonus is based on twenty cents per point of allowance, or as a short cut, two cents per point of rating.

In the case of general foremen, the allowance is taken as one-fortieth of the sum of the ratings of the foremen reporting to him, and the bonus is based on forty cents per point of allowance, which, as a short cut, is one cent per point of rating. (Appendix "B" is shown as a typical summary for one plant.)

The allowance and bonus figures are then carried to a printed bulletin sheet, which is posted in a conspicuous place in the plant in a neat glass case, subject to the inspection of all concerned. At payroll periods the total time worked under each foreman is roughly computed, and the percentage of time lost is deducted from 100 per cent, and the result posted in the column shown.

It may appear that computation of the time worked under each foreman would be quite burdensome to the time department, but a little calculation will show that a five or ten per cent variation in the total time worked will only appear in about the fourth place of the bulletin rating, and will not

affect the bonus materially one way or the other. The reporting of the time worked under each individual foreman has been left to the foreman himself or a clerk, who reports to the safety man, who, in turn, ordinarily operates the system; and if the total time reported by the foremen checks within reason against the timekeeper's records of the total time worked, it is accepted as correct.

Here, again, I want to make the point of the psychological effect. It was felt that if the men were convinced that the system was being administered fairly it need not be scientifically exact to accomplish the result desired. Therefore, we accepted the approximation of the time worked, rather than going to the expense of actually keeping a check on the time records. In some departments it happened that the time was already kept as desired for this purpose, and of course where this was the case it was used.

When the ratings are posted at each pay period, there is also posted on the glass of the bulletin board a typewritten summary of the time losing cases, giving the name of the workman, name of the foreman, nature and cause of the accident, the time lost, and usually some warning pertinent to the record.

The Bonus is Paid at Quarterly Intervals

In the above discussion, the system has been referred to on an annual basis; in actual operation the bonus is paid at quarterly intervals, and new bulletins are posted at each quarter, no lost time being carried over from one quarter to the next; so that if a foreman has made a poor record in one quarter, he is encouraged to make a fresh start in the following quarter. At the end of the quarter the amount earned is computed in proportion to the time saved out of the allowance. A cumulative record is carried in successive pay periods so that the last column automatically gives the rating of time saved out of the allowance.

In conclusion, I wish to present some statistics as to the actual results accomplished during one year's operation of this system. It was applied to an average of 5,783 men who were supervised by an average of 215 foremen. The bonus set up amounted to approximately \$28,700 for the year, about \$4.96 per man and \$133 per foreman. The amount earned was approximately \$22,200, about \$3.84 per man and \$103 per foreman.

We had a couple of plants with a rather bad record—one plant in particular having paid during the previous year for compensation and medical service arising from accidents \$35 per employee. This plant employed from 500 to 700 men. In the succeeding year, we paid out in compensation something less than \$8 per employee, and for bonus about \$4 per man, so that there was an actual net saving in the total expenditure of about \$23 per man per year. Another plant paid in the previous year approximately \$40 per man for compensation and medical service, and in the succeeding year only about \$14 per man for compensation and medical, and a bonus of about \$4 per man, showing a saving of about \$22 per man per year.

In the plant in which there was the least improvement, the sum of the compensation and bonus paid just exceeded the amount paid for compensation alone the year before, and statistics indicate that the weighted lost time was reduced by approximately 70 per cent over the previous year in three of our plants, and from 40 per cent to 50 per cent in the balance. The actual net saving in the departments to which the system was applied was in the neighborhood of \$10 per man per year.

I trust that I may be pardoned for lugging these actual figures into this talk, but it again illustrates that any good safety device actually pays.

In the above figures, no allowance was made for the expense of operating the system. This was mostly done by the existing safety organization, and the total expense for this department was very little, if any, greater than it would have been if the bonus system had not been employed. When the system was first proposed, it was feared by a great many of the production men that production would suffer on account of it, but in the whole year's operation no complaint on this score has been brought to our attention, and on the other hand, it has undoubtedly served to increase production since it has prevented the unaccounted-for loss of time which inevitably occurs whenever a serious accident occurs.

In connection with the statistics, it is interesting to note that 35 foremen out of a total of 215 went through the entire year without an accident, but no foreman failed to receive some bonus. It has been found to develop a healthy spirit of rivalry, and the bonus, being distributed quarterly in the form of checks to the assembled group of foremen in each department, it gives the safety man a very good opportunity to review the record of each man during the previous quarter and draw the necessary lessons therefrom.

As we are extending this system to our outlying plants, we are saying to the foremen affected that we feel we have been paying the insurance company or the compensation department money on account of accidents which we would much rather pay to the foremen if they can prevent accidents, and at the same time we expect to make a saving on the total cost. Now that we have the benefit of the experience in the record quoted above, we are finding it very easy to make real safety men out of foremen who were formerly quite indifferent.

In closing, I wish to repeat that I am not advocating the adoption of the bonus system for accident prevention, as such. I only wish to give others the benefit of our experience with it, and in that connection I shall be very glad to answer any questions and to show privately to anyone interested, the actual detailed records which I have with me.

CHAIRMAN DUNNEBACKE: There is no question but that the idea of paying a cash bonus to foremen for doing safety work which we generally consider as being a part of the everyday work, is rather revolutionary. However, it is also true, as Mr. Loney said, that any principle or any movement that you want and can put over through a financial means, instead of altruistic ideas, will go over quicker. Now, no doubt there is many a manager who would be willing to pay real honest money for safety work if he knew that he could get that money back. Here is one instance of a company that is doing that. They are actually paying out cash bonuses to foremen for doing safety work, and by doing that they are saving money. It is a business principle. They are not only saving money but back of it all they also get these other things that we get through humanitarian ideas, love of their fellowmen.

For instance, there is one case, Mr. Loney cited, where over the past year they paid \$35 compensation per man in the plant. After they put in the system the next year they paid \$8 and an additional \$4 bonus to the foreman, with a total cost of \$12 against \$35 the year before.

Here is a system, machinery that is all working and has been working for eighteen months. While I am not satisfied in my own mind as to whether we should pay foremen cash for doing safety work, here is a system that is working and actually paying money to the men. As Mr. Loney says, if you are interested in it, and want to go into it, you are absolutely welcome to his machinery.

H. E. MILLER (Chevrolet Motor Company, Detroit, Mich.): I should like to ask Mr. Loney what the reaction has been among the men on the production floor, the

actual producers, on the paying of the cash bonus to the foremen, when they are participating in none of the dollars and cents.

MR. LONEY: I am going to ask Mr. McCarthy, one of the operating men, to answer that question.

M. J. MCCARTHY (Fisher Body Corporation, Detroit, Mich.): Mr. Loney stressed the point as far as the cash is concerned. The cash bonus has gone on for eighteen months, but I want to say that the cash part of it is practically out of their discussions at this time. The bonus affords the plant management an opportunity to see at the end of that bonus period what percentage of reduction has been made in accidents. Consequently, at the end of that bonus period, the whole period for all the foremen, the percentage is worked out. For instance, in one period it might be 78 per cent of the bonus paid. The next period will come along and if the bonus paid is less than the previous bonus period, we have had a greater number of accidents. If the bonus paid is higher, then the accidents have been less, of course. If it is higher, naturally a higher bonus is paid, and if it is lower, someone has to explain why.

The Foreman Sees the Injured Man In His Home

I will mention a welfare point. When a man has an accident the foreman doesn't let it go at that; it is called to his attention by the safety man and the foreman calls at the injured man's home that night to see if there is anything that can be done. He will get him in to work a great deal quicker by showing this interest. Don't forget the cash is some incentive of course. But they all want to get that percentage higher than it was in any previous bonus period. I can cite one shop in particular, the die shop, where in the last bonus period they had 96.6 per cent of the total amount of bonus that should have been paid. An unfortunate accident was all that kept us from 100 per cent.

The bonus is the greatest thing I have ever seen. A lot of people condemn the idea of paying cash to a foreman, but I have worked at quite a few manufacturing plants and it is the greatest thing I have ever seen.

As far as the workman is concerned the cash paid to the foreman seems to have gotten out of his mind entirely. The cash part of it seems to be forgotten. The chart being shown in their plant brings up the percentage. The men in the shop don't mention the cash, but they will speak of the percentage of bonus that was paid. It seems to bring out the point that accidents are being prevented in their department if the large amount of bonus is paid, and the actual cash being paid the foreman doesn't seem to enter into it. I have never heard a complaint about it. But the greater percentage of cash bonus paid in that department naturally makes them feel that they are helping to cut down accidents.

MR. LONEY: I should like to hear from any more of the Fisher Body men here operating the system or in contact with it. Have you ever had any grievance, fancied or real, on the part of the workmen on account of the foremen getting money? If any of you have, I should like to have you speak right up.

MR. MILLER: Our men have never participated in the actual cash plan.

MR. LONEY: The underlying theory is that this foreman, if you want to put it that way, is his brother's keeper in regard to accidents. It isn't the workman's job so much. It is the foreman's job to train the workman to be safe, and the foreman is being paid for his work in training the workmen, and not the workmen. It would be rather ridiculous to pay a man to save himself from getting hurt. The man who trains him, I believe, is entitled to his reward.

O. J. OLSEN (Fisher Body Corporation, Detroit, Mich.): Is Mr. Saborin here? Mr. Saborin is the general foreman over the metal shop; that is metal stampings after it leaves the presses. Mr. Saborin and several others, in my mind, stand out among all the foremen. The first thing Mr. Saborin did was to put his house in

order. That was housekeeping and that is the important part of the whole business in safety. Then he went further and equipped guards on the machines. All right. He wanted to go further than that. There were a lot of accidents occurring in the department. One of them was to a man who was continually going into the hospital for slight lacerations. So he gave the medical authorities a list of his foremen and when any of them had any accidents the first aid attendant notified Mr. Saborin several times a day in regard to them.

By this analysis Mr. Saborin found that a particular man was continually going to the first aid room. He looked into it and found that it could be corrected by putting a little tape on the man's finger; so the man gets this tape on the finger every morning or twice a day.

There is another man in our organization, a foreman in our wood mill, who has about 30 miter saws or table saws. This foreman has gone through 14 months without a lost time accident. The miter saw is a very dangerous piece of equipment.

You talk about the men under the foremen and their reaction to the fact that the foreman is getting a cash bonus. There was some little reaction to that, but it was only in a few isolated cases. I should like to have Mr. Saborin tell you whether in his group of men (I think he has around 250 men) has any experience with that.

Apparently the Bonus to Foremen is Not Resented

S. SABORIN (Fisher Body Corporation, Detroit, Mich.): The fellows don't feel they should be in it because we are keeping them working.

MR. OLSEN: They feel you are keeping them on the job. I think that is a good answer.

There is another man here, in the Press group. Mr. Schnapp, have you heard anything from the men under your supervision about resenting the foremen getting a bonus and they not getting part of it?

MR. SCHNAPP (Fisher Body Corporation, Detroit, Mich.): Not at all.

MR. OLSEN: Mr. Luce has charge of the press shop, is superintendent of it. Mr. Luce, have you heard in your contact with the foremen, anything about it? I know that Mr. Luce is very close to his foremen.

FRANK LUCE (Fisher Body Corporation, Detroit, Mich.): The press room workers are all working on piece work and we find that they like to get the piece work and they don't feel that the foremen are getting too much.

MR. OLSEN: You haven't heard any of the men say that they felt they ought to be a party to it?

MR. LUCE: No, sir.

R. F. THALNER (Buick Motor Company, Flint, Mich.): The testimonial from the foremen is all very well and good, but how many of the fellows come in and kick to the foremen? I think the testimonial you want to get is from the men in the department. They are the fellows talking it over.

MR. OLSEN: Mr. Thalner, I personally have gone down below the foremen.

CHAIRMAN DUNNEBACKE: I am going to reserve any future discussion on this subject until after the next speech. We may then have some time left and may have some more pro and con on the idea.

The third and final paper is one dealing with the question of safety as a part of every foreman's responsibility and the subject is going to be handled by Mr. Art Williams, who is now safety director for the Chrysler Motor Car Company. He has had many years of experience along safety lines with the American Telegraph and Telephone Company. He was last Tuesday elected to the chairmanship of the Automotive Section and I am sure we will get some very good information from Mr. Williams' talk.

Safety—A Part of the Foreman's Responsibility

A. M. Williams, Safety Director, Chrysler Corporation, Detroit, Mich.

I had a very, very nice long formal paper prepared here. I thought a whole lot of it. After Dr. Myers got through this morning I made up my mind I would put it in the waste paper basket. It seems to me that our whole job, before I get down to the subject assigned to me, is keeping this entire safety program and our educational program in very nice balance. What I mean by balance is this: We can start a safety inspector out in the plant and say, "Now, Bill, we have checked our accidents for last year and find that 85 per cent of them could not have been prevented by improved mechanical conditions. Fifteen per cent of them might have been. Therefore, weigh your time and let's go at this 85 per cent."

That is the job that we have to keep uppermost in our minds all the time. Naturally, as soon as he gets down on the floor he runs into Bill Jones and the safety competition is pretty keen. It is over in our place, has been running now for two years, and the management is doing a lot of racing and a lot of rooting. Some are on the carpet for bad records and some for good records, and every foreman is fighting to get his men back; no bonus in it, by the way, but just his own reputation and his own obligation as head of his department; his reputation is at stake. Naturally the foreman says, "Well, when am I going to get that guard on that machine? I put an a.d.o. (as we call them, merely a memorandum) through the maintenance department, asking for a certain machine, day before yesterday, and there hasn't been a darned thing done about it yet. When am I going to get it?"

To get the foreman away from the mechanical side of it and to talk about Bill Jones and Charlie Smith working on a sheeter, with long sleeves, possibly in violation of safety rules, to get him back on the educational side of it, is the big job, because every foreman (I know how they feel because I was a foreman myself for years) looks at the mechanical side of it; he is machine minded, material minded. And he doesn't give enough thought to that third side in the triangle.

I don't know whether we are going to tie a string around the fellow's finger to keep him in balance so that he will have something to remind him or not. If we don't, he is continually being driven right back to the mechanical thing instead of standing on two feet and saying, "Wait a minute, Bill; that thing is going through. I am making a memorandum now and we will see that you get it. But how about these new men down here? You had three new men yesterday. You go over the safety rules with them and see they qualify. They may not be, just through ignorance; they are green here and they may slip. If they do slip your record for the last year and a half without an accident in your department is knocked into a cocked hat."

Naturally when we started this, our foremen asked for help. They said, "If I am going to teach, if my job is partly that of a teacher, what have I got to work with?"

Well, we went through all the educational material we could pick up and you boys have contributed a lot of it. We stole your ideas wherever we could find them, we wrote many of you for ideas; remember the foremen were asking for this information. They were asking for help. We got out altogether six pamphlets, by trades, so that a man could have a first reader in safety to use in teaching the green man about the hazards of his job. We started each one of these with general rules that are common to all of the six.

Then the last part of the book is devoted to the specific hazards of the department that the man is working. "How about these new employees now? We are taking on a great big bunch of men and I can't see all of them. Can't you give us a lift?" the foremen asked.

So we set up a routine at the request of the foremen and when the new employee comes into the employment office and is qualified by the interviewer for the job, he

next goes to the physical qualifier; but before he goes, the qualifier calls his attention to the fact that he is going out on a welding job and there is a book of instructions to welding operators and he will be expected to learn those rules and stand an examination on them. But he doesn't get the book yet. He goes over to the physical qualifier and the physical qualifier notes on the card of introduction that he is going on this type of work. He also, while talking with him and getting his history and writing him up, checks that same angle and says: "You are going to be given one of these books and later you will be examined, because there is a safety campaign on in this plant and if you want to get yourself into ill repute, I don't know any better way than for you to get mugged up in an accident."

He goes back to the employment office and the clerk, after giving him the tools, gives him the book. The man who introduces him to the foreman talks to him on the way out. He is turned over to the foreman and the foreman gives him the final shot and says: "Some time in the next three or four days I am going to get to you and see if you can pass the examination on these rules." In the beginning, the question was whether the men would read the rule books. The question from the foreman was, "Will they read them?" I think they are put across in a friendly way and it brings out one point, if you will permit me to digress. As chairman of the Automotive Section, I am going to submit to the Executive Committee sometime in the next two or three months the plan of standardizing, or appointing a committee on standardizing, safety rules, safety instructions, for use by all of the plants, something that all men who are working in automobile plants will get in the same way, at Packards, at Buicks and at Chryslers. Therefore, when the man leaves your plant and comes to mine he is familiar with these rules, he has been over them and knows what to expect, and what to expect in the way of discipline.

Industry Parallels the Army Organization

I made a few notes here, getting back on safety as a part of the foremen's responsibility.

Industry today tallies very, very closely, or follows very closely the old military traditions of the Army. In fact, when we set industry up in large groups as we have today, we just simply stole the system from military experience; and we should gather this from it, that responsibility and authority always must rest on the same shoulders and cannot be split. There are many safety departments that are made responsible for the prevention of accidents. The responsibility is placed there, and the foremen feel that it is the safety department's job. My job is to get out production. Our job must square with the organization. It must also square with the man in industry as he is. In squaring it with industry, my picture is this, that we must place the responsibility for the accidents back on the same shoulders that carry the authority for the discipline, the authority for the production in each department.

In other words, we can say to the foremen, "There is your safety job right there on the floor, Bill. It is yours, and whatever you do with it, if it is a good record, will be yours; and if it isn't it will also be yours. We are going to help you shoulder it but we are not going to carry it for you. We are going to help you in any way we can. We have a potential malingering in your department which we are going to help you clear up. If you want some help in getting mechanical conditions corrected, we will do that. If you want an instruction book, something that you can sit right down with a man and go over with him, that will simply pin his attention and your attention right down to the high spots that this man must get to keep himself in the clear, we are going to help you.

"We are also going to do this: We are going to put a performance rating on the whole job; we are going to give your department a mark to shoot at and that is going to be determined with the rate of hazards in your department. So that you in

the press room are on an equal basis with the man out here handling material, or the man over here on other machine operations.

"And to get that we have worked out something that we are proud of. It has run a couple of years and the foremen are all sold on the fairness of it, and the man in the press room can compare his department with the man in the other department. We secured the figures from the insurance reports, worked them out and translated them through the wage rates in the different trades, so that it represents the thing in man hours, and the foreman has something in man hours that he can show every man in his employ. He doesn't have to talk to the man in dollars and cents and set up in his mind the thought that the company doesn't care anything about his life, that it is merely a dollars and cents proposition to them. When you talk in hours, that means the hours of time saved, and something of the loss that all of the men will sustain. For instance, here is a report that goes out to the physicians every two weeks. It is a performance rating report. The first is the inter plant, and the next is the intra plant. Each sheet in the intra plant shows each department, the name of the foreman, the number of hours allowed, the number of hours we might expect that we would lose due to accidents; also the number of hours that were actually lost, and then the percentage of hours saved, and they are rated on a percentage basis.

The Original Estimate Very Nearly 'Right

We worked these figures out expecting that we were going to shoot at it at 30 cents per hundred dollars of pay roll rate; and the first quarter that we ran this two years ago we came out almost to a cent. We were only 4 per cent off. This report takes us down to the current quarter, to the tenth of the month. This is the last report I have and there will be one other that will close out the quarter. This shows that, according to the insurance figures, on a basis of 30 cents per hundred dollars of pay roll, we could have expected 39,000 lost hours at all plants—39,000 lost hours. We didn't lose that many; we lost 12,000; so we made a net saving of 70 per cent. That will give you the picture of about what the rate will run for the quarter.

In press rooms (going back for one moment to pin down the 85 per cent theory due to education), we got across to the press operators in our plant this year that our amputations have been reduced 80 per cent. So we can feel we are getting down pretty nearly to the minimum of accidents from the educational side of it, so far as press operations are concerned; therefore, the 20 per cent will be largely the job of better dies and better guarding.

I will wipe the whole slate and bring this one point: If safety is a teaching job we will have to think of teaching and all the fringe that goes along with teaching. In our schools the teacher not only follows the curriculum and gives the student all of the material in the curriculum, but you have the adjustments that that person has to make to social and political life; and there is one big adjustment yet to make and that is the adjustment to industrial life. That is a part of the foreman's job as a teacher, and if in years gone by we had put our teaching on a premium basis or on a bonus basis, I wonder if we would have had the same value and would have secured the same value in this training (as you might call it), that we have secured in preparing young America for the place that he must occupy in social and political life.

CHAIRMAN DUNNEBACKE: We have ten minutes before twelve o'clock and as much thereafter as you wish to take for discussion. I will throw the meeting open to discussion on any of the three papers, Dr. Myers', Mr. Loney's or Mr. Williams'.

E. F. BLANK (Jones and Laughlin Corporation, Pittsburgh, Pa.): I am very much interested in Mr. Loney's paper on this cash bonus plan. It brings up three questions which I would like to ask. First, is not safety an operating problem?

Second, isn't the foreman's job one to prevent accidents or look after the safety of his employes as much as it is to get out production? And third, if this is true, why pay the foreman any bonus to do his duty? Mr. Loney stated that this plan wasn't a panacea for all the accidents. There are a good many other plans. It seems to me there are a lot of simpler plans that will get the same results. I think most of us have ratings and charts in the time and pay roll departments which take less time. It may not be so much work as it appears on the surface.

We are using the competitive plan and think we are reaching the workmen better than we have ever been able to reach them before. I have the same reaction that Mr. Miller had in regard to "Doesn't this react unfavorably among the men themselves?" It is a good thing for the foremen and makes them pay some attention to safety in their departments. I should think a plan which would let the men in would be much better; and as far as getting a reaction from the men themselves, about the only way you can get that is to put some "gumshoe" workman out there and let him find out what the men are talking about. They won't talk to Olsen or McCarthy or to the foremen because they know they are identified with the plan.

CHAIRMAN DUNNEBACKE: Mr. Loney, will you answer that?

Give a Bonus for Safety as Well as Production

N. M. LONEY (Fisher Body Corporation, Detroit, Mich.): If I understand Mr. Blank right, the first point that occurred to him was that this foreman was expected to produce safety as well as production. I am going to ask Mr. Blank an individual question. Does Jones and Laughlin Company pay you a bonus for good performance? The General Motors Corporation does. As you all know, they have a published system awarding every one a bonus according to production. If a man gets a bonus from his production and safety is equally important with production, why not give him a bonus for doing part of his job?

As I said in the beginning, if I conveyed the impression that in my mind this is the only system for securing safety, then I am all wrong, because this is only a tool. We are using all the other tools available. Please don't run away with the idea that we think this is the only way to produce results. As I remember it, the difference between Mr. Williams' system and ours is that we have possibly a little more tangible reward, and the spirit of competition for getting money I think is just as strong as the competition for getting on. I know I am interested in competition for the money I get and I don't doubt that our foremen are interested to know that they are in competition with the other foremen to get this financial reward.

MR. BLANK: Those three questions are pretty well answered. The only thing I would bring out is Mr. Loney's answer with regard to the bonus. As I understand, your bonus is for efficiency and good service. My point is that that bonus should take into consideration the prevention of accidents the same as it does the reduction of scrap, the cutting of operating costs, and it ought to be allied in that same bonus. My thought is that perhaps this scheme is just divorcing safety a little bit from the main event. We try to make safety part of the main event and not a side show.

MR. LONEY: As I stated in my paper, we have some pretty hard boiled production men who fought this system rather bitterly before it was installed. I asked the leader of this opposition, "Do you know of any case where this has interfered with production?"

He answered no; so it has not interfered with production, and the foremen have not sacrificed production to get it. I just want to repeat again that we tell our foremen, "Your job to get safety is just as important as to get production," and possibly we err in over-emphasizing the safety; but some of the departments of General Motors do what you propose. They make a certain assignment, the amount earned on account of safety. As I said a while ago, I believe that if the men

understand what it is all about, you get better cooperation. I don't believe that any manager can go out and explain to his workmen the insurance rating scale which is used in setting up these rivalry systems, which to my mind have this inaccurate feature, that they are somebody's opinion. Here is something that is nobody's opinion except a group opinion. It is a mere matter of arithmetic after you have the group opinion to apply it to the original case.

E. H. COTCHER (Supervisor of Safety, The Murray Corporation, Detroit, Mich.): You might be interested in knowing that the Program Committee of the Automotive Section, in suggesting this pair of papers, had in mind just this discussion that has come out. Psychologists tell us that there are two actuating motives that influence humanity, the financial motive and the vanity motive. As you will note, these two systems take into consideration these two motives and we put this on the program for the very purpose of bringing out the strong points of each of the motives. We mustn't overlook the fact that no individual is actuated entirely by the financial, nor is any individual actuated entirely by the vanity motive; so I have been gratified with the discussion. We deliberately set the stage for it. However, it appeals to me that there is something worth while in both Mr. Loney's proposition and the one that Mr. Williams is conducting, and I think if we follow out Dr. Myers' suggestion and try to dig out what we can from these things for ourselves and go back and see what use we can make of them, we will be doing well.

The Bonus as An Aid to Cooperation

CHAIRMAN DUNNEBACKE: Dr. Myers' talk created a great deal of interest and it just occurs to me there is possibly someone in the crowd who would like to ask Dr. Myers a question on some phase of his subject. I think we still have time for a few words from Dr. Myers if anybody has some particular question he would like to bring up.

H. E. MILLER (Chevrolet Motor Company, Detroit, Mich.): Dr. Myers' message struck me as being so inspirational to all of us, whether we be safety directors, managers, foremen or what not, that I should like to go on record as favoring the printing of his message in pamphlet form. I should like to have a copy of it to keep on my desk as an inspiration for the years to come.

MR. SMITH (St. Louis, Mo.): I think there are two parts to both of these questions that might be well worth considering, and that is the case of the bonus, the fact that the foreman gets a bonus serves as an incentive for the workmen that come under him. In the case of the foreman who does not get a bonus, if he protects himself as a foreman he will get more wages.

CHAIRMAN DUNNEBACKE: The big point for me is, if everyone realizes that through the bonus system his foreman is going to give him more profits and he is reasonably assured that he can work from day to day without accidents, there is his reward. Anything else?

MR. COLE (Atcheson Graphite Company, Niagara Falls, N. Y.): During the discussion on this bonus, one gentleman brought out the point that the men were so interested in the percentage that they were carrying this thing on. I believe that this method has been a tool to create interest in safety. I should like to ask the gentleman who made the statement, if he believes now that if they took off the financial payment of this bonus it would interfere in any way with the safety movement in this plant?

CHAIRMAN DUNNEBACKE: That is an interesting question. I should like to know, myself. Suppose you reach your millennium of having no more accidents, or supposing you cut out the cash bonus altogether. Do you feel reasonably certain that the interest in safety would continue?

· **MR. LONEY:** I am sorry I am not able to answer that question. It is a question that often turns over in my mind. All my life I have practiced the theory of not crossing a bridge until I came to it, and we are not anywhere near the portal of that bridge, so I beg to be excused from answering it.

ADJOURNMENT .

**SIXTEENTH ANNUAL SAFETY CONGRESS
NATIONAL SAFETY COUNCIL**

Cement Section

New Section Officers

Chairman, F. E. TOWN, Manitowoc Portland Cement Company, Manitowoc, Wis.
Secretary, A. J. R. CURTIS, Portland Cement Association, Chicago, Ill.
Poster Committee Chairman, R. B. FORTUIN, Pennsylvania-Dixie Cement Corporation, Nazareth, Pa.
Membership Committee Chairman, HENRY A. RENINGER, Lehigh Portland Cement Company, Allentown, Pa.
Program Committee Chairman, R. FRAME, Alpha Portland Cement Company, Easton, Pa.

Retiring Officers

Chairman, R. FRAME, Alpha Portland Cement Co., Easton, Pa.; *Vice-Chairman*, T. F. HALPIN, Marquette Cement Manufacturing Co., Chicago, Ill.; *Secretary*, A. J. R. CURTIS, Portland Cement Association, Chicago, Ill. *Committee Chairman: Membership*, HENRY A. RENINGER, Lehigh Portland Cement Company, Allentown, Pa.

Tuesday, September 27, 1927

R. FRAME, Chairman

**Insurance Manager, Alpha Portland Cement Company,
Easton, Pa.**

The first session of the Cement Section of the National Safety Council was called to order at ten o'clock by the chairman, R. Frame, insurance manager, Alpha Portland Cement Company, Easton, Pa.

CHAIRMAN FRAME: It is a privilege and a pleasure for me to welcome all you men to the Cement Sectional Meeting of the National Safety Council. As you have observed, there are a great many attending the Congress—a larger gathering here in Chicago than we have had for some time. We are grateful to the National Safety Council for giving us these fine accommodations, because they increase our comfort as well as our interest in the meeting.

Everyone here today is vitally interested in the subject of safety. I hope all of you will enter into the discussions. If any questions or any particular points come up I hope you will feel free to ask questions and let us have the benefit of your ideas.

It is not my purpose to deliver an address. We have more important things on the program and we will pass to them rapidly. The Cement Section is to be congratulated on having with it today the chairman of the Committee on Accident Prevention and Insurance of the Portland Cement Association. It shows that his heart is in the right place—he is back of this movement. He has given the very best he has to encourage and to keep the cement industry in the front ranks where it belongs. It is a great pleasure to introduce Mr. J. B. John.

Address

J. B. John, President, Sandusky Cement Company, Cleveland, Ohio.

We are glad to see such a nice delegation here today. The meetings that were held several years ago by this same group brought together about a half dozen men. Our section has grown every year, obliging us to get larger and larger quarters and we hope this progress continues. Last November when Mr. Brown appointed me chairman of the Portland Cement Association's Committee on Accident Prevention, I had several alibis but now I am glad he insisted that I go along with it because it has given me an opportunity to look on the inside and see what is being done. I think it is wonderful the way our work has been accomplished, the strides we are making in such a short time and over such a wide and diversified field. It is amazing with how few accidents we can run our quarries and mills today.

When the association decided several years ago to give a trophy to the plant which had the fewest accidents for the year, one of the plants in the competition had eight or ten accidents a day. I believe they were lost time accidents. The next year there were fewer lost time accidents, but after about the fourth year one of the plants of the Lehigh Portland Cement Co. went through the entire year without a lost time accident. Last year and the year before, I think, two plants went through the year without lost time accidents. The biggest surprise to all of us is that up to to this time this year there are 23 plants without lost time accidents. It is marvelous when we stop to think of it.

Some of the committee are wondering if we will have to buy a factory of our own to make trophies for the mills. They are wondering how we are going to get around to put all the trophies up, but I assure you we will manage it in some way and we would be glad if all the plants could run through the year without lost time accident. Also they would be awarded in one way or another.

This work in the cement industry was started in a small way. It was at a time when we were having many accidents. Many of us felt, as superintendents of the plants, that we knew better how to avoid accidents than some man from Chicago who might come to talk safety.

The job of the delegates and the safety men who came out to help us was all up hill. They were received with the icy stare and obtained only luke-warm cooperation from superintendents and executives. That went on for quite a time. However, things have changed and you would be surprised at the splendid letters we are receiving from the management of the different plants telling us of the great work we are accomplishing. Just last week I received a letter from Mr. Kirk, the president of the Crescent Portland Cement Company, which made me feel that if I hadn't received any more than his letter all the work I have done or can do as chairman of this committee would be well worth while.

Now I want to say to you men here that I know you are receiving the full cooperation of the executives of your companies. However, so far as positive action is concerned, you men are the ones who have to put the work over. You are closer to the employee than we are; you are constantly in and around your plants and you are the

men who must carry on the greater part of the work. But as I stated to you in Cleveland two years ago, if you are doing this work for a salary you have the wrong job—you should request your boss to give you another. To put this work over you must have the welfare of every employee in your plant at heart.

I do hope we can continue our recent splendid improvement. It is a noble work and we have proven beyond a doubt that when we cooperate with one another we can and will accomplish surprising results. I hope all of you will listen carefully to the statistics which very clearly show the remarkable progress that is being made.

CHAIRMAN FRAME: I particularly want to mention Mr. John's reference to the support which is being given to accident prevention work by the executives of the various companies. They have made it possible for us to have this large delegation here and there is every indication that managements throughout the cement industry are strongly behind this movement; more so, in fact, than ever before. I know you were all interested to hear Mr. John state there are 23 plants still members of the Trophy Club. We would like to see every one of those plants win the trophy and those who were wondering just what would happen if they all came through with lost time accidents will no doubt be gratified with Mr. John's assurance that whoever goes through with a clear record will be certain to receive one of these fine trophies.

Next will be an address by Mr. Curtis of the Portland Cement Association, who has been in active charge of this particular activity. The cement industry is to be prided on its plant accident record. Mr. Curtis will tell you in a complete manner what has been done in the past year.

Let me impress upon all of you gentlemen that it is not too soon to start work for 1928. Nineteen hundred and twenty-seven will soon pass away and those who want to go out and join the 1928 Trophy Club could well afford when they leave this meeting to go back to their plants to organize as soon as possible and put new spirit in their work. Get the cooperation of everyone in your plant. Work the hardest you know how between now and January 1 and then you will be certain of having a very fine start. Mr. Curtis.

Report of the Secretary

A. J. R. Curtis, Portland Cement Association, Chicago, Ill.

The Cement Section has at the present time 79 members. It had 70 members last year. During the present year there have been four resignations and 13 new members received. I will read the names of the new members. As I do so you will notice that there is in this organization an increasing number of active concerns that do not manufacture cement. They represent somewhat similar industries which have been classified with us in this section. Here is the list:

- Canadian Johns-Manville Co.
- Fort Scott Hydraulic Cement Co.
- Great Lakes Portland Cement Corporation.
- Hermitage Portland Cement Co.
- Howard Co.
- Lawrence Portland Cement Co. (Maine plant).
- Midland Terra Cotta Co.
- National Gypsum Co.
- Northwestern Terra Cotta Co.
- Standard Sanitary Mfg. Co.
- Valley Forge Cement Co.
- Wilson Portland Cement Co.

It is a dangerous thing to become contented with one's record and I am afraid that to talk about some of our records may introduce a great hazard of contentedness. A good record is worth repeating if it shows up more clearly the necessity and the way to greater progress ahead. Realizing how far we have to go to acquire absolute safety reminds one of the man who studies long years to get an education merely to realize how much he still has to learn.

The improvement of 1926 over 1925 was encouraging. People called it satisfactory. Our lost time accidents were cut from 2,548 in 1925 to 2,174 in 1926. There was a corresponding decrease in the man-hour loss. There was a fine decrease in the fatalities which had previously remained at a relatively fixed rate. In 1925 there were 61 fatalities and in 1926 there were 45 fatalities.

Referring to our June no-accident drive, there may be some thought that an effort lasting only a month is hardly right in principle. But it seems to me if any safety effort ever justified itself this June campaign did. The exhibits in this room demonstrate some of the benefits of the campaign that you might not otherwise become acquainted with. But what are these exhibits as compared with the great exhibits we might bring here of 142 less men injured than during the preceding June? What are these exhibits compared with the five lives as represented by the reductions from the fatal accidents of June, 1926?

Our June record has given us a new basis of comparison. We found we could decrease accidents to 26 per cent of the rate during the preceding June. This was because we all pulled together. I have never seen anything in the cement industry to compare with the way everybody join hands from the presidents all the way down the line. I have heard of only one man who refused to cooperate, and he was dismissed.

Look at the workmen's pledge cards that have been placed around the room on these bulletin boards. You can hardly realize the thrill that came to us as these pledges came in package after package. Several thousand a day came in during June—individual assurances of earnest workmen that they would put the campaign across. That is the spirit that made it possible for us to go through with 26 per cent the number of accidents suffered the year before.

Fifty of the Mills Had a Unique Experience

Superintendents tell us there was the greatest satisfaction in the plants that never before succeeded in operating an entire month without an accident. Approximately 80 mills out of 133 that finished the campaign with perfect records had at some previous time operated a month free from accidents. But there were fifty mills, approximately, that never before had been able to operate a month without an accident. Practical operating men will recognize this as more evidence of the earnestness and hard work which characterized this campaign.

If anyone desires to count the results of such a drive merely in material accomplishment, I might call attention to the fact that the public and press supported the move better than anything else undertaken by the cement industry during the whole year. It is gratifying to know that our sincere and genuine safety efforts are rewarding us handsomely in good-will advertising.

In any study of accident records such as ours there is difficulty in comparing the large plant with the small plant. We have plants in the industry employing several hundred men and others with perhaps fifty. The greater hazard faced by the big mill is obvious. Therefore, I would like to comment particularly on the fine showing being made by the large mills. Some have not succeeded in winning a trophy, as yet, but they are doing fine work nevertheless.

I would like to accord the Lehigh Portland Cement Company that recognition to

which it is entitled by mentioning it here at this time. Everyone of its 20 mills came through June without accident. There are many others, of course, that probably have done as well proportionately but the Lehigh stands out because of a number of mills and man-hours involved.

I spoke of the immediate benefits of the June campaign. You naturally wonder what followed. There were 101 lost time accidents in July as against 50 in June, with no way to account for the increase except "letting down" such as we used to feel, as children, when school was out.

I was disappointed when the report came to me showing 101 lost time accidents for July. However, that was about 50 per cent of the number suffered during the preceding July, which reported over 200 lost time accidents. Cutting in two our July accidents is certainly a record not to be sneezed at.

The August record was also significant. In 1926 we had 220 lost time accidents; in 1927 we had 144. We had six fatal accidents in August, 1926, and only three in August, 1927. As the figures stand at the present time we have had approximately 400 less lost time accidents and 8 less fatalities than we had at this time last year. In 1926 we had 45 fatalities; in 1927, to date, we have had 22.

One great reason why we succeed in our safety activities is that the foundation work consisted of developing a fine system of reporting and recording accidents with their causes and consequences. Great credit is due all of you for the way the reports are sent in. I hope you will continue to see that these immediate reports get into us right away, and also that the finals are sent in without delay. In don't believe there is another section that is able to as quickly and as closely focus on its problems as we are, because there is probably no other section that has the records behind it. An efficient reporting system is the backbone of successful safety work.

Plants With Clean Records So Far in 1927

I would like to read the list of plants that have operated so far this year without accident. These fellows are all entitled to congratulations. There were six plants which had operated without accident up to this time last year, while a similar list this year contains the names of 23 plants. They are as follows:

- Alpha Portland Cement Co., Martins Creek No. 3, Pa.
- Alpha Portland Cement Co., Ironton, Ohio.
- Bessemer Cement Corp., Bessemer, Pa.
- Canada Cement Co., Ltd., Belleville, Ont.
- Canada Cement Co., Ltd., Hull, Que.
- Cowell Portland Cement Co., Cowell, Calif.
- Diamond Portland Cement Co., Middlebranch, Ohio.
- Kansas Portland Cement Co., Bonner Springs, Kans.
- Lehigh Portland Cement Co., Tola, Kans.
- Lehigh Portland Cement Co., New Castle No. 1, Pa.
- Lehigh Portland Cement Co., New Castle No. 2, Pa.
- Lehigh Portland Cement Co., New Castle No. 3, Pa.
- Lehigh Portland Cement Co., Oglesby, Ill.
- Lehigh Portland Cement Co., Ormrod, Pa., No. 3.
- Lehigh Portland Cement Co., Sandts Eddy, Pa.
- Louisville Cement Co., Speed, Ind.
- North American Cement Corp., Hagerstown, Md.
- Pacific Portland Cement Co., Cement, Calif.
- San Antonio Portland Cement Co., San Antonio, Texas.
- Texas Portland Cement Co., Dallas, Texas.
- Universal Portland Cement Co., Duluth, Minn.
- Universal Portland Cement Co., Pittsburgh, Pa.
- Virginia Portland Cement Corp., Norfolk, Va.

To those who represent the plants which have operated so far this year without mishap, I would advise doubling your efforts along every line which you know to be advantageous in preventing accidents. Don't get this far along and then drop out. We have had several sad letters from those who had worked hard, put their time and heart into it and then lost out by some foolish little accident.

The Portland Cement Association is interested in seeing you win this prize. When a group of men as sincere in this work as the portland cement executives are, put up a prize for successful plants they don't want you to lose out. They are anxious I know to give trophies to the 23 who still have perfect record. In fact, I don't know how they would pay for them, but I know many who would be anxious to give 150 trophies. As you will appreciate, it is quite a strain to pay for a lot of trophies which cost about \$600 each. Taking two men to the Spring Meeting costs at least \$200 on the average. On the present list there are several from the Pacific Coast and other distant points. Taking all the necessary expenditures into consideration each trophy award costs the Association well over \$1,000.

But isn't it worth it if we can save lives and prevent accidents and wipe out compensation and other costs of one kind or another? We must also consider the improvement in operating efficiency and morale.

I am sorry to say that there are still a few plants that have a lot of accidents. The trophy contest is most interesting to perhaps 50 per cent of the plants that have the better records, while those who are down in the dumps feel they have no chance for the trophy and the scheme probably does not appeal equally to them. There are about 25 per cent of the plants that don't seem to be making as good progress as they should. One or two are quite bad. One, for example, has had 139 lost-time accidents this year. There isn't any other mill near that. Another has had 65, another 31, another 27, and so on. So one of the things we want to focus our attention on this coming year is the mill who is habitually way down the list and doesn't make comparable progress.

Twenty-Two Fatal Accidents During the Year

There have been 22 fatal accidents so far this year, 4 of them being due to slides. I think two of those slides were coal slides, one was a stone slide and one was a cement slide. In the cement slide the man was blown out of an old type wooden stockhouse by the slide and pushed into a screw conveyor. There were four fatal accidents of the railroad type, due to either men being run over or crushed by cars. There were three fatal accidents due to contact with machinery, two fatal accidents due to screw conveyors, that is, a man stepping into a screw conveyor. There were two burned to death and four electrocuted. There were several other minor shocks and burns but four electrocutions are entirely too many. There was one death due to premature explosion so far, one drowning and one case of a bucket falling on a man. There is apparently more care being exercised in the handling of buckets and in inspection of cables. Bucket and cable accidents show quite a decline. There is apparently less care being exercised in the packing and shipping departments. You probably notice in the list of significant accidents—and it is true of a large number of minor accidents that we don't report—that packing house carelessness is too prominent a feature.

You are familiar, of course, with the winning of the trophy last year by the Mitchell plant of the Lehigh Cement Company, and the Fort Whyte Plant of the Canada Cement Company. The delegates appeared in accordance with the terms of the contest at the spring meeting of the Portland Cement Association and received the formal award from the President of the Association at New York, and then on May 28 the Mitchell trophy was dedicated at Mitchell, Indiana. The Mitchell dedication has made the means of getting a great deal of good will in the community.

The attendance was estimated at 1500 to 2000. The people in the town are learning to look toward the cement plant not as a liability, but as a source of good things to the community.

The school children marched down in costume, and there was an athletic tournament and a barbecue. The company in that case took the winning of this trophy not only as an occasion on which to celebrate a safety record, but also as an opportunity to help the public appreciate the cement mill as a community institution.

The second trophy at Fort Whyte, Manitoba, was dedicated on July 25. Since the plant is reached from Winnipeg only over a mud road and there was some probability of rain the company arranged a guest luncheon at the leading hotel in Winnipeg and later took the visitors out to the plant in cabs. The mill closed down and the employees, with their families and friends, enjoyed a splendid occasion. I presume there were 350 people in attendance at what proved to be a real town affair. The manager of the western lines of the Canadian Pacific Railroad and some of the officials of the Canadian National journeyed a long way to attend. Local officials and industrialists to the number of about 40 were present. We are looking forward, hopefully, this coming year to the possibility of having a great many of these affairs.

One of the outstanding developments of the year was the regional safety meetings. All of them proved successful. The idea of holding eight meetings worked out splendidly. The first one was held at Birmingham. We had the full cooperation of all of the public utilities and industries around Birmingham. There was an attendance of 71 men representing ten cement mills. The next was held at LaSalle on March 21. The attendance included 161 men, representing 13 mills. At Kansas City on April 14 the attendance reached 66, with 11 mills represented. The meetings at Allentown on May 20 was the largest of all, with 235 men present and 29 mills represented.

A regional meeting was held at Detroit on July 12, being the first meeting of this kind there for some time. There were 48 men present, representing 12 mills. At Albany on August 2 there were 91 present, representing 10 mills. We have one meeting of the series yet to be held on October 25 at Los Angeles. All of the California mills are getting together for a fine meeting.

Early Planning for the New Year

We are all much interested in the Safety Trophy Contest of the United States Bureau of Mines. The trophy is donated by the Hercules Powder Company. The cement companies have been winning that trophy quite regularly. There is just one trophy and it has come to the point where there is difficulty in awarding it. Some 14 quarries had perfect records and the judges had a tough time of it trying to make a fair award. The trophy went to the North American Cement Corporation quarry at Martinsburg, West Virginia, which had the greatest number of man-hours of any quarry with a perfect record. It is noteworthy that twelve of the fourteen quarry organizations which came through without an accident belonged to cement companies.

The thing which is likely to do more than anything else to raise our general level this year is to make sure that the general safety committees meet by the middle of October for the purpose of planning for next year. The general committees should submit the matter to the departmental committees and get their plans started. At a meeting early in November the plan should be put in final shape and on December 1 it should be announced to all employees. That will give the workmen a month to think about it before the new program becomes effective. It won't be a case of waiting until after the first of the year to perfect the plan which should have become operative January 1.

CHAIRMAN FRAME: I think you will agree that Mr. Curtis has been very much on the job during the past year. The records he has quoted are quite remarkable in themselves and should offer a great deal of encouragement to us. I know there are a lot of new faces here today, as well as a lot of others which have been seen

with us on previous occasions. The finest part of these meetings is the discussion which usually follows the papers.

W. R. DUNN (Vulcanite): I am very sorry to say this is my first appearance at a meeting in a good many years, but I have come to the conclusion that to get real meat out of this safety proposition one must attend the meetings. What you hear looks different from what you see in the pamphlets or the reports that you receive from the association office. It has been my practice heretofore to have the younger men in our institution attend these meetings because I felt they were in closer touch, they were the ones who should attend so as to derive the most benefit from what they hear.

When we hung that flag up at Vulcanite we had no idea we would go through the month without an accident. Before that there wasn't anything to indicate to the men that we did want to get through without an accident. But when the flag went up they immediately conceived the thought that that meant no accidents. In fact, they look at the flag every day as they go by and I am going to ask them whenever they pass the flag to salute and take their hats off. If we can get them into the habit they will always have the safety idea before them.

You have said quite a lot today about the trophy proposition: in fact, it has been hinted that it is going to cost a lot of money. I hope it will not cause the Portland Cement Association to go into bankruptcy due to the many trophies they will have to hand out. But if there is anything like that going to come about I would suggest before it reaches that point that the companies themselves buy a trophy for their employees, because I feel they will appreciate that even a great deal more than if they received it from the association.

Medicine for the Chronically Sick Plant

C. L. ADAM (Universal): Mr. Curtis' report mentioned a number of plants that are not improving. My suggestion is that we get into personal touch with the plants that haven't been doing so well. I would suggest at the earliest opportunity that Mr. Curtis, if it can be arranged, visit those plants personally and if possible arrange a meeting with the responsible executives of those companies and show them how far down the line they are, if they do not already know. I believe that personal touch is going to cost a little more money and time but I think it will be well worth it. One visit to each of those plants, in my opinion, would be worth six months of correspondence.

CHAIRMAN FRAME: We certainly do want to get at the plants that are way down the scale. We have a wonderful opportunity to do some fine work. We had made no headway in cutting down the fatal accidents.

C. F. STODDARD (Bureau of Labor Statistics, Wash., D. C.): I want to rise for two purposes. One is to congratulate this association on the work it has done in accident prevention. My second purpose in rising is to introduce myself because of my connection with the Bureau of Labor through which all of these statistics are supposed to come. I want to urge upon the association and the various organizations or plants in the association that these accident figures be compiled and sent in with regularity. That was brought to my attention fortunately by the last report of the Cement Association. These reports usually come to my desk and I review them and fix them up for the *Monthly Labor Review*. In the last report I noticed particularly there were quite a few who did not report completely. So the report itself was not complete. Presumably most of those plants are in states that require regular accident reports and it would not be much trouble for those reports to be duplicated and sent to the association so they can be included in our general and annual report.

I want to urge upon the plants to send in those accident reports, and that they

report not only the number of accidents, the fatal accidents and so on, but the man hour, and all the various details that are required and necessary to make up an accident report.

I want to close by asking the secretary one question if he has the information at hand. He mentioned the fact that 23 plants have gone so far this year without a lost time accident. I am just wondering in how many of those 23 plants the records extend back beyond the nine months of this year. I believe it would be interesting if the figures are at hand to show how many of those plants have extended back into 1926 showing more than the nine months without a lost-time accident.

CHAIRMAN FRAME: Practically all of those plants started their clear record earlier than January 1, 1927, but the trophy rules require that the 365 days start from January 1, and that is the reason for our reference to it in that regard.

L. M. McDONALD (Canada): I would like to say a word in regard to the work of the Portland Cement Association for the past year. Without a doubt we have obtained more material to work on at the plants during the past year than any previous year in the history of the association. Undoubtedly many radical changes must have taken place in the association to have made it possible for that material to come out. I realize perfectly that it gave them a great deal of work. For that reason some appreciation should be extended to the association for the work entailed. Many of the circulars that we have received did in some sense or other pertain to the cement industry, but I believe one of the greatest assets that we have had is the summary of accidents which have taken place each and every month.

Each Accident Should Spur on the Safety Work

Now all cement plants have similar hazards. Whether they exist or not, you never find out until you have an accident, and by comparison of those accidents which have transpired from month to month in the various plants you sometimes pick up something of a hazardous nature which exists unknowingly in your own plant. I believe the greatest material for safety meetings that can be handed out is a summary of those accidents. I sincerely hope that every member of the cement industry will take full advantage of the material which is given in those reports.

You have got to profit by an accident to go ahead in accident prevention work. But why is it necessary to have an accident if you can profit by the experience of somebody else?

I believe those who have been behind this accident prevention work this year should be congratulated for the material they have sent out because of the great benefit and help and assistance it has been to the plants during the past year. It has helped more than anything to have 23 plants today in the running for the trophy. I sincerely trust it will continue. If it is in their program for the coming year I would certainly most heartily endorse it.

CHAIRMAN FRAME: There are many in this room who fully agree with Mr. McDonald's remarks. I think he refers to a report that bears the title, "Significant Accidents in a Certain Month." I know Mr. Curtis has a great supply of these bulletins at his office. If you can use more, or if you want to distribute them to your foremen, or your safety committees, if you will write to Mr. Curtis I am sure he will give you a full supply and will do it willingly.

T. F. HALPIN (Marquette): In Mr. Curtis' remarks a while ago he said something about planning ahead, and I am wondering if he had in mind any definite plan for the coming year.

MR. CURTIS: When we have found a plan that gives reasonable success, it is wise to continue it a while before abandoning it for another. Several of our 1926 activities may well be continued. In general, we will use two kinds of activities—

the cooperative and the competitive types. The trophy is a competitive type scheme. The No-Accident campaign is a cooperative scheme. It doesn't work until every fellow adds his help. I believe the No-Accident campaign will be worked again next year, although I believe the next time we do it we will make some changes.

There are a number of new ideas available. For example, providing a card and button for the man who works safely for a whole year. The cards can have the year stamped across them in big letters in some way so they can be a little different from the ones issued the previous year. A suggestion has been made to give a medal for conspicuous acts in safety work. I feel that the significant accident report is something we ought to be making good use of. You can have as many as you can use. One of the companies distributes eighty copies.

One thing I didn't report on, which might be worth while mentioning, is the progress of the *Accident Prevention* magazine. Last year I suggested increasing the circulation of this magazine. During the year the distribution to mill men has been trebled and we are not through yet. A recent survey showed that 70 per cent of our men read the English language as well as speak it. I think perhaps some men who don't read English very well will get some benefit from seeing this magazine occasionally. In a thing of this kind there is no economy in not sending it to everybody who will be benefited. During the next month or two will be an especially opportune time to send in your suggestions for increasing our mailing lists.

G. A. LAWNICZAK (Alpha): I have been thinking since we have a trophy for those that go the whole year without an accident we ought to have something for those that go through the no-accident month. Take the June campaign—we have six letters in the word "safety." For every plant through the month without a lost-time accident the word "safety" should be sent to them in a gilded gold or bronze.

CHAIRMAN FRAME: Thank you, that is another idea. We are always looking for increased interest in the campaign.

We will pass on to a subject that is of vital interest to everyone engaged in accident prevention work. You will all agree that if we can interest workmen in the safety game it will mean a quick solution of all our problems. We are particularly fortunate in having with us a gentleman who is capable of discussing this particular viewpoint from every angle. I take great pleasure in introducing at this time Mr. W. P. Sabin, assistant to the president, Ash Grove Lime & Portland Cement Company, Kansas City, Missouri.

How to Interest Men in Their Own Safety

W. P. Sabin, Secretary and Assistant to President, Ash Grove Lime & Portland Cement Co., Kansas City, Mo.

I am glad the subject assigned to me did not read: "How to *keep* men interested in their own safety," because the human mind is so constituted that we are *more interested in creating* than in *using* what we create. We are by nature explorers, inventors and creators. The green fields in the distance, the dim horizon, the unplumbed depths, the vast undeveloped resources about us, the untried, the untasted and the unfelt all beckon to us until we become restless and dissatisfied with our environment, our conditions and our possessions, and soon lose interest, wholly or to a degree, in the things with which we have become familiar.

We see this simply illustrated in the play of a young boy with building blocks. He will painstakingly build a house and immediately knock it down, in order to build another. In the natural functioning of this normal human instinct, when untrained and uncontrolled, we find the explanation of our variable interest.

Self-interest should lead a man to exercise every precaution to preserve his physical body intact. Fear of pain, pride in physical strength and personal appearance, fear of being a dependent on the charity of others, desire to maintain earning power, ambition to succeed in a chosen vocation, responsibility for the welfare and protection of a family, a sense of the unfairness to those who may have to share the blame or help bear the burden, and an unselfish desire to help others should be sufficiently motivating influences to keep every man constantly on guard against physical injury. These influences should operate naturally, and they will where men have been trained to *think*. The men who take the initiative in accident prevention, and are most active in carrying on the work, are the thinkers.

The benefits derived from thinking seriously about safety matters have been put in another way in the statement that educational safety work has been responsible for 75 per cent of the progress made in accident prevention. In view of this fact, it would appear that educational methods are worthy of a very large part of our attention. Such methods should be considered as appeals to reason and instinct. A man who knows no fear may be reached through his home affections, through his pride, his ambitions, or his instincts. Men do not live merely to toil; they live, as well, to play, and, as a rule, are easily reached and interested through appeals to their play, or sporting, instincts.

Willing Interest Stimulated by the Campaign

One of the objects of an educational safety campaign is to create and maintain *willing* interest.

"Some one said it couldn't be done;
Some one said that it could;
Everyone found that it was easily done,
When everyone said they would!"

It is much better to have the whole-hearted support of an employee than to have the half-hearted cooperation which results when you compel a man's interest. What we want is real interest and a man cannot be really interested in something he knows little or nothing about and in which he does not have a willing, active part; therefore, he should be interested, informed and given something to do.

It would appear from this premise that the responsibility for the initiative rests with the employer, and this fundamental principle has been fully and repeatedly demonstrated in my company's experience, extending over a period of twenty years. Due to the inherent personal injury hazards of our business, to the human element, to the absence of mechanical safeguards, and to the inexperience of the staff in the prevention of accidents, our early accident record was not one of which to be proud. However, very early in our operating experience the management saw the need of doing something to protect our men against personal injury.

About this time, our legislators conceived the idea that personal injury accidents could be prevented by legislation, and so they filled our statute books with laws, expecting to legislate accidents out of existence. Like many others, we accepted the idea and spent much thought, time and money equipping wheels and shafts and gears, and other dangerous equipment and places, with mechanical safeguards. This was a good safety step but we have since learned it only went about a fourth of the way. An enclosed screw conveyor did not keep one of our night-shift men from falling into it, after he had removed a section of the lid and dropped off to sleep while sitting on the edge of the box.

A belt and rope, left hanging on the wall, did not save a workman from suffocation in a rock tank; and the track anchor, left hanging in the cab, did not save one of our engineers from death by scalding when a locomotive crane tipped off a fifteen-foot trestle.

I could tell you of other similar instances, but those mentioned will serve to emphasize the relative unimportance of such devices where the individual has not been sold and trained on safety first. We soon discovered the fallacy of the effort to legislate accidents out of industry and turned to the really effective method of preventing accidents: namely, interesting and educating our men to the importance of constantly thinking in terms of safety first. Due to labor turnover and other difficulties attendant upon efforts to maintain steady interest, this was not, nor will it ever be, a small job, but we feel we have made some progress, since, with a force of 300 men and a plant comprehending every operation from stripping in the quarries to loading the finished product into railroad cars, we have had only one lost-time accident since March, 1926. We tried many plans and methods and made some progress before the improvement was notable, but we kept at it persistently. We put up posters and warning signs: we had safety committees; we had a dummy figure which climbed a ladder—one step for each day without a lost-time accident; we had barbecues: we had mass meetings on the plant lawn in which prominent outside safety workers participated, and we finally went a whole month without a lost-time accident.

Operation of the Safety Court

Then, we organized a safety court, with Judge, Prosecutor, Sheriff, and Jury. In this court, any employee could prefer charges against another employee for any infraction of safety rules or disregard of personal safety. The accused was permitted to choose his own attorney from among his fellow employees. Court sat one night each week and was open to the public. We were striving at this time to get all of the injured to report for first aid. We made progress, but during the life of this experiment we had two lost-time infection cases which were due to failure to secure first aid.

During the twelve months following our no-accident month we conducted a Safety-First and First-Aid campaign, stressing the danger of infection in small cuts, scratches and nail punctures. The plan and result of this drive is described by our efficiency engineer, Harold E. Williams, in a paper read at a district meeting of the National Safety Council in Kansas City, Missouri, last March. He said:

"During this period, the lost-time accidents gradually decreased until the last three months, in which time we had no lost-time accidents. However, the total number of accidents reported also dropped, showing that either our total accidents were growing less in number or that, as was suspected, only the number of the more serious accidents was on the decrease. On the latter assumption, another safety drive was inaugurated, this to start July 1 and end December 31, 1926.

"One noteworthy feature of this drive over anything that had been previously done was the executive work of the committee in studying the effects of different kinds of propaganda. As a result of this study, it was decided that although the posters we had been using had their effect, they lacked punch because they did not apply specifically to our local conditions and thus had no personal appeal.

"In an effort to overcome this deficiency, a large board was erected, across the top of which were nine white bulls-eyes, with an electric light in the center

of each one for night display; the first three for April, May and June, the months just past in which we had had no lost-time accidents, and the last six for the succeeding months to the end of the drive. The light and bulls-eye were to change to red for any month in which we had lost-time, the others to remain white as before. At the bottom center of the board were the date numbers, which were to change to red in the same manner. In the center were placed the two hands of a clock, one pointing to the date, the other to the month. To the right and left of the numbers indicating the day, were placed two bulletin boards, one for general safety, suggestions and cautions, the other for local items only. The local items were to call attention to safety infractions by individuals. These were obtained from reports made anonymously by a local secret service from within our own organization, after which they were edited and placed on the bulletin board. These bulletins were generally in the form of tactful ridicule, without disclosing names, although in a few instances, where the offender was persistent, the names were given and a bit of the tact removed from the ridicule.

Four Teams Compete in a Safety Race

"By this system many unsafe practices were eliminated. At first this was due undoubtedly to the individual's horror of being ridiculed, and later to his change of viewpoint, caused by environment; he, not knowing who belonged to the secret service nor at what time he would be reported for an unsafe practice, began to take stock of his own indiscretions."

From the standpoint of lost-time and decrease in total number of accidents reported, this six-months' safety drive was quite satisfactory, but there were two minor cases of infection, with no lost-time, but nevertheless showing that we had not yet succeeded in getting all accidents reported, and so (quoting again from Mr. Williams' paper):

"It was decided to divide the employees into four teams; each team to have a captain in the plant and a lieutenant in the quarry. Each team also had a color, a name, and was represented by a wood image of a mule. These mules were placed on a wooden race track on the front of the safety board. This track was divided into 186 spaces, thus making six spaces per day for a 31-day month, the spaces per day remaining the same for any month, regardless of the number of days in the month.

"The rules of the race were as follows:

"First—For any team without an accident for any day, the mule representing that team would advance six spaces.

"Second—For any employee sustaining an injury drawing blood, and receiving first aid, five spaces would be advanced.

"Third—For any employee sustaining an injury, not receiving first aid within thirty minutes, an advance of only one space would be made.

"Fourth—Every month was to be a heat, and every year a race, there being a prize given the team winning the race. Each member of each team was given a button of the same color as the mule representing his team, which button was to be worn at all times while at the plant.

"Each man was personally interviewed by the captain of the team to which he belonged and given the following instructions:

"First—To get first aid for all wounds, regardless of how small, the explanation being that any wound, puncture, splinter, or anything in an eye is a potential case of infection and must have treatment within thirty minutes, this limit being based upon the efficacy of iodine.

"Second—To report to the first-aid station anyone sustaining an injury, with-

out first aid, first calling the individual's attention to the fact that he should receive treatment.

"After a few days under this system, it became apparent that a court of last appeal was needed to pass on disputed cases where first aid was not administered. Our assistant superintendent was chosen to act as judge on such cases, and very few have come before him in disputed cases that have not lost their case, his assumption being that they were guilty of not seeking first aid or they would not be there, and this seems to be the correct attitude for the majority of such cases.

"The following figures show that this system had at last accomplished what at times has appeared impossible, viz., getting the men to report for first aid.

"The month before putting this system into effect, we had five men report for first aid.

"The first month under the new system, 68 reported—11 failed to report within 30 minutes.

"The second month, 73 reported—9 failed to report.

"The third month, 126 reported—3 failed to report.

The Record Due to a Change of Viewpoint

"While a large part of this record is due to competition direct, we believe the greater part is due to change of viewpoint and will eventually be due entirely to this change. As a concrete example of the effect of environment in an effort of this kind, I will point out the instance of one man who sustained a slight injury and refused to get first aid on the ground that it was 'all foolishness'. Since this first offense, he has never failed to get first aid, as he found his viewpoint was very unpopular with his associates."

While this may appear to have been a drive to secure prompt reporting for first aid, the effects of the campaign were much more far reaching and were undoubtedly due to the interest created. Just how effective it has been may be gathered from the following comparison:

In 1925, we had 20 lost-time cases, which resulted in 163 days of lost-time at a cost of \$1.13 per hundred dollars of payroll.

In the first three months of 1926, we had 11 lost-time accidents and 54 days of lost-time at a cost of 5c per hundred dollars of payroll.

Since March 31, 1926, we have only had one lost-time case with 16 days of lost-time at a cost of .0126 per hundred dollars of payroll.

This improvement we attribute to three things:

First: Creation of interest.

Second: Steady maintenance of interest.

Third: Prompt reporting of injuries, thus permitting first aid in time to avoid lost-time.

Recognizing the necessity of keeping the fires of enthusiasm burning, the committee in charge of our safety work planned to have a monthly contest in connection with the mule race, and at the end of the April heat the winning captain challenged the captain of the third team to a contest in horse-shoe pitching. At the same time, the captain of the second team challenged the captain of the fourth team to a game of marbles.

The horse-shoe pitching contest proved to be quite an exciting event. The game of marbles started off a little slowly, as neither contestant had shot a marble since his boyhood days, but as it progressed the contestants became more skillful and toward the end of the contest each was able to hit a marble after ten or fifteen minutes of earnest effort. The result of the game was perhaps due more to endurance and determination than to technical skill.

At the end of the May race, the winning captain challenged the captain of the third team to a game of baseball. The game was umpired by the captains of the other two teams. This was a fast and exciting game. At the end of the second inning, when the excitement was running high, some of the spectators conceived the idea of "egging" the umpires because of unfair decisions and favoritism, and the plot was executed with wet asbestos.

Three of these contests were held at the noon hour, making it possible for most of the men to attend. The baseball game was held at 4:30 p. m. and was attended by every man who could be spared from his post of duty.

Many of the plans and methods we used were temporary in character, as such plans and methods must be if interest is to be maintained, but a few have been of a more permanent character, and, in fact, are still in use, to-wit:

We have always striven to impress upon the minds of new employees the hazards connected with their work, and with the importance of unceasing vigilance against accidents. At the time they are employed men are especially anxious to please and the necessity for working safely can be more easily impressed upon them when their minds are in this receptive condition.

Quite a number of years ago we adopted the plan of making our accident prevention work a section of our semi-monthly foremen's meetings. We had established the practice of having the foremen get together for a conference, dinner, and entertainment at the close of the day. At first, these meetings were held every two weeks but latterly, due to improved conditions, they have only been held monthly. It was our idea that by making our staff of foremen and department heads our safety committee we would be more likely to reach and interest all of them, and through them the individuals in their respective departments. The plan worked so well it has been continued for years without question.

Good Housekeeping an Important Part of the Work

In addition to this general committee, there is a sub-committee composed of three men, which is changed from time to time. Their job is to make a periodical, general inspection for unsafe practices and conditions.

We also learned through our own experience, and by observing the experience of others, that "good housekeeping" is an important factor in keeping down accidents, and therefore we inaugurated some years ago a monthly Clean-Up Contest. The results have been so satisfactory we have never felt like discontinuing it.

Another thing that has contributed to a better showing on accidents has been our physical examination requirements. Every man who seeks employment with our company must submit to a thorough physical examination by our plant physician and surgeon. This enables us to reject the applicant if he is unfit for any job we have open, or, if we can use him, to place him where he can work safely so far as his physical defects are concerned. Subsequent examinations are made yearly, semi-yearly, or more frequently if necessary, in order that any serious physical defects which have developed may be caught.

We believe that these plans have been successful because they have had the willing support of the men. They have benefited from the physical examinations, they benefit from, and enjoy, the monthly Clean-Up Contests, and the safety section of the foremen's meetings has always been full of interest.

Let me repeat, "The responsibility for the initiative rests with the employer." In order to secure a man's interest in safety, the employer must put a premium on safety, and definitely line up with safety in such a way as to appeal to and

engage a man's attention and interest. A man thinks of the thing in which he is interested, and if he thinks safety he will work safely.

The employer must *show his interest* by providing proper mechanical safeguards and safety devices, by adopting and insisting on safe practices, and by keeping the spirit of safety alive in the minds of his men.

The problem of interesting workmen in their own safety has been successfully solved in various ways by many industries and employers of labor. There is no *one*, royal way—there are *many*, and they vary in effectiveness according to the time, the place, the mood, the environment, the number to be reached, the method of presentation, and the personality of the leaders. However, any plan presented should be carefully analyzed before attempting to carry it out. A plan that will work in one place may not in another. A plan that will work with ten men may not be at all suitable for a hundred men. An idea that will appeal to a hundred men may fall flat with five hundred. That is not all—a plan that would “go over” fine with one group of 500 men may have absolutely no appeal in another similar group.

The Wide-awake Foreman Is an Important Individual

The greater portion of our industrial safety effort today is spent in organizations of considerable numbers. With a large group of workers, the limited time and opportunity, and the impossibility of sufficient personal contact with each man, we must resort to group and mass work insofar as the main body of an organization is concerned. Key men can be, and should be, labored with individually. They in turn can pass the information and enthusiasm and spirit along through subordinates, sub-foremen, and gang bosses to the individual workers. But individual work must be supplemented and supported by plans and methods which in their presentation and execution will have group and mass psychological appeal, such as committee meetings, safety publicity, bulletin boards, slogans, suggestions, safety rallies, sport contests, and general educational work.

The real wide-awake, sincere foreman, the type that feels in his heart that he is responsible for the safety of his men, is an extremely important factor in getting and keeping workmen interested in accident prevention, and the principal safety committee should consist of foremen. The foremen should be held responsible for accidents in their respective departments, and should see to it that a committee of one or more workers is appointed or elected to function in each department; this committee to work with its foreman and to be changed every thirty or sixty days.

This may be the means in many cases of changing the attitude of a worker from one of antagonism to one of friendliness, for as soon as he feels a responsibility for promoting safety, he becomes interested and an active booster. While the various measures used seem more or less temporary in character and benefit, they are cumulative in effect and the ultimate result will be the formation of the *habit* of thinking and acting safely under all conditions and circumstances.

The work of an active safety committee is always noticed. We see them when they make their inspections, and also see the results of their inspections in safer jobs and cleaner working conditions. Furthermore, as already pointed out, a man who has been on the safety committee makes a better and more careful workman, for he has not only been obliged to think, act, and live safely, but his experience in safety work has educated him to its importance.

Safety First is not a movement that will continue indefinitely from its first momentum. We must keep it vitalized by feeding it new ideas, and since it

is a psychological law that thought, sooner or later, passes over into action. It is important that all our efforts should be of a constructive nature, and of sufficient frequency to favorably influence individual behavior.

According to a Spanish proverb, if you live with wolves, you will learn to howl. Let us add a safety-first proverb to our accident prevention literature:

Live with Safety-First enthusiasts and you will learn to be a Safety-First booster!

CHAIRMAN FRAME: Mr. Sabin's paper fairly bristles with new ideas. I know he is willing to answer any questions which you would like further information on concerning the various methods they have used in his plant. I know you are asking yourselves this question: Has it paid to go through with the different methods at this Ash Grove plant? But it is well emphasized by his statement that they have had no accidents since March, 1926. It seems to me, Mr. Sabin's plant is well on the road to complete not only one year without any accidents but they are going to do two years just as easily as they have accomplished one.

Essential That Bulletin Boards Be Well Kept Up

I also wish to mention his reference to bulletin boards. It seems to me no bulletin board can meet with full success unless it is well kept up and is an important object around the plant. Also, his reference to physical examinations, and I want to call your attention particularly to this secret service in effect at his plant. I think that is what we need to bring to light the unsafe practice on the part of the men while they are in their shops or while they are at their work around the plant. It has always seemed to me that is what has contributed to accidents.

His court of inquiry is another thing of great importance. We will go into that further this afternoon about fixing the responsibility for accidents. Mr. Sabin is here and will answer any questions.

MISS J. A. WEDER (Giant): I would like to ask Mr. Sabin what they have done about physical examinations. When you instituted it what did you do about old employees who had some condition that you knew was a hazard to the industry?

MR. SABIN: When we instituted physical examinations at our cement plant we had to take into consideration the old employee. We have some employees who have been with us for a quarter of a century. For that reason we decided if we found the man who had physical defects, which seemed to unfit him for the job he was on, we would endeavor to place him elsewhere in the organization where he would not be subjected to any particular strain. We applied that rule throughout and it worked well.

E. SHEA (Marquette): I think it was mentioned here this morning that 70 per cent of our workmen speak English and read English. I would like to know from the speaker or any other representative where conditions exist where they have foreign workers who don't speak or read English, how they deliver the message of safety or accident prevention work?

MR. SABIN: I am sorry I cannot answer that, because our employees are all English-speaking excepting a few Mexicans.

D. ADAM (Lawrence Portland Cement Co.): In our plant we have about eight different nationalities. We have Hungarians, Slavs, Russians, and others. When a new man comes into the plant we immediately get an interpreter. Generally, our foreman can talk sufficiently to the men to make them understand.

G. W. BURGESS (Missouri): We have that problem, gentlemen, of foreign labor. We have Poles, Hungarians, Russians and Mexicans. We find it rather easy to reach these fellows by reason of having men around or close to our executive staff who can interpret the language. We are fortunate in having some foremen who are linguists. They also translate the messages we receive from the Safety Council. We have these messages translated and the bulletins that we place on the board

translated into the Slavish, Russian, Czechoslovakian, and Mexican languages. We find it creates a good deal of interest when those fellows can walk up to the bulletin board and read something in their own language.

MR. SHEA: How do you post that? Do you post the English literature right along with the foreign?

MR. BURGESS: If we want to reach the Mexican we post the English with the Mexican. If we want to reach three of them we post the three right along side each other.

F. H. SASS (Universal): We have quite a few non-English speaking men in our plant. We have 25 to 30 different classes of men out there. However, we believe in telling it to them in English. We are Americans and we believe in dealing in English. However, at our safety rallies throughout the week we have an interpreter who interprets to the men who can't read. You take the great majority of these men and you will find they are married and have children at home who attend the public schools. This written matter that we get up is all printed or written in English and they take it home and have the children read it to them. We don't put up any bulletins in any foreign languages whatsoever, outside of the warnings on heat prostrations and so on.

Dealing With the Foreign-born Employee

A. VAKSDAL (Corning Glass Works, Corning, N. Y.): A few years ago I was a foreigner myself, but I am an American now. I never found it difficult to understand a safety campaign. If you put things up in such a way that they don't have to read it, such as the flag in red, yellow or gold meaning no accidents, the fellows know what it means whether they can read English or not. There are many foreigners who can't read their own language and you can't reach them any other way than to put such things up and let them see it for themselves.

J. R. CLINE (Universal): We have a system in our packing and loading department of asking a man, a Greek or a Spaniard, or some other foreigner, to make up a paper to read at his own local safety meeting. They have written in English and delivered by these Spaniards and Greeks in English, but they are delivered in their own way to their own class. Another thing, all these fellows can understand pictures. The bulletin board is well kept up.

Another thing we do at our safety meetings is to tell these fellows to take their safety home. We feel we are doing everything possible to make safety in the mills as it should be. If they follow out what they are told they will be safe in the mill, but the biggest thing is to tell them to take their safety home.

F. B. HUNT (Nazareth): We probably have more of the foreign labor to contend with at our plant than anywhere else. In fact, when we started our June campaign we had four men speaking in four different languages along with the English language to start that campaign off, and we got good results. We also worked through the foremen as Mr. Adam of the Lawrence company just mentioned.

No doubt you men who are from the east, who attended the Allentown regional meeting of the Lehigh Valley Safety Council, remember how Mr. Farace spoke in Italian. Mr. Farace is a yard foreman at Plant No. 3 of Alpha (by the way, one of the plants which has had no accidents since May, 1926). They are getting results by using those same men in that way.

We have another method which has given good results. We use in our pay envelope a safety magazine which fits right into the envelope. Perhaps some of you men are familiar with it. It is called the *Safety Pin*. We have been getting good results from it. We have found that a number of foreigners take it home and their children read these safety slogans and safety bulletins and in turn explain these bulletins to their parents.

CHAIRMAN FRAME: I think it is a great mistake for any one to neglect his for-

eign employees. They have proved themselves on many occasions to be a very reliable source of labor. Now a loss in one of those families means just as much to those people as it does in any American family. A foreign widow has just as much of a struggle to get along without her husband as anyone else. It seems to me we have to do more constructive work with these foreign employees and I think it is a great mistake for anybody to neglect them. They can be reached. There has been a lot of evidence shown here whereby it can be done.

The gentleman who reported he was a foreigner not so long ago, you will notice, is now a master of English. Without him telling us we could hardly know what his past experience had been.

R. B. FORTUIN (Penna-Dixie): We have numerous one-month campaigns during the year, and recently we had a three-month campaign. We arrange a mass meeting for each one of our campaigns and at these campaigns we have some foreigner, or someone speaking in a foreign language fluently, such as Hungarian, Slavish or Russian, explain the high lights of the campaign. After we finish with that we take two or three of these foreign interpreters around to our foreign element and they explain the campaign to them. We find we get wonderful results in this way. In addition to that all our signs throughout the plant are printed in the foreign language.

Get the Men to Learn the English Language

G. C. HUTH (Universal): The present immigration law, I believe, has made this proposition a whole lot better than it was before. We attempt at our mill to get these foreign fellows to learn the English language and become thoroughly American. This is just a suggestion and might work with some of the mills. We haven't hired a man for the past five years who refused to take out his first papers.

MAJOR RENINGER (Lehigh): In some plants where we have as high as 62 per cent of foreign labor, we find the foreigner will pick up the English language far quicker than we will pick up the Polish language if we lived over there. We have had very little trouble keeping these men in safety work, and some of the records we have made were made in plants where we have as high as 50 to 60 per cent of foreign labor.

We have gotten along with the posters of the Safety Council through some of our foreign foremen who can talk English. Once in a while we have an interpreter to explain what they are for. We have endeavored for several years to get as many foreigners as possible to go to school. The company runs a naturalization school and tries to get these men educated to the extent that they can take out their first papers and become American citizens. We haven't had to make any great special effort to educate the foreigners. We find with their children in school, if they get any piece of literature to take home, they have their children read it and explain it to them.

It has been our custom for the last few years to give one of our safety calendars to every man in the organization. They take those home and I personally asked a great many of the foreigners: "Do you know what is on the back of it?" And they reply: "I get my boy to read it," or "I get my girl to read it." They take them home and someone in the family knows enough English to get the message. We have gotten excellent results and we don't have any more accidents with foreigners than we have with Americans.

J. SELLWOOD (Duluth Furnace Co., W. Duluth, Minn.): I would like to ask Mr. Sabin a question relative to the physical examination given the older employee. Do you have one final examination or do you have them at stipulated times? We at our plant are putting through all our new employees with a physical examination, but as yet have done nothing to find out the disabilities of the older employees.

MR. SABIN: We applied it to every employee at the plant when we took it up,

regardless of the length of service. Every employee since then has been examined. At the present time an applicant can't get on the force without first submitting to an examination. There is a subsequent examination. Those usually are about a year apart.

MISS M. JORDON (Indiana): I would like to ask Mr. Sabin one question about his court of inquiry. Does it create any ill-feeling among the employees if a man has been found guilty by a jury of fellow employees? If he is found guilty how do you fine him for his disobedience of the rule?

MR. SABIN: So far we know there has been no ill-feeling created. The matter is handled very tactfully. The lawyers are selected from their own ranks. They are fined in various ways, but it is more the thought of being up before the crowd than anything else.

MR. LAWANZAK (Alpha): This physical examination of men is a very vital question in many communities. We have never put on a physical examination for that reason. I was always a little skeptical whether it would go through or not. I wonder whether Mr. Sabin has any figures to show whether it really paid, and whether sending the men into the departments they would fit in decreased the number of accidents.

MR. SABIN: That is a bit difficult to answer as to whether or not the accidents were decreased. We really think they were for this reason. We have some accidents which unquestionably resulted from physical defects. We found a man dead one day. The post-mortem showed he had heart trouble. If he had been examined he wouldn't have been employed in that position. We had three cases of that kind. So I think I can say that physical examinations definitely decrease the number of accidents, at least the number of fatal accidents.

DR. E. M. PARTLETT (Pittsburgh, Pa.): I examined about 1,700 of our employees some five or six years ago and found that 33 per cent had hernia, which is a matter to keep in mind from the standpoint of accidents as well as compensation; 28 per cent had other troubles. I think about one-half of the men operating motors and engines were color blind and quite a number were flat-footed, and so on. I think it is excellent from a safety standpoint and health standpoint, and also from a morale standpoint to have these physical examinations.

G. C. HUTH (Universal): There is a pertinent question that comes up in connection with this physical examination. Almost every red-blooded American likes to earn his own bread and butter, but what is to become of these men who are disqualified from employment? We are having the physical examinations in our plant and as time goes on more of the industries will have it. I am wondering what is going to become of the poor fellow who can't get a job.

G. W. BROWNELL (North American): We have for the past five years given a physical examination to all of our employees. I am sure the examination has more than paid us. The men in whom we found defects we asked to sign a release. By that I mean a man with perhaps hernia would go on record as being in that condition and anything that would aggravate it or make it more serious would naturally be taken into consideration before compensation was awarded.

ADJOURNMENT.

Tuesday Evening, September 27, 1927

The Annual Dinner meeting convened at eight o'clock, Walter J. King, president of the National Safety Council, acting as toastmaster.

MR. FRAME: It gives me extreme pleasure to introduce to you as our toastmaster, Mr. Walter J. King, president of the National Safety Council. It is certainly a great pleasure to be favored with Mr. King's presence and I am sure we are all going to enjoy him in this part of our meeting this evening.

TOASTMASTER KING: Everyone hates a toastmaster. I think I was selected because they know I can't make a speech. I don't think a toastmaster should make a speech; he is simply here to introduce the men who can talk.

I listened to the superintendent of the Lehigh Portland Cement Company, Mr. Weitknecht, of the Mitchell plant, I was very much impressed with his address. That thought he put across today of prevention was fine. You have got the stuff to put it together, cement, which is a fine thing. As one of the officials of the National Safety Council it gives me a great deal of satisfaction to know what you have accomplished during this past year. Just think, 100 per cent membership!

I have a friend in your organization (some of you may know him), Major Reninger. The Major has kept me very thoroughly informed regarding your activities and it is a matter of congratulation from all of us who know what you are doing.

Tonight you are going to hear from a speaker whom you will all enjoy. Mr. Isaiah Hale is well known to most of you. There is only one thing about Isaiah—he doesn't talk very loud and those of you who are sitting in the back of the room will have to be quite attentive in order to hear what he has to say. Hale, the gang's all here.

Address

Isaiah Hale, Superintendent of Safety, Atchison, Topeka and Santa Fe Railway System, Topeka, Kan.

I have no idea why I have been wished on you tonight, and there is a fear in my heart that before I go much further some of you, too, may wonder why I have been. I feel sure, though, I am not the first man without merit who has horned himself into your program. It isn't a difficult thing to arrange, when you have a friend or two who may, or may not, tell the real truth about you. A single engagement of this kind isn't always the real difficult thing to arrange; the task is to get in here and then get back to the street; because many a man who has come here on a program of this character, care free and buoyant and hopeful, never lived to get back to the street with his reputation as a talker or his self respect quite intact.

The reason for my presence is so mysterious that I am reminded of the story of a policeman who saw a fellow leaning over the rail looking into the smooth surface of a stream flowing underneath. After watching him for an hour or so he walked over to this man, tapped him on the shoulder and said, "What are you doing here?"

Slightly inebriated the fellow said, "I was just looking."

"What were you looking at?"

"I was just looking down there."

"What were you looking at down there?"

"I was looking at the moon; that is the moon isn't it?"

"Yes, it is the moon, but what of it?"

"That's what I want to know. If that is the moon down there, tell me how the hell did I get up here?"

So many more times have I sat out where you fellows are than I have stood here, that sitting out there I know mighty well what comes into your mind. You settle back as comfortable as you can and say to yourself, "I wonder what sort of a bird this is we have with us tonight, and how long he is going to take to wear out his welcome?" I once heard some men talking, after listening to a fellow blow his own horn. They were comparing the fellow who talks extemporaneously with the fellow who reads a formally prepared paper; and one old fellow who had suffered often and much said, "I like to have a guy get up and read his paper because when he reads it you can watch him and when he gets down to the last sheet you know that *that bird is through*." But I am going to do neither. To avoid the chance of making a detour and getting off of the road, I am going to take the liberty of looking at some notes. I shall keep in mind, too, that old one comparing a speech with the wheel of a wagon, in that the longer the spoke the larger the tire.

A Common Sense Viewpoint of the Question

I shall only be able to hit the high spots in what I want to say, and following my usual custom I shall talk very seriously. I am going to do my best to talk common sense to you in spite of the fact that one of the most uncommon things in the world today is common sense. I recall I didn't even get any advertising out of this introduction, but as information I am the safety superintendent for the Atchison, Topeka and Santa Fe Railway System. I want to talk to you fellows much as I would to a bunch of our superintendents, trainmasters and master mechanics, who correspond to your managers and plant superintendents.

You may not agree with me in what I say. I concede your right to your own opinion; what I say to you is merely mine. As a place to start, may I suggest the viewpoint of your employee on life, as a whole? His mental attitude toward his job is the most neglected asset in your business today. It isn't necessary for me to thrash over a lot of old straw to tell you something of the aims and purposes of the safety movement, because you know quite as much as I do about it. With us, our first effort was the same as yours. We began safeguarding our machines and cleaning up the whole property, only to find, after we had spent oodles and oodles of money and years and years of valuable time, that all we had done had gone for a little more than naught, because we were not making any inroads on our casualty toll.

I then did a little mental cruising in what had theretofore been an uncharted sea, with the result that I made up my mind that in a changed viewpoint, in a little different mental attitude toward his jobs, lies the thing which alone will make a man an efficient and a safe workman, that will let him get out of the rut and out onto the broad highway of life where the going is much smoother and the route toward success is more direct and sure, provided only you can change the man's viewpoint and make him reasonably sure of himself.

Safety is only a by-product of any number of things. We might just as well talk of loyalty, and efficiency, and integrity and faithfulness. The one obstacle which, more than any other, has impeded your progress along safety lines is a disinclination, or at least a lack of inclination, on the part of a great many men to give its aims and purposes a careful and serious enough thought to determine for themselves whether or not it is worthy of their own interest and support. And therein lies a second obstacle in front of the first one, because my observation

has been that a surprisingly number of men are constitutionally opposed to any effort so laborious as thinking seriously about anything.

Some of those from whom we had a right to expect the most, foremen among them, were very slow to warm up to our safety work. Not because they were hard-boiled, not at all. I believe it was rather because many of them were loath to believe that there is or could be any better working system than that under which they had worked for many years, and for which they felt a certain responsibility because they helped bring it about. It was because of their failure to fully realize the meaning of or appreciate the wonderful privilege and possibilities of foremanship.

Safety more than any one policy sponsored by your management or mine, must rely upon supervision, not only for its advancement, but for its very life. The foreman is the keyman. Not only what the foreman may say in the presence of his men but, more important still, the manner in which he says it, will either breathe life into the cause or choke it in its infancy.

Contrary to a too common belief, safety is not something that will ever boil up from the bottom, if it ever permeates the fiber of your organization, or mine, it must percolate down from the top. There is no need to try and sell the safety idea to your rank and file until your management has been sold on it.

The Accident Is Not Seen In the Making

Foremen are seldom eyewitnesses to accidents. There comes over my desk every report of an injury to a Santa Fe man and I don't believe I have seen a report in two years in which the foreman admitted he had seen the accident; but too often, fellows, the foreman fails to see the accident in the making. Too often he fails to see in an irregular practice a personal injury in the making, which, if continued long enough, will ultimately cause an injury. I have an idea that when many men have been made foremen, they were not exactly clear as to just what a foreman is. So they went to the dictionary, turned to the word foreman and found that a foreman is an "overseer." They said, "That is all right as far as it goes, but what is an overseer?" They then looked up the word overseer and found an overseer is one who oversees, one who looks things over, one who overlooks—and so the foreman has been overlooking a good deal ever since.

Too many foremen have an idea they must watch their men; they must stand guard over them, if you please, to see that they make more than a mere bluff at doing an honest day's work. In my humble opinion it is the first duty of management, and a foreman is part of management, to feel and to show an interest in their men. I tell our foremen that their first duty is to give their men a right viewpoint on their relationship with the Santa Fe Railroad; if they have not the right viewpoint they are not the men we want in our employ. That applies equally to the foreman and the man. I tell them it is a foreman's duty to give their men higher ideals, to teach them not only their own individual responsibilities but to give them a decent appreciation of the rights of other men; and above all to make them see in their job the best friend they have in the world.

I argue with our men that if our job is our best friend (and it is), that it is only a matter of common decency and fair play for them to treat their job like a friend and be good to it. I frequently, almost daily, ask our men if they have ever tried to appraise their job in money. I ask a man who earns \$150 a month if he realizes that that is 6 per cent on \$30,000. The man earning \$200 a month is getting 6 per cent on \$40,000. I ask them if they guard their jobs as zealously as they would \$30,000 or \$40,000 in a safety deposit vault? As a matter of fact, a man's job is worth more to him than the money it represents, because if he so wills nobody in God's world can take it away from him. On the other hand, a man who has a job worth \$150 a month has more than \$30,000; he can increase it

to a \$40,000 basis almost over night if he wants to, and in much less time than he can increase his hoardings from \$30,000 to \$40,000.

I claim it must not only be the duty of foremen, but their very great privilege, to make their men realize that this thing of doing only what is necessary to get by is never quite enough; it should be the duty of foremen to make their men realize that the secret of real happiness or success doesn't lie in doing the things we like to do but in liking the things we have to do, regardless of what they may be. They should make their men see in their job a stepping stone for today and not a resting place for tomorrow. They should make their men realize that two-thirds of promotion consists of motion; and, fellows, it is just as true in the accomplishment of it as it is in the spelling of it. They should make them realize that the limitations of any man are not the things he wants to do but can't, but the things he doesn't do because of laziness or indifference. They ought to make their men realize that while it is easy enough for a small man to make a big job shrink, it takes a big man to make a small job grow. There isn't on our railroad today a job that cannot be made a bigger and better job, nor is there one in the cement industry.

Trying to Boost the General Morale

I use a good deal of emphasis in trying to make our men realize that this thing of giving counterfeit labor in exchange for honest labor isn't a good basis on which to work, because the man who gives counterfeit labor for honest wages becomes in time exactly what he thinks and acts—a counterfeit himself. The man who hides out on his job during the day and cheats you and steals from you every chance he gets will never be a credit to you. This thing of following the path of least resistance is the thing that makes rivers and men crooked. Give me the man that follows the path of least resistance and I will show you a crook at heart.

I no longer follow the old orthodox way of talking safety, as I did when I started fifteen years ago; I never go around and tell a man, "Don't do this and don't do that." To the limit of my humble ability I am trying to boost the morale of our men; I am trying to increase their loyalty. My real ambition will never be reached until I can put in their minds and heart an ambition to be somebody and to do something worth while.

Safety isn't something that a department head can ram down a man's throat. In the first place, getting it that way would not do any good; he must want to believe in it. His conversion, when it comes, will come when he has the wish and determination to pick up the banner as an honest-to-God crusader because he believes in principle that safety is right and just. I never heard a finer story on cooperation than was told in one of the National Safety Council conventions some years ago; it was so long ago that I hope very few of you who are here tonight have heard it. It was told by Mr. Kettering, vice-president of the General Motors Research Corporation. You may easily imagine what Mr. Kettering has above his ears. He said—and I am going to take the liberty of repeating it—"I once stood upon the shores of one of our seas and while standing there my attention was directed to the myriad of little pebbles that lay at my feet, pebbles that seemed to be serving no useful purpose. As I stood there I couldn't help but wonder what thought the all-wise Creator might have had in mind when he lined the shores of our seas with that endless fringe of pebble. Shortly after, I walked down the shore a considerable distance, and I came to a gigantic seawall thrown up by the hands of man and which in the intervening years had, on a number of occasions, turned back waves that would have brought destruction and chaos and loss of life. Imagine my surprise when upon examining that wall I found it was made almost entirely of those little pebbles which I had thought were serving no purpose at all. I couldn't help but draw a parallel in my own mind between those little inconsequential pebbles on the

shore of the sea and ourselves who are little more than consequential pebbles on the shore of the sea of life. Like the pebbles, we serve no very useful purpose until we are brought into close and intimate contact and relationship with other men and held there by the cement of mutual understanding and trust."

I tell our men on our railroad that when we all understand each other and trust each other as we have a right to understand and trust each other, some day (though I may not live to see it) we are going to build a safety wall around our property which in the years to come will turn back those waves which have brought physical suffering and heartaches and sorrow into our homes. I remind them, too (as I would now remind you), that just as that concrete wall would have been weakened in its construction by the absence of any one pebble in it, so will this safety wall we are trying to build be weakened by the absence of each individual Santa Fe man who does not make himself a part of it.

The Fundamental of Sincere Cooperation

I received a new slant on cooperation the other day when I heard of a man who was asked what is meant by cooperation. He thought a moment and he said, "Well, as I see it, the first essential toward cooperation between me and others is for me to make myself so other men can work with me." There is a lot of food for thought in that for the man who has difficulty in working harmoniously with other people. We are very prone to attach to the other fellow the responsibility for our failure to do that. The real fact, if we only knew it, is that other people not only find it difficult but often impossible to work harmoniously with us—and with us means with you and with me.

I am just hitting the high spots here, and am sorry I've not the time to enlarge on some of these thoughts.

I have never had any hope of carrying my appeal to the rattle-headed, irresponsible type of man who has no aim in life beyond getting and cashing his next pay check; who has no definite purpose in life, who daily follows the path of least resistance, and who, lacking this definite purpose, is a floater and will some day find himself washed up as a bit of wreckage on the shore of the sea of life, bitter and sore against the world because time has brought success to other men and only defeat and disgrace to him.

One of the problems of every big organization is the man who knows a lot of things that are not so (if you get me). My observation on that is that the thing a man is down on is generally something he is not up on, and that opens a very wide and expensive field for whatever educational efforts that man's supervisor may feel himself equal to. It isn't often difficult to locate the distributor in your ranks because the man who is against something always talks louder than the man who is for something. I am warning our men against the "ballyhooer" who comes around and tells them about their inalienable and God-given rights as American citizens, and a lot of other rot of that kind. Neither you nor I have any rights until we prove ourselves worthy of them. I am warning our men against those fellows who tell them they must stand for their rights, that all men are born equal, which is more rot. It may be true, fellows, that all men are born equal, but let me remind you that it is your own fault if you remain that way.

One of my pet ideas is that one of life's hardest bumps will come when a man tumbles to himself. As an illustration of what right thinking and wrong thinking may do for a man, it has been but a comparatively few years since Walter P. Chrysler, whose name adorns the radiators of a good many cars on our highways, was an engine wiper at \$1.80 per day in a Santa Fe roundhouse in a little Kansas town. As an engine wiper, he was a good one, and had he so willed, I doubt not, he could have been wiping engines there today, perhaps at a slightly increased pay. However, he didn't choose to stay there. While other men were listening to soap-box orators

and attending secret meetings in some back room where they were told how their rights were being taken away from them, and all that sort of thing, Chrysler was burning a midnight kerosene lamp and putting onto a tracing cloth the gasoline engine he afterwards put upon the highways. I would like to remind you, as I do our men, that if Mr. Chrysler should step down from his eminence in the business world and go back to that little Kansas town, he would find any number of his old associates who cultivated that wrong viewpoint toward their jobs, who listened to these agitators, who five years ago in July walked out of Santa Fe service on a strike, and who since that time have been walking the streets of that town, out of a job because they have been unable to get work anywhere else. The really pathetic part of it is that most of those men in a short time would have been entitled to an old-age pension that would have kept them in reasonable comfort as long as they lived.

I wish you men would go back and tell your men, and especially your young men, that loyalty is one of man's cardinal virtues, loyalty to his government, loyalty to himself and to his job. The most worthy of human achievements, and what ought to be the greatest of human desires, is to be useful; and one doesn't have to be a genius to be useful, because industry and faithfulness and integrity will make a winner of any ordinary man. The man who tries to do something and fails is entitled to lots more credit than the man who tries to do nothing and succeeds.

An Ambition to Be Somebody Worth While

Some day I am going to make a safety talk and from the time I begin until the time I sit down, not once am I going to mention the word safety. Rather, I hope I may be able to say something that will put into the hearts and minds of men an ambition to be somebody and do something worth while. I wish I might do that because someone has said that the height of service is helpfulness to others, and I can conceive of no greater service to another person than helping that man to find himself. It isn't every man that knows what he is worth. You may have heard of the fellow who showed up at the employment window of some large industry and asked for a job. The agent nodded to him to come inside and later on was told, "I will give you a job."

The man said, "What will you pay me?"

The foreman said, "I'll pay you what you are worth?"

"Well," replied the man, "I wouldn't work for that."

And it isn't every man who knows what he is worth! I feel that you men should constantly remind your men that just ahead of every man in your service there is a better job than his and just behind him is another job not quite so good. Some day, in the very nature of things, there is going to be a shift, and that man should daily ask himself, "When that shift comes which way will I go?"

Within the last few days I had the pleasure of talking to one of our large shop organizations. I reminded them (and this is only a thought for you) that no man in our service was ever recognized because of his record at being the first man to reach the clock to punch out when quitting time came. I said to them, "I really believe if I were you fellows, I'd be on the job a few minutes before eight o'clock. I'd change my clothes, lay out the day's work as far as I could and actually have it under way when the starting whistle blows; and then I'd give an honest day's work for the honest day's pay I felt I was going to get, and if I didn't feel I was going to get an honest day's pay I wouldn't stay a minute. I'd work along happily until the quitting whistle blew, and when it blew I'd look at the job in my machine and if I could finish it up in a few minutes I believe I would finish it. Then I would change my clothes and wash up and I'd check out in a more or less dignified and orderly way." I noticed some of them smile, and I said, "I know what you fellows are thinking; you are saying to yourselves, 'Oh, but Hale, that isn't being done!' I know it isn't being done and that is just exactly the reason why Hale would do

it." It doesn't take much of a man to do the things that everybody else does. I ask you as I asked them, how long do you suppose a young man in one of our shops could do that sort of thing when the general foreman or the master mechanic came by and said, "Who is this young chap who seems to be so interested in his work?" We give too much concern to what the job cannot do for us and not quite enough to what we can do for the job. A lot of men are so busy planning what they will do tomorrow, they forget all about what they planned yesterday to do today.

I am not asking our men for their interest in this safety movement; I am asking for their enthusiasm. I want them to add their heart service to their head and hand service. The very best work in your line of endeavor or mine is done by the man whose conscience won't let him do any other kind. And so I can't get very far nor stay long away from the thought underlying all I've said to you, that in a changed viewpoint, in a different mental attitude toward our job lies a panacea for most of our industrial ills. I honestly believe that, through awakening of this ambition, our advancement in responsibilities, our acquisition of things every man wants most in life, the respect of his family and friends—all absolutely depend on the man's mental attitude toward his job. Roger W. Babson, probably the world's most eminent statistician, recently announced that only one man out of 50 in America ever thinks; that only one man out of 500 ever originates anything, even an idea that is worth anything to anybody else; and then he said this (and please get it), that at the age of 50 years, 53½ per cent of the male population of America are down and out and have quit.

Management Carries Responsibilities Not Always Recognized

To me, it is a very sad commentary on our much vaunted civilization and intelligence and our talk of brotherly love, and that sort of thing, when we are told that at 50 years of age, at what ought to be the best years in any man's life, that 53½ per cent of us have quit cold. Do you know why they have quit? In my opinion, it is because they never tried; they never tried because they never cared; and they never cared because they never had the right sort of influence from men like you, and possibly from men like even my humble self.

I would remind you that management, which is supervision, carries with it responsibilities that are not always, or even often, recognized. An impressive number of summers and an equal number of winters have taught me a lot of things. They have taught me, for one thing, that other people treat me just about as I treat them; they have taught me that when I go out looking for trouble I never have any difficulty in finding it, and they have taught me that the Golden Rule is the sum total of all wisdom for getting on in the world. I want to tell you men, many of whom are in authority over large bodies of men, that it isn't the Golden Rule when you take flesh and blood and make out of it nothing more than a mere commodity at an agreed price per hour or per day. I tell our foremen that the man who builds tracks or bridges or locomotives, or makes cement, and who does not at the same time undertake the task of building character among his men, presents a mighty sorry spectacle as a leader of men, and as a foreman has no value whatever.

We hear a great deal today about service. Service is only a modern symbol for countless human virtues that have been known since the beginning of time. Service was a mother solicitude for her children; service was in the long hours of toil that your fathers and mine gave to us; in the hardship endured and the burdensome debts unrepudiated; it was all of these and a million other little things that only the Recording Angel will ever number. But service is the

one thing that every man must put into his job or into his life if he ever expects to take anything worth while out of either one of them.

I don't believe that success in life is ever possible except through service; there is no open gateway to success, fellows; if you reach it, you must climb the barriers, not always or often an easy thing to do. The pity of it is that multitudes go wandering through the years looking for a break in the wall, for an easy way through, only to lie down at the end of the trail weary, and disappointed and unsatisfied. John Burroughs, the naturalist of California, said before his death, "A man's life may stagnate as literally as water may stagnate," but just as motion and direction is the remedy in the one case, so is some definite purpose and activity the remedy in the other."

Less and less each year is the world condoning or excusing failures in men; and more and more every year is the world bowing down and kow-towing before the man who early in life made up his mind what was right and then had the guts to go ahead and do it, regardless of what anybody else did or what anybody else thought. In railroad just as in manufacturing, catastrophe is only a step or two behind integrity; and if you will go with me and look under the hood of any failure stranded along the great highway of life, we will find there unmistakable evidence of where some fellow tried to use a substitute for common honesty. There is no substitute, there never has been, and yet you and I know men who are daily trying to use a substitute and hoping they may get by with it.

I can't tell you how very happy I am to have been here with you. I have appeared in many cement plants over the country, and I am very happy to be here for no other reason than the fact that Lester T. Sunderland has been a life-long friend of mine and there isn't a man in the world for whom I have more respect. Certainly I recall no one who in the same measure and in the same way held out a helping hand to me in my youngster years when I needed help. I only hope someone may tell him that I have been here. I should have stopped right there, but let me tell you one of the privileges of foremanship is to reach over and lean out and offer a helping hand to some poor devil who is in a rut and who only wants a kindly word and a little bit of encouragement from you.

There is something pathetic about a rut. I heard it said not long ago that a grave is often the last six feet of a long, long rut. A poor devil lives in a rut and is laid away in one.

In expressing my appreciation to the officers of the Cement Section and to Mr. King, it would be amiss not to tell you how very grateful I am to you for your very close and sympathetic attention.

(The members arose and applauded.)

TOASTMASTER KING: Mr. Hale, I think I voice the sentiment and the opinion of everyone here in this wonderful audience when I say you have rendered this company a great service. You have run true to form in giving us what you have given us. It is a real contribution. It has made this evening complete. I am mighty glad you have been with us and we appreciate all you have done.

Have any of you boys anything further for the good of the cause? If there is nothing further, I wish to express my appreciation and thanks for your kind invitation to be with you this evening. It has been a most enjoyable evening.

ADJOURNMENT.

**SIXTEENTH ANNUAL SAFETY CONGRESS
NATIONAL SAFETY COUNCIL**

Cement and Quarry Joint Session

Wednesday, September 27, 1927

**R. FRAME, Chairman Cement Section
Insurance Manager, Alpha Portland Cement Company,
Easton, Pa.**

**L. R. CARTWRIGHT, Chairman Quarry Section
Vice-President, Mid-West Crushed Stone Company,
Indianapolis, Ind.**

The joint session of the Cement and Quarry sections of the National Safety Council convened at two-thirty o'clock, R. Frame, insurance manager, Alpha Portland Cement Company, Easton, Pa., presiding.

CHAIRMAN FRAME: This session is a joint meeting. As many of you men know, the cement and quarry industry have a lot in common and it has always been the practice to have one joint session at which we could discuss the subjects pertaining to our mutual interest.

I am going to ask Major Reninger to announce the nominations of officers for the Cement Section for this coming year, and immediately following will be the elections.

H. A. RENINGER (Lehigh): There is one thing I want to bring out that I am very proud of as far as the Cement Section goes. That is in regard to the new membership in the National Safety Council. We have 13 new members, making a total of 79 in the Cement Section, with no cancellations, giving us a 100 per cent clear record, and the only section in the National Safety Council having a 100 per cent record in membership.

There were four companies who were reported as having cancelled their membership. These companies—the Pennsylvania, the Dexter, the Penn-Allen, and the Penn-Dixie—have not cancelled their membership but have all combined under the Penn-Dixie. They are all actively represented in the Cement Section.

Another question was brought up by Mr. Curtis in connection with community activities, upon which I would like to touch. What can we do in the way of helping the community? Those of you who have plants in large communities, are not up against it as much as the smaller community. Where you have a small community, as we have in a number of places—at Mitchell, Indiana, for instance, where the plant is more or less the chief manufacturing concern—we believe there is a field for our safety committees to do some good, active safety work. Perhaps it isn't so necessary that we go into public safety as we have to in other cities, unless you are on a main

highway, but I believe we have a field in the schools. There should be put into the school system a course of safety, starting with the child in the first grade and keeping on up to the seventh or eighth grade.

Years ago it was hard to do that, for the simple reason that we didn't have the material and when we came to the teacher and said we would like to put across some safety work and asked what she could give us in the way of help she would have to go and dig out stories and plays and different things; and, of course, she didn't always have the time to do it. However, with the inception of the Educational Section of the National Safety Council, we have gathered a great amount of information from cities all over the country and a course has been outlined. This course has been studied by some of the best educators. It has been worked out in detail now so that the mind of the child from six years on can absorb that information, and I believe we can do a great deal of good. Get the school authorities in your community interested and have them become members of the National Safety Council.

Let us get our school people interested in home safety and public safety. Eventually when the child has reached the age to enter into industry he will have absorbed a great deal of that safety we are trying to give him now. It will become more or less of a habit and that is what we want in safety work.

I think it might be a good plan to have one representative of every plant here and hold a meeting this afternoon or tomorrow morning and get one of the National Safety Council people here to talk to us. If we can, let us get Miss Stevenson to talk to us on school safety and what we could do. Are you men interested enough to get together after adjournment of this meeting and have a talk by Miss Stevenson or some one of those girls of the Education Section who are familiar with this work? How many of you would like to come to a meeting of that sort?

(A number of men raised their hands).

The School Children Are the Workmen of Tomorrow

We can set that meeting for four-fifteen. I know that many of you are interested in this work and have suggested that we do something of this sort. I would like to have one representative from each plant. We could go into the details and find out what we might be able to do.

CHAIRMAN FRAME: Major Reninger will be glad to answer any question in regard to this matter.

MISS M. JORDAN (Indiana): I think that would interest everyone here because the school children of today are going to be the workmen of tomorrow, and if you start in now teaching them the rules of safety and how to be careful in their play, in their household duties, if you get them at that age when they start working in your mills and plants you won't have nearly as much trouble with them.

I want to know if the procedure of that will go through the school boards.

MAJOR RENINGER: Yes. You won't have any trouble if you show them just what you have to offer.

CHAIRMAN FRAME: The average school superintendent, from my experience, will readily admit that he knows very little about the aims and the progress of the National Safety Council; and he will just as readily admit that it ought to have its beginning in the public school and he will welcome any suggestions from any community man as to what might be done.

MAJOR RENINGER: There are outstanding cases where industry could take hold of this thing. Mr. Kreglow, of the New Jersey Zinc Company, backed up this work with the schools. I am going to ask Mr. Kreglow if he won't review briefly their success.

MR. KREGLOW (N. J. Zinc Company): Most of the men who are interested in safety are members of the school boards. However, we have found the teachers very friendly toward it and also the superintendent. A number of times we took them along to our

local meeting and we got them interested. We have memberships for everyone of our school buildings. We also have the safety patrol. I think it is the right way to attack the problem and it is going on now without any trouble at all.

MAJOR RENINGER: The Nominating Committee of the Cement Section wishes to report as follows:

Report of the Nominating Committee

Chairman, T. F. Halpin, Marquette Cement Mfg. Co., LaSalle, Illinois.

Vice-Chairman, F. E. Town, Supt., Manitowoc Portland Cement Co., Manitowoc.

Secretary, A. J. R. Curtis, Portland Cement Association, Chicago, Illinois.

Chairman Membership Committee, Henry A. Rening, Lehigh Portland Cement Co., Allentown, Pa.

Chairman Poster Committee, R. B. Fortuin, Penn-Dixie Cement Corp., Bath, Pa.

Chairman Program Committee, Russell Frame, Alpha Portland Cement Co., Easton, Pa.

I want to present these names as the ones placed in nomination by the Committee as officers for 1927-28. Signed by the Committee, Mr. White, Mr. Fortuin, and myself.

CHAIRMAN FRAME: Of course, it is your privilege to nominate any other gentlemen for the positions which are open at this time. It will now be in order to listen to any other nominations you care to present.

(It was regularly moved and seconded that nominations be closed).

CHAIRMAN FRAME: It has been regularly moved and seconded that the gentlemen proposed by the Nominating Committee be elected to serve as officers for the Cement Section for the ensuing year.

(The motion was put to a vote and carried).

CHAIRMAN FRAME: I declare the gentlemen duly elected. I take pleasure in presenting Mr. Halpin, of the Marquette Cement Mfg. Company, your next Chairman.

Mr. Curtis tells me he received a telegram from Mr. Town regretting that it is impossible for him to attend the session. Mr. Curtis will again serve as Secretary of the Section.

Now we come to the first subject on our program—"Fixing Accident Responsibility." The first question when an accident occurs is, who is to blame for the accident. We believe it would be of interest to discuss this, and I am sure it was placed in able hands when Mr. W. L. White, Jr., General Superintendent of the Sandusky Cement Company, Cleveland, Ohio, was selected to present the subject. I take great pleasure in introducing Mr. White.

Fixing Accident Responsibility

W. L. White, Jr., General Superintendent, Sandusky Cement Company,
Cleveland, Ohio

Fixing accident responsibility is a most serious problem. It calls for a decision, which, under any circumstances, is hard to make; one which must be carefully studied, and only a cool, clear, unbiased opinion is to be used in handing it down.

The safety movement, as we know it today, particularly in the cement industry, is really an innovation compared to the age of the industry. The year 1919 saw the beginning of extensive accident prevention work by the Portland Cement Association, and, while there were a good many individual plants and companies which paid particular attention to the prevention of accidents before that date, yet, nationwide attention to accidents began in that

year. Attention to accidents means placing the responsibility on the party directly responsible for them. Little or no attempt was made to fix accident responsibility in years previous to 1919.

It might not be amiss to state here that the first day I started with a cement company there was an accident at the plant which resulted in a fatality, but, to be honest, perhaps through inexperience, or youth, or both, it did not make the impression that an accident does today. I do not recall any attempt to fix accident responsibility in the first years of my work. The general attitude in the cement industry was to take an accident, serious or otherwise, with a shrug of the shoulders, as if it had to be, or, as if it were part of the routine operation of the plant or quarry.

There are four headings into which "Fixing Accident Responsibility" can be classified:

- (1) Executive or company policy
- (2) Plant Manager or superintendent
- (3) Plant Safety Committee
- (4) The individual

(1) It is a well-known fact that the attitude of the superior officer or executive, president or board manager, or whatever individual or group directs the policies of an organization, is reflected down to the humblest employee. If this individual, or group of individuals, is not squarely behind the welfare of the employees, and does not sanction safety work, it has a bearing on results secured by the company. This might be termed more psychological than actual, and, therefore, a president could hardly be accused of being the cause of an accident. However, careful analysis shows that he is responsible to a much greater degree than a casual glance first discloses. The mere fact that most individuals and groups look up to leaders for initiative is sufficient cause for the statement that the executive is responsible in a certain measure, for accidents if he, or they, are indifferent to the safety movement.

The Modern Executive Must Be Behind Safety Work

It is inconceivable that an executive of today is not squarely and actively behind the safety movement. There are some who are passive, though, and such should certainly be held liable for at least part of the responsibility of the accidents occurring in their organizations.

(2) The second party on whom the responsibility of accidents rests, is the plant manager, or superintendent. In a great measure, the entire success of safety work depends on him. If safety is not being pushed energetically, or, as in some few cases, is not even considered, then this man is directly responsible, except, perhaps, in the rare case where his good intentions are held in abeyance through the orders or wishes of his superiors. A good plant manager includes the safety movement as part of his daily duty. I say daily because safety work is largely missionary work, and the true safety man can be likened to a missionary who toils unceasingly, day after day, without any thought of reward, gratified entirely, through love of his work, with but small visible results. He must be a keen student of human nature. His interest must never lag. He must be able to put across the idea of safety, not only to the safety committee, which should be directly under his supervision, but also able to put the idea across to the individual, through his actions and speech.

The following case occurred during the war period. The common labor at the plant was composed mostly of the rag, tag and bob-tail which had escaped the draft, and more negro than white. During a particularly rainy period, with the coal storage low, it was necessary to put a force of laborers

shoveling from the coal pile into the screw conveyor under the coal trestle. This screw conveyor was guarded with a heavy bar grating, bolted down to the concrete. The plant superintendent was in this particular department for some little time, principally with the intention of putting across the safety idea to these men, as several serious accidents in screw conveyors had occurred prior to this time. No sooner had the superintendent left the storage, than one of the negroes removed the grating, straddled it, and started to shovel in coal.

He slipped, fell in the screw, but miraculously, had only the flesh and muscles of the calf torn, instead of losing his entire leg. While he lay on the stretcher waiting for the doctor, the superintendent asked him why he did it, and he was frank enough to admit that he wanted to hurry his work up, that is, fill the coal tanks over the boilers, and then sit down and rest, which is characteristic of the negro as you know. This accident brought the superintendent face to face with placing the responsibility, and he felt guilty because he did not have the ability to read human nature better, or else was unable to sell an idea, and, from that time on, this superintendent became a better safety man.

The Functioning of the Safety Committee

The injured man was not censured at the time. He was suffering enough pain without giving him mental stress in the bargain; but on his return from the hospital, coming back to work, he became one of the best safety men in the plant.

Perhaps you have all had similar experiences, and the plant executive who is unable to strike the chord of safety, and cannot sell or put across the idea of safety, lacks one of the fundamental characteristics which will make him a success.

(3) It is no easy task to have a safety committee function properly. In the early beginning, when safety committees were first organized, while it was not the rule, yet a good many plants had a safety committee in name only. This committee might be composed of any number of men, meetings would be called at various irregular intervals. Sometimes the members of the committee were "too busy," having a small repair job to work on, and considered the operation of the mill of more importance than the safety committee meeting. Again, the spirit of the organization would be dominated by the plant executive because he took it upon himself to turn down all recommendations except those which he himself might bring before the committee, feeling that an employee was "treading on his toes," or presuming beyond his station, or overstepping his authority. In other words, the safety committee was not being handled right by the plant executive. A good executive will have a good safety committee, and this is the third group upon which the responsibility for accidents rests. It is not right for a superintendent to take upon himself the duties of a safety committee, so to speak, nor to inspect the plant at such times as he may see fit, perhaps with one member of the safety committee or alone, nor to install certain safety devices and consider good safety work being done. Such practice, in reality, is nothing but the result of egotism on the part of the superintendent.

A manufacturing plant as large as the average cement plant today needs a safety committee that consists of not less than six, and ten is considered approximately the right number for a three thousand barrel plant.

The committee itself must be made up of real safety men, whose enthusiasm must be ever to the front. The members of the committee should not

necessarily be chosen by the superintendent, as the employees know best who of their number is most interested in safety work.

The committee should meet at regular intervals, and, in addition, have special meetings when the occasion demands, such as a serious accident, and it is only right to place in its hands the fixing of accident responsibility.

A man does not have to be college bred to make a good safety man, but he should be one of sound sense, a thinker, and have a good understanding of the idiosyncrasies of human nature, coupled with unflagging interest and endless patience. When all of these characteristics are found in one man, he is a jewel well worth keeping and generally demonstrates his worth through the results obtained. However, it is not difficult to find many of these characteristics in the average plant employee. If the safety committee is properly organized, and has the shining example of a good superintendent, it is bound to function efficiently.

Bad Safety Records Pull Down the Average

The accident records of the Portland Cement Association show that there are a "vicious few" plants which apparently lack something to bring their safety records to at least normal, and this record of the few pulls down the record of the majority through an excessively large number of man hours lost on account of various kinds of accidents. On the other hand, there are a number of plants which have an enviable safety record. A major portion of the success of this record can be traced directly to the safety committees.

It will not do to appoint a safety committee and then, on the day or days specified for the regular meetings, permit its members not to attend on account of some breakdown in the mill, or other excuse which might be forthcoming; or, on the other hand to cancel the meeting until the next day, or the day after, as the superintendent may have something which he considers needs his attention. There should be, as stated before, a specified time for the meetings and the schedule should be adhered to, and, except for unforeseen, serious reasons, no member should be allowed to be absent. If there are one or two members who would rather not attend, it is usually an indication of lack of interest, and they should be removed without further consideration, and others appointed in their places.

Neither should the plant superintendent, through the authority vested in him, become a jury of one and veto valuable suggestions offered by various members of the committee, merely because they might not strike him as the right move. If the suggestion is approved by a majority vote of the committee, unless he questions it at the time it is discussed and gives reasons sufficient to vote it down, the resolution should be placed on the books and the work done as suggested. Too often a peremptory veto takes the pep or enthusiasm away from the committee, and this, in turn, is reflected throughout the organization. With what result? Either there is an increase in accidents or a failure to obtain results in periods when drives are put on, such as the recent campaign of the cement industry in June of this year. Accidents in plants can be reduced if the safety committee is functioning properly, under a good executive. If they are not reduced after the organization is started, then it must assume its share of blame for all accidents, major or minor, which occur, for it has failed to do its duty, which is, first, putting across the safety idea to fellow employees, and, second, providing the good example.

No doubt some of you have observed members of your own safety committees doing foolhardy things in the plant, or making disparaging remarks in the presence of other employees. If these failings are not corrected after a heart-to-heart talk, they should be dismissed from the committee and the

fact published throughout the plant, which, as a rule, is sufficient punishment and makes them better safety men. Sometimes one hesitates to use the big stick, but it is necessary with certain types. It is rather difficult, perhaps, to cite cases where safety committees have flagrantly violated their duties. Actually, the idea of the formation of the safety committee originated from the fact that the plant executive cannot reach each individual throughout the plant, not coming into daily contact with as many of them as the members of the committee do, and on its shoulders rests the responsibility, which is very heavy. If this idea is instilled into the minds of its members, there is no doubt that the committee will never be censured nor taken to account for accidents which might occur.

(4) Fourth and last comes the individual himself. Except in catastrophies, where many are injured, and some killed, it is the individual who is generally responsible for the accident, and that responsibility must rest on his shoulders. Only, however, after a thorough investigation. If the plant superintendent is a safety man, and his safety committee is working properly, the injured employee has had an opportunity, through observation of the actions of his fellow workers, and discussion with them, to learn about the safety movement and has been instructed regarding all hazards about the plant. If he does not benefit through these methods he is entirely to blame.

The Other Side of the Subject

There are certain individuals who seem to be unlucky and who are continually unfortunate. In one particular case it was necessary to discharge the man. He would be injured, and, a day or two after his return to work, he would have another accident. Within the course of a year he suffered ten accidents, not quite one a month. It was finally decided that he was too great a risk and he was let go. Such is an unusual condition, however.

These comprise the four headings into which responsibility for accidents can be classified, but they are only one side of the subject. There is another side, which some people have emphasized, that is, the sentimental. It is not the intention to take that up in this paper as sentiment should not be used in handling safety matters. The only sentiment which enters into the situation is this; the man, or men who are responsible for an accident, and on whom the responsibility is placed, are usually punished sufficiently through the knowledge that they are the cause of pain and monetary loss to a fellow being, and further punishment should not be meted out, except in cases of gross carelessness, other than the publishing of the fact that they were directly responsible for the accident. That is as far as sentiment should be considered in handling this matter. Nor should generosity be considered in placing the responsibility.

There is one type of accident which cannot be accounted for even after a thorough investigation, and the responsibility for such accidents cannot be placed on anyone's shoulders. Particular reference is made to a fatality experienced at a cement plant in 1926 where one man was electrocuted and two others severely shocked while pulling on a cable from a car puller. These men were in the packing department and it was their duty, in connection with packing cement, to unroll the cable from the drum of the car puller, attach it to the last car of the string, and, after this hook was attached, pull the cars in front of the packing house door. These three men took hold of the cable, after starting up the motor of the car puller; two of them were knocked ten feet, one unconscious and the other severely bruised, but the third, presumably from a weak heart, was electrocuted.

Just who should be held responsible for this death is still a question. Starting at the top, the president of the company is a safety man; the superintendent has been giving, and continues to give, all there is in him to have an excellent record at his plant; his safety committee is composed of good safety men, and the general attitude of the whole organization of the plant places it in the front ranks of the safety movement. A thorough investigation of this electrocution brought forth the fact that it was caused by a faulty electrical connection. The first deduction would be that the plant electrician, who, incidentally, is a hearty worker on the safety committee, was responsible, but, if this conclusion is reached, why should not the plant executive take his share of the blame, or, going higher, why should not the head of the operating department, or even the president be implicated? To place the responsibility on any of those individuals would be wrong, because the motor received regular inspection, and the short circuit, which was the cause, evidently happened shortly after the motor was inspected, without giving any sign of happening at that time, and it could have happened the first time the machine was started up after it was inspected. It would, therefore, be most unfair to place the responsibility of that accident on the shoulders of any one individual.

In Numerous Cases Responsibility Difficult to Place

Another fatality which a cement company recently experienced, happened to a young foreigner while stripping in the quarry. He was excavating in a pocket. A large stone suddenly slipped out of the bank. Close inspection failed to disclose the possibility of this stone moving. It fell against the man's leg, breaking it above the knee. He was removed to the hospital and the bone was set and the leg placed in a plaster cast. Examination several days later showed that the set was broken. An operation was performed, but the man died from strombosis or blood clot. Perhaps the quarry foreman should be blamed for this accident in that he did not detect the loose stone at the location where the man was injured. We all know that careful inspection does not always disclose defects, and the company feels that this man is not to be blamed for the original accident. Being a muscular fellow, the doctor claimed, was the cause of the original set being broken, and they had every reason to believe he would survive the operation. Strombosis is apt to happen to anyone undergoing an operation however slight, where blood vessels and arteries are cut. On just whose shoulders the responsibility for this fatality should rest is a difficult problem to solve, but the doctor came in for censure, perhaps unfairly.

Numerous cases where it is difficult to place the responsibility even after a most thorough and careful examination, could be cited.

There is another type of accident which occurs frequently in cement plants, which is to be most heartily condemned, that is, accidents caused through "horse-play." The responsibility can invariably be placed on one or several men, and those men should first be given a fair chance to stop the practice, and if they do not heed the warning, dismissal is called for.

One reads and hears of so many horrible results such as those of ruptured intestines through the application of compressed air, or, electrification of the drinking cup, which caused the death of an employee who had a weak heart, and, while meant as a joke, such practice can be called nothing but horse-play and should not be tolerated. This is one of the few cases where accident responsibility is easily placed, and the person condemned should not be given much consideration.

I had occasion to discuss safety with an officer of one of the cement com-

panies some time ago, and remember distinctly his making the remark that he had not been pushing safety work as he should in that year, and the record of his company was much worse than in previous years. This I took as an indication of his thoughts on the matter and have watched the record of that company from that time on, and the results obtained by it have been truly remarkable. In fact, it is now near the head of the list in the length of time during which no accidents have occurred at their various plants, where before this record gave anything but a good impression.

If all executives have safety work at heart it would do worlds of good in reducing the number of accidents in their plants, for every individual would be proud of the fact that he was doing his little bit to have a good safety record, and one of his reasons for this satisfaction is the knowledge that his superior officer is keeping a close check on the plant's accident record.

On the other hand, there are numerous cases where safety work comes from the heart of every one concerned, from the president to the humblest employee, yet the accident records are deplorable. The records at the various plants where this is a fact will go along unblemished for months at a time, except for an occasional scratched finger or other minor-no-lost-time accident, and then, suddenly be spoiled by a fatal accident.

Unceasing Effort for Safety Is Necessary

I have in mind one plant in particular which would build up a wonderful record; all the members of the safety committee and the organization as a whole were on their toes to make the record 100 per cent for a year at least, when, out of a clear sky a fatality would occur; for instance, an electrocution where a man stepped from the crane girders down to the bucket and touched the trolley cables. Part of the craneway did not have a roof over it and it was raining at the time of the accident. That he neglected to shut off the current on the trolley cables before he went to repair the bucket, was assumed. The man was worked over for hours, but without result.

A year went by with a very good record before another accident occurred. This was the electrocution previously mentioned, where a man was killed when pulling the cable on the electric car puller.

About twelve months later, an employee working in the basement of the silos, in crawling over a screw conveyor which was three feet above the floor, got caught in the screw, tearing his leg out at the hip. The man died shortly thereafter.

Such accidents as these can be enumerated indefinitely, although the general trend is toward reduction. Various methods are tried in an effort to overcome and reduce them to a minimum. Placing the responsibility for such accidents has been gone into in this paper. It is poor practice, however, to close the door after the horse is stolen, and the best way to prevent waste of time, trouble, and perhaps hard feelings due to placing accident responsibility, is to prevent accidents, or, to close the door of the stable before the horse is stolen, and this can only be done through unceasing effort on the part of every one, or, in plain words, constant missionary work.

CHAIRMAN FRAME: Mr. White has given us something to think about when we try to fasten responsibility for accidents and for deaths. I know he will be glad to answer any questions.

A. JONES (Indiana Limestone Co., Bedford, Ind.): In Mr. White's talk he spoke of an accident that occurred through a rock falling out from the face of the ledge and breaking a man's leg. I would like to ask if they ever decided what was the cause of that rock slipping.

MR. WHITE: The formation of the stone at this particular quarry was up and down. This stone slipped out of the side. Why, we don't know. There wasn't any blasting at the time. The quarry is regularly inspected by the foreman and whether there was moisture there that let go all of a sudden we don't know.

E. W. BALDWIN (Solvey Process Co., Detroit): This question arises in my mind: If a man has had ten accidents in a year, shouldn't he be let out a little before that. We let a man out if he has had two, three or four.

CHAIRMAN FRAME: You mean lost time ones?

MR. BALDWIN: Yes.

CHAIRMAN FRAME: That is one way to create safety rules.

W. R. DUNN (Vulcanite): I recall an accident some 15 years ago where the rock was of a vertical formation at the top, that looked as if the rock was about ten feet wide. You couldn't tell what it looked like when you were down at the bottom, 50 feet below. The rock tapered to about one foot at the bottom. Naturally, you would suppose the rock was ten feet wide below the same as it was at the top. Without a warning of any kind it crushed down and toppled over and killed nearly all of the men in the quarry.

P. E. SANDT (Edison): May I ask Mr. White or Mr. Dunn what time of the year, if they recall, when these slides occurred? We have a great many in the spring of the year and it is a case of constant education with our men to keep everyone on their toes in the spring of the year.

MR. WHITE: I believe there is a misunderstanding on that. This pocket proposition, as we have it down in this quarry, is not over six or eight feet. We dig the clay out to expose the limestone. This stone just kicked out and was big enough to fall against the man's leg and break it.

MR. DUNN: In that case I mentioned, the rock was perfectly dry. The accident occurred about midsummer.

CHAIRMAN FRAME: You heard Mr. Curtis report this morning on the splendid accident record which had been obtained by a number of members in the Portland Cement Association so far in 1927. He mentioned the fact that there were 23 plants which so far have a clear record. It has been said many times that one of the most difficult problems after you have gotten a fine record is how to keep it up. That will be a burning question with a lot of our members in the Trophy Club. In this connection I am delighted to introduce at this time Mr. W. H. Weitknecht, superintendent of the Lehigh Portland Cement Co., Mitchell, Ind. Mr. Weitknecht's plant is the one member that has won two trophies. He is going to take up a new angle this afternoon.

How Can a Mill with a Perfect Record Keep It Up?

**W. H. Weitknecht, Superintendent, Lehigh Portland Cement Company,
Mitchell, Ind.**

I feel that I am in the position of that writer on farm topics in a leading farm paper, who wrote splendid articles on successful farming for some years, only to have his farm mortgage foreclosed sometime afterwards.

How can a mill with a perfect record keep it up? I hope we haven't been foreclosed. I know we haven't, but we haven't quite kept it up. That perhaps calls for an explanation and we are always willing to justify our position on any question or condition.

In 1923, we had what we called a very enviable record, but we were beaten for the trophy by a few fractions of man lost-time per hundred thousand man hours. In 1924, we succeeded by having, I think, just one and a fraction lost-time hours per hundred thousand man hours. In 1925, without any other lost-time accidents, we had a fatality in November chargeable to us, and yet it did

not result from any negligence on the part of any of our employees. It was due to carelessness, rather, on the part of the railroad company. In 1926, I am very glad to say, we were one of the companies that had a perfect record and we won the trophy again. In 1927 we continued the good work until about the middle of July when, after the whistle had blown, one of our men leaving his work to go to the clock house to register out was bumped by another employee in his Ford; he fell on the concrete pavement, giving his left knee a twist to such an extent that he was unable to report the following day. He reported for work the following Monday, this having happened on Thursday night. So we have two days' time lost on our record.

Perhaps that in a way—the type of accidents and how they happened—is a justification for my being here, since we have not had any serious accident in the industry arising from the employment itself.

We believe that the knowledge of any subject is the true basis for success in that line, and we have come to know that personal injury accidents can be prevented. After what you men have heard today you dare no longer rest on a belief that it can't be done. For if 23 cement plants (cement being an industry known to be hazardous) can operate for seven or eight or nine months, employing many thousands of men, without a single lost-time accident, you know that plants can be run without personal injury accidents.

Responsibility is Preventive and Corrective

That brings to you the matter of responsibility, which is twofold—preventive and corrective. The preventive side, of course, is involved. Who can say that the employment offered to the employee was in accordance with his capacity? The employer knows more about that employment than the employee possibly can know. Instruction is required before that employee goes to work. Was that instruction competent? Did it cover the nature of the work and the performance of it sufficiently? That is a responsibility for the management, more so than of the employee, through its foreman. So that the responsibility of the management as a result of the accident to the workman extends far more than to safe places. It involves, also, to a large extent, safe practices. Have you had foremen in whose departments accidents happened because the men practiced what the foremen had practiced, what they had seen him do? Isn't that a responsibility?

The other is corrective. It deals with placing the responsibility after the accident has occurred, and that is perhaps more specific and more personal. Who is responsible for it? A responsibility, to have any effect or force, must be personal, it cannot be impersonal. That is the duty of the investigating committee which we have in our program of safety work. But you say, if you have had so few accidents, what investigation of accidents does the safety committee or the accident investigating committee engage in? The answer is it engages in preventive investigation. There are many near accidents that almost result in personal injury. There are bad practices that should be discovered, and will be discovered if you have a good safety committee and a good organization; and it is just as much their duty to investigate the possible cause of any accident before it happens and place the responsibility, as it is to have the accident happen first and then fix the personal responsibility. For it follows that if you have in your industry a number of minor accidents, not lost-time accidents, but near accidents that might have resulted seriously, you are going to have personal injury accidents that will be serious.

Now, we have come to the point where our accident investigation work deals almost wholly with those near accidents and those bad practices, as a preventive measure. We try to discover the bad practice, we try to discover the responsibility for a near accident, and place it before the accident has happened. And you will find, I think, that that will be one of the keynotes of maintaining continued interest on the part of your safety committee in the way of accident prevention.

Before the Portland Cement Association awarded those splendid trophies for the best record, our company, because of the number of mills they had, began those contests at the different plants, instituting a no-accident-month campaign; and it unified the work of the safety organization of the several plants of the Lehigh Portland Cement Company and put every safety committee, every employee, every foreman on his toes. They wanted to win the safety flag. After they won that they wanted to win the cup. It was the incentive of competition that started them. We now have so many cups and so many flags that we can decorate our entire plant with them. But every cup that we get and every flag that is sent out to the mills seems to be more appreciated by the men than the first one. They know, first of all, that accidents can be prevented. They know they are standing on a record of which they not only feel proud, but one they must defend.

We are never satisfied, we always want more. Capitalize that spirit in your organization. We want to win the trophy in 1927 and we want to win it twice in succession. Those of us who attended these meetings were told by our safety committee if we wanted to win the association trophy in 1926 that we must have a perfect record, because the progress made in the reduction of lost-time accidents is such that hereafter no mill will win the trophy unless it wins it on a perfect record.

Men Must Acquire Safe Practice Habits

In 1927 we said the same thing, and much as it has hurt to lose those two days it has served to do one thing: it has served to make the men more circumspect in the real sense of the term. They look around; they are no longer content with taking care of their own safety, but are looking around for the safety of others. That is the very thing I have been trying to impress upon our safety committee. They cannot possibly be safety committeemen and serve in the plant only. They cannot be safety men at mass meetings and not be safe men on the job. It is a matter of habit. They must develop safe practice habits. There again, if I may digress a moment, if you instruct your men and supervise their work in safe practice habits, you will prevent accidents; and that is the chief reason why plants will get along with relatively few personal injury accidents. If they cannot minimize their accidents because of the natural deficiency and delinquency of some workmen, the unlucky fellow, as we say, let him go. Be fair to the others. Transfer him from that department to another where the work is less hazardous, but if he is a fellow who stumbles over his own feet give him a few nice talks and say, "John, if this thing happens again we will let you go; you must look for employment elsewhere."

And after several transfers from hazardous to less hazardous and still less men. The wife of one of the men came to me begging for the re-employment of hazardous occupations, he still has near accidents, we let him go. We recognize a responsibility not only to that man, but we recognize a responsibility to his fellow the man. I said, "Has it ever occurred to you what a serious thing it would be for your husband to become crippled while in our employ? You are thinking only of the immediate future. He is not safe to work in the line of employment in which he wants to work. He doesn't want to be a common laborer. He is a better grade workman, as far as mechanical ability is concerned; but we cannot continue him."

We are careful not to humiliate him by letting the rest of the employees know why he was let out. Speak to him and let him quit. It is labor's respectful resignation, just as you, an executive, do not expect to be bodily discharged in being given your walking papers, but you are politely asked to resign.

What about this spirit that pervades among the men of the plant or the safety organization? They call attention to things, they want that thing prevented. They don't want the man to get fired. It isn't a question of winning the trophy, it is a question primarily of realizing our responsibility to that man and to his fellowmen.

and on the other hand keep up the proper spirit of the organization; because it is in that spirit you maintain your accident prevention work and keep the work together.

Bulletins are important. Important also are accident investigations as a preventive measure, the discovery of bad practices, plant inspections for every purpose, instruction for their correction. This further in the matter of responsibility—and I am stressing that because it is the vital thing to keep up the spirit of the organization—is the fixing of definite responsibility. We have our departments compete against each other in friendly rivalry. Every department is a family and every man in that department is a member of that family, and if any accident, near accident or bad practice is discovered, the whole organization feels its responsibility. If the discovery indicates gross carelessness on the part of some individual, if it indicates a very bad practice, or if it indicates a bad practice that hasn't been eradicated, the foreman, as the head of the family, is taken into account.

That particular near accident—that fool thing—may be discussed and brought to the attention of all of the safety committee, together with some keymen in every department; and how do you think that foreman feels when that thing comes up for discussion? He isn't boo-hoed, he isn't reprimanded by the committee. It is the force of public opinion, and he would rather take a whipping than come to that safety committee meeting.

Personal Responsibility Is the Keynote

Responsibility—continued responsibility, definite responsibility, and personal responsibility—is the keynote not only of accident prevention but of keeping up the spirit. What makes you men do your job from day to day? Why are you there? Why don't you go some place else some day? You'd like to go fishing or hunting, but do you do it? You can't go off unless you have made proper arrangements. Why? Because you have a feeling of responsibility. Why do you do the work the way you are doing it? Partly because of a sense of responsibility.

The same thing applies with individual foreman and with individual employees. You want to bring the matter of responsibility for personal injury accidents right to the individual, group the individuals with a head, which is the foreman, and then continue to call attention to that very fact.

I might mention special safety committee meetings. We have them every once in a while. I think we average two meetings a month, one a regular meeting and one, possibly, a special meeting. The reason for calling special meetings throughout the year is to keep up the interest. They know it isn't simply a regular meeting. We try to keep the regular meetings interesting by discussing the significant accidents that are reported every month by the Cement Association. We try to keep up the interest by discussing such accidents as we have had in the organization. Incidents which come to our attention are noted and sent out to the various organizations for the continued interest, and to call specific attention to cases of personal injury accidents such as might happen with us. It puts us on the alert; and perhaps last, yet not least, are such meetings as this one today. We have three of our foremen here at this meeting. We are fortunate by reason of having had the best record for several years among the Lehigh organizations, and therefore have had the privilege of having two or three men sent to every Safety Congress by the Portland Cement Association. When the National Safety Council held their meeting in Louisville a few years ago we had the good fortune to send three men there.

So meetings of this kind are very important. That is why I am glad to see the Cement Association take up the program of regional meetings and sectional meetings. The men get together, as we do here, workmen, not merely executives or general managers or safety engineers, but workmen who have served on the safety committees, and prospective candidates for safety committees; and what is the result? They come back with the proper spirit, which it is the responsibility of the manage-

ment to inculcate in them before they leave. They come back to their safety committees and report to them, and sometimes they don't get through in the first meeting. We continue to have a report at the next meeting, or we call a special meeting, and in that way we continue to keep the matter of accident prevention alive.

But as I said in the beginning, the keynote of the whole thing is the fact that the men know that it can be done, and they would be ashamed today if our accident record got bad. They keep up the spirit and I, for one, believe that we have our employees at Mitchell thoroughly sold just that way.

CHAIRMAN FRAME: Mr. Weitknecht has given us a sound, sensible, well organized and conscientious method by which he controls accidents in his plant, which radiates from himself as a superintendent and, as you have gathered from his remarks, extends through every one of his foremen down to the very men themselves, who have begun to appreciate that an accident record means something to every plant. He has brought to the surface many interesting thoughts on accident prevention. Some of you, I know, have questions to ask Mr. Weitknecht.

V. ROBERTSON (Canada): I would like to ask the speaker, after they have had an accident, which, of course, is investigated, is that investigation made by the executives or by the safety committee?

Special Committees Often Appointed

MR. WEITKNECHT: It is made by a subcommittee of the safety committee, which is an investigating committee usually appointed for the occasion. We appoint a special committee for every particular occasion; it tends to distribute the work and it gets more people interested. Those people who investigate accidents are better safety men because they have served.

MR. ROBERTSON: Are the findings of that investigation made public or are they confidential?

MR. WEITKNECHT: The findings usually are made public. We have had but few, but I cannot recall an accident where the cause was not evident. The reason for the investigating committee is more to ascertain just exactly in what practice this accident had its origin. If there is any mystery attached to it, it is fully explained. Usually the matter is gone into in detail at the next meeting of the safety committee, and sometimes we have a special meeting just for that purpose. I might add this: prior to the June no-accident campaign we had mass meetings and we had departmental meetings where we got a large number of men together in our shop. These men were addressed by the foremen. The men in the quarries, which are about two miles away, were called together and we had special meetings. So we may call a special meeting at any time when some particular near accident has happened. When I say near accident, I mean some occurrence which almost resulted in an accident. We make it a point to bring it to the attention of the safety committee and they to the department committees, and that is the duty of the accident investigating committee.

CHAIRMAN FRAME: I want to emphasize that a little bit stronger if I may—Mr. Weitknecht is right after the near accident. They have gotten to the point where they have few lost-time accidents. He is transferring his activities into looking into every near accident and thus he maintains a clean slate.

MR. HEALY (T. H. Martin Co., St. Louis): Do you have any difficulty in getting the men to adopt respirators where necessary?

MR. WEITKNECHT: Yes. However, we have few places where they are necessary. We have one place in a certain part of our packing house; but we have found that there is a risk involved in their use. We haven't found a single case where inhaling of cement dust such as exists in our plant has injured anyone. I think that is a matter of record for the Portland Cement Association.

CHAIRMAN FRAME: In that connection I wish to announce to anyone who is interested in respirators, the New York State Department of Labor has recently issued a pamphlet in which it is discussed from every angle. After reading that it is my personal opinion that its practical use is limited in the cement industry. You can get that pamphlet from the Department of Labor, Albany, New York.

DR. E. M. PARTLETT (Pittsburgh): I was glad to hear you say what you just said about limestone dust, because it is so. I have interested myself in that for some years. I have some data that limestone dust is free of silicate and is harmless.

QUESTION: Do you make these men who are involved in accidents appear before the safety committee?

MR. WEITKNECHT: We have not had any serious accidents. A man was injured and lost two days' time and he was before the safety committee largely as an example to the others. We don't want these men to feel that they cannot appear before the safety committee. We want them to feel somewhat like the real honest-to-goodness boy who, while he may get into mischief, will tell the truth, but he hates like anything to face his dad.

When Responsibility Is Definitely Placed

A. C. HEWITT (American Limestone Co., Bellefonte, Pa.): There are two questions I would like to ask, one from Mr. Weitknecht, and another of more general interest. When you investigate the cause of accidents and find that the responsibility can be definitely placed on a particular individual, how do you handle that case? You say that you make public the findings. Do you make public the responsibility and cause shame on the fellow who caused the accident?

MR. WEITKNECHT: All accidents that require any investigation are like gossip in our plant. You can't keep it secret and we don't want to. It is reported and then investigated by the committee. If it is of a very serious nature we call a special meeting of the safety committee. If not, it goes over into the next meeting. The findings go to every department and become public. We even issue in particular cases notices on the bulletin board. We have had so few to issue that the practice has almost been discontinued. But that is exactly what we do if we find some fool stunt practiced.

MR. HEWITT: I would like to have some idea of how many cement plants—not companies but individual plants—have a full-time safety man who does nothing else except safety work?

CHAIRMAN FRAME: I think there are very few of them. That is my personal opinion, however, and I may be wrong. I will ask those plants represented that have a full-time safety man in their plants to please stand up.

(Twelve men arose.)

CHAIRMAN FRAME: That is better than I expected.

R. E. HOFFMAN (Atlas): The gentleman beat me to the question I intended to ask. I have heard four talks today and I haven't heard the mention of a safety supervisor except just now. I would like to know from some of the plants that have safety supervisors what part they play in their success?

G. C. HUTH (Universal): I am a safety supervisor but I don't care to talk about myself. However, I can tell you about my job. My job as supervisor of safety is a combination job. I supervise the safety men of the mill. The biggest job that any safety man has, I believe, is getting the job out of the office and putting it out to the fellows who are actually doing the work. The safety supervisor organizes and helps them along. I think ultimately the fellow on the job should carry all the work. That is the way I have been trying to work it out.

A. J. EALES (Bessemer): I don't know just how to explain this, with regard to my own personal job. I don't handle the employment of the men at all. That is done by the foremen individually. I spend most of my time around the plant, not in the quarry. But with regard to putting the safety thing over, I think the foreman is your

best man for that. The men will take more from your foreman than they will from your safety man. Your safety man can handle the foreman, but the ultimate success rests with the foreman.

CHAIRMAN FRAME: Since we have gotten into the engineering phase of this important subject I notice we have with us today an engineer associated with one of the largest cement manufacturing concerns in the United States. I see Mr. Carlson sitting there and I wonder if he won't add just a few words to the importance of engineering in regard to the prevention of accidents.

A. G. CARLSON (Universal): I am not going to attempt to tell you how to prevent accidents, but I will say something about how we prepare equipment to help prevent accidents. The Universal Company has spent thousands of dollars for safety equipment. In recent installations this safety equipment is considered part of the job and the cost of same is swallowed up in the construction work. Every job, before it leaves the office, is inspected to see that all dangerous places are properly guarded. Previously, safety features were things the companies delayed putting on until forced to do so, and this cost them more money than if they had been installed at first. I think it is safe to say, since we have installed safety devices, there have been considerably less accidents. Before we had all the safety equipment, we had considerable accidents which cost the company more money than the installation of the safety equipment.

A Month to Investigate Plant Conditions

D. ADAM (Lawrence): Our friend, Mr. Hoffman, I think, asked a question which has remained unanswered. I happen to be a safety engineer. In 1924 I took over the duties of the safety engineer in our company. I faced 1,276 lost days, some permanent disabilities and two deaths. I was told to go to it, which I did. Today we have 110 lost days and 11 lost-time accidents.

When I first started in the safety work I took a month to go around the plant with my eyes open, my ears open, and my mouth closed. In that month I learned a lot. In three months' time I realized that guards and bulletins were good, but they didn't mean everything. I realized the only way to get the men interested in the safety movement was to tell them the reason why.

Our results merit what I tried to do. I introduced a Thursday afternoon talk which I consider has been the backbone of the safety work in our plant. I get a man from each department for half an hour and sit down as man to man with him, talk from an ordinary, common sense point of view and tell him about the rules and regulations of our organization; why they were made, how they are based, the reason they were made, and the benefits that would accrue from them. In that way we eliminated all our accidents. Previous to that we had one every week.

It doesn't go home unless you have a heart-to-heart talk with the man. We can collect the ideas at this meeting, formulate them and transfer them on to the individual.

In that connection I would like to mention this: Sometimes it is not always possible for a fellow to talk and explain those things to a man. I attended the public speaking class this morning at eight-thirty given by Professor Hardy. As Professor Hardy says, the main point in a talk is to get at the fellow direct, not to shoot over his head. Don't be dogmatic about it and say they must do it. It is not a case of, "you have got to do it." Tell them why they have got to do it.

MR. BLACK (Philadelphia): I wish to say something in regard to the dangers of dust. My company conducted an informal investigation. This investigation involved going over the records of physical examinations of in the neighborhood of 25,000 men exposed to cement and limestone dust and other dusts of that nature. The evidence was definite that their average health was so high that we came to the conclusion their health was above the average of workers alongside of them.

We put those various dusts, including dusts of silicate, granite, and that sort of thing, under microscopes and we found, without exception, that where you find a

sharp dust it is dangerous, but where you find a dull dust it is not dangerous, unless there is poison in the dust itself. That was our conclusion. It would be hard to support it in a general way.

CHAIRMAN FRAME: Thank you very much, Mr. Black; we are glad to know of your findings on this important question.

Is Mr. Jacobsen in the room today? I wonder if he is prepared to tell us something about his observations on the safety engineer?

H. G. JACOBSEN (Bates Valve Bag Co.): It has been my experience, if you want to get my angle on it, that in safety work, if we have 100 plants possibly we have 100 different methods, inasmuch as we have 100 different managers, and they all work more or less differently. They all have different personalities and they attack the problem somewhat differently, although possibly along the same main lines, and generally if they use common sense, they arrive at somewhat the same results.

Mr. John this morning spoke about the difficulty that was met with during the years that we had to do the pioneer work, and I can speak freely on that subject. It was difficult to get the various companies to report their accidents and take hold of them in a real two-fisted manner. I think that period has been passed and I am certainly more than pleased to be here today, because I never have yet seen a meeting quite as well attended as this one, nor have I seen a meeting that has been attended by men of such caliber as I see here today.

Safety Suggestions Come From Everybody

CHAIRMAN FRAME: I am sure we all have a very fond recollection of our pleasant association during the years Mr. Jacobsen was in charge of accident prevention work for the Portland Cement Association, and we all know what strenuous efforts he put into the organization of the various plants and the ground work he laid for the success we have recently attained.

J. R. KLINE (Universal): I have similar lines to offer about the general safety work in our plant. We are safety men at the plant all the way down. We take suggestions from anybody in the mill on any subject and give him a reasonable answer. There have been at least 1,800 suggestions made at our plant this year and every one of them has been put on record and sent out to the departments that take care of them. Each department has meetings at least once a month. Every man attends a meeting at least once a month. I talk to them at the meetings, tell them anything and everything. I give them reasonable answers to their inquiries about plant operations, safety work, or the general topics of the community.

CHAIRMAN FRAME: Don't lose sight of the fact, gentlemen, that Mr. Kline's plant is a member of the 1927 safety club.

I would like to ask Mr. Weitknecht about a problem that has been a prominent one in the cement industry almost ever since operation began. I refer to the guarding of screw conveyors. As you men know, we have had a large number of deaths and very serious injuries caused by screw conveyors. The Alpha Company recently had a fatal accident at a location we thought splendidly protected. The screw conveyor is contained in a concrete box some 26 inches high from the floor. The sheet metal covers on the top are securely bolted down. Somehow, it seems, the pressure was so great that it warped or caused the sheet metal covers to raise up and spill out the cement into the tunnels. We had a man working in these tunnels whose duty it was to clean up the spill. There was no witness to the accident but from the best information we could gather, we think that for his own convenience this man unbolted the sheet metal cover from the screw conveyor or laid it to one side, which is contrary to our safety rules. He happened to have some other duties in one of the other tunnels and when he came back he somehow or other got into the trap which he laid for himself.

I know of two other fatal accidents that happened just recently on the screw conveyors. We have made wonderful progress along many other lines, but the

screw conveyor is the troublesome problem. I would like to ask Mr. Weitknecht how they take care of screw conveyors in his plant.

MR. WEITKNECHT: We have screw conveyors in our tunnels, I presume, very much like those existing in other plants. In the last 20 years we had two fatal accidents. We used quite different methods. We had the same condition with the material flooding the conveyor, lifting the lids, shifting them, or even tearing them loose from their moorings. We finally decided that from a mechanical equipment standpoint we would make that particular thing foolproof. We made bar grates and put them over the conveyor and bolted them down in such a way that it would take an employee a long time to unbolt them. These bar grate covers will stand the twisting of conveyor screws before they become loose. They are fastened to anchor lines, anchored to anchor bolts. Wherever we have a possible flooding condition we have those grates bolted down. They are bolted down so hard that the conveyor will tear before the grates give way and there is a strict order that no employee has anything to do with those except the foreman and special repairmen, so if anything goes wrong with those conveyors we know who is responsible. It is the duty of the foreman himself when he knows that work is being done on the conveyors in the tunnel to make a personal inspection, besides having the report of the special repairman for that job.

Experience With the Dangerous Conveyor

MR. KLINE: Do you use a sheet metal cover at any point in addition to the grating bars with the idea of keeping down the dust, too?

MR. WEITKNECHT: We have done that, but in our tunnels we have little dust now. Cement sacks are frequently laid over the grating.

CHAIRMAN FRAME: Has anyone a different method?

MR. HEWITT: I was formerly with Security and about ten years ago they had almost that same identical thing with their conveyors through the stock house. If Mr. Brownell is here perhaps he can tell what is being done there at the present time.

G. W. BROWNELL (North American): I don't believe there is any variation over what Mr. Weitknecht said.

G. E. BARTLETT (Lehigh): All our conveyors in our plants are put in the same way as Mr. Weitknecht spoke of. We have our covers on the top of the grating. They just keep the dirt out and it cuts out all the dust in the plant. We have never had any accident with the conveyor since we adopted that plan.

I want to say in connection with my work as a safety man, I put in all my time in safety work. Mr. Adam spoke about the treatment of the men. My method in treating men harmonizes with his.

CHAIRMAN FRAME: Are there any representatives of the various state departments? If so, we would like to hear from them.

T. J. QUIGLEY (Dept. of Labor, Harrisburg, Pa.): With reference to the accident statistics as compiled by the Department of Labor and Industry for the Commonwealth of Pennsylvania, I am just going to call your attention to the difference between mechanical safeguarding and education. Our statistics prove conclusively that of all the money spent in the Commonwealth of Pennsylvania for safeguarding machinery, only 25 per cent of all accidents are preventable through mechanical means, and 75 per cent of all accidents occurring in industry cannot be prevented through mechanical means of safeguarding. In other words, it is a campaign of education, not only to educate the men but the management. If the management is thoroughly sold on safety, and if the foreman, whom I believe to be the most responsible man in connection with every plant, is a real safety man in connection with every plant, is a real safety man he will not permit certain conditions to exist in his plant, which are responsible for accidents.

In my work of investigating accidents and inspecting quarries there is seldom a case where I investigate a quarry that I don't find conditions which should not exist.

Yet the foreman is passing through that quarry every day and never sees them. Now there is no use passing the buck to the men. The foreman has his duty to perform. In connection with the accident mentioned by Mr. White, I wish to say I investigated that accident. They had removed the surface and the men were working in between the rocks just cleaning out the clay. The stone itself wasn't more than three feet high but it fractured the man's leg. He was taken to the hospital, was operated on and died. There was no way that man could have told that the stone was loose because the place where he was working was not over seven inches wide and he was just removing the clay from in between the rocks. The accident could not have been prevented.

One of the methods we are now practicing for the prevention of accidents is holding meetings right where the men work. In many instances I succeed in getting the plant management on pay-day to shut down twenty minutes before regular quitting time and during that time I address the men on accident prevention. In many other cases they shut the mill down twenty minutes before lunch time and then I talk to the men.

It is my opinion that a talk to the men right in the industry, talking to them right where they are working, pointing out to them how accidents are occurring and showing how they can be prevented, is the greatest means of preventing accidents that I know of. You have got to talk to them in their own language. You want to talk to them in the language they understand.

Further Activities in Pennsylvania

J. S. ARNOLD (Director, Bureau of Inspection, Harrisburg, Pa.): I would like to add another word in connection with what Pennsylvania is undertaking to do now with special reference to mines other than coal mines, pits, and quarries. Mr. Quigley who just spoke to you has been made chief of our quarry section. He will have a force of instructors under him who will be men trained to know the work as nearly as possible. They will be men who have had previous experience along those lines and what experience they have lacked will be supplied before they go out into the industry. The advantage of that is that a man with special training is far better prepared to talk about safety in your particular industry than a man who has not had that special training.

DR. D. E. M. PARTLETT (Pittsburgh): In that particular connection, I want to tell you gentlemen of the Department of Labor and Industry in Pennsylvania, that we have gone over a certain number of your rules and regulations at each safety meeting in order to become better acquainted with the rules and regulations throughout the state, and I think that is an excellent thing to do.

CHAIRMAN FRAME: I would like to call on Mr. Jack Dempster to give us a few words.

J. A. G. DEMPSTER (Canada): We are trying to run an accident prevention campaign by just an appeal instead of by legislation, if you see what I mean. We try to show to the man that, being a human being, he is the one who will suffer the most in the long run. As soon as we came to the point where we realized that they were all human beings, our records began to pick up.

Back in 1920 and 1921 the company from which I come had practically the worst accident record in the whole of the Portland Cement Association, but in 1925 we won the Portland Cement trophy for a perfect year. We went 521 days without a lost-time accident. Today, were you to visit our plant, outside of the few posters that you will see displayed, outside of the guards that you will see up, you wouldn't know that an active safety campaign was being waged all the time. But it would take you a week, probably a month, before you found out that our plant and our company are as one big family, simply because every individual man has been taught that he must be a safe worker.

We use no methods that are different from anyone else's. Management has its own responsibilities, it is true, but we are proud that we have a loyal body of safe workmen, men who know that, outside of the loyalty to their plant, an accident means something to them. We have also tried as much as possible to do away with the word "accident". In looking through the dictionary you will find that "accident" is something for which no provision can be made, it is something that happens unforeseen, something that is wished on you. We claim that an injury is not really an accident, because it is something that can't happen. We always have shown the men where the accidents have been caused, and as soon as they understood the policy the management assumed with regard to them our accidents stopped.

Among Effective Methods Is the Plant Publication

One method we use is the plant publication. We never know whether that does any good or not. It is a humble, mimeographed thing. It is not put out as the official voice of the company. It is not an attempt to high-hat or patronize the men; it is just a medium of conveying orders or wishes or commendations from the office, from the man higher up to the man lower down; and by attempting to place all on the level in that little publication we may have accomplished something.

Which of our methods has brought about the greatest results, we probably will never know. Today we are proud to stand in rank with some of the highest in the land, United States or Canada, as a plant and a company that is second to none in accident prevention.

CHAIRMAN FRAME: Has anyone else anything to add to the meeting.

A. JONES (Indiana Limestone Co., Bedford, Ind.): I don't feel like leaving this meeting without giving you another angle of this safety work. I am with quite a large organization. We employ in the limestone industry some 5,000 men. We are closely situated to Mitchell and I just want you to know the influence of the Mitchell plant on the community it is connected with. The Mitchell plant has been doing a lot of safety work in the schools in Mitchell and I have found out that they have spread that work to Bedford, Indiana. It has come into our territory and is tying up with our safety work. It had gotten so that we became ashamed of ourselves and we attended some of their meetings at Mitchell, and it has been my pleasure to become acquainted with Mr. Weitknecht and his assistant there. Whenever they make a good record we are proud of it, because they are now helping us to organize a safety-first campaign. However, it has been through the instrumentality of the Mitchell plant that we started this work, so I want to throw a bouquet right now to the Mitchell plant while I have an opportunity.

CHAIRMAN FRAME: I don't think Mr. Weitknecht knew what was coming when he tried to beat out Mr. Jones to the floor.

MR. WEITKNECHT: No, otherwise I would have insisted on my rights and addressed the Chair first.

In connection with general accident prevention, I want to give you this by way of illustration: Some years ago I was called into a meeting that had to do with the solving of a problem, and one of the men who was there said, "Now, let's put the thing over, let's all get very enthusiastic and put the thing over." Another man said, "That is all right as far as it goes, but is it a problem that requires enthusiasm alone? We know it has to be done, we know we can do it; what we want is resolution."

I said at the beginning of my talk we have settled the matter in our own minds, not by what we have done, but you men certainly should have had it settled in your own minds by what the cement plants have done so far this year. You know the thing can be done. It isn't enthusiasm you want. Of course, you want to be proud of it, you want to be glad of it because it gives you stimulus, but what you want to do now is to go home and carry this resolution with you. Get the determination and

enthusiasm from your workers. You who are responsible for the work must become resolute and not merely enthusiastic, because you have many difficult problems and enthusiasm will soon be robbed if it has too many variations.

CHAIRMAN FRAME: I will now turn the Chair over to Major Reninger, who will conduct the discussion on School and Community Safety for those of you who are interested in that particular phase of safety work.

CHAIRMAN RENINGER: I have asked Miss Telford to address us on this subject. She is Field Secretary for the Education Division of the National Safety Council. Miss Telford has had over three years of experience in traveling over the United States, making a study of safety in the schools in cities like St. Louis, Chicago, Cleveland and Detroit; and it is through her efforts and the efforts of her colleagues, Miss Stevenson and Miss Smith, that we really have the education magazine as it is today. It is through their visiting the schools that they have been able to collect the data and give it to us in the form that the teacher can use.

Address

**Miss M. Laverne Telford, Field Secretary, Education Division,
National Safety Council**

May I first of all, before I say anything about the program that I want to present to you, define safety education? Forgetting for the moment pedagogy, forgetting technical phraseology, forgetting the important philosophy associated with the safety movement, may I say that safety education as I see it is teaching children to become conscious of the hazards which surround them, teaching them how to avoid those hazards, and in teaching them, making them anxious to do so? I am thinking of a positive rather than a negative program. We are not saying, "Don't go skating on thin ice," but we are saying to them, "What is the danger of skating on thin ice?"

It seems to me the first thing to bear in mind in a school program is that it must be positive, secondly, it must meet the needs of the group for which it is designed. If you lived in the Iron Range in Minnesota, for example, and your children went to school there, one of the things you would feel should take a major place in safety education would be the danger of percussion caps. Percussion cap accidents are all too common in the Iron Range.

So those are my first two points. Thirdly, it seems to me we have a right to present to the school people, regardless of the school's size, a safety education program. This, I think, is important, because there is a tendency on the part of people in smaller towns to say, "Safety education is extremely essential in Chicago, but we don't need it in this town." Then next I want to present the thought that safety education has a place in our schools regardless of the type of school, regardless of the size of the community in which that school is located.

What we have been trying to do along these lines, with the assistance of the school, with the assistance of the public-spirited citizens, is to develop a correlated safety program to meet present-day conditions, to be designed along the lines that school people insist present-day school programs must be designed. You will find people talking about habits, safety attitudes, and safety skill. We want a correlated program because the school program now is full, there are a great many things to teach children in the comparatively short time they spend in school. So we say to the school people, "We are not talking about an addition of a new subject to the curriculum; we aren't asking for thirty minutes from nine to nine-thirty o'clock on Friday morning; we are talking about injecting safety material into your existing subjects. Talk it in the language class, write about it in the penmanship class."

My illustration on that particular point is a personal one. When I went to elementary school I took the Palmer Method of penmanship. I don't know how many times I was at my desk writing over and over again the phrase, "This is a specimen

of my penmanship." The phrase, "This is a specimen of my best penmanship," isn't particularly important in my everyday life.

We went to the school people and said, "If that is the way you are going to teach penmanship, why don't you give children something to write that will mean something to them?" We talk about safety projects and problems in connection with arithmetic, history and geography, and in the other subjects of the curriculum. It is true that the majority of school safety work to date has been done in the elementary schools, but it is spreading to the junior and senior high schools.

Because it is a correlated program I am discussing today, because it must vary in each community, I can't bring it to you in a brief way and say, "Here is the safety education, won't you take it back to your own community and see if you can't get it across in your schools?" We can't do that; we can't give you examples of safety education, asking you to take them back to your school people and say to them, "Here is something they are developing in Worcester, Mass.; it seems to fill the need there, why can't we do something like it in our community?"

The thing I want to ask of you specifically is that all of you take home with you that little leaflet published by the Education Division of the National Safety Council, so that you will have listed and described in just a sentence or two the school material that is now available. Will you take back with you to your superintendent this little leaflet on safety teaching in the modern schools? And then will you also take a copy of *Safety Education*, a monthly publication of the Education Division of the National Safety Council, a magazine that is designed for the use of teachers and students? And will you go over this material yourself and present it to the school people in your community and say, "This seems to me to represent the type of work that is being done in our progressive schools; hasn't it a place in our own schools?"

Safety Also Taught Through Student Activities

You can't go into a school and teach safety education. I can't come into your plant and make your men safe. But you can call to the attention of your school people the fact that the subject of safety education is important enough in the school field to have become a subject of discussion at the meeting of the Society on the Study of Education.

I have talked up to this time only of safety education in the curriculum. Safety is also taught through student activities, through local safety councils and through payrolls. That may have a place also in your community. The purpose of a junior safety council is to group the children into a small organization, giving them something to do, like being in charge of the passing of the classes in the corridors. They may have charge of the condition of the playground, or the inspection of the playground equipment. At dismissal time they may see that the children, particularly the younger children, are escorted safely across adjoining streets and highways.

There are two very definite methods of presenting safety to your school people—one, safety through class instruction in the class room, and the other, safety through child activities.

I wonder if you are thinking what relation all of this has to your work? If some of you are thinking of asking that question, I will answer it by telling you this: About two years ago I went across the Iron Range in Minnesota. Shortly after I reached Hibben, a student in one of the Hibben schools had come to school with a percussion cap in his pocket. He then took it out and held it between his thumb and his fingers. Mind you, he was in school. He tapped it with his pencil, and when the excitement was over they found his thumb, his first finger and part of the second had been blown away entirely. Immediately the authorities went to every school in Hibben, to all of the other schools along the Iron Range and put up notices relative to the danger of children handling percussion caps.

Don't you suppose the safety engineer in the mining range then talked to his men about the careless handling of percussion caps, and don't you suppose some of those

men went home and talked to their families about it? There was a very effective tie-up between the subject that had been presented to those children by that accident and the man's memory of the instructions which he had received from his safety engineer.

I believe the teaching of safety must begin in the kindergarten. It must begin even before that, if possible.

The Education Division of the National Safety Council not only has certain school publications, but they have a magazine, a junior Safety Council handbook, they have a manual for teachers, various leaflets such as Safety Supervisors' programs. Safety in Women's Sports, and so forth. We are glad to offer wherever it is possible a limited amount of field service, have someone come in and talk to your school people and make an attempt to present it to them from the school person's point of view. We are glad to be of assistance by correspondence wherever it is possible.

I appreciate the opportunity of talking to you, primarily for the reason that from our small office in New York City we can't look out across the map of the United States and effectively pick out interested locations; so if you can help us find out where the interested localities are you will have rendered us a service, as well as perhaps starting a worth while thing in your own community.

The Problem in a Moderate Sized Town

R. B. FORTUIN (Penn-Dixie): We have a problem in the town of Nazareth, which has a population of 5,000 people. There are six cement plants, a brick plant, a foundry, three silk mills, and several other industries of a like nature in and around that town. Several years ago membership in the National Safety Council was given to the public schools by several individuals in the town, with this thought in mind: that after one year's membership the school board would probably feel that they were deriving sufficient benefit out of their membership, to carry it on in the future. The membership expired this past year. Major Reninger got in touch with me and asked me to look into this thing. I went to see the superintendent of schools. He said to me, "I don't want anything to do with it; what do we get out of it? We get a magazine, put that magazine in the library and nobody looks at it."

Now here's a situation where the superintendent is antagonistic to the situation from the start. He never supported it when it was a contributory membership. Now a few of us have gotten together and started proceedings for the future. We have gone to the burgess of the town. He has heartily endorsed the program we have in mind. We have gone to several members of the school board and they have assured us of backing, and we have gone to a number of leading men in industries in town and they have assured us of support. What we intend to do is to go before the Parent Teachers Association and present this idea somewhat as was outlined, and in that way force the school board to bring this membership back into the town.

CHAIRMAN RENINGER: Just as soon as you are ready to have a meeting with those people I feel that we can count on Miss Telford coming up to assist you in explaining the situation to the Parent Teachers Association and the superintendent. I feel sure that she will be glad to do that because we are trying to outline a program to have her come and check up on the Allentown and Easton schools, and I know she will be only too glad to help you out there.

MISS TELFORD: I have a postscript I would like to add. May I make this generalization, on general pitfalls that I think all of us fall into? I don't know your specific situation but you made me think of this general situation, that in all schools, particularly in small schools given over to one type of industry or two or three industries, there is a fear on the part of the school people that the safety education is a camouflage cement safety program that we are calling it safety education and putting into these schools our own courses. I see no way to meet the objection of

school people on that score, other than to present it to them from another angle entirely.

If I should be talking to the teachers in your school I should say, "We all agree that the function of our schools is to teach people how to live." That is the very thing we want to do, teach them how to live. But, specifically, what does that mean? Can you teach people how to live in this age, for instance, without talking about automobile dangers and other dangers? Tell them that a certain part of the program of the National Society for the Study of Education was devoted to safety education. It was on the program of the Department of Superintendence, which I pointed out was the largest professional educational meeting in this country.

Starting the Program in a Unique Way

MR. FORTUIN: We have started our program in a unique way. Last June, I believe, was the first time we tried it. We have something like 55 foremen living in the town of Nazareth. In order to bring this safety idea into the homes of this group we had the NATIONAL SAFETY NEWS sent to the homes of each and every one of these foremen and other members of the Safety Council in the plant. Now it was brought out earlier in the day that there are a great many men who do not speak English very well or do not read it as well as they speak it. The children of these men naturally read the articles out of the magazines to the parents.

After an investigation we found that the NATIONAL SAFETY NEWS was the only reading matter outside of the *Bethlehem Daily-Globe* that went into a great many of the homes. We feel that within a couple of months we have accomplished a great deal in a small circle of 55 families. We have quite a number of men come back to us after receiving this copy of the NATIONAL SAFETY NEWS and tell us how much the family enjoyed the various articles in the magazine, and it brought out this: they asked us just how some of these articles pertain to their particular jobs in the plant.

MISS TELFORD: *Safety Education* can be purchased now in single subscriptions as well as in the school membership. Do you suppose that some of your families, the children of the families could find something interesting in that sort of thing? A poster which is a part of each issue of the magazine. I am just suggesting that you add *Safety Education* as well to your NATIONAL SAFETY NEWS.

A. J. EALES (Bessemer): You mentioned something about having difficulty in your school board in support of this safety campaign. I don't see why you should have that difficulty. We have a community of not quite 4,000. We have our schools fairly well sold on safety to the extent that we have two schools, the elementary grade building and the junior and senior high schools. We have a bulletin that we send to the schools. It is changed at least once a week. Not only that, but I get into the schools for talks at least twelve times a year.

Last year the railroads had a school campaign. The agents at both depots asked me if I would give a talk. It happened that they came a month apart and we got in on that. In cooperation with the other plants in our community we have a joint safety meeting semi-annually, with a good entertainment along with it. We had so many children attending this meeting that we decided to hold a meeting for the children in the school during the day. They were let off an hour earlier in the afternoon for this event.

In the high school in our community instead of having a daily chapel program once a week, they enlist speakers to talk to them. Quite often I get in as a speaker on an occasion like that.

Then there are things in the community that the schools are interested in and you might help them out. We had a danger sign in front of our grade school building. They wanted a stop sign on the street there. I happened to be the burgess of the community and that helps some. We got them the stop sign; and incidentally we can get more out of the school board by cooperating in that way.

CHAIRMAN RENINGER: I have asked Major R. C. Haven to come and give us a short talk on what we can do in community work in addition to the school work. After he has given us that talk, it seems to me, if it is the opinion of this gathering, that we organize a committee of half a dozen or more to work out a program of what we can do in the small community where we have other industries besides the cement industry, to put across a community program. If you people think that is a good idea we can carry it out. We could work out a program, nothing elaborate, so that we could get this problem of safety in the schools, which means home safety and public safety. Major Haven will give us five minutes on what we might do in the small community.

R. C. HAVEN (National Safety Council): I don't know why the Major asked me to tell you men and women what you can do in the community, when you have more experience than I can give you in small community work. You fellows are really doing the job. That isn't applesauce, but it is absolute fact, and there are men sitting here who haven't spoken who have done wonders in their towns, both large and small. I don't believe there's another section that has thought out this idea or grasped this idea of going out into the community. There are a lot of things I can say, but if I am going to talk five minutes I have got to get down to brass tacks.

Put the School to Active Safety Use

The school is the common ground where people meet, it is the place to start activities, and it is the place where you work out your political and a lot of other problems. So if you are going to use the schools, use them. I don't know of another place you can use to better advantage. But don't try to teach school safety entirely. I wonder if you men have gotten to the point where you have sort of analyzed the accident situation in your community outside of your own plant. When you go back to your home town, start a little research work, find out where your accidents are occurring and then concentrate. It may be in the homes, it may be through automobiles, it may be through fire, or they may occur in other ways.

Find out about the parents and teachers' home inspection blanks, where you can send a little blank into the home. Perhaps it is your automobile accidents, and really that is the thing that is causing us more concern, as far as industrial safety is concerned, than the industries themselves. What does an accident mean to your factory if a man is killed by an automobile? It affects your labor community just the same as though a couple of sacks of cement fell on him.

Then your fire prevention. You would be surprised how many little fires start in your community that might burn the town down. You will find a lot of these things.

I haven't told you very much that you can do. The Major wanted me to tell you what you can do locally. I would go back, if I were you, get the men together in the plant and sit down and tell those fellows what you have learned here, the contacts you have made; and say, "Let's get together, let's go to the burgess or mayor and tell him the seriousness of the situation." That, of course, would have to come after you have found out just what your situation is. At this meeting a course of action can be decided upon.

It is pretty hard for me to stand up here and work out the details. I would much prefer to leave just one or two thoughts with you. The first is this: Don't go back to your home town feeling, "Well, I attended the Cement Section; I can report to the boss and tell him I was there and have done my duty." Remember that you are the keyman. You are the keymen who have been sent out from your community to bring back to that community something that will help them.

Then there is just one other thought. Did you ever analyze, did you ever stop to think what an accident really means? Suppose you went out here tonight to your hotel room and found there was a telegram for you saying that mother was struck by an automobile today, or perhaps your wife, or perhaps one of your children; have

you any idea what that accident would mean to you? Well, now, that is not an impossible possibility when you think there are between 20,000 and 25,000 people going to be killed this year by automobiles. What if you got that message? Men, just think of what an accident means and I believe that you will go back feeling that you are something more than just an ordinary man in your community.

You don't have to do that. All you need is to go back with a little energy and determination. Find out the accident situation, get the safety men together and the people, and then work out a little plan which the National Safety Council will be glad to help you with.

CHAIRMAN RENINGER: Those of you who have local safety councils naturally are tied up with them. You can have a little safety council of your own in your own community. What do you fellows think we ought to do? Do you want the Cement Section to work out the program with the help of the National Safety Council and the Education Division? Do you think we could furnish you with some information that you could use in your villages and in your towns? I have gotten to that point where I feel that in the cement industry we have gone ahead, we have shown the people throughout the country and we have shown the executives what we can do in the industry. Don't you think it is up to us to broaden out and help our own community?

D. ADAM (Lawrence): I have tried to the best of my ability to interest the local schools in safety. Once I invited the superintendents of the schools and the teachers to an evening show. In the afternoon we invited the school patrol under the supervision of the teachers to attend the theater. It is purely a sales proposition. You try to sell the safety idea to your men at the plant. In the same way you can sell the proposition to the school.

CHAIRMAN RENINGER: Does anyone have any recommendations to make?

A Committee for More Active Safety Cooperation

MR. FORTUIN: I have had this in mind for sometime: I don't know if it is exactly up to the Council itself, but someone has got to take the lead in it and if the Cement Section does, it will demand sufficient recognition to develop it into something bigger later on. Suppose we have a committee or a group to lay out a plan of procedure to extend over a period of time. In other words, to make it sort of a campaign to institute safety in the community. This information or data can be written up and a plan organized for it and that should be sent out to the various cement districts and in the next three months or in the next six months we, in each of our own individual sections, can endeavor to accomplish what is outlined therein.

R. S. HUEY (Universal): I don't know whether the scheme that is being worked in our town would work in most of these towns or not. Our town is probably a little larger than most of these cement communities. However, the activities of the safety work have been sort of taken over by the Chamber of Commerce and they have a program on accident prevention and safety during the winter. They have a meeting every month, with sectional meetings at this general meeting, where they have metal and woodworking, truck drivers schools and so forth, with a general meeting afterwards in which everybody participates. They have a first-class speaker of national importance come and talk to them. They have been instrumental in getting the men in industry and the police department and everybody else working together on this.

They started a campaign, a safe driver's campaign, in which every automobile owner was asked to sign a pledge to drive safely and this year they have cut the accidents down considerably. They had 22 last year. They have cut them down so there have only been six so far this year. They are working together with the school board and I think practically all this work is being done in our schools. In their English classes they have the pupils write "Look to the right and look to the left," and all

such things. In their arithmetic they are given the number of accidents and such things as that. It is brought home to them in the way Miss Telford has mentioned.

If you get some sort of an organization working like that, a committee which will get the interest of the community and get them out with a good program, you will certainly get results.

CHAIRMAN RENINGER: We weren't thinking so much of that; we were thinking of towns like Nazareth, or Mitchell, or some of the smaller towns of 3,000 or 4,000 population. For the big cities the National Safety Council has its organization, but it is to get some simple program for the smaller towns. If you men are interested enough we will go ahead with this and try to work out a simple program for the cities where probably they have one teacher in the schoolroom, or maybe two or three. Let us see if the Cement Section can't be a couple of jumps ahead of the other sections in this work, as it is in accident records. Let's have it to our credit that this plant in this district has started the safety work in its community. That is what I have in mind. If you feel that it is worth while and are willing to go along with it, we can get the Education Division to work out a program with us and we will shoot it to every cement company in the country.

MR. WEITKNECHT: I make a motion that the officers of the Cement Section constitute a committee to confer with the Education Division of the National Safety Council to develop a program and submit it to the cement industries where that program would be applicable.

(The motion was seconded, but to a vote, and carried).

CHAIRMAN RENINGER: I am very glad we had this meeting, I think a great deal will be accomplished.

ADJOURNMENT.

*SIXTEENTH ANNUAL SAFETY CONGRESS
NATIONAL SAFETY COUNCIL*

Cement, Quarry and Mining Joint Luncheon

Wednesday, September 28, 1927

A. J. R. CURTIS, Chairman
Assistant to General Manager, Portland Cement
Association, Chicago, Ill.

The joint luncheon session of the Cement, Quarry and Mining Sections of the National Safety Council was called to order by the chairman, Mr. A. J. R. Curtis, assistant to the general manager, Portland Cement Association, Chicago, Ill.

CHAIRMAN CURTIS: Whether your problem is to find a substitute for gasoline, cure an illness or meet the competition of a foreign competitor, the orderly procedure is the same. First of all you must diagnose the situation, find out what the problem really means; secondly, you must devise ways and means to meet the situation the diagnosis has revealed—you must prescribe a remedy.

This procedure is adopted by anyone, consciously or unconsciously, that elects to accomplish things in an orderly and logical manner.

In safety work many industries have been taking headache medicine—doping themselves with a “cure-all” supposed to be good for what ails them. They have taken the dosage without thought about the fundamentals of the problem and without an adequate diagnosis.

The reason we have made such startling progress in safety work in the cement industry is because we have diagnosed our case and then found remedies for specific illnesses. We have done this by means of a fine system of statistical records and reports. This report system, inaugurated in 1919, shows us what and where the accidents are. The records indicate what season of the year a certain type of accident is likely to occur. They enable us to measure the efficiency of this scheme or that scheme in the promotion of safety in our plants and quarries.

Ethelbert Stewart, United States Commissioner of Labor Statistics, speaking before the Cement Section of the National Safety Congress in Detroit early this year, commented favorably on our statistical system.

“I find that statistics of the Cement Section of the National Safety Council are the very best that come to my office,” Commissioner Stewart said. “You are doing a piece of work that must inevitably result in a rapid decrease in your accident rate. I do not know whether or not you are making effective use of these figures, but they are significant and you certainly should be doing so.

“In the first place you have any industry devoted to the manufacture of one definite product—cement. Your product does not go, as would be true in the chemical industry, into everything from lipsticks to laundry soap. In gathering your statistics

you have something definite to work on and you have succeeded in doing the basic thing, that is, finding the man-hour exposure in your industry and relating your accidents to that. Statistics cannot reduce accidents, but they can tell you where the accidents occur. They can and do tell you where to apply your precautionary measures and where to spend your money. They make it unnecessary to spend money along several lines when most of your accidents are occurring along one or two lines. Comprehensive accident statistics are worthwhile and I congratulate your industry and the many individual manufacturers who are cooperating to make this statistical work so effective.

"I have been able to show others that you have reduced your accidents. Statistics form the basis for a lot of standard jokes like the mother-in-law joke and everyone thinks he can take a whack at a statistician and his statistics; but, nevertheless, if you are going to improve the accident in your plant you must know where the accidents occur and that requires statistics.

"Your statistics have made it possible for me to show others that you have reduced your accidents. I hope to impress you with the importance of continuing and further perfecting your statistical work, not only for yourselves, but for the influence it is going to have on the other sections of the Safety Council on your own and other industries."

We are so well sold on the diagnosis theory because we can take our limited means and get excellent results. We don't have to guess—we can take one direct shot and make it tell. We are able to do this because our records have revealed a specific situation—the case is diagnosed and we can take steps to remedy a definite problem that confronts us.

All mining and quarrying industries can make the same sort of case study. The experience of the cement industry points to the expediency of this method because in our industry we face problems in both of these divisions.

Let me give an example of what statistics have done and will do for us. Our records show a growth in screw conveyor accidents at a certain time of the year. For the past nine years we can trace a growth in lost-time accidents of this type at a certain period.

Instead of spreading our funds to battle all sorts of accidents at this given period we can centralize our efforts to combat screw conveyor accidents when they are again in the ascendency. So we gathered a large number of opinions of experts on how to eliminate conveyor mishaps.

This symposium will be sent to all mills when the time comes. Plans will be made well in advance to meet the situation when it arises.

I believe that a large portion of accident success is based, as I have said before, on the diagnosing of the problem in hand and then prescribing remedies for the specific illness.

Now, we are to be favored with a brief address by a man in a position to be familiar with the inside details of the accident situation. Mr. W. W. Adams is statistician for the United States Bureau of Mines, Washington, D. C., and he has kindly consented to talk to us from the point of view of the Bureau. I take pleasure in introducing to you Mr. Adams.

Safety in the Quarry Industry

W. W. Adams, Statistician, United States Bureau of Mines, Washington, D. C.

Safety in the quarry industry is a matter of direct concern to 92,000 men who are employed in the industry and it is also of almost equally direct concern to their immediate families. Thus between 300 and 400 thousand people are personally affected by the accidents that occur in connection with the

annual production of stone in the United States and in connection with the crushing and other work that immediately follows its extraction from the earth. From 120 to 150 of these men are killed by accidents each year, and 14,000 of them are non-fatally injured.

Through the cooperation of the producing companies, the United States Bureau of Mines conducts an annual canvass of accidents and employment covering the quarrying of stone, and such subsequent work as crushing, rock-dressing, and the manufacture of lime and cement. This work began in 1911 and statistics covering the past 16 years are now available. These statistics are based upon reports furnished voluntarily by the producing companies on blank forms supplied by the Bureau of Mines. Each non-fatal injury reported to the bureau involves disability of the employee for more than the remainder of the day on which the accident occurred. In other words, the Bureau's statistics are limited to what are known as "lost-time" accidents. While many of these injuries cause the employee to lose only one or two days, some of them involve the loss of several weeks or months. Taking them in the aggregate, they average about 15 days per injury. Any company whose temporary injuries average less than 15 days each has a relatively safe plant, or is lucky, or is doing effective safety work. If deaths and permanent disabilities are drawn into the picture and given their customary equivalent weights in lost days, the average accident in the quarry industry represented a loss of 104 man days in 1925 and 94 man days in 1924. In this average each fatality and permanent total disability is considered equivalent to a loss of 6,000 days and each permanent partial disability 800 days, the last-named figure being borrowed from the reports of the Industrial Accident Commission of California until sufficient reports of this class of injuries accumulates in the Bureau's records to develop a new average.

An Intensive Study of Quarry Accidents

In addition to the Bureau's annual canvass of accidents which is based on reports from all producing companies in all states, or as nearly all of them as we can obtain, a special and much more intensive inquiry into quarry accidents has been under way during the past two years. This study is based on full and complete reports—a separate and detailed report for each accident—from a limited number of companies. Each of these companies employs at least 25 men inside the quarry. They are the companies that are participating in the National Safety Competition which is being conducted by the Bureau of Mines. Two such annual contests have been completed, namely, that of 1925 and that of 1926. One of the purposes of the safety contest is to determine which quarry has the smallest loss of time from accidents in proportion to total man hours of exposure. The quarry that establishes the best record receives a bronze trophy or statue known as the Sentinels of Safety, which is the gift of the Explosives Engineer magazine. Credit for providing the trophy and for very material aid in connection with the contest, is due very largely to the enterprise of Mr. N. S. Greensfelder, the editor. The trophy is held for one year by the winning company, and is then surrendered to the winner of the next year's contest. Each year the name of the winning company is engraved on a pedestal of the trophy and each employee of the winning quarry receives an engraved certificate of honor issued by the Bureau of Mines and signed by the director of the Bureau.

The Bureau's annual canvass of quarry accidents affords a broad picture of the accident situation as it affects the whole industry or any large portion or phase thereof; it also furnishes an annual account of the volume of employ-

ment required to produce the country's annual stone supply and of the total loss of life and limb as well as the loss in Man days that went into the cost of producing the stone. The more detailed reports furnished in connection with the National Safety Competition are usually supplied as a carbon copy of the report which the company is required to send to its insurance carrier or to the state compensation commission. In this way the Bureau is furnished with valuable detailed information on accidents with a minimum of inconvenience to the company.

It will thus be seen that the Bureau of Mines statistics of quarry accidents are collected by two methods from a common source, namely, the quarry companies. It will also be observed that the statistics differ in scope, geographically, and in the degree of detail with which the information is supplied. From these two sources of information and similar information from other branches of the mineral industry, it is apparent that quarry accidents occur less frequently and cause a smaller loss of time in proportion to number of employees than do accidents at metal mines or coal mines. In other words, quarry work is not as hazardous as coal mining or metal mining, considering each of the three industries as a whole. Moreover, differences also exist between the hazard of different kinds of quarries. Perhaps the chief distinction in this respect is between quarries that produce dimension stone and those that produce non-dimension stone. Quarries that produce crushed or non-dimension stone have higher accident rates than those that produce dimension stone. For example, the fatality rate for the non-dimension group, in and about the quarry, in 1925, was 33 per cent higher and the injury rate was 7 per cent higher than the corresponding rates at dimension stone quarries; in 1924 the rates were respectively 76 per cent and 18 per cent higher. A comparison covering all years since 1916 shows that, without exception, the group rates for both fatalities and injuries, have been higher at stone quarries producing non-dimension stone, the excess ranging from 5 per cent in 1921 to 118 per cent in 1920 for fatal accidents, and from 1 per cent in 1917 to 122 per cent in 1921 for non-fatal accidents. Moreover, possible differences in length of work day at the two classes of quarries have no material effect upon this relationship. This is shown by figures which have been compiled for quarries working uniform shifts, that is, eight hours, nine hours, or ten hours.

Increased Accident Frequency Unaccounted For

In crushed-stone or non-dimension-stone quarries, where no care need be exercised to prevent breaking the stone, it might be expected that the rate from accidents from explosives would be higher than that in quarries producing dimension stone that is intended to be used for building or monumental purposes. This, in fact, has often been the case, as shown by the annual reports which the Bureau of Mines has received from the producers of stone. It does not, however, fully account for the higher frequency of accidents at crushed or non-dimension-stone quarries. A comparison of the annual figures for the two classes of quarries during the past seven years, shows that some other classes of accidents also, as a rule, occur more often at quarries that produce crushed or non-dimension stone. Crushed-stone or non-dimension-stone quarries show higher injury rates for accidents caused by handling rock at the quarry face, also for accidents from falls or slides or rock or overburden. Haulage accidents also are usually more frequent at crushed-stone quarries. Accidents caused by falling objects, which records for earlier years showed were of more frequent occurrence at crushed-stone quarries, have been materially reduced during the past four years, and in 1925 the crushed-stone rate for this

class of injuries was actually lower than at quarries producing monumental or building stone. A somewhat similar situation prevails as to accidents from flying objects; the rates for this type of accidents have been high for both kinds of quarries, but during the past three years the non-dimension quarries have established the better record. Machinery accidents also are among the major cases of injuries at both classes of quarries, but in the past few years the crushed-stone quarries have reduced their injury rates from this cause and since 1922 these rates for machinery accidents have been lower than at dimension-stone quarries. The net advantage, however, still lies with quarries that produce dimension stone; that is to say, the injury rate covering all classes of accidents combined is still lower for the dimension-stone quarries.

Quarrying Less Hazardous Than Other Mining

Accident prevention is a national as well as local problem. It is therefore appropriate that national associations, such as the Portland Cement Association, the National Crushed Stone Association, and others, should undertake or maintain some group action looking to the prevention of accidents. In 1925, more than forty states contributed to the production of stone in the United States, and in more than 34 of these states accidents were suffered by the men who produced the stone. To the extent that quarry accidents are similar regardless of location of plants, it would seem that the national associations might with advantage undertake a study of the accident-prevention problem. It has already been said that the quarry industry is less hazardous than coal and metal mines, both as regards accident frequency and accident severity. This, however, is no more than might reasonably be expected because nearly all quarry work is done in the open daylight, whereas most of the operations at coal mines and metal mines are conducted underground, where the light, which is necessarily artificial, is often not adequate for maximum safety; also in the underground work, there is the additional hazard of falling overhead material. The quarry industry should therefore not be content if it merely maintains an accident rate better than that for the mining industry, but should strive to lower its rate from its own previous levels. This has already been done to some extent so far as fatal accidents are concerned, but not to any material degree as regards injuries of a non-fatal character.

Of the 92,000 men working at quarries in 1925, the operator's returns to the Bureau of Mines showed 52,000 working in and about the quarry pits and 40,000 working at the outside plants. About three-fifths of the accidents occurred to the men working in and about the pits. These accidents accounted for 101 deaths and 8,632 lost-time injuries. The fatality rate per thousand 300-day workers was 2.28 and the injury rate was 195. The injury rate was the highest on record since 1915, when the statistics for inside and outside accidents at quarries were first segregated. On the other hand, the fatality rates previous to 1925 were, in four cases, better, and, in six cases, worse than the rate in 1925. These figures show that more progress has been made in the prevention of fatalities than in the prevention of injuries. A comparison of these figures with those for outside plants shows that more progress has been made outside than inside the quarries, and this fact has contributed favorably to the record for the industry as a whole.

The number of days a quarry is in operation is largely a matter of contracts and weather conditions. Perhaps choice plays little or no part. Yet it may be interesting to know that it is apparently safer for a quarry to work full time than part time. That is to say, the accident rate per day diminishes as the number of days the plant is in operation increases. A quarry that is in operation a full year is likely to have a lower accident rate per day than if it

60 per cent of the total quarry workers in the United States. These facts are referred to because the cooperation of the company as well as the employees must be obtained to make safety work effective. A relative small number of companies have it within their power to give a tremendous impetus to quarry safety work that will benefit 80 per cent or more of the entire industry.

The accident rates for the whole quarry industry are but slight indication of what individual companies can accomplish. For example, the industry's accident-severity rate for work inside the pits, as nearly as it can be computed from available records, was 8.202 in 1925 and 6.931 in 1924; the corresponding group rate for companies in the National Safety Competition was 7.599 in 1925 and 7.760 in 1926. Yet in the 1925 safety contest, seven quarries out of 102 and in the 1926 contest fourteen quarries out of 118 operated their plants the entire year without a lost-time accident. In 1925 sixty plants or 59 per cent of those enrolled had accident-severity rates of less than 1 and in 1926 67 plants or 57 per cent had rates of less than 1. Thus it is seen that the group average of 8.202 in 1925 and 6.931 in 1924 for the whole industry, and the National Safety Competition group averages of 7.60 and 7.76, respectively, in 1925 and 1926 are by no means the best that individual quarries can do in the elimination of accidents to their employees. In fact, the 1926 contest showed that 97 plants, or 82 per cent of the total number, had accident-severity rates that were better than the group average; 21 plants, or 18 per cent of the total number, had rates that were higher and therefore worse than the group average. This means that 18 per cent of the companies were mainly responsible for the group average being as high as it was. Had it not been for the many good companies, the rate would have been much higher. The record, in fact, showed that the companies whose rates were better than the average had a group rate among themselves of 2.314, while the rate for those whose record was worse than the average was 38.695; 2.314 for the good companies; 38.695 for the bad companies, an average of 7.760 for both combined. The bad companies had a rate that was more than 16 times that of the good companies.

Comparing Accident Experiences Is of Value

The purpose of these and similar statistics is to make it possible for individual quarries to compare their accomplishments in accident prevention with what has been done by other companies. Any individual company may be remarkably successful in the elimination of certain classes of accidents and equally unsuccessful in combating other types. Neither the degree of success nor the degree of failure can be known without some standard of measurement. The National Safety Competition of 1926 has shown that while all of the quarries combined had a group rate of 7.760, yet 82 per cent of them had lower rates than that figure. The rates ranged from zero to more than 200. Rates for the individual companies have been published, but in such a way that the identity of each company is concealed. Each company has been advised of its own rate and of its relative standing among all companies. Copies of a circular containing these rates are available to any company upon request. Incidentally it may be stated that the circular also contains the rates of coal mines, metal mines, and non-metallic mineral mines. All of these rates have been calculated on a uniform basis and are therefore strictly comparable. The method of compilation is simple. Any company may easily prepare its own accident records in the same way. Those companies that see fit to do so will find that they are following a practice that has become standard not only in the mineral industry, but in other industries as well. Following such a prac-

tice, any company may readily learn how it ranks with other plants of the same type or with any other industrial unit.

It is hoped that the companies represented at this meeting may find it practicable to place their accident statistics on this standard and widely accepted basis. In the event that any company establishes a safety record better than those indicated in the National Safety Competition, the Bureau of Mines would appreciate it if the company making the record would inform the Bureau of the fact. The Bureau desires to learn of cases of this kind so that suitable public recognition may be given.

ADJOURNMENT.

**SIXTEENTH ANNUAL SAFETY CONGRESS
NATIONAL SAFETY COUNCIL**

Chemical Section

New Section Officers

Chairman, DR. LEONARD GREENBURG, U. S. Public Health Service, c/o Yale Medical School, New Haven, Conn.
Vice-Chairman, C. F. WHITEMORE, Western Electric Company, Chicago, Illinois.
Vice-Chairman, E. C. ROGERS, The Grasselli Chemical Company, Cleveland, Ohio.
Vice-Chairman, C. E. RICE, The Dow Chemical Company, Midland, Mich.
Secretary, WILLIAM A. BAXTER, The Newport Company, Milwaukee, Wis.
Poster, Slide and Safety Kinks Committee Chairman, H. L. MINER, E. I. duPont de Nemours & Company, Wilmington, Del.
Membership Committee Chairman, E. C. ROGERS, The Grasselli Chemical Company, Cleveland, Ohio.
Publicity Committee Chairman, CARL F. COFFELT, Victor Chemical Works, Chicago Heights, Ill.
Industrial Poisons Committee Chairman, S. E. WHITING, Liberty Mutual Insurance Company, Boston, Mass.
Program Committee Chairman, C. F. WHITEMORE, Western Electric Company, Chicago, Illinois.
Engineering Representative, A. L. ARMSTRONG, Eastman Kodak Company, Rochester, N. Y.
Statistics Committee Chairman, C. E. RICE, The Dow Chemical Company, Midland, Michigan.
Executive Committee, THE OFFICERS AND—
S. H. KERSHAW, National Safety Council, Chicago, Illinois.
I. V. KEPNER, Pennsylvania Salt Manufacturing Company, Philadelphia, Pa.
J. S. SHAW, Hercules Powder Company, Wilmington, Del.
DR. C. L. REESE, American Institute of Chemical Engineers, Brooklyn, N. Y., c/o E. I. duPont de Nemours & Company, Wilmington, Del.
PROF. C.-E. A. WINSLOW, School of Medicine, Yale University, New Haven, Conn.
JOHN ROACH, Deputy Commissioner of Labor, State of New Jersey, Trenton, N. J.
H. C. PARMELEE, Chemical and Metallurgical Engineering, New York City.

HOWE, American Chemical Society, Washington, D. C.; S. H. KERSHAW, National Safety Council, Chicago, Ill.; J. L. KISTNER, Elliott Service Co., Chicago, Ill.; DR. C. L. REESE, American Institute of Chemical Engineers, Brooklyn, N. Y.; J. S. SHAW, Hercules Powder Co., Wilmington, Del.; PROF. C.-E. A. WINSLOW, School of Medicine, Yale University, New Haven, Conn.

Tuesday, September, 27, 1927.

S. E. WHITING, Chairman

Assistant Chief Engineer, Liberty Mutual Insurance Company, Boston, Mass.

The first session of the Chemical Section of the National Safety Council was called to order at nine-forty-five o'clock by the chairman, S. E. Whiting, Assistant Chief Engineer, Liberty Mutual Insurance Company, Boston, Massachusetts.

CHAIRMAN WHITING: I am very glad indeed to welcome you to the Chemical Section meetings at the Sixteenth Annual Safety Congress.

Those of us who had the opportunity yesterday to attend the General Meeting heard the invocation of the Reverend Dr. White on the general safety problem. He sought Divine assistance in solving the "unleashed hazards" that our modern civilization has created. I feel that the Doctor must have had this chemical industry particularly in mind because, as you all know, every month or so some chemist gets up some new combination of atoms or perhaps electrons and puts them into production in our factories. It is then up to us safety men to prevent our workmen from being injured by these newly unleashed forces.

I am not a chemist myself but I am speaking entirely by the book when we talk about new things. Here is a bulletin of a very prominent firm of consulting chemists, dated September, 1927. In a single paragraph it tells of one specific new development,—the expanding use of solvents. A list of fourteen relatively new solvents is given, but very little is said about hazards. They do mention benzol as a possible hazard and it is to the credit of the Chemical Section that something definite is generally known about the hazard of this solvent. It will take time to determine them all.

Most of the list we know only by names with some idea of their explosive possibilities as one hazard. There are also skin irritant possibilities and also toxic possibilities. Even Dr. Winslow, who has done so much for us on benzol, doesn't know all those qualities for the other solvents. It will take time to determine them all.

I think this section has been working along the entirely proper and practical line of investigating these new processes by actual field tests of air contamination and of the employee's health. Yet there is an inevitable waiting period before we shall know the actual facts. What you practical safety supervisors of chemical plants can do in the meantime I feel (as a layman) is this: I don't think you should wait until the specialist has told you the exact hazards of any new chemical whatever. I think you should not assume it is harmless, from either the explosive, the skin-irritant or the toxic standpoint. For example, many of us know that one particular new process

has recently led to a very serious industrial accident not far away from here,—a genuine catastrophe. We do not want to wait for such lessons as that before we correct any explosive hazard. We do not know that some new skin irritations may not crop up. We do not know that there may not be some more insidious systematic effects. Thus, some medical men are now even connecting so serious a disorder as cancer with skin troubles from certain oils. And as to any possible toxic qualities of these new substances, we haven't any answer at all as yet.

What are we going to do in the meantime? We can at least try to enforce every proper precaution against those perhaps remote possibilities. On explosion hazards, we can insist on proper control of temperatures and pressures, the elimination of sources of ignition and the adequate ventilation of dusts and vapors. As far as the skin of the worker is exposed, we can insist on protective clothing from head to foot. We can insist on proper hygiene of the workers and good housekeeping in the plant.

Another thing we can insist on is good hygiene on the part of the new process itself. The chemist gets out his new process and he is interested mainly in being sure that it produces a particular reaction with a particular finality of purity or whatever he calls it, and he isn't primarily interested in whether or not he spills dusts or vapors all around the plant, exposing the workmen to them. On the other hand, you look at the new process from the outside standpoint and can undoubtedly suggest mechanical ways of making that process itself more hygienic so as not to put the burden of protection entirely on the workmen,—or the janitor.

On the other possible hazard,—the toxic effect of new substances,—nobody knows how safe it is for a workman to breathe a contaminated atmosphere, contaminated in some new manner. Yet you do know that he has to breathe continuously and, therefore, you are entirely justified in asking your management to allow you to adequately ventilate all work rooms or to adequately protect the worker with respirators (if driven to it) so that the worker can maintain his proper birthright of breathing only God's pure atmosphere.

Taking up our program now, we begin with the statistical situation in the chemical industry as it has changed during the past year. This is presented by Mr. C. F. Whittemore, Health Hazards Department of the Western Electric Company, Chicago.

The Accident Situation in the Chemical Industry

C. F. Whittemore, Health Hazards Department, Western Electric Company, Chicago, Ill.

1. *Definition of Chemical Industry*

In outlining the accident situation in the chemical industry, we must first define the field covered by our accident statistics. Those who were at the Detroit Congress last year will recall Dr. Ethelbert Stuart's plea for greater uniformity in statistical practice. He felt that a sharper line should be drawn between chemical and non-chemical industries. While such a reclassification would aid the statistician, it is doubtful if an exact division can be made because the far reaching influence of chemistry enters so many industries not entirely chemical yet very closely related.

After all, we have a rather closely-knit group known as "The Chemical Engineering Industries," having in common an interest in chemical processes such as decomposing, electrolyzing, fermenting, and catalyzing. There are other processes of mutual importance such as compressing, humidifying, conveying, combustion, pulverizing, screening and mixing that bind this group of apparently unrelated industries more closely together. The products of the industries included in the following group may be, therefore, entirely different but the unit operations are basically the same:

Cement and Lime, Ceramics, Coal Tar Products, Coal By-Products, Electrochemical Products, Explosives, Cellulose, Fertilizers, Fine Chemicals, Food Products, Glue and Gelatin, Heavy Chemicals, Leather, Oils, Vegetable and Animal, Paint and

Varnish, Petroleum Refining, Pulp and Paper, Rubber, Soap, Sugar and Wood Chemicals.

2. *Scope of Statistics Compiled in Chemical Section of National Safety Council*

This chemical engineering group has been subdivided, however, in organizing the National Safety Council, some of the component industries being set apart, as for example, sugar manufacturing in the Food Section; leather in the Packer's and Tanner's Section; paper and pulp, petroleum, and rubber in separate sections of corresponding names. This leaves the following in our Chemical Section and the accident reports discussed in this paper apply to this group:

- Acid Manufacturing.
- Coal Tar Distilling.
- Dye Manufacturing.
- Explosives Manufacturing.
- Paint and Varnish Manufacturing.
- Smelting and Copper Refining.
- Miscellaneous Chemical Plants.

The miscellaneous chemical plants include the manufacturing of various pharmaceutical, soap, solvent, salt and cellulose products which might be classified further but such sub-division would be of doubtful value as there would be only one or two members in each group.

Summary Reports of Industrial Accidents

3. *Present Method of Compiling Data*

Every year each section of the Council asks its members for a summary report of industrial accidents for the calendar year just ended. A printed form is furnished for compiling (1) the average number of employees, (2) the total hours worked, (3) the number of accidents causing lost time beyond the remainder of day or shift, (4) the number of days lost as a result of these accidents, (5) frequency rate, and (6) severity rate for the entire company or for each branch if desired. On the reverse of this report blank each item is fully explained and a scale of time charges for deaths and permanent injuries is given. These reports are entirely confidential. In publishing information thus collected, the names of all participating companies are withheld and are known only to one member of the staff who compiles the statistics for publication. A key number is assigned to each member who may therefore compare his accident experience with that of other plants in a similar line of business when he receives the annual report.

4. *Cooperation*

Although the number of plants reporting this year is greater than last year, there is still room for improvement for the total number of returns corresponds to only about one-half the number of members. The reports requested are so brief, it seems as if many more responses should be received. Will every delegate present, please take one copy of the report blank home, and if his company has not reported before, read over the explanatory notes first to convince himself and then arrange to cooperate next year by sending to Council Headquarters, the figures covering his company's 1927 accident experience. The more data we have, the better picture we shall get of the true accident situation in the chemical industry.

5. *Outstanding Facts Revealed by Data for 1926*

Analysis of this year's summary report reveals the following outstanding facts relating to the Chemical Section for the year 1926:

Each injured person lost an average of 125 days.

The average number of days lost per person employed was 5.6.

For every 71 non-fatal accidents there was 1 fatality.

The number of plants reporting 1926 records represents an increase of 66

per cent over 1925. Last year 65 reported and this year there were 108 returns.

Accident frequency rate has been reduced over 12 per cent (from 20.91 to 18.26).

Accident severity has been reduced more than 15 per cent (from 2.71 to 2.28).

6. *Comparison of These Facts with Experience of All Sections Combined*

Although the true test of success or failure lies in comparison of each section's record with their own previous year's showing, it is also interesting to compare data for the Chemical Section with similar figures for all sections combined. Our average time lost by each injured person, 125 days, is considerably higher than the average of 78 days for the entire group, although the average time lost per person employed is slightly less than that for the council as a whole. Twice as many fatalities, 1 for every 71 non-fatal accidents have occurred in the Chemical Section as compared to 1 in 140 for the entire membership. This year's increase in companies reporting in our section 66 per cent, is considerably higher than the increase of 42 per cent for all sections. Our accident frequency rate reduction is lower, but compares more favorably with that of the whole council if we note that the Chemical Section's rate is only 18.26 compared to 24.59 for all sections combined. Our accident severity rate has been reduced more than that of all sections, 15 per cent, against 4 per cent, but in this case, there was more need for improvement in the chemical group.

7. *Conclusions*

In conclusion, the data obtained this year for 1926 show improvement in rates of both accident frequency and severity. There is a decidedly favorable trend due undoubtedly to organized and well directed efforts to create and maintain safe working conditions.

That such improvement can be accomplished without slowing up production has been shown by the American Engineering Council as a result of a very thorough study of trends in productivity and accident rates of about 14,000 companies employing in 1925 two and one-half million workers. A summary of this report was discussed by Mr. J. E. Hannum at the Newark meeting of the Chemical Section last April, and published in the August number of the NATIONAL SAFETY NEWS. The results of the same survey have also been summarized by L. W. Wallace in the September number of Mechanical Engineering. Their investigation has proved that material reductions in accident rates can be obtained simultaneously with increases in production rates. Such favorable performances were made in the acids and heavy chemicals, by-products coke, and explosives industries.

Discussion of Mr. Whittemore's Paper

CHAIRMAN WHITING: We have been making progress, according to Mr. Whittemore, during the last year in the industry as a whole. He points out an important flaw, however. Some of you gentlemen are not in this game of statistical competition and you ought to get into it. You may need this competitive argument sometime, especially if you are at the tail end of the list, with your management in trying to sell them on the idea of giving you further support in safety work.

I know some of the chemical industries have secured an astonishing reduction in their accident record. They seem to be too modest to get up and tell us about it, but they have proven it can be done. Some of you might like to ask Mr. Whittemore a question on this matter.

MR. WHITTEMORE: I have sample blanks on which your statistics can be turned in to Council headquarters and will give them out for you to take home.

CHAIRMAN WHITING: Please start the practice of supporting this statistical rec-

ord. It is bound to help you in the long run. Your figures will be treated confidentially. Do you want to come into this discussion on statistics, Mr. Greenfield?

C. W. GREENFIELD (du Pont Viscoloid Company, Arlington, N. J.): Not just now.

JOHN S. SHAW (Assistant General Manager, Hercules Powder Company, Wilmington, Del.): Mr. Chairman, I assume these average figures such as 125 days per man include the loading for permanent disabilities?

MR. WHITTEMORE: Yes. The usual assignments have been used, both the days actually lost and the loading for dismemberments, deaths, etc., as scheduled on the summary blank.

CHAIRMAN WHITING: I believe Pennsylvania Salt is sending in their statistics, and I would like to have Mr. Kepner say whether it is of practical assistance to him.

A Line on Where Accidents are Occurring

IRA V. KEPNER (Pennsylvania Salt Mfg. Company, Philadelphia, Pa.): I can't just say of what relative value these records are in selling the management, but they certainly do keep us advised as to our accident severities and frequencies. Very often it gives us a line on just where the accidents are happening and how effectively we are reducing them. We can compare our progress year after year.

I am sending my statistics to the National Safety Council, and when I look over the experience of the others it makes me feel that probably we are not so bad after all when we are compared with some of the others. Yet I feel when we do have an accident, particularly a fatality, we belong down at the bottom of the list.

I might say, patting myself on the back, that we are fifth on the list. I don't know who the other fellows are who stand 1, 2, 3 or 4, because they are only known by numbers. You each know your own number because the Council gives you the key. I would like to hear from the other fellows in the Chemical Section who stand 1, 2, 3 and 4. They are probably all in this room. I would like to know how they do it.

CHAIRMAN WHITING: We are ready to hear from Number 1, if he will admit it—or even from the highest number.

W. A. BAXTER (The Newport Company, Carrollville, Wis.) We also send in our accident experience but it is nothing of which I am proud when we compare it with some of the others. I was just wondering if I was doing this work properly. For example, I see one firm here that has 1,732 employees and they show only one temporary disability. I don't know how it can be done. Either I am a very poor safety organizer, or I don't compile these figures correctly or some of you fellows are cheating.

A lost-time accident, as I see it, is one where a man loses time beyond the same shift or day period. I have in mind that if you send a man to a doctor with a chemical rash and the doctor tells him that he will have to take a couple of days off, some of you might put him in another department where he can continue at work, but where the doctor says he should take a couple of days off, I list him as a lost-time accident. I would like to know what some of the other members of the Council do in that respect.

CHAIRMAN WHITING: On this question of "faking" records, I know that companies in various industries in their accident competitions do sometimes allow what you might call faking; that is, they will bring back a slightly disabled man who ordinarily would stay out a few days and give him a light job. That may be faking in one sense. In another sense it may not be faking at all; it may be the very best medical treatment for that man,—the best psychological treatment for that man may be to have him back on a job, to have him doing something to keep his mind off his injury.

The real fakers from the employer's standpoint are those who are drawing an employee mutual benefit, an insurance compensation and some private benevolent association's weekly stipend, all of which together give them better wages than they are getting when they are working. Naturally that fellow wants to loaf, but you don't want that to be put over on you

Again, referring to the bringing back of the partially disabled man and putting him on light work, what is the harm of it? It does at least make everybody talk and think more about accidents,—which is getting at the fundamental of accident prevention. So I don't think it is altogether illogical to have a man who is slightly injured come back to work in spite of the doctor's fears that he might be further aggravating that injury. Of course, you must use good discretion, but the doctor also must use discretion and not baby the man too much for his own medical welfare. Perhaps one of these people who do the faking will be glad to get up and tell us how they do it?

One railroad in the East in competition with another railroad actually brought back a man with a broken leg and sat him on a chair doing nothing, just to avoid a lost-time accident. There is no fairness in going to any such absurd extent, but keep in mind the psychological effect on the mind of the worker who comes back on the job after a minor injury. It is said that the Ford Motor Company follows such practice at times even with bed cases. They give that patient something to do while he is in bed, putting nuts on small bolts or any light job just to keep his mind occupied. This is just what the doctors call "occupational therapy," and it may really help in the problem of minimizing the period of convalescence.

Our next subject is upon what accidents happen in that holy of holies of a chemical industry,—the chemist's private sanctum. My impression as a layman is that once in a while these fellows blow themselves up. I recall one laboratory at an eastern college where a research man blew himself up and was killed and another such case in an engineering school. So we safety men who have the whole plant responsibility are properly interested in what goes on inside any laboratory. Dr. J. W. Stillman of E. I. du Pont de Nemours & Company, Wilmington, Delaware, is going to tell us about it.

Prevention of Accidents in Chemical Laboratories

Dr. J. W. Stillman, E. I. du Pont de Nemours & Company, Wilmington, Del.

In discussing this subject, for the sake of completeness, it will be necessary to review many precautions which are well known and probably generally practised. In one sense this repetition is of real value in familiarizing those who are responsible for the manufacture, handling and use of chemicals with the rules of safe procedure. It is proposed in this paper to make a rather complete survey of the operations which are common to chemical laboratories, giving suggestions as to steps which may be taken to avoid accidents and in a few cases illustrating the point by describing accidents which have happened when safety has been overlooked or ignored.

Of course, the first topic to be considered should be the design of the building to be used for laboratory purposes, but this varies so much, depending upon the purpose for which it is to be used, that it is difficult to outline a standard plan. One or two essential points can be mentioned, however. It is unwise to have laboratory rooms open out of another room which is used for laboratory purposes, because in case of fire in the outer room, escape from the other rooms might be cut off. The same thing applies to the arrangement of tables within the rooms. Aisles between tables should be open at both ends in case a sudden fire should make escape in one

direction impossible. All exit doors should open outward and fire extinguishers should be placed at accessible points, particularly good locations being beside doors or windows where they can be reached from the outside. Adequate ventilation is very necessary in the chemical laboratories where the fumes which are the product of many reactions are in most cases at least irritating. Hoods equipped with an exhaust fan should be a part of the permanent building equipment. Very attractive hood designs are obtainable made up with alberene stone. A new method which has proved to be very satisfactory is to have the exhaust flue built in behind the rear wall of the hood with intake openings in the form of slits about three-quarters of an inch wide and graduated in length so as to give a uniform draft. A row of these slits is placed in the back wall both at the level of the table top and at the top of the hood.

Precautions in Dealing with Poisonous Gas

In cases where there is considerable amount of a poisonous gas being used and where there is danger of the gas escaping through leakage or in the changing of apparatus, as for example when carbon monoxide is being used as a raw material for calytic reactions, a special ventilating system designed to exhaust the entire air of the room in a given time should be installed. This gas is usually prepared at or near the point where it is to be used and is a treacherous poison because it has no color or odor to act as a warning. The danger is well understood on account of the newspaper publicity which has followed the numerous accidents, which in many cases have been fatal, from the carbon monoxide expelled in the exhaust gases of automobiles. A wise precautionary measure is to have a gas mask, equipped for protection against the gas likely to escape, placed outside the laboratory and plainly marked so that if it is necessary to enter the room when it is filled with a poisonous gas, the equipment to do it safely will be at hand. Also, in case an accident should occur, those who are working with this gas should be provided with inhalation apparatus designed for the treatment of carbon monoxide poisoning and should be instructed in first aid methods.

Untidiness, which usually is the result of carelessness, is repulsive to almost everyone, but that it can be a contributory cause of accidents is many times overlooked. Neatness, which will of course promote greater efficiency in the worker, should be classified as one of the primary requisites of safety in the chemical laboratory. When chemicals are spilled, the remains immediately should be cleaned up. If stray particles of various kinds are allowed to accumulate over a period of time, mixtures may result which will of themselves start a fire, which, being communicated to scraps of paper or other waste, will spread rapidly. Special care should be exercised when using sodium, sodium peroxide, phosphorus, etc., to see that all strays be collected and disposed of.

It has recently been advised that if metallic mercury is spilled in handling, every effort should be made to have all of it cleaned up on account of its poisonous qualities. Mercury is used extensively in the laboratory as a confining and indicating liquid in gas pressure gauges and in gas analysis apparatus, and while it has been known that it is poisonous if taken internally, the idea that liquid mercury exposed in the open room would give a concentration of vapor which would be dangerous to the health when the air is breathed has caused some discussion. Frequently, in cleaning and handling the mercury, some is spilled on the table or floor and in the past no particular effort has

been made to clean up the spilled mercury thoroughly since it was considered entirely harmless. Now evidence¹ is brought forward which tends to show that sufficient mercury is volatilized from the scattered drops in the room to give a concentration of mercury in the air which will cause mercury poisoning. The poisoning develops slowly on account of the low concentration of mercury, but the lungs seem to retain it from the air breathed. If the evidence is correct, precautions should be taken to reduce the amount of mercury spilled to a minimum and to avoid keeping it in open vessels. In general it can be said that the floors and tables of the laboratory should not have cracks or depressions which will permit the trapping of waste chemicals.

The work table should be kept free from apparatus or chemicals which are not actually in use. When apparatus is set up it should be placed well back from the front edge of the desk. This will provide larger working space and also avoid accidental upsetting of the apparatus. Also when vessels containing hot or corrosive solutions are placed on the table, even temporarily, they should be set far enough back so that they will not be brushed off by a person passing by.

Carefully Label All Bottles

All bottles should be marked with a label which is easily legible in order to avoid the use of the wrong reagent as well as to prevent the contamination of the reagents when refilling the bottles. If a rule is adopted that the janitor is permitted to discard the contents of any bottle having no label, the habit of carefully marking the bottles will soon be learned by the chemists. Only small stocks of chemicals or flammable liquids should be kept in the laboratory. Unless a chemical is being used continually, a pound or half-pound should be a sufficient amount to keep on hand and a gallon of alcohol, benzene, ethyl acetate, etc., should meet all requirements for these solvents. The stock of reagents should be classified and arranged in a neat, orderly manner in a cool, dry part of the laboratory. The flammable solvents should be segregated and should be so located that in case of fire exit from the room will not be cut off.

Glassware for immediate use should be stored in a way to avoid breakage. Severe cuts are the result of reaching into a closet and coming into contact with the ragged edge of a piece of broken apparatus. Beakers, flasks and bottles can be taken care of by providing a large closet at the side of the room which is equipped with shelves and doors to keep out dust. Condensers and complete units of glass apparatus such as Soxhlet extraction apparatus should be kept in drawers, preferably with cotton on the bottom. No more apparatus should be placed in the drawer than can conveniently be arranged on the bottom. In other words, one piece should not be piled on top of the other, for then there is danger of breakage in opening and closing the drawer. Pipettes and burettes can be protected by equipping the drawer with strips of wood running lengthwise of the drawer in which are cut grooves just large enough to admit the piece of apparatus in question.

Large stocks of standard apparatus and chemicals for the use of the whole laboratory organization and selected according to the nature of the work being done should be kept in a central storeroom in charge of a competent stores-keeper. Excess stocks of either apparatus or chemicals when no longer needed should be returned to the central storeroom. If this is not practicable because of accounting difficulties, a group of chemists doing similar work should be provided with a storeroom or storehouse and the excess stock can be classified and kept here. Some one person should be responsible

(1) Dennis, *Ind. & Eng. Chem.* 18 (1926) 1205.

for this storehouse. An up-to-date record of the stock should be kept and care should be taken that explosive or flammable compounds are not allowed to accumulate to a dangerous amount.

To return to the central storeroom, there are one or two rules to be observed here. All volatile flammable liquids should be suitably protected and kept in a proper building located at a reasonable distance from other buildings. This building should be kept as cool as possible and should be well ventilated. A drain should be provided to carry off any spillage. Suitable fire extinguishers should be provided and are best located on the outside of the building.

It is customary practice to store chemicals by arranging them alphabetically according to their metallic constituents; for example, all nickel salts are classified under N and all sodium salts under S. It is debatable whether or not this is the best method. Included in the list of chemicals which are ordinarily used will be many oxidizing agents belonging to such classes as nitrates, chlorates, permanganates, peroxides, etc. The most of the compounds of this sort would not start a fire of themselves but on account of their ability to give up oxygen when heated, as a class they will promote and intensify a fire once it has been started. This is recognized by the postal authorities, and only a very small quantity of an oxidizing agent is permitted to be shipped by mail. The suggestion, therefore, is made that it perhaps would be better to take at least the extra supply of oxidizing agents out of their alphabetical classifications and place them together in a fireproof building, room or compartment.

Special Construction for Shelving

Glassware should be kept on shelves with raised strips across the front to prevent any pieces from being knocked or jarred off. No pieces should be allowed to extend over the edges.

Metallic sodium and potassium, on account of the fact that they react readily with the moisture of the air and ignite spontaneously, have to be kept under kerosene. The safest plan is to transfer the sodium or potassium, when received, to glass jars equipped with tightly fitting glass stoppers. Each jar should then be set in an enamel bucket for protection in case the glass jar breaks. If kept in tin cans, the kerosene may leak out unnoticed. A separate fireproof building should be provided for the storage of large quantities of sodium and potassium, and frequent inspections should be made to see that sufficient kerosene is in all the bottles.

Yellow phosphorus also requires special care in storage on account of its fire risk. Yellow phosphorus must always be kept under water in a similar manner to the sodium under kerosene, but phosphorus and sodium must be kept in separate buildings because of the danger of adding water to a sodium container by mistake. Care should be taken in winter to avoid breakage of the bottles through freezing of the water. A double container, as suggested above, is a wise precaution.

An accident which illustrates what may happen through the careless handling of chemicals can be described appropriately at this point. This accident occurred in the student laboratory at a large university and aroused a great deal of interest on account of the legal aspects of the case.² A young woman student was carrying out an experiment which called for the heating of a mixture of mercuric sulfide and lime in a glass tube closed at one end. The mercuric sulfide was issued to the students by an attendant in the storeroom. The lime was placed in bottles on the side tables and was obtained

(2) J. Ind. & Eng. Chem. 13 (1921) 1079.

by each student for himself. Some students were working on previous experiments which called for the use of potassium chlorate, which was also on the side table in bottles. It is supposed that the young woman selected the wrong bottle, because an explosion followed the heating and, as a result, the young woman lost one eye. The contents of all bottles on the side tables were examined after the accident and found to contain nothing but the reagent called for by the label. The unused portion of the mixture heated by the student was found to contain mercuric sulfide and potassium chlorate but no lime.

The student brought suit against the university on the basis that there had been negligence on the part of the instructors in not analyzing the contents of every bottle on the side table to see that they agreed with the label. The lower court awarded damages of \$25,000 to the plaintiff, but this was later reversed by the higher court when the decision was appealed.

The Lesson Taught by the Accident

The first lesson to be gained from this description is that too much emphasis cannot be placed on the proper labelling of containers, which has already been referred to. Next, it teaches that the operator, whether student, instructor or industrial chemist, should exercise care in selecting the proper container by noting the label before using the contents. It is obviously impossible to analyze the contents every time a bottle is refilled, but in refilling bottles special care should be taken to see that the material is the same as called for by the label.

As a result of this accident, many colleges have sought by various means to reduce the possibilities for such an accident. The danger lies not entirely in the selection of the wrong reagent from several placed at the disposal of the students, but also in the fact that there are students who, anxious to "see what will happen," will try mixing together various chemicals which they find accessible. One authority has gone so far as to recommend that colleges should exclude from their courses for beginners an experiment which calls for the use of a reagent which might be dangerous if mixed with any other reagent used throughout the course. This is quite evidently an impractical suggestion, but one institution has a plan under which a list of chemicals which cause danger reactions is withheld from the students except on permission of the head of the department and a signed statement by the student that he is familiar with the chemicals and their characteristics and will not hold the college responsible for accident.

This accident points the way to a service which colleges and universities can perform which will not only protect themselves from the results of accidents but will prove to be of great benefit to the chemical industry. In the training of chemists, there has been a general lack of instruction based on the question of safety, and this ought to be remedied. The so-called physical and chemical properties of the various common reagents which are to be the chemist's future tools are thoroughly studied but very rarely is mention made of the physiological properties of the same compounds. Certain compounds such as potassium cyanide which are especially dangerous poisons are warned against, and in the same way a few of the more flammable and explosive compounds are mentioned specifically. What is required is a general classification of chemical compounds with emphasis laid on their safe handling. It would be a hopeless task to pick out every combination of chemicals which would be dangerous, for in his daily work the chemist is called upon

to handle many unusual compounds, but these can easily be classified, however, according to general rules.

For example, it is well known that oxidizing materials on the one hand react readily with reducing materials on the other hand. Now, from the point of view of safety, it might be added that this reaction is usually accompanied with the evolution of heat, which may lead to spontaneous combustion, and in many cases if external heat is applied the reaction may proceed with the violence of an explosion. To return to the accident described above, sulfides in general are reducing agents and mercuric sulfide, therefore, belongs in this classification. Potassium chlorate is one of the outstanding examples of an oxidizing agent met with in the study of chemistry. So the accident which probably was caused by heating a mixture composed of a typical reducing agent and a typical oxidizing agent gives a very good example of the generalization laid down above. Neither one of the two components can be classified as a dangerous substance according to the usual standards, so that a study of safety based on the listing of dangerous substances would be futile.

Safety Instruction at the University

It seems to the writer that the college or university is the proper place for this safety instruction to be given, for it is from these institutions that the chemical industry draws its workers, and the new employee is not fitted to take his place in the industry where he may endanger other lives as well as his own, if he does not understand the materials he is about to handle. The chemical industry as well as industry in general has made rapid strides in the adoption of safe procedures in the last few years, but their task would be much simplified if the principles of safety could be learned at school at the same time and along with other chemical principles.

An accident which occurred several years ago in the laboratory of a large manufacturer of toilet articles, and which resulted in the death of two men, is an example of the dangers involved in the handling of flammable materials.³ The chemist and his assistant were carrying out a reaction which involved the use of ether. Both men were familiar with the ordinary course of the reaction, but in this case the belt came off the stirrer which resulted in local overheating inside the reaction vessel and ether fumes escaped into the room. The chemist had one of his assistants open the windows for better ventilation, and he stepped over and threw a switch controlling the stirring apparatus. This caused a spark which ignited the ether vapor in the room, and the resulting puff blew the man standing at the window through the opening. He was not seriously injured. The fire which followed caused burns to the chemist and the assistant working directly with him which resulted in their death the next day. The laboratory was practically a total loss.

Almost everyone realizes the extreme flammability of ether, but a point which is not often realized is that the vapors will travel along a surface, as for example, the laboratory table top, and a spark or flame at some distance from the source of the ether will ignite the mass of vapor. In using ether or similar volatile flammable liquids, no open flame should be allowed on the same table. If the ether is to be boiled or distilled, the heat from an ordinary incandescent bulb is sufficient for the purpose. Of course, electric switches or devices which may cause a spark should not be operated when ether or other volatile flammable liquids are being used nearby.

(3) J. Ind. Eng. Chem. 11 (1919) 490.

Compressed gases in cylinders here come to be included in the list of essential supplies for a laboratory. Among those most often used are oxygen, hydrogen, carbon dioxide, nitrogen, ammonia and chlorine. If welding is done, acetylene should also be included in the list, and recently a number of the less common gases have been made available in cylinders. One precaution which is applicable to all gases is that the cylinders should be kept in a cool place. If exposed to heat the pressure will be increased and the cylinders become a menace to safety. Whenever possible, tanks of compressed gas should be placed on the outside of the building and sheltered from the direct sun. Piping can then be run from the tank to the laboratory table with a needle valve control just inside the building wall. A corrosive gas such as chlorine cannot be conveniently handled in this way.

In using oxygen it should be remembered that oil should be avoided in all valves and lines. Also hydrogen and oxygen should not be used interchangeably with reducing valves or pipe lines. Not only do the two gases form explosive mixtures, but the hydrogen may contain traces of oil which is used in connection with the compression of this gas. To avoid the interchanging of connections, oxygen tanks are equipped with right-hand and hydrogen with left-hand threads.

Hydrogen Sulphide a Primary Reagent

Another gas which is coming into use in cylinders is hydrogen sulfide. This can be called one of the primary reagents of the chemical laboratory. Formerly it was prepared by the action of hydrochloric acid on iron sulfide in a Kipp generator, which, however, was not very satisfactory because the capacity of the generator was comparatively small, and in cleaning and renewing it more or less of the gas escaped into the room. Hydrogen sulfide has the unpleasant odor of rotten eggs, and, contrary to the general opinion, it is quite poisonous. During the war, a chemist was given the assignment of selling the waste nitre cake from nitric acid manufacture, and in doing this he frequently made demonstrations of the possibilities of its use. While working in a small, poorly ventilated room which was used as the laboratory for a company whom he was trying to interest in nitre cake, the chemist was overcome by the hydrogen sulfide gas and later died from its effects.

Hydrogen sulfide causes irritation of the eyes and respiratory tract and as little as 0.10 to 0.15 per cent in the air will cause death in one-half to two minutes.

Laboratories should be and generally are now equipped with a hood which is ventilated by a strong draft from a suction fan. With such equipment hydrogen sulfide, chlorine and other poisonous and corrosive gases can be handled in perfect safety. The hood should be used for all reactions in which irritating fumes or smokes are given off.

Chlorine is another corrosive gas, but chemists are quite familiar with its characteristics. The greatest danger from chlorine lies in the sticking of the valve at the top of the cylinder. Due to the presence of moisture, the chlorine may corrode the valve stem and then, when pressure is applied, the valve or its threads may be twisted off. If a valve does stick in this way, the tank should be moved out-of-doors to a place away from where people are working, before an attempt is made to open it.

Chemists should realize that they are dealing with materials which, when isolated, are not in themselves dangerous in many cases, nevertheless are hazardous to life and property when grouped together as they are in general chemical research work. It should be the duty of each chemist, if it has

not been a part of his school training, to learn the characteristics of his materials, with the idea of handling them safely in consideration of his fellow worker as well as of himself. Minor accidents should not be expected; they should be prevented.

CHAIRMAN WHITING: Dr. Stillman says he has left one idea with us. He is mistaken; he has left many ideas with us. I would like to ask whether or not the head of a chemical laboratory will permit the ordinary safety man to go into his quarters and make safety suggestions. What is the general attitude, not of you, Dr. Stillman, but of Chief Chemists in general toward the safety man going into his private quarters?

DR. STILLMAN: I am quite sure that the chemist is perfectly willing to have the safety man come into his quarters and even dictate to him if necessary. I know I have always felt that way and I am quite sure I can speak for others too. The chemist realizes, at least subconsciously, that he hasn't the safety training of which I spoke, and when somebody who knows the safety side of it but doesn't know the chemistry side of it goes into the laboratory, I think the chemist will be perfectly ready to listen to him.

Stopping Leakage in Chlorine Cylinders

C. E. LYON (Hooker Electrochemical Company, Niagara Falls, New York): I would like to add just a word to Dr. Stillman's remarks. In reference to the possible stoppage of leaks in chlorine cylinders about which he spoke, a water spray where there is a leakage of gas does not stop the leakage. However, in the case where a cylinder is tipped over on its side and the liquid runs out, water does assist, because evaporation of the hydrate is much slower than the ordinary liquid. In the case of escape of gas, there would be no advantage in adding a water spray.

CHAIRMAN WHITING: Would you recommend tipping over the cylinder so that the leak would be near floor level and make the liquid run out?

MR. LYON: In case of a bad leakage that is the only thing you can do, in any case where the entire cylinder is apt to leak out.

JOHN S. SHAW (Hercules Powder Company, Wilmington, Del.): I think that was a very excellent paper, Dr. Stillman. There is just one thing I want to add. One of our engineers recently found that the chemist in one of our laboratories overlooked his electric wiring. The chemist would continually buy more electric apparatus thus loading the circuit and he would forget all about the wiring. The insulation on the wires was just about gone when our safety engineer inspected that laboratory. I would also like to suggest in the design of the laboratory that it should be made too large because laboratories all grow small in time. I was very much interested in the suggestion that Dr. Stillman made in regard to a right-hand thread for oxygen and a left-hand thread for hydrogen.

On the West Coast a few years ago the poles were reversed in an electrolytic process for making hydrogen and oxygen, and during all of one shift the electrician pumped hydrogen into an oxygen gasometer and oxygen into the hydrogen. The result was that we bought some of those cylinders which had a fifty-fifty mixture of oxygen and hydrogen in them. When the welder started his work he was killed and others were injured. The cylinder blew up just like a bomb. It made a report about as loud as a wheel mill in a black powder works. It was very severe.

There is one more point. I didn't learn from Dr. Stillman how he picks up the mercury after spilling it.

CHAIRMAN WHITING: We are still waiting for the reply he promised us. Before he sums up we have a college professor here, and I know he will be glad to tell us what he does to prevent his students from being injured; Dr. Smyth.

PROFESSOR H. F. SMYTH (University of Pennsylvania): I teach in the University of Pennsylvania but not in the Chemistry department, although very close to it. I see a good deal of their work, and I see a good deal on the health hazards of their work which they do not realize. I was particularly struck with what somebody had to say about hydrogen sulphide. It is one of the most toxic gases which we have to deal with. That raises another point.

A good many people think about hydrogen sulphide as they do about other things. I saw a report the other day about some work on solvents used in lacquer, a subject I have been very much interested in. This particular individual said the solvent was comparatively harmless as he found from the result of his experiments, although conceding it might be very harmful in higher concentration but he claimed the bad odor of that solvent would be in itself a protection against it when in use industrially. That is not so.

I don't believe that anything smells bad enough to keep the average workman from accustoming himself to the smell and using it recklessly in the same way in which the chemist accustoms himself to the smell of hydrogen sulphide. It is a curious thing that in low concentration it smells like the devil, like rotten eggs, but not when it is in high concentration. You cannot depend on the smell of hydrogen sulphide to protect you and make you realize that you are handling a dangerous substance or to enable you to protect yourself with ordinary commonsense in the handling of it. Don't depend on the smell of any chemical unless it is highly irritating, unless it produces an immediate reaction on your mucous membrane; that is, makes you sneeze or chokes you up. Don't depend on odor alone to protect you from any toxic substance.

The Sense of Smell Not a Reliable Protection

I was going through a plant the other day. It was a very well constructed plant where they had taken very excellent care of the excess fumes. I had never been in a plant of that kind before where there was so little odor. There is a very definite odor to the solvent being used, and the safety man who was taking me through said, "I don't think you can smell any of it at all." Well, he couldn't smell any of it because he was in it every day. His mucous membrane was accustomed to it, but I knew what they were using for I could smell it. To depend entirely on the smell of any chemical or solvent to protect the worker is like leaning on a broken reed because you can't do it.

We handle very dangerous things with impunity and we think we are going to get away with it always. I was amused a few years ago when I was doing experimental work on anthrax spores. It is a very highly toxic spore. I was doing some experimental work in the use of disinfectants, and I had collaborating with me an instructor of the chemical department which was next to our department, and we took into the chemical department some anthrax spores in test tubes. When he heard of it he was horrified. Yet it is fourteen years ago since we have had any infection in our own laboratory from any bacteria which we handled, and we have handled a good many. In the chemical laboratory of which the head was so horrified at my bringing those spores into the laboratory, there is never a winter goes by but that we see fumes flowing out of the window. Usually they have chemical accidents every year; the man who worked with me had been overcome with gas. Yet, the head of that laboratory was horrified because I took some anthrax bacilli in a culture tube into that department.

Don't get so familiar with the dangerous things you are handling as to lose your respect for them. There is a very interesting monograph got out recently in which is emphasized that very side of it to the chemists—a monograph by Henderson and Haggard on Noxious Gases. It is very well worth reading for the chemist.

who doesn't realize that the gases he handles are very dangerous, provided they are not treated with respect.

E. J. RIEDERER (Atlas Powder Company, Wilmington, Delaware): I was rather surprised to hear the statement made that sulphide of hydrogen was found recently to be rather a dangerous gas. When I went to college some years ago, prior to 1900, we received a classification of the dangerous gases and among those were ammonia sulphide and hydrogen sulphide and we were told that we should never use them except under the hood. I fear the extensive education in the colleges in trying to give all the chemistry at hand in the four years' course, has caused the elimination of some important points which were taught twenty-five or thirty years ago.

CHAIRMAN WHITING: Regarding hydrogen sulphide, the Chemical Section has already issued a single-page sheet giving all you need to know about it. Evidently you safety men should post this sheet in the laboratories where the chemists can see it.

W. A. COOK (Travelers Insurance Co., Hartford, Connecticut): Dr. Stillman, you mentioned, and I think it is generally conceded, that an oxidizing agent is not particularly dangerous in itself. Yet I have had reported cases of potassium chlorate exploding of itself when exposed to air or heat.

DR. STILLMAN: I would not say off hand it would explode unless there was something present besides potassium chlorate.

Keep the Cylinders From Tipping Over

F. A. ADAMSKI (National Carbon Company, Cleveland, Ohio) In our laboratories we use some compressed gasses and they are shipped to us in various shaped cylinders, some squat and some tall, and these are used rather intermittently. Sometimes they are used only one day and then they are set aside. Should there be some means provided for these cylinders to be fastened up so that they cannot be tipped over?

What danger would there be of the head being knocked off in cases where they do fall down? There is also, I think, a danger of the cylinder falling and hitting some one. Can anyone suggest some means for making an attachment for the cylinders to the work tables or walls or to some other place?

W. F. SIEVER (Youngstown Sheet & Tube Company, Youngstown, Ohio): In our place in Ohio we have a means of transportation for such bottles. They are placed on certain trucks which have a strap of iron connected around the top and which makes it impossible for the cylinders to fall off. We also have a general rule that if for any reason the cylinders cannot be tied to some supporting railing they should be laid down on the side and the caps provided against the breakage of the tops of the valves must remain on the bottles unless they are in actual use.

With permission I would also like to relate a little incident which may serve as a means of passing to you a safety idea which is to see that these bottles are exhausted of their gasses before they are returned to the manufacturer, especially those of oxygen and hydrogen. We had an accident in Youngstown which was caused by one of these bottles being declared as scrap and sent to the junk yard. In the process of being junked the bottle was put under shears and clipped in two and the man who used the shears was very severely injured because the bottle was still under high pressure.

CHAIRMAN WHITING: That is a very excellent and practical point. Is there any other question for Dr. Stillman? If not, I will ask him to close the discussion—and please don't forget about the mercury.

DR. STILLMAN: Well, I am not going to try to tell anybody how to chase a drop

of mercury around the floor and catch it. My suggestion will be around the other way a little bit and that is: If the table top, for example, is provided (as many of them are these days) with a raised edge, and the center of the table is cupped just a little bit, mercury will be deposited in that depression so that you can get it up. The same thing applies to the floor. If it has no cracks or depressions, that is to say, if it is a cement floor with a base board as part of the floored surface there won't be much danger of the mercury getting in. The danger in mercury is that it gets into the cracks in the floors and table tops where it is allowed to deteriorate. It gets in down there where it is impossible to get it out. But as far as trying to catch an elusive drop of mercury, I am not an authority on that subject.

I am glad to be set straight on the point of the chlorine. I introduced that rather tentatively because I didn't have the information which I should have had. It only came to me as hearsay.

Finally, on the question of the cylinders of compressed gasses, at the laboratory with which I am connected, we have found it very successful to have, as I suggested in my main paper, a cover provided on the outside of the building in which to accommodate a single row of cylinders and to have the cylinders placed individually side by side with a pipe running through the wall from the inside of the building to those bottles. You have a coupling thread to meet the standard type of cylinder and that coupling is so situated that it holds the cylinder tight against the wall and it cannot move. In that way the risk is avoided of the cylinder tipping over. Also, if the gas is not actively in use, the rule is that it must be returned to the storeroom.

Speaking of accidents caused through gas cylinders tipping over reminds me of one which occurred a few years ago. A man had become so used to handling these gasses under high pressure that he had become very careless and he would just wheel the bottles on a truck and dump them against the pile. Finally the whole row tipped over like a bunch of dominoes and the last one exploded. No one knows why it did explode and luckily it didn't communicate with the others. It was also fortunate that it didn't hurt the man. That is what may happen, however, under those conditions.

CHAIRMAN WHITING: I am glad to have this talk on the handling of gas cylinders in a proper way because I know one case where a cylinder let go and knocked the man's head off, literally.

Before going to another excellent paper which we shall have this morning, I want to state that the Nominating Committee for next year was appointed some weeks ago. It consists of Mr. I. V. Kepner of the Pennsylvania Salt Manufacturing Company as Chairman, Mr. A. L. Watson formerly of the Hooker Electrochemical Company and Mr. Crass of the Grasselli Chemical Company. They are expected to report their nominations for our new officers at the meeting tomorrow.

The question of solvents is becoming an extremely important one and we have a high authority here to tell us how we can prevent dangers in handling solvents, particularly from static electricity. Mr. A. A. Backhaus, of U. S. Industrial Alcohol Company will speak to us.

Dangers From Static Electricity in the Handling of Solvents

A. A. Backhaus, Production Manager, U. S. Industrial Alcohol Company,
Baltimore, Md.

Frictional or static electricity has long been known. Rubbing a glass rod with silk, a stick of amber with wool, stroking a cat's back to hear the crackle, shuffling over a carpet to give another person a spark shock, these are all familiar examples of methods whereby static may be produced.

The long time required to ascribe this phenomenon as the probable cause of mysterious fires occurring in the handling of flammable liquids and gases, is another illustration of mental inertia.

Many years ago Professor Monroe recognized static as a probable cause of so-called spontaneous ignition. (*C. E. Monroe—J. Am. Chem. Soc.*, 21, 317—1899). It is, however, within the last 15 or 20 years that the subject of dangers from static electricity in industry has received general attention. The advent of the automobile brought with it the handling of gasoline in enormous quantities, by many people and under various conditions. It is not surprising that under these circumstances the dangerous little static spark had many favorable opportunities. The literature references given at the end of this paper contain sufficient proof that static and flammable substances make a dangerous combination.

Figure 1. Apparatus Used by Dolezalek to Develop Static.

Fires and explosions constitute the dangers from static in the handling of solvents. Only those substances which are flammable and which have vapor pressure characteristics to produce explosive mixtures with air are dangerous.

Many solvents used in industry are flammable and produce vapors which form explosive mixtures with air, consequently, static is a possible source of danger in handling solvents. In general, static may develop in the handling of solvents as follows:

- 1—Liquid solvent flowing through pipes or tubing.
- 2—Liquid solvent passing through a gaseous medium (e.g. air).
- 3—Solvent vapor issuing from an opening into a gaseous medium (e.g. air).
- 4—Gas passing through liquid solvent.

The list of conditions thus enumerated is small. However, practically all handling of solvents comes within the range of these operations. From the fact that static fires have been confined to relatively few solvents, it must be

concluded that dangerous static arises only under certain limited conditions. If it were possible to define accurately these conditions, it would not be difficult to prescribe preventives.

Handling solvents through pipe lines or tubing is universal practice. What danger, if any, is involved?

It is a well known fact that when some liquids flow rapidly through small pipes electric potential will develop. Dolezalek (*Zeitschrift Chem. Ind.* 35, 166, 1912). and later, Holde (*Berichte d. Deut. Chem. Ges.* 47, 3239 1914), and others, have demonstrated experimentally that electrical charges will develop in this way. Figure 1 shows apparatus used by Dolezalek. Using gasoline and petroleum ether in a similar apparatus, potentials of 50 to 2,200 volts were obtained by Holde, in copper tubing 2.5 mm. diameter and 95 cm. (about 3 feet) long.

Method to Avoid Static Fires in Dry Cleaning Plants

According to Bruno Muller (*Chemiker Zeit.* Feb. 1, 1923 p. 97-98) a potential of at least 300 volts is required to give a spark strong enough to ignite gasoline.

Assuming that a potential of 300 volts is required to ignite the ordinary solvents used in industry (carbon bisulphid with its very low ignition temperature would undoubtedly ignite more easily), the question as to whether a particular solvent is likely to develop dangerous static while flowing through pipe lines must be related to its electrical conductivity.

To avoid static fires in dry cleaning plants in Germany, M. M. Richter recommended the use of magnesium oleate. It is stated that a concentration of 1/20 per cent of this soap is sufficient to prevent dangerous static in washing wool in gasoline. The soap increases the electrical conductivity sufficiently so that the charge will "drain off." Specific conductance of the gasoline soap solution is of the order 1×10^{-10} .

Bruninghaus (*Recherches et Inventions—Vol.* 7, 735, 1926) has shown that under certain conditions the presence of metal powder will render gasoline non-electric. He concludes that the substance which causes static inactivity is a substance which increases conductivity.

In view of the importance of electrical conductivity in this study a search was made to find specific conductance data for the common solvents. Unfortunately, data were found for only a few. These are shown in the table.

Specific Conductivity of Liquids (Reciprocal Ahms)

Gasoline ¹	2×10^{-12} (15°C)
Benzol ²	2.5×10^{-12}
Methyl Alcohol ³	0.2×10^{-4}
Ethyl Alcohol ³	0.103×10^{-4} at 25°C
Propyl Alcohol (N) ³	2×10^{-5}
Iso Amyl Alcohol ³	1.5×10^{-5}
Acetone ¹	0.321×10^{-4} (25°C)
Ethyl Ether ³	1×10^{-5} or smaller
Water ³	0.9×10^{-4} at 18°C

1—(Chem. Zeit. 148 (1911) p. 1375)

2—(Holde, Ber. 47 (1914) p. 3239)

3—(Jones & Lindsey, Z. Phys. Ch. 56 p. 129)

- 4—(Walden, Z. Phys. Ch. 54 (1906) p. 128-130)
- 5—(Keyes & Winninghoff, J. A. C. S. 38 (1916) p. 1178)
- 6—(Keyes & Winninghoff, J. A. C. S. 38 (1916) p. 1178)
- 7—(Walden, Z. Phys. Ch. 54 (1906) p. 128-130)
- 8—(Holde, Ber. 47 (1914) p. 3239)
- 9—(Kendall, J. A. C. S. 38 (1916) p. 2460)

An examination of the table shows that many solvents are fairly good conductors. Such solvents when flowing through pipe lines are safe statically. With liquids whose specific conductivity is low, dangerous accumulation of static may be avoided by using pipe lines which are good conductors and well grounded.

What has been said thus far applies to the handling of solvents in liquid form and confined in pipe lines. Under this condition there is little danger from static with conducting solvents.

Uncertainty Regarding a Safe Relative Humidity

The real danger starts where the pipe line ends. Here the fireworks may begin. If the line ends in the air and the stream of liquid falls, a new condition is encountered. Under these conditions high static potentials may develop with any liquid, even water. Possibilities of static from this cause are very thoroughly covered in a paper given by Naylor & Ramsey before the Petroleum Section of The National Safety Council in 1923. There is no simple grounding method of taking care of and rendering harmless static produced by liquid spray. The simple safety measure in this case is to avoid static by avoiding the spray, which can be done by discharging the liquid at the bottom of the receiving vessel or tank.

If conditions are such that liquid spray cannot be avoided, the only safety measure is to condition the air, so that the electric charges on the droplets will dissipate themselves. Ionizing the air for example with ultra violet light or X-rays, or humidifying the air will render such static harmless.

There seems to be uncertainty as to what is a safe relative humidity. In Wm. D. Milne's very interesting paper on "Fire Hazards in Churns and Spreader Rooms," read before the Rubber Section at the Twelfth Safety Congress, a relative humidity of 40 to 45 per cent is said to give a "safe" atmosphere.

The exact relation between humidity and static dangers seems not to have been covered experimentally. It is the intention of the author to investigate this question.

Dangers in the Use of Hydrogen Gas in Air Navigation

The third general method encountered in handling solvents covers solvents in vapor phase, i. e., in gaseous form. Some very interesting work has been done in connection with the study of static produced by gases. The use of hydrogen gas in air navigation involves dangers and accidents from static ignition of hydrogen gas. Articles by Nusselt and by Pothmann appearing in 1922 in the *Zeitschrift des Vereines Deutsche Ingenieure* are very interesting. The following is translated from Nusselt's article:

"Although hydrogen is used extensively in industry, an unusual and undesirable property of this gas has become evident in connection with its use in air ships. In the hangar the gas bags are filled with hydrogen gas

delivered through pipe line from the gas works. The distributing pipe is usually laid in a trench in the hangar and connected with the supply main. The distributing pipe has a number of branch outlets to which hose connections are made for filling the individual gas bags of the air ship with hydrogen. It was frequently observed that hydrogen gas, blowing out through leaks would ignite spontaneously. This occurrence had been observed by Count Zeppelin in Friedrichshafen and in his first air ship hangar pails of water and wet blankets were kept on hand to extinguish such fires. It was further observed that on opening valves on compressed hydrogen cylinders, flames would issue. Naturally, these spontaneous fires resulted in loss of air ships. In one case, after a newly built ship had just arrived in a new hangar, replenishing of gas bags was in progress when suddenly flames shot out of the water drain of the filling header and destroyed ship and hangar. In another case, two marine air ships were in one hangar. A sailor had just finished filling a gas bag in one of the ships. After detaching the connecting hose from the gas bag, he laid the open end on the floor in the hangar, contrary to orders. The valve on the main pipe was not tight, so that some hydrogen bled out of the open end of the hose. Suddenly flames shot out of the open end of the hose and both ships as well as hangar were destroyed by fire. As these cases increased during the war the Reichsmarineamt created a commission to study the spontaneous ignition of hydrogen."

The Conclusions of Nusselt

The work done by Nusselt in connection with the problem is summed up in the following conclusion which he draws:

"The results of my experiments may be summed up briefly as follows: In spite of many attempts it was impossible to cause spontaneous ignition of pure and clean hydrogen from a leak in a line. Spontaneous ignition can take place only when dust particles flow out with the hydrogen. Because of the friction during discharges, the dust particles become electrically charged. Sparks from these charged particles lead to the ignition of the gas."

The results published by Pothmann covering his study of static with gases, particularly hydrogen, also how that clean gas is non-electric. However, when a liquid or solid is present in the jet of issuing gas static charges will accumulate.

The steam jet, utilized in the old Armstrong hydroelectric machine, will develop static of high voltage. The invisible portion of the jet at the opening from which the steam issues is not charged. It is only after condensation takes place that static charges develop, presumably due to friction of the droplets through the gaseous medium.

The Use of Air For Agitation

There are many anhydrous liquids which will not generate dangerous static flowing through pipes; likewise, gases in motion through the air will not develop static unless solid or liquid particles are present.

Very little practical information is available covering the fourth condition listed at the beginning of this paper. The use of air for agitation is a common practice in chemical industry. Air is extensively used for agitating alcohol to render the contents of a tank uniform. To my knowledge, no accident has ever

resulted from this practice, due probably to the fact that alcohol is, relatively speaking, a good conductor.

It is doubtful if this practice is a safe one in the case of solvents having low conductivity.

A scientific investigation of this problem would be very helpful.

Danger of Ignition From Steam Generating Static

CHAIRMAN WHITING: I think all of you handle solvents more or less which might catch fire unexpectedly from this static source. I know Mr. Backhaus would be very glad to answer any question on the details of static. I would like to ask him one in regard to dry cleaning plants where they use steam jets as a fire protection methods. Possibly you have them in some of your chemical plants where you have an appreciable vapor leakage in a room and you want to smother it. Is there danger of ignition from the steam generating static?

MR. BACKHAUS: I believe there is an element of danger in that practice. In a condition of that kind you usually have a very high concentration of the solvent vapor. If the atmosphere has a vapor concentration above a certain critical concentration then that vapor will not explode. There is a low limit and a high limit above which or below which the mixture is not explosive, and outside these limits you could have a high development of static from the steam jet and still not get an explosion. But there is no doubt that there is an element of danger in the use of steam for extinguishing fires.

CHAIRMAN WHITING: Could Mr. Armstrong of the Eastman Kodak Company tell us any of their experiences in the handling of solvents?

A. L. ARMSTRONG (Eastman Kodak Company, Rochester, N. Y.): I would like to say first that I sat in on the New York State dry cleaning laws. I was on a board in Rochester that went over these laws and they have written into their laws that in all dry cleaning plants they must maintain a humidity of sixty per cent. Previous to that law being passed I think it was definitely proved by the dry cleaning industry that forty per cent relative humidity would kill the danger of static from benzine and gasoline which were exclusively in use. They don't use much acetone in cleaning and dyeing works.

I know of only one explosion and that occurred about three weeks ago in Rochester in a dry cleaning plant. I was there about 25 minutes after the explosion occurred, and we learned definitely that a steam humidifying jet was not provided in the dryer. We have a similar cleaning plant for the cleaning of filter cloths and in our ventilating system we put a low pressure steam jet back of our fan and maintain a humidity of about sixty.

Use of Chains to Drain Off Static

If steam is fed in back of the fan, I do not believe you need ever fear static coming from your steam because the steam would have to pass through the fan with the air and it would be thoroughly mixed and would give you a proper relative humidity in all parts of your room.

Another thing which came up in our plant was the use of chains to drain off static. They are very extensively used. They are used by the Standard Oil Company. In fact they use a chain in the center of their pipe and pass the liquid over this chain, and in some cases they don't drag a chain on the ground any more as they used to do. It is claimed that the chain takes all the static out.

We have a process where it is necessary to handle dust at a very high velocity through a pipe and this generates much static, so much so that we get sparks two,

three and four inches long. We had to stop operation and spend practically a month on research before we found out why we couldn't eliminate the static. The reason for this was that the chain which we had inside the pipe was not solid, that sparks would build up and would jump from one link to the other. We replaced that chain with an ordinary stranded copper cable about an eighth of an inch in diameter. All our groundings are being done with that type of cable now.

Another weakness we found is the practice of merely laying on of a ground. If you attach it to the pipe and lay it against the container into which your solvent is flowing it will not give you a good ground. We put a regular lug on the end of our cable which is soldered on, and we drill through the pipe and solder in an eighth inch bolt with a lock nut and use a wing nut, so that we have a perfect ground at all times. That is absolutely necessary because I can say from actual experience with acetone that any static spark that is visible to the eye will ignite acetone vapors. Now, that is a pretty small spark but it will actually do it.

Difficulty In Getting Quality of Hydrogen Wanted

E. C. ROGERS (Grasselli Chemical Company, Cleveland, Ohio): Several speakers have referred to the matter of hydrogen. I just wonder what hydrogen users do to insure that they get what they order when they order hydrogen. Here is an example of what I mean: We have ordered ninety-nine per cent hydrogen and we might get back anything from what we ordered to a tank containing as much as fifteen per cent oxygen. With those things going on we are apt to have some unhappy experiences. I am just wondering what to do to insure ourselves that we get what we order. If we test it we are apt to blow up a chemist in the act of testing.

A. B. NIXON (Hercules Powder Company, Parlin, N. J.): We test every tank of hydrogen by merely taking a small gas sample in a large open-mouthed bottle and then applying a flame to it. It is absolutely safe, and if it explodes it can't hurt anything because the bottle is wide open.

CHAIRMAN WHITING: Another static problem is that of handling sulphur. Mr. Kepner, will you tell us your experience?

I. V. KEPNER (Pennsylvania Salt Manufacturing Company, Philadelphia, Pa.): I brought this question up some years ago in reference to the problem we had in handling sulphur. We receive our sulphur in ships, and it is loaded from the ships into the hopper drop cars—railroad cars—and taken up to our storage bin where it is dropped. Time after time we have had explosions and they were really severe and generally caused a fire. I have told this two or three times but I will tell it again for the sake of some of you who probably haven't heard it yet. We were at a loss to know what had caused these explosions so we had the underwriters come down to investigate the fires and they said it was static.

The Problem of Handling Sulphur

We got the electrician and had him ground all the bins and then we thought everything was properly taken care of. The underwriters came down and said that is fine, captain, you will never have any trouble now. We didn't have the next day. We dropped the car as usual and everything was fine and we thought we were all set. After we thought we were sitting pretty it blew one of the employees clear off the bridge and set his clothes on fire. We didn't know what to do about it. We had our fire hose and everything handy ready to put out the fire after it started but no one could give me any real data on it. We didn't know what it

was. They said static, but how were we going to take care of it if we were already grounded?

Some years ago I presented the problem at our Wilmington midyear meeting and thought perhaps some one might give me a solution of this mystery. One of the boys from the Hercules Powder Company spoke of a ship they had which was unloaded with a clam-shell bucket. He said, all at once the ship took fire and there was a terrific explosion and the ship burnt to the water's edge. Some chap conceived the idea of spraying the sulphur as it was falling. They tried this out and have had no more explosions since. I thought it was a good stunt and I took it back to the plant. The pipe fitter got a couple of automatic sprinklers and rigged them up and turned on the spray where we dumped our sulphur and we haven't had an explosion since. Now all our bins at the various plants are all equipped with the same sprays and that has been the answer to the problem of static in the handling or dumping of sulphur.

If any of you have a similar problem I wish you would try it out. It worked for us and I am sure it will work for you. It has saved us a lot of money, and I think it has only cost about five dollars per head.

Method of Correcting the Problem with Sulphur

MR. ARMSTRONG: We had the same problem with sulphur and we used low pressure steam to correct it. I would just like to add one thing on static and that is the choice of metals. If there are any of you people who have a lot of grease on your scrubbing tables this will help you. It has been the general practice to use zinc and some have tried out aluminum. An aluminum or zinc chute for dust or materials which will build static charges, will not carry the charges away due to the fact that in a very short time it oxidizes and you have zinc oxide or aluminum oxide which are not good conductors.

CHAIRMAN WHITING: Are there any other questions? Those of you who are handling solvents must keep in mind the fact that because you haven't blown up yet is no proof that you haven't any static and Mr. Backhaus' recommendations should be put into force. Have you anything to say in closing the discussion, Mr. Backhaus?

MR. BACKHAUS: No, except something on this question of compressed gasses. I might relate an experience in our own laboratory in connection with compressed acetylene. We were using a small cylinder of this in the laboratory and it was standing up on a little pedestal about two feet off the floor when not in use. For some unknown reason it fell down and in falling it hit the concrete floor and the valve broke off. That was followed by a terrific explosion although the amount of gas involved was relatively small.

Now, we don't know what caused it but my own supposition of it was that it was static. The high velocity at which the acetylene issued from the small opening of the valve generated enough static to cause the explosion of the mixture of air and acetylene.

CHAIRMAN WHITING: Before we close, there is a question asked of Dr. Stillman. Will you please reply.

DR. STILLMAN: The question is: "Do you consider a routine laboratory or a research laboratory the more hazardous and why?"

A research laboratory may in some ways be more hazardous for it is dealing with new problems all the time and in that way meeting things which are not familiar. The plant or routine laboratory on the other hand has a process more or less familiar and hazards which are more or less known, if it is a routine labora-

tory in the sense of a control laboratory in the plant and I should say the hazards in that laboratory are not any greater than in the plant itself.

This question brings up something which I meant to mention before. The chairman at the opening said that the chemist in turning over to the plant a new process in many cases did not inform the plant of the dangers involved or the character of the materials being manufactured. It seems to me that such a situation is a case of the chemist falling down on his job. He has not given the complete information which is necessary. The suggestion that those of us who are connected with research laboratories should take home with us is that we should furnish all such information we have when a new process is turned over to the plant.

CHAIRMAN WHITING: I hope the safety man will ask the chemist for full instructions on safety, of any novel process or apparatus.

ADJOURNMENT.
