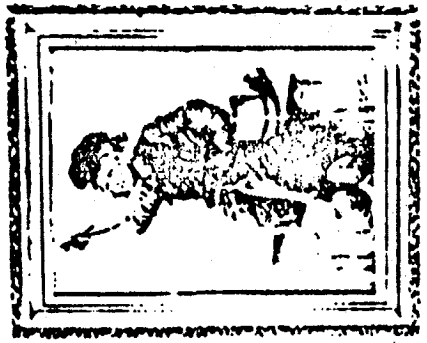
NATIONAL LEAD COMPANY

F-95-55



The "Dutch Boy" trade mark, which has identified National Lead Company products since 1907, is synonymous with protection in the minds of millions. It is, as well, a symbol of quality, a pledge of dependable service.

RADIATION SHIELDING

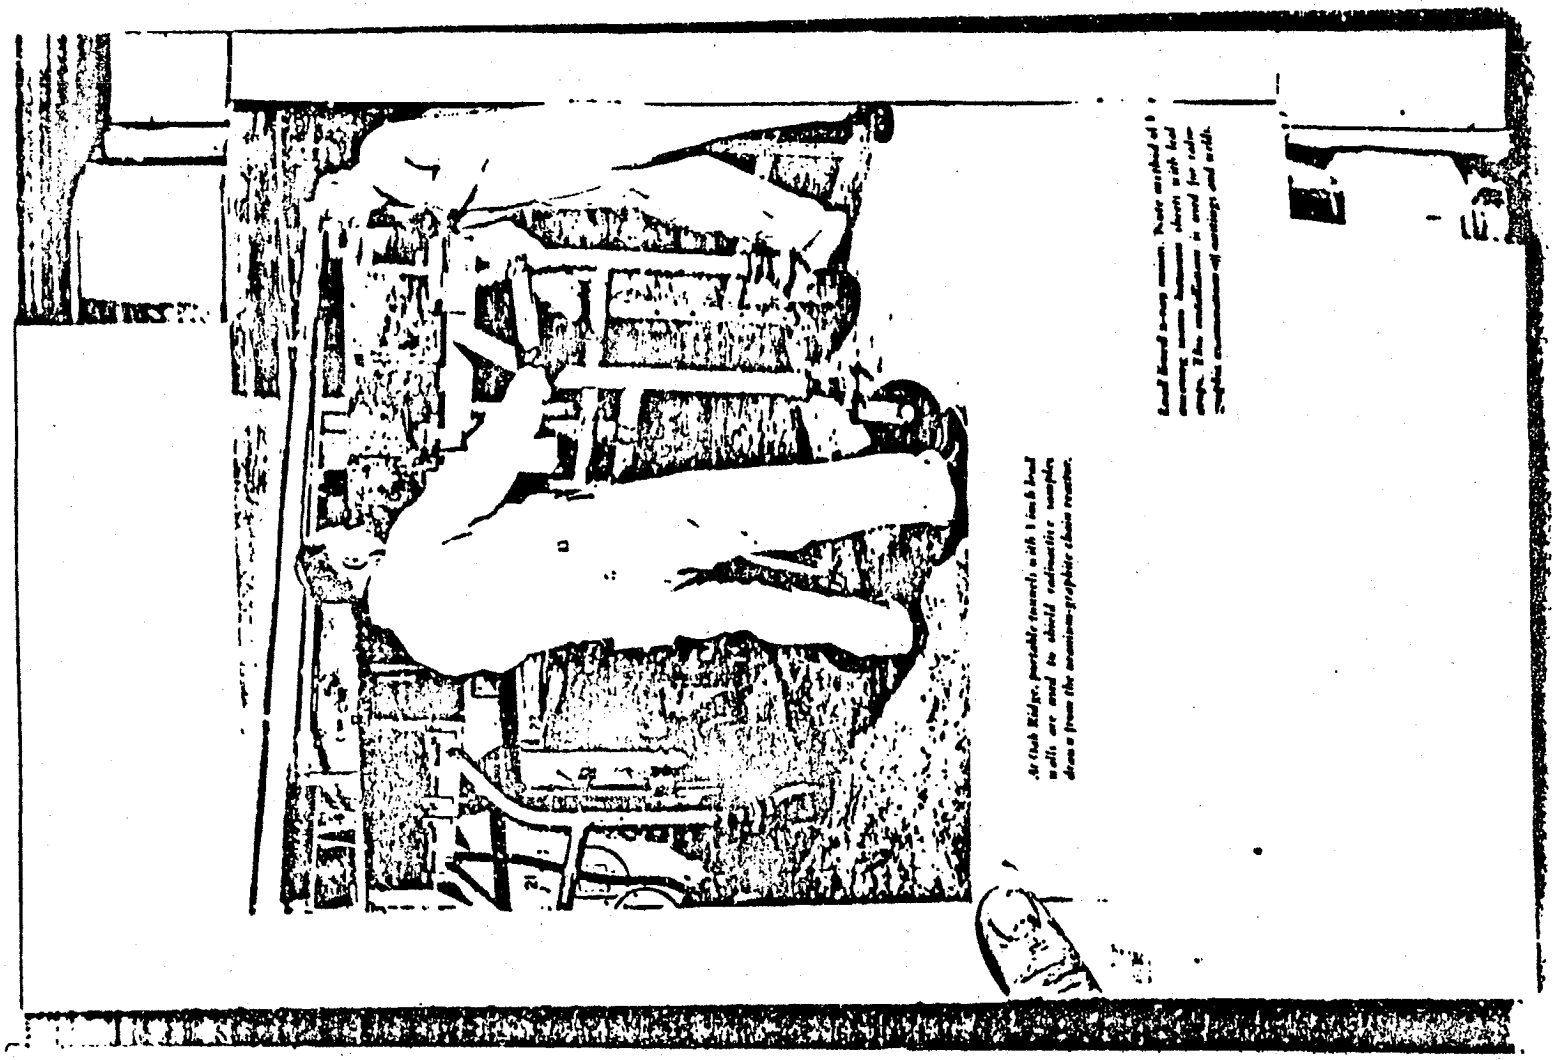
Materials for protective purposes have long been major items in the portfolio of products of National Lead Company. Paints ... to protect wood, masonry and metal structures from deterioration by weathering are in this category. Bearing metals to protect machinery parts from the wear and tear of friction, may be included. Lead wool and calking lead to protect against damage by leakage at pipe joints and tunnel "[illegible]" also qualify, as do lead mats placed under buildings to protect the structures from the effects of vibration. Lead sheathing and sleeving is used to protect underground and underwater cables from attack by boring insects and corrosive elements. Lead in many fabricated forms is of vital importance in the chemical industry, protecting all manner of equipment from attack by corrosive substances. Lead sheet is relied upon in practically all X-ray installations to shield personnel from harmful radiation.

It may thus be seen that devising, producing and marketing "materials of protection" is an old story at National Lead Company.

Out of this background, this long and varied experience, National Lead Company comes well prepared to meet the needs of a new industry based upon the splitting of the atom.

The shielding problems associated with atomic energy and its byproducts are, of course, somewhat similar to those of x-rays and radium, but they are greatly magnified by wider use and higher intensities.

F-99-55



Of the four types of rays or particles involved in atomic disintegrations — alpha, beta, gamma and neutron — we are concerned here with gamma and neutron emission. Alpha particles can be stopped by a few inches of air or a sheet of paper. Beta particles, faster and more penetrating than alphas, are usually absorbed by an inch or so of wood.

Gamma rays are another kettle of fish with. High energy gammas will not be completely stopped by even a foot thickness of any dense material. On the other hand a quarter inch lead sheet will absorb low energy gamma radiation.

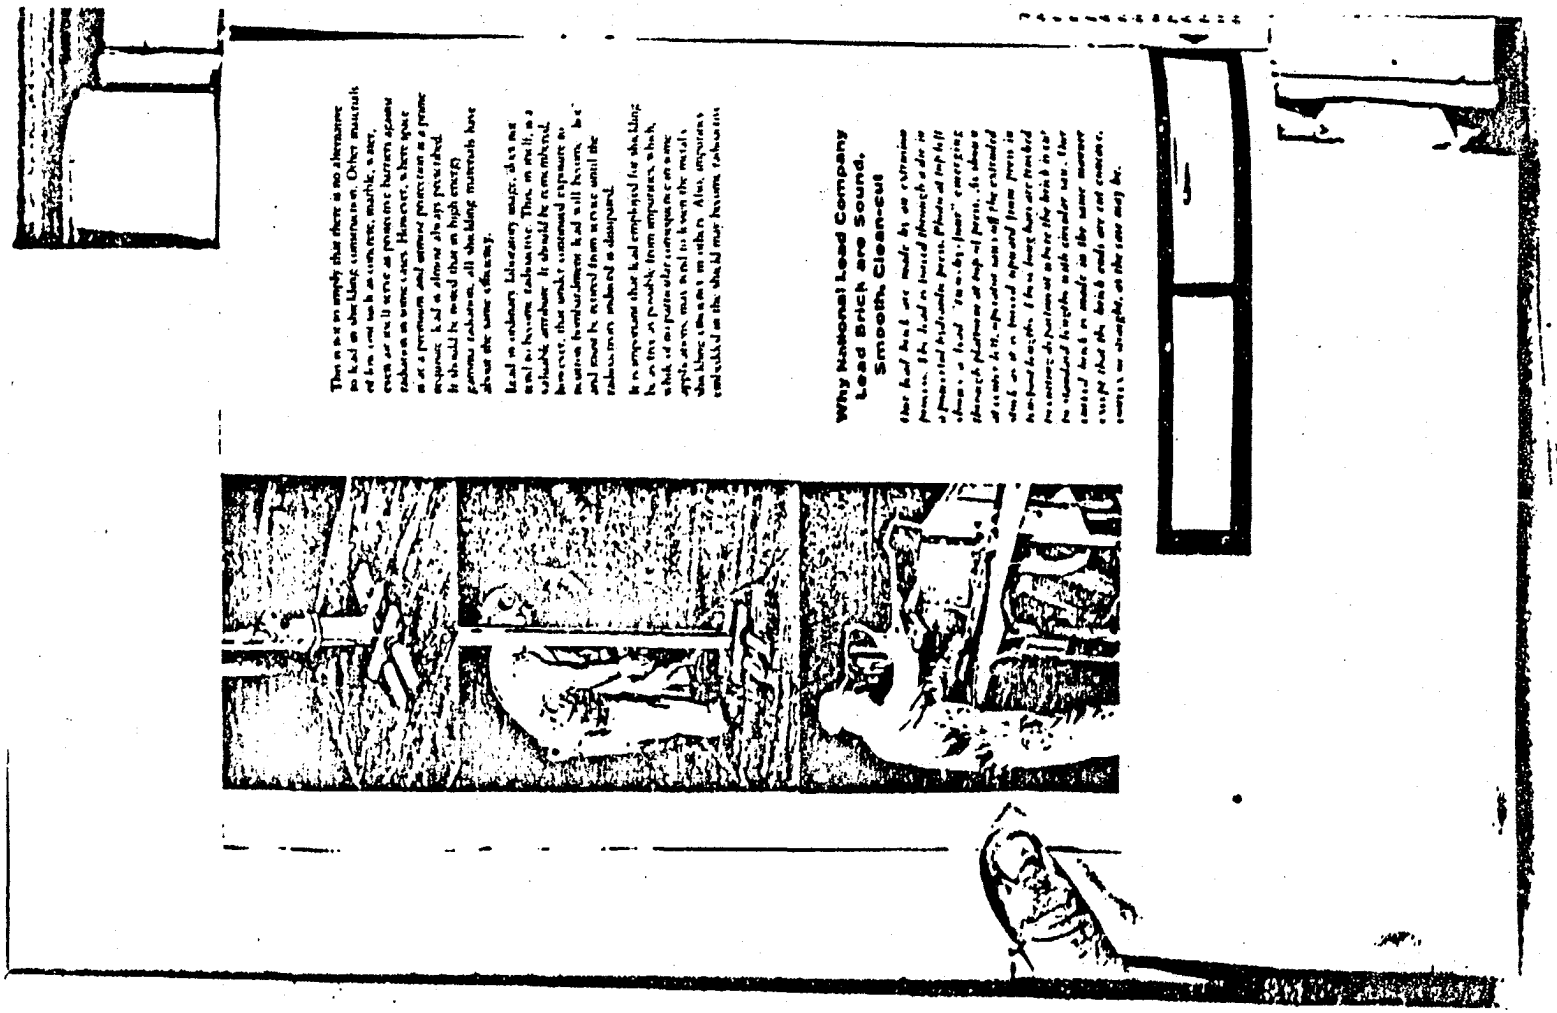
Neutrons produced in an atomic pile or accelerator are uncharged particles that will interact with atomic nuclei in various materials. According to their energy levels, neutrons are classified as very fast, fast, slow and thermal.

Metallic cadmium or hydrogenous materials such as water or paraffin are generally used as shielding against neutrons. However, since gamma rays are emitted when neutrons are absorbed, it is still necessary to provide a shield of lead or some other dense material. The use of protective shielding is advised in all cases, regardless of the type of radiation, the thickness of the shield depending upon the penetrating power of the rays.

The most important factor in the absorption of radiation is density. Lead, with a specific gravity of 11.35 is the densest commonly available material.

In the usual gamma radiation ranges, lead is considerably more effective than iron, for example, which has a specific gravity of "8." There are a few other materials of even greater density than lead but these are generally used as shielding because of their use in the quantities in which they would be needed.

F-95-55



Why National Lead Company Lead Brick are Sound, Smooth, Cleanest

Since it is a metal, lead has an advantage over aggregates such as concrete and other types of masonry in that when properly fabricated, it is of consistently high density and especially so when the lead has been formed by extrusion, drawing or rolling processes. Moreover, the normally smooth surface of metallic lead is not prone to collect dirt or other substances which may become contaminated. Should contamination occur, it may be removed with a cleansing agent such as nitric acid in four parts of water.

One of the convenient forms of lead for barrier purposes is brick. As furnished by National Lead Company, the brick is produced by an extrusion process in regular lead pipe presses equipped with proper dies.

National Lead supplies brick of many types and sizes, the most popular being 2" x 4" x 8" and 2" x 3" x 6". One type has the contour of the conventional building brick with all sides flat. Another is a curved brick, with all segments forming end-to-long faces rather concave or convex. Especially cut brick of this curved type are made for connecting. With these so-called "interlocking" brick there is no practical limit on size or shape of wall-type shields.

When a "brick wall" barrier is built over any particular shielding setup, the adherence of the curved type is obvious — there are no straight vertical or horizontal seams that could block rays as may be the case with conventional brick.

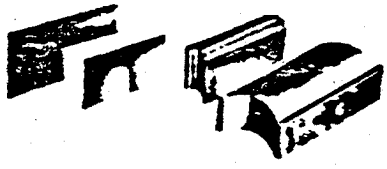
Both types of brick stack compactly and may be used as building elements of any practicable height with little risk of toppling.

It should be emphasized here, perhaps, that extruded brick as produced by National Lead Company have a through and through uniform density which does or may not be true with gravity cast brick. Also the bonds and the joints of extruded brick materials are smoother and cleaner than is the case with the cast variety.

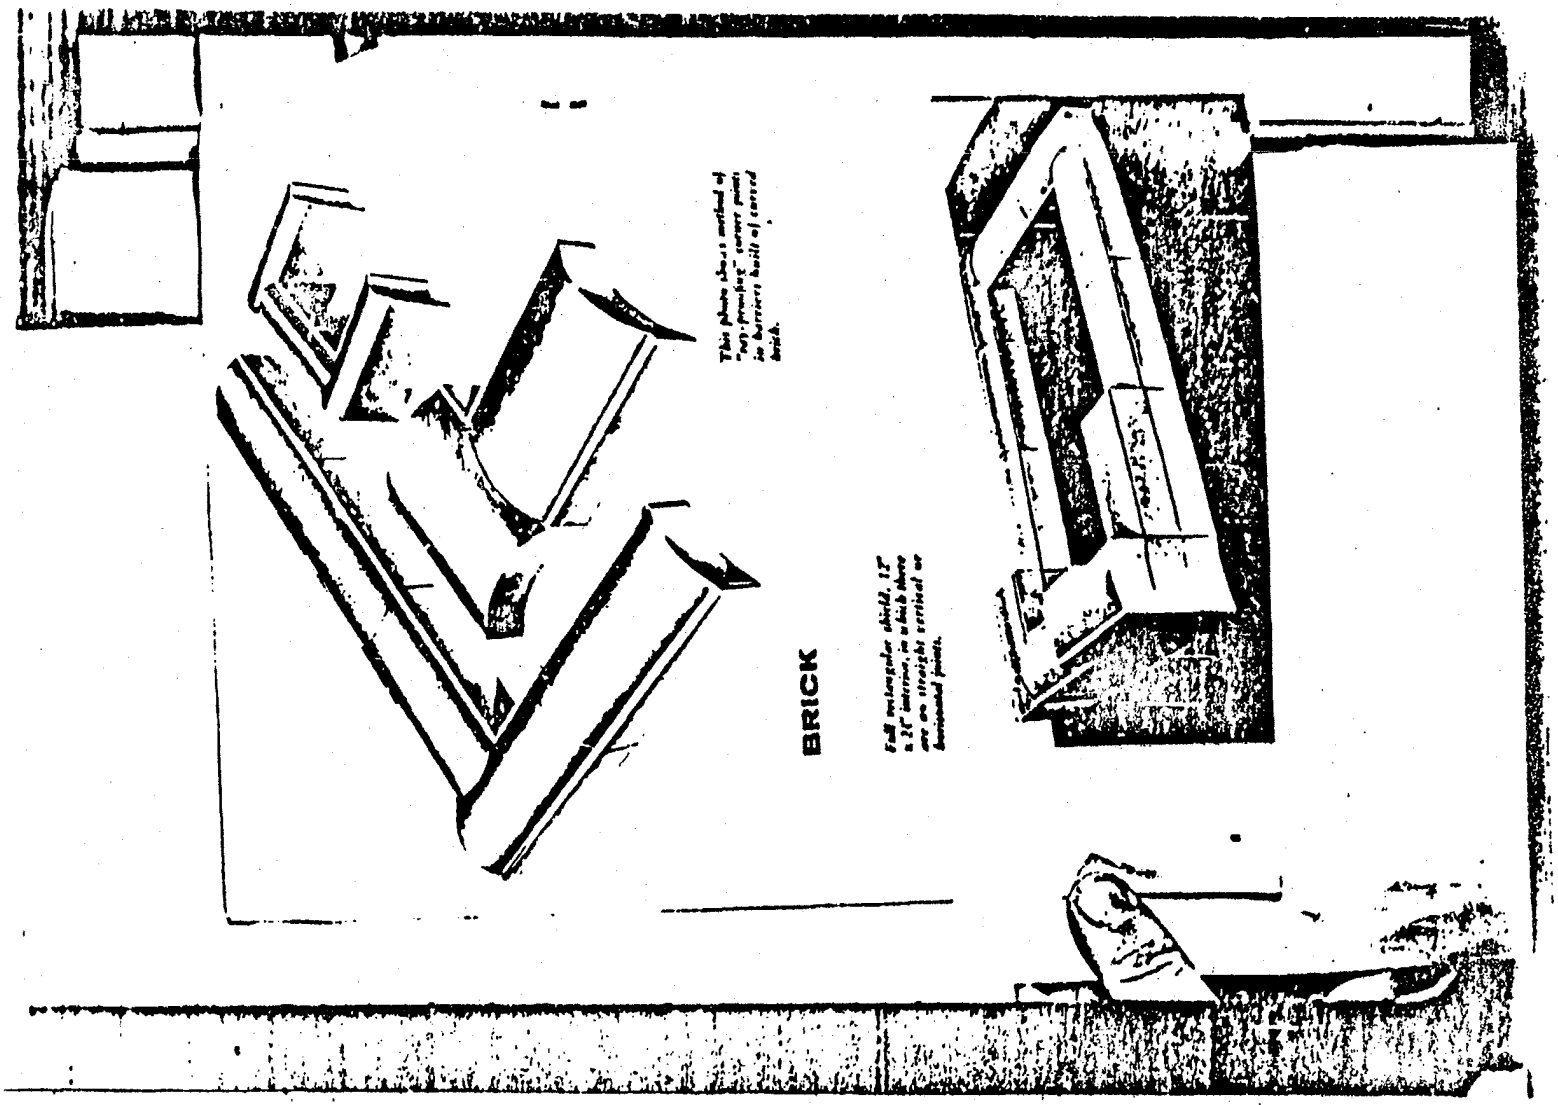
In addition to brick, National Lead Company produces lead shipping containers, cartons, tubes and other "housing" for radioactive materials, as well as "key point" containers for the safe keeping of film. As a leading maker of lead pipe work, the Company has the facilities for manufacturing virtually any type of lead radiation barrier. A nation-wide network of plants and warehouses offers assistance of prompt, farsighted delivery. ●

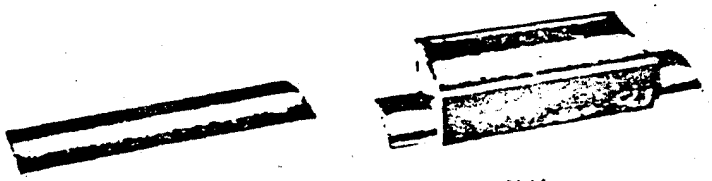
Typical straight-side and curved lead brick produced by extrusion process by National Lead Company.

Two lead brick size 3" x 4" x 8" — one cast in an open mold (right), the other extruded through a die in a hydraulic press (left) — were sawed in half lengthwise, to show internal structure. After planing and buffing, the halves were photographed. The photos were retouched to kill highlights and achieve uniform tone on both brick. The mold and shrink-hole were also touched.

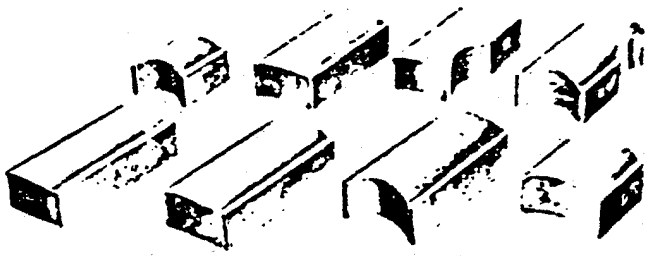


F-95-55





For bench or table barrier installations, using curved brick, requiring full-area surface contact, suitable lengths of lead "foundation strip," on which to lay first course of brick, are available.



WEIGHT OF LEAD SHIELDING

Lead weighs 11 lbs. per cubic inch—710 lbs. per cubic foot. A conventional flat-sided lead brick 2"x4"x8" weighs 20.2 lbs. A small, flat-sided lead brick 2"x4"x8" weighs 19.66 lbs.

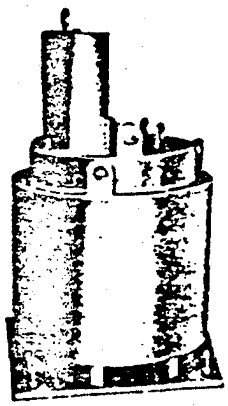
NATIONAL LEAD COMPANY CURVED BRICK

	Regular size	*Small size*
Model A, Standard brick	25.25 lbs.	14.33 lbs.
Model B, Header male	26.25 lbs.	14.88 lbs.
Model C, Header female	26.25 lbs.	14.88 lbs.
Model D, Header, half-brick male	13.50 lbs.	7.33 lbs.
Model E, Header, half-brick female	13.50 lbs.	7.88 lbs.
Model L, Male brick	26.25 lbs.	15.25 lbs.
Model M, Left corner brick, female	25.75 lbs.	15.05 lbs.
Model N, Right corner brick, female	25.75 lbs.	15.05 lbs.

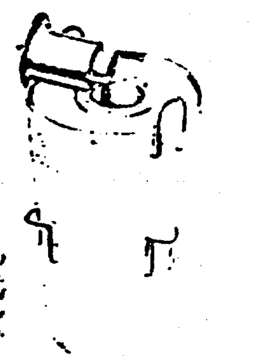
Lead as sheet form weighs approximately one pound per each 1/64" of thickness per square foot. Thus so-called "4-lb." lead (eight pounds per square foot) is approximately ⅛" thick. The standard size for lead sheet weighing sheet or sheet pounds per square foot is 4'x8'x⅛". The standard size for lighter sheet is 4'x8'x1/16".

F-95-55

CASKS

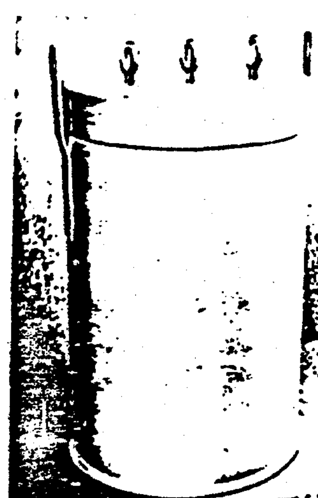


Lead (steel-jacketed) Exposure Radiation Cell (approx. 13,500 lbs.) of complex construction.

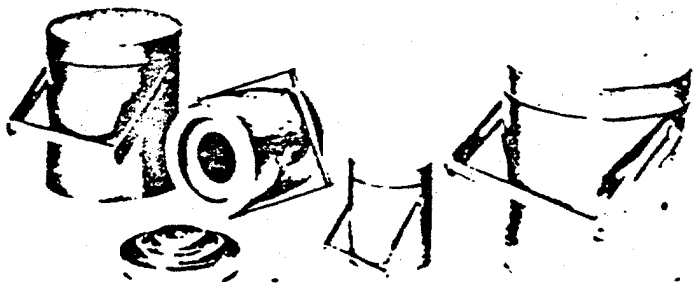


Lead (steel-jacketed) Transfer Cask (approx. 3,000 lbs.) equipped with drainage duct in "hot" cavity.

Lead safe for storing Cobalt-60. This is virtually a solid lead cube, approximately 20" x 20" x 20" with five extruded lead "drawers" with small cavities in which the radioactive material is kept. Safe weighs about 1200 lbs.



Typical lead "pig" or cask used for storage of radioactive materials.



SHIPPING CONTAINERS FOR RADIOACTIVE MATERIALS

We manufacture a complete line of stainless steel-clad lead containers for shipping radioactive isotopes. The standard cartons shown here have ½", 1", 1½" and 2" lead protection. Cartons in all these sizes are 11½" diameter, the depths varying from 21½" in the largest size to 11½" in the smallest. Weights range from 98 lbs. down to about 6 lbs. Handles are designed to lock down on cover in transit. They may also be easily removed for convenient insertion of container in larger storage casks.

These shipping containers are of top quality construction throughout. The lead shield is fabricated by a special method to eliminate all possibility of porosity.

SPECIAL HI-HARD BRICK

Where extra conditions are severe, that is, where brick are subject to much mechanical abuse in erection or dismantling of furnace, we are prepared to furnish special lead brick with a Brinell hardness about four times greater than that of conventional brick. That is to say, whereas regular lead has a hardness of 4, this special product has a hardness of approx. 17. The small amount of antimony contained in Hi-Hard brick affects a slight reduction in the density — from 11.35 to 11.11. In other words, an increase in hardness of about 400% is obtained which represents 98.20% of the shielding efficiency (density) of regular lead.

F-95-55

REQUIRED LEAD SHIELDING THICKNESS FOR GAMMA RAYS

The table below, prepared by the National Bureau of Standards, is frequently used in determining the thickness of lead shielding needed for shielding from gamma ray sources in laboratories.

To use the table select the column for the energy required. (Use next higher figure if exact value is not given.) The entry gives thickness in centimeters of lead for different source strengths at 1 meter for 8 hours per day to give 50 milliroentgens. Then add algebraically the correction terms for other working ranges or times to obtain the shield thickness required.

Example: Shield is needed for handling 500 millicuries of radioactive material emitting 1.5 million electron volts (Mev) gamma rays at a minimum working distance of 50 cm, and 4 hours per day.
Shield thickness = 8.60 + 2.77 − 1.39 = 9.98 cm of lead
(a) (b) (c)
in which a = from entry, b = correction for danger range = 50 cm, c = correction for 4 hours per day.

Photon Absorption as a Function of Energy

In addition to movable shielding as typified by the lead items described here, National Lead Company produces heavy minerals such as barites and magnetite for mixing with concrete in the construction of massive shielding.

Information on these high density materials may be obtained by writing National Lead Co., 111 Broadway, New York 6, N.Y.

While the potentialities of "mobile" shielding have not been fully explored, a paste-red lead shielding material has been developed by National Lead Company. This is a high viscosity, high density paste made by combining dry red lead with a non-drying oil, with additives added to insure uniform and lasting dispersion of solids in the liquid. A gallon of this paste shielding weighs 29.2 lbs. The specific gravity is 3.5
