COMPLIANCE STATEMENT

104-Week Dietary Chronic Toxicity and Carcinogenicity Study with Perfluorooctane Sulfonic Acid Potassium Salt (PFOS; T-6295) in Rats

All aspects of this study were in accordance with the Good Laboratory Practice Regulations as set forth in Title 40 of the US Code of Federal Regulations Part 792, issued November 29, 1983 (effective December 29, 1983), and with any applicable amendments.

ABSTRACT

The purpose of this study was to assess the chronic toxicity and carcinogenicity of Perfluorooctane sulfonic acid potassium salt (PFOS; T-6295), also referred to as T-6295, when administered in the diet to rats for at least 104 weeks. Due to excessive mortality, female animals in Group 3 were terminated during Week 103.

Male and female Crl:CD®(SD)IGS BR rats were assigned to six groups (70 animals/sex/group for Groups 1 and 5; 60 animals/sex/group for Groups 2, 3, and 4; and 40 animals/sex/group for Group 6). Each group received diets containing acetone, the vehicle (Group 1), 0.5 (Group 2), 2 (Group 3), 5 (Group 4), or 20 (Groups 5 and 6) ppm T-6295. Group 6 was placed on recovery after 52 weeks of treatment.

Food was provided *ad libitum*, except when animals were fasted. Water was provided *ad libitum*. The animals were observed twice daily (a.m. and p.m.) for mortality and moribundity; findings were recorded as they were observed. At least once prior to treatment and weekly thereafter, each animal was removed from its cage and examined; abnormal findings or an indication of normal was recorded. Body weight data were collected weekly through Week 17, once every 4 weeks thereafter, and at Week 105. Food consumption data were collected weekly for the first 16 weeks and once every 4 weeks thereafter. During Weeks 4, 14, 27, and 53, blood and urine were collected for hematology, clinical chemistry, urinalysis, and urine chemistry tests from 10 animals/sex in Groups 1 through 5. Blood was collected for cholesterol and triglyceride determinations from all animals prior to the terminal sacrifice during Week 105 (Week 103 for females in Group 3) and the recovery sacrifice (Group 6) during Week 106. Blood films were also prepared for animals at the terminal and recovery sacrifices. Five animals/sex in Groups 1 through 5 were sacrificed during Week 4; livers were collected and weighed. [The liver samples were collected for PFOS analysis, mitochondrial activity, hepatocellular proliferation rate measurements by proliferation cell nuclear antigen (PCNA), and determination of palmitoyl-CoA oxidase activity. In addition, liver samples were collected for PFOS analysis (Weeks 14, 53, 103, 105, and 106), hepatocellular proliferation rate measurement [by PCNA at Week 14 and by bromodeoxyuridine (BrdU) immunohistochemistry at Week 53] and palmitoyl-CoA oxidase determination (Week 4 and 14).] A section of duodenum was also collected at Week 53 for BrdU immunohistochemistry. During Weeks 14 (Groups 1 through 5) and 53 (Groups 1 and 5), necropsies were performed on five and 10 animals/sex,

respectively. Surviving females in Group 3 were sacrificed and necropsied during Week 103 because of reduced survival. The remaining animals in Groups 1 through 6 were sacrificed and necropsied during Weeks 105 and 106. At necropsy, macroscopic observations were recorded, organ weights were obtained (Weeks 14 and 53), and tissues were placed in fixative as specified by the protocol. At the terminal and recovery sacrifices, sections of the heart and liver were preserved in 2.0% parafomaldehyde/2.5% gluteraldehyde in 0.1M phosphate buffer, processed, and embedded in epoxy resin for possible future electron microscopy from 10 animals/sex in Groups 1, 4, 5, and 6. Animals that died on test or were sacrificed at unscheduled intervals were also necropsied, but organ weights were not recorded. Microscopic examinations were done on selected tissues (adrenals, brain, eyes, kidney, liver, mesenteric lymph node, pancreas, spleen, testes, and ovaries) from the animals necropsied during Week 14 and on all tissues from the animals in Groups 1 and 5 that were necropsied during Weeks 53, 105, and 106. In addition, microscopic examinations were done on the tissues from animals that died or were sacrificed due to poor health. Macroscopic lesions, liver, lung, kidneys, pancreas, thyroid, testes, and mammary gland (females), and urinary bladder were examined for animals in Groups 2, 3, 4, and 6 that were sacrificed during Weeks 103, 105, and 106.

Liver sections from five animals/sex/group from Groups 1 and 5 were stained with Oil Red "O" and examined microscopically. In addition, liver samples from five animals/sex/group were processed and evaluated by electron microscopy.

Survival after 104 weeks of treatment was 22.0, 22.0, 34.0, 50.0, 45.0, and 27.0% for males in Groups 1, 2, 3, 4, 5, and 6, respectively, and 50.0, 30.0, 20.0 (after 102 weeks), 34.0, 52.0, and 48.0% (after 104 weeks) for females in Groups 1, 2, 3, 4, 5, and 6, respectively.

There was a significant increased trend in survival that occurred in the males that was due to significant increases in survival in mid-high (5.0 ppm) and high-dose (20.0 ppm) groups as compared to that of the control group. None of the other treated groups in the males revealed any significant differences in survival. No significant trend was noted in survival in females. There was a significant decrease in survival in the mid-dose (2.0 ppm) group and not in the mid-high (5.0 ppm) and high-dose (20.0 ppm) groups as compared to that of the control.

There were no clinical observations attributed to administration of the test material.

Males given 20 ppm (Groups 5 and 6) had significantly lower mean body weights compared to animals in the control group during Weeks 9 through 37. During recovery the mean body weights for Group 6 males were similar to mean body weights for Group 5 males. Females in Group 5 given 20 ppm had significantly lower body weights compared to animals in the control group during Weeks 3 through 101. Mean body weights for females in Group 6 given 20 ppm were statistically lower than mean body weights for control females during Weeks 3 through 61, but their mean body weights became nearer to the weights of the control females when placed on recovery. At Week 105, mean body weights for surviving males were 98, 108, 103, 101, and 96% of controls for the low- (0.5 ppm), mid- (2.0 ppm), and high-dose groups (20.0 ppm), respectively. At Week 105, mean body weights for surviving females were 101, 107 (Week 101), 100, 86, and 105% of controls, for the low- (0.5 ppm), mid- (2.0 ppm), and high-dose groups (20.0 ppm), respectively.

Mean body weight change was statistically significantly lower for males given 20 ppm diets for Weeks 1 through 15 and Weeks 15 through 29. Mean body weight change was statistically significantly lower for females given 20 ppm for Weeks 1 through 15 and Weeks 29 through 57 (Group 5 only). Mean body weight changes for males and females in Group 6 were significantly increased during the several weeks of recovery. Animals at lower dose levels occasionally had statistically significantly decreases in body weight gain; however, these occurrences were inconsistent over time between sexes and were not clearly dose-related.

Although not always statistically significant, males given 20 ppm tended to consume less food during Weeks 1 through 24. Food consumption was similar for males given 20 ppm compared to animals given the control material during Weeks 28 through 104. Statistically significantly lower food consumption was noted frequently for females given 20 ppm during Weeks 2 through 44. Food consumption for males and females was similar in all the other treated groups compared to animals given the control material.

Dietary administration of PFOS for approximately 53 weeks was associated with mildly higher urea nitrogen for males and females fed 5 or 20 ppm; mildly lower glucose for males and females fed 20 ppm; mildly to moderately lower cholesterol for males and females fed 20 ppm; and mildly higher alanine aminotransferase for males fed 20 ppm.

None of these effects were considered adverse. The effect on cholesterol was no longer apparent after 104 weeks of treatment. There was no effect on hepatic palmitoyl-CoA oxidase activity.

Terminal body weights in males and females at Week 14 were comparable between control and treated groups. At the Week 14 interim sacrifice, absolute and relative liver weights were significantly increased in the males given 20 ppm. In females given 20 ppm, only the liver-to-body weight percentage was significantly increased. Test material-related histomorphologic changes were limited to the liver in the males given 5 or 20 ppm and in the females given 20 ppm. The changes consisted of hypertrophy of hepatocytes in centrilobular areas in males and females, and midzonal to centrilobular hepatocytic vacuolation. The incidence and severity of the changes tended to be greater in the males.

At the Week 53 interim sacrifice, terminal body weights were significantly decreased in the females given 20 ppm. In the males, absolute and relative liver weights were increased in the group receiving 20 ppm. In addition, absolute and relative spleen weights were decreased in males given 20 ppm. There were no clear or consistent gross observations at the Week 53 interim sacrifice that could be attributed to the administration of the test material. At the Week 53 interim sacrifice, centrilobular hepatocytic hypertrophy and vacuolation was increased in incidence and severity in the males given 20 ppm. Generally, in the females given 20 ppm, only centrilobular hypertrophy was seen, and the change was less severe than that noted in the males. In addition, minimal to slight centrilobular hepatocytic pigment was found in the females given 20 ppm. There were no other histomorphologic changes that could be associated with the administration of the test material. Liver findings in several unscheduled deaths given 20 ppm resembled those seen in animals sacrificed at Week 53.

At the terminal sacrifice, the livers of animals given 5 or 20 ppm exhibited a slight increase in macroscopic findings, including enlarged, mottled, diffuse darkened, or focally lightened. Hepatotoxicity, characterized by centrilobular hypertrophy, centrilobular eosinophilic hepatocytic granules, centrilobular hepatocytic pigment, or centrilobular hepatocytic vacuolation was noted in the animals given 5 or 20 ppm. An increase in eosinophilic clear cell altered foci and cystic hepatocellular degeneration was noted in the males given 2, 5, or 20 ppm.

The data suggests that the hepatotoxicity did not persist in the recovery-sacrifice animals. In the unscheduled sacrifices between Weeks 54 and 105, animals given 20 ppm had increased hepatocellular centrilobular hypertrophy, eosinophilic hepatocytic granules, and centrilobular hepatocytic pigment were noted. Increased hepatocellular centrilobular hypertrophy was seen in animals given 5 ppm.

A significant positive trend was noted in the incidences of liver hepatocellular adenoma for males. This was associated with a significant increase in the high-dose (20.0 ppm) group over the control. The high-dose recovery (20.0 ppm) group animals in this case exhibited a significantly decreased incidence when compared to that of the high-dose (20.0 ppm) group. Significantly increased incidences were observed for thyroid follicular cell adenoma in the high-dose recovery (20.0 ppm) group when compared to either the control or the high-dose (20.0 ppm) group. There was also a significant increase in the combined (adenoma and carcinoma) thyroid follicular cell tumors in the high-dose recovery (20.0 ppm) group animals as compared to that of the high-dose (20.0 ppm) group. None of these cases were associated with any significant trend. Thyroid follicular cell carcinoma did not show any significant effect.

There were no other significant neoplastic findings in the males.

Significant positive trends were observed in the incidences of hepatocellular adenoma and hepatocellular combined adenoma and carcinoma in the females. These cases were associated with significant increases in the high-dose (20.0 ppm) group as compared to the control. All these tumors were incidental and noted at the terminal sacrifice. A marginally significant increase for thyroid follicular cell adenoma and carcinoma combined was observed in the mid-high (5.0 ppm) group but not in the high-dose (20.0 ppm) group as compared to the control group. In fact, thyroid C-cell adenoma and thyroid C-cell combined adenoma and carcinoma actually showed significant decreases in the high-dose (20.0 ppm) group as compared to the control. There were significant negative trends in the incidences of mammary fibroadenoma and mammary combined adenoma and fibroadenoma. These cases were associated with significantly lower incidences in the respective high-dose (20.0 ppm) group when compared to that of the control. However, the low-dose (0.5 ppm) group animals for these cases exhibited significant increases over the control. A significant decreased incidence was found for the high-dose recovery (20.0 ppm) group in the incidences of mammary carcinoma as compared to the high-dose (20.0 ppm) group. There was no other significant group effect

in mammary carcinoma. There was a marginal significant negative trend for the mammary combined fibroadenoma/adenoma/carcinoma. However, the low- (0.5 ppm) and mid-high (5.0 ppm) groups for this case exhibited significantly increased incidences over the control.

There were no other significant neoplastic findings in the females.

There were no statistically significant increases in cell proliferation as measured by Proliferative cell nuclear antigen (PCNA) immunohistochemistry at weeks 4 and 14, or by bromodeoxyuridine (BrdU) immunohistochemistry at week 53.

Liver samples were obtained from each of the 20 rats during necropsy at terminal sacrifice for examination by transmission electron microscopy (TEM). Liver samples were assessed for ultrastructural changes that may be related to chronic toxicity of the test material when administered in the diet. Electron microscopic evaluation identified mild to moderate changes related to treatment. Mild to moderate smooth endoplasmic reticulum hyperplasia and minimal to mild hepatocellular hypertrophy were the prominent features found to be different between the high dose group and the control animals. Other changes included a slight increase in the amount of glycogen in treated animals compared with controls.

The chronic toxicity and carcinogenicity of the test material, Perfluorooctane sulfonic acid potassium salt (PFOS; T-6295) was assessed following dietary admixture to male and female Crl:CD®(SD)IGS BR rats at dose levels of 0.5, 2, 5, or 20 ppm. Based on anatomic pathology findings in the liver, the no-observable-adverse-effect level for Perfluorooctane sulfonic acid potassium salt (PFOS; T-6295) is considered to be 2 ppm.

PURPOSE

The purpose of this study was to assess the chronic toxicity and carcinogenicity of Perfluorooctane sulfonic acid potassium salt (PFOS; T-6295), when administered in the diet to rats for at least 104 weeks. Due to excessive mortality, female animals in Group 3 were terminated during Week 103.

REGULATORY COMPLIANCE

All aspects of this study were in accordance with the Good Laboratory Practice Regulations as set forth in Title 40 of the US Code of Federal Regulations Part 792, issued November 29, 1983 (effective December 29, 1983), and with any applicable amendments.

TEST MATERIAL AND VEHICLE

Test Material

The test material, Perfluorooctane sulfonic acid potassium salt (PFOS; T-6295), Lot No. 217, is a light colored, free flowing powder and is 86.9% pure. It was received at Covance on June 4, 1996, and September 4, 1997. The test material was stored at room temperature.

Information on synthesis methods, stability, composition, or other characteristics that define the test material was provided by the sponsor and is on file with Covance.

Vehicle

The vehicle, acetone (Spectrum Chemical Mfg. Corp., New Brunswick, New Jersey and Gardena, California), Lot Nos. LH0253 and NS0231 (expiration date: June and September 1, 2000, respectively). The shipments were received at Covance on June 23, 1997, and September 8, 1998, respectively. The vehicle was stored at room temperature.

Information on synthesis methods, purity, composition, or other characteristics that define the acetone is on file with the manufacturer.

Carrier

Certified rodent diet (#5002 meal, PMI Nutrition International) was used as supplied. The lot numbers are recorded in the data. The diet is routinely analyzed by the manufacturer for nutritional components and environmental contaminants.

Reserve (Archive) Samples

A reserve sample (5 g) of the test material was taken and stored at room temperature. This sample was transferred to the sponsor on June 12, 2000.

Disposition

Remaining test material was returned to the sponsor on June 12, 2000, after authorization from the sponsor.

TEST ANIMALS AND HUSBANDRY

Animals

Male and female Crl:CD®(SD)IGS BR rats were obtained from the Raleigh, North Carolina, facility of Charles River Laboratories on April 7, 1998. At initiation of treatment, the animals were approximately 41 days old; the males weighed from 135 to 226 g, and the females weighed from 128 to 182 g.

Identification

Each animal was assigned a temporary number upon arrival. Before initiation of treatment, a microchip identification device was implanted into each animal. After randomization for placement on test, each animal was assigned a permanent number, and the microchip was coded with the permanent number. All data for an animal are recorded under these numbers.

Justification
Historically, rats have been used in safety evaluation studies and are recommended by appropriate regulatory agencies.

Husbandry
Animal were housed in Animal rooms 316, 332, or 345 for 13 days during acclimation and then were moved to rooms 3004 or 3005 for the duration of the study. Environmental controls for the animal rooms were set to maintain 18 to 26°C, a relative humidity of 30 to 70%, and a 12-hour light/12-hour dark cycle.

The animals were housed individually (except for the first 6 days of acclimation when animals were group-housed) in stainless-steel cages (see Protocol Deviations for exceptions). Some animals were placed in polycarbonate cages during the study when health problems dictated.

Certified rodent diet (#5002 meal, PMI Nutrition International) was provided *ad libitum* during acclimation (see Protocol Deviations for exceptions).

Water was provided *ad libitum* (see Protocol Deviations for exceptions).

Samples of the water are analyzed for specified microorganisms and environmental contaminants. The results are on file with Covance-Madison.

There were no known contaminants in the diet or water at levels that would have interfered with this study.

Animals not selected for the study (42 males and 40 females) were sacrificed and discarded.

Acclimation
Four hundred and two males and 400 females were received on April 7, 1998, and acclimated in Animal Rooms 316, 332, or 345 for 13 days then moved to rooms 3004 and 3005 before initiation of treatment. In general, animals in this shipment appeared

healthy. During acclimation, the animals were examined for abnormalities indicative of health problems, and body weights were recorded for all animals at randomization.

PROCEDURES

This study was conducted in accordance with the Protocol dated April 15, 1998, and with Protocol Amendment Nos. 1, 2, 3, 4, and 5. Protocol deviations are in Appendix 1.

Major Computer Systems

The Path/Tox application, supplied by Xybion Medical Systems Corporation, was used for the direct on-line capture of in-life toxicology and anatomic pathology data. The Randomization and Data Extension Systems (RADES) and Automatic Form and Label Generation System (AFLGS) applications were used in conjunction with the Path/Tox system to randomize animals and produce labels and forms, respectively. The Talisman application was used for the dose preparation information, and the Millennium system was used for the collection of dose analysis data, and the Clinical application was used for the collection of clinical pathology data. The Report Generation System application was used to pull the information from the Path/Tox and clinical applications into Word for reporting purposes. All version numbers of the applications can be found in the log book for the application.

Group Designations and Dose Levels

The animals were examined by a laboratory animal veterinarian on April 14, 1998, and were found to be suitable for study consideration. Selection of animals for the study was based on acclimation data. Animals were assigned to treatment groups using a computerized blocking procedure designed to achieve body weight balance with respect to treatment group. At the time of randomization, the weight variation of the animals did not exceed ± 2 standard deviations of the mean body weight for each sex. Group mean body weights were analyzed using Levene's test for homogeneity of variance at the 5.0% probability level and were found to be homogeneous. Animals were assigned to the study according to the following design.

Group	Number of Animals		Dietary Levels (ppm T-6295)
	Male	Female	
1 (Control)[a, b, c]	70	70	0
2 (Low)[b]	60	60	0.5
3 (Mid)[b]	60	60	2.0
4 (Mid-High)[b]	60	60	5.0
5 (High)[b, c]	70	70	20.0
6 (High Recovery)[d]	40	40	20.0

a The control animals received the control diet (basal diet with acetone).
b Five animals/sex in Groups 1 through 5 were sacrificed at Weeks 4 and 14 for hepatocellular proliferation rate measurements, biochemical analyses (palmitoyl-CoA oxidation), and histopathology (Week 14 only).
c Ten animals/sex in Groups 1 and 5 were designated as interim sacrifice animals. These animals were sacrificed after at least 52 weeks of treatment.
d Animals in Group 6 were treated for at least 52 weeks, then treatment was discontinued, and the animals were observed for reversibility, persistence, or delayed occurrence of toxic effects for at least 52 weeks posttreatment. During recovery, the animals received basal diet only.

Dosing Procedures

Dose Preparation. Dietary concentrations were based on the test material as supplied. Before initiation of treatment, diets of 0.5, 1, 2, and 20 ppm concentrations were prepared for stability and homogeneity analyses. Diets were prepared at least once every 4 weeks during the treatment phase of the study.

Preparation of Diet for Group 1. The appropriate amount of certified diet was weighed and mixed with an appropriate volume of acetone.

Preparation of Base Diet. A specified amount of certified diet was weighed into a labeled container. The required amount of test material was weighed and transferred into a labeled container and the appropriate volume of acetone was added to the container and mixed manually. Additional volume of acetone was added as necessary until the test material dissolved. To prepare a premix, the certified diet was transferred into a labeled Hobart® mixing bowl. The test material and acetone were added to the mixing bowl, overlaid with a portion of diet from the mixing bowl, and thoroughly mixed. A portion of

diet from the mixing bowl was transferred to a second mixing bowl, mixed manually to recover residual test material, and returned to the first mixing bowl. The contents of the mixing bowl were thoroughly mixed.

Preparation of Diets for Groups 2 through 4. Each dose level was prepared independently. A specified amount of certified diet was weighed into a labeled container and a specified amount of base diet was weighed for each dietary concentration. A pocket was formed in the feed in the mixing bowl and the amount of base diet was transferred to the pocket. The contents of the mixing bowl were thoroughly mixed for 15 minutes.

Preparation of Diets for Groups 5 and 6. A specified amount of certified rodent diet (#5002) was weighed into a labeled Hobart® mixing bowl and a specified amount of base diet was weighed for each diet. A pocket was formed in the feed in the mixing bowl and the amount of base diet was transferred to the pocket. The contents of the mixing bowl were thoroughly mixed for 15 minutes.

Samples for dose analyses were taken directly from the mixing bowl.

The diets were stored at room temperature in covered containers until dispensed into feeding jars.

Method of Administration. Dietary admixture was used because the potential route of exposure in humans is oral.

The dose preparations were administered *ad libitum* (see Protocol Deviations for exceptions). Animals in Groups 1, 2, 3 (males), 4, and 5 received the test diet for at least 104 weeks. Animals in Group 3 (females) received the test diet for at least 103 weeks. Animals in Group 6 received the test diet for 52 weeks.

Retention Samples. Samples (approximately 100 g) were taken from each dose preparation during the inlife phase and stored at room temperature. These samples were discarded on June 15, 2000.

Dose Analysis

Analyses for the concentration of test material in the dose preparations were done by Covance using an analytical method, MP-M383-MA, supplied by the sponsor and validated by Covance.

Homogeneity was determined from the dose preparations mixed pretest and from preparations mixed for Week 1. One sample (approximately 100 g each) from the top, middle, and bottom of the dose preparations were collected, divided into three subsamples for extraction and analysis, and analyzed for test material content. All samples were stored at room temperature until analyzed within 7 days of mixing.

To evaluate the stability of the test material in the carrier, one set of samples (approximately 100 g each) were taken from the preparations mixed pretest, stored at room temperature for 28 days, then analyzed. Homogeneity samples collected from the middle of the pretest dose preparations were analyzed within 2 days of mixing and used as the baseline value. An additional set of samples (approximately 100 g each) were taken from the preparations mixed for Week 1, stored at room temperature for 33 days, then analyzed. Homogeneity samples collected from the middle of the dose preparations for Week 1 were analyzed on the day of mixing and used as the baseline value.

For dose confirmation, samples (approximately 100 g each) from all dose preparations were analyzed in duplicate. Homogeneity samples collected from the middle of the dose preparations for Week 1 were used for dose confirmation results. All samples were stored at room temperature until analyzed.

Observation of Animals

Clinical Observations. The animals were observed twice daily (a.m. and p.m.) for mortality and moribundity. Once prior to treatment and weekly thereafter, each animal was removed from its cage and examined; abnormal findings or an indication of normal was recorded. In addition, the time of onset, location, size, appearance, and progression of each grossly visible or palpable mass were recorded.

Body Weights. Individual body weight data were recorded at the time of randomization, weekly for Weeks 1 through 17, once every 4 weeks thereafter, and at Week 105.

Food Consumption. Individual food consumption data were recorded weekly for Weeks 1 through 16 and once every 4 weeks thereafter.

Administration of Bromodeoxyuridine. Seven days before the Week 53 interim sacrifice, osmotic pumps (ALZET® Model 2ML1) were surgically implanted in five animals/sex/group from Groups 1 and 5. The osmotic pumps were preloaded with approximately 2 mL of bromodeoxyuridine (BrdU) at a concentration of 20 mg/mL. The animals were anesthetized by administration of acepromazine-ketamine-xylazine, and one pump/animal was aseptically inserted subcutaneously (dorsal surface). The incision was closed with wound clips, and the animals were monitored during clinical observations until the time of sacrifice to ensure that there were no clinical signs of infection. One Group 5 male implanted with the osmotic pump was sacrificed before the Week 53 sacrifice.

Clinical Pathology

Blood and urine samples were collected from 10 animals/sex/group in Groups 1 through 5 during Weeks 4, 14, 27, and 53. Blood films were made and held for possible future examination from animals sacrificed at unscheduled intervals and from animals at scheduled sacrifices after at least 52, 103 (Group 3 females), and 104 weeks of treatment. In addition, blood was collected for cholesterol and triglycerides from all remaining animals at the terminal and recovery sacrifices.

Animals were fasted overnight, and urine was collected chilled overnight (approximately 16 hours) before blood sampling. Blood was collected from a jugular vein. The anticoagulant was potassium EDTA for hematology tests. The samples for clinical chemistry samples were collected without anticoagulant. Animals were bled in random order. The following were evaluated.

Hematology

- red blood cell (erythrocyte) count
- hemoglobin
- hematocrit
- mean corpuscular volume
- mean corpuscular hemoglobin
- mean corpuscular hemoglobin concentration
- platelet count
- white blood cell (leukocyte) count
- differential blood cell count
  - segmented neutrophil count
  - lymphocyte count
  - monocyte count
  - eosinophil count
  - basophil count
- blood cell morphology

Reticulocyte smears were made and held for possible future examination.

Clinical Chemistry

glucose	alanine aminotransferase
urea nitrogen	gamma glutamyltransferase
creatinine	aspartate aminotransferase
total protein	calcium
albumin	inorganic phosphorus
globulin	sodium
cholesterol	potassium
total bilirubin	chloride

Urinalysis

appearance	glucose
volume	ketones
specific gravity	bilirubin
pH	blood
protein	microscopic examination of sediment
urobilinogen	

Urine Chemistry

sodium	16 hour excretion of:
potassium	sodium
	potassium

Serum PFOS Analyses

During Weeks 4 and 14, blood samples (approximately 2 mL) were collected for serum analyses from five animals/sex/group in Groups 1 through 5 (animals selected for hepatocellular proliferation and biochemical analyses). During Week 53, blood samples (approximately 2 mL) were collected from five animals/sex/group in Groups 1 and 5 (from animals selected for interim sacrifice) and from all remaining animals at terminal and recovery sacrifices. Animals were fasted overnight. Blood was collected from a jugular vein, allowed to clot at room temperature, and centrifuged. Samples were collected without anticoagulant. Serum was harvested and stored in a freezer, set to maintain -60 to -80°C, until sent to the sponsor for analyses of PFOS levels and metabolites. Analysis of these samples is the responsibility of the sponsor; results are not included in this report.

Anatomic Pathology

Necropsy at Unscheduled Intervals. A necropsy was done on each animal that died or was sacrificed at an unscheduled interval. Animals sacrificed at unscheduled intervals were anesthetized with carbon dioxide, weighed, and exsanguinated (see Protocol Deviations for exceptions). A blood film was taken as part of the necropsy procedure for sacrificed animals.

Interim Sacrifices

During Weeks 4, five animals/sex/group/interval in Groups 1 through 5 were fasted overnight, bled for serum chemistry, anesthetized with carbon dioxide, weighed, and exsanguinated. The abdominal cavity of each animal was opened, the liver was removed and weighed. Liver samples were collected for palmitoyl-CoA, cell proliferation, and PFOS concentration analyses and for mitochondrial activity. Animals sacrificed during Week 4 were discarded after liver collection. During Week 14, five animals/sex/group/interval in Groups 1 through 5 were fasted overnight, bled for serum chemistry, anesthetized with carbon dioxide, weighed, and exsanguinated. Liver samples were collected for palmitoyl-CoA, cell proliferation, PFOS concentration analyses, and for histopathology. During Week 53, 10 animals/sex/group from Groups 1 and 5 were fasted overnight, bled for serum samples (five animals/sex/group), anesthetized with carbon dioxide, weighed, exsanguinated, and necropsied. The liver was weighed and liver samples were collected and frozen for analysis. Animals sacrificed during Weeks 14 and 53 had macroscopic observations recorded, selected organs weighed, and selected tissues collected and preserved. A blood film was taken for each animal sacrificed at the Week 53 interim sacrifice. Animals were necropsied in random order.

Terminal Sacrifice

After at least 104 weeks of treatment (Week 103 for females in Group 3), the remaining animals were fasted overnight, bled for serum samples (five animals/sex/group), anesthetized with carbon dioxide, weighed, exsanguinated, and necropsied. Animals were necropsied in random order.

Recovery Sacrifice
After at least 52 weeks of treatment and 52 weeks without treatment, the remaining animals in Group 6 were fasted overnight, anesthetized with carbon dioxide, weighed, exsanguinated, and necropsied.

A blood film was taken as part of the necropsy procedures at the terminal and recovery sacrifices.

The necropsy included a macroscopic examination of the external features of the carcass; all external body orifices; the abdominal, thoracic, and cranial cavities; organs; and tissues.

Cell Proliferation Tissue Collection and Immunohistochemical Evaluation. During the Week 4 and 14 tissue collection from animals in Groups 1 through 5 (five animals/sex/group), representative samples of the left lateral lobe and any macroscopic lesions of the liver were collected and preserved in zinc formalin. Liver samples were fixed and embedded in paraffin and blocks were sent to Pathology Associates International (PAI), PAI evaluated the samples (left lateral lobe only) for proliferation cell nuclear antigen (PCNA). In addition, liver sections were stained with hematoxylin and eosin and examined microscopically by PAI. The cell proliferation report is in Appendix 7.

Palmitoyl-CoA (PCoA) Oxidase Analyses. During the Week 4 and 14 tissue collections from animals in Groups 1 through 5 (five animals/sex/group), a sample (approximately 500 mg) of the right lateral lobe of the liver was collected and flash-frozen in liquid nitrogen. The samples were stored in a freezer set to maintain -60 to -80°C, until analyzed by Covance for PCoA oxidase activity.

Organ Weights. At the interim sacrifice during Weeks 14 and 53, the following organs (when present) were weighed; paired organs were weighed separately.

adrenal (2)
brain
kidney (2)
liver
lung
ovary (2)
spleen
testes
thyroid (2) with parathyroid
uterus with cervix

Organ-to-body weight percentages and organ-to-brain weight ratios were calculated.

Liver PFOS Analysis. A portion of the liver was collected from five animals/sex/group from Groups 1 through 5 at the Week 4 and 14 interim sacrifices, from five animals/sex/group from Groups 1 and 5 at the Week 53 interim sacrifice, and from all remaining animals at the terminal and recovery sacrifice and flash-frozen in liquid nitrogen and stored in a freezer set to maintain -60 to -80°C, until packed on dry ice and shipped to the sponsor for PFOS and metabolites analyses. Analysis of these samples is the responsibility of the sponsor; results are not included in this report.

Mitochondrial Analyses. During the Week 4 tissue collections for animals in Groups 1 through 5, liver samples (approximately 1.5 g) were collected and analyzed by the sponsor for mitochondrial activity. Analysis of these samples is the responsibility of the sponsor; results are not included in this report.

Tissue Preservation. The following tissues were collected and preserved in 10% neutral-buffered formalin (see Protocol Deviations for exceptions).

adrenal (2)
brain
cecum
cervix
colon
duodenum
epididymis (2)
esophagus
eye (2)
femur with bone marrow (articular surface of the distal end)
Harderian gland
heart
ileum
jejunum
kidney (2)
lesions
liver
lung with mainstem bronchi
lymph node (mesenteric)
mammary gland (females only)
ovary (2)
pancreas
pituitary
prostate
rectum
salivary gland [mandibular (2)]
sciatic nerve
seminal vesicle (2)
skeletal muscle (thigh)
skin
spinal cord (cervical, thoracic, and lumbar)
spleen
sternum with bone marrow
stomach
testis (2)
thymus
thyroid (2) with parathyroid
trachea
urinary bladder
uterus
vagina

Bone marrow smears from the femur of each animal at scheduled sacrifices were prepared, stained with Wright's stain, and retained for possible examination.

In addition, at the terminal sacrifice, sections of the heart and liver were collected from 10 animals/sex in Groups 1, 4, 5, and 6 and preserved in 2.0% paraformaldehyde/2.5% glutaraldehyde in 0.1M phosphate buffer (see Protocol Deviations for exceptions). The tissues were processed and embedded in epoxy blocks for possible future examination by electron microscopy.

Histopathology. Tissues (as appropriate) from each animal in Groups 1, 5, and 6 sacrificed at the Week 53 interim sacrifice were embedded in paraffin, sectioned, stained with hematoxylin and eosin, and examined microscopically.

Adrenals, brain, eyes, kidneys, liver, mesenteric lymph node, pancreas, spleen, testes, and ovaries from the animals necropsied at the Week 14 interim sacrifice were also embedded in paraffin, sectioned, stained with hematoxylin and eosin, and examined microscopically.

Tissues (as appropriate) from each animal in Groups 1 and 5 sacrificed at the terminal sacrifice and any animals that died on test or were sacrificed at unscheduled intervals were embedded in paraffin, sectioned, stained with hematoxylin and eosin, and examined microscopically.

Lesions, liver, lungs, kidneys, pancreas, thyroid, testes, mammary glands (females), and urinary bladder from each animal in Groups 2, 3, 4, and 6 sacrificed at the terminal and recovery sacrifices were embedded in paraffin, sectioned, stained with hematoxylin and eosin, and examined microscopically (see Protocol Deviations for exceptions). Parathyroids were processed with the thyroids, but were not examined.

At the Week 53 sacrifice, BrdU immunohistochemistry was performed by PAI on the livers and duodenums from five animals/sex/group in Groups 1 and 5 that received BrdU. In addition, sections of the liver and duodenums from these animals were stained with hematoxylin and eosin and examined microscopically.

A pathology peer review was conducted by a pathologist designated by the sponsor.

Liver sections from five animals/sex/group from Groups 1 and 5 were stained with Oil Red "O" stain and examined microscopically.

Liver sections in epoxy blocks for five animals/sex/group from Groups 1 and 5 were processed and evaluated by electron microscopy by Pathology Associates International (report included in Appendix 8).

Slides of the pancreas from males found dead, sacrificed at an unscheduled interval, or sacrificed at the Week 14 and 53 interim sacrifices, terminal, and recovery sacrifices were sent to Tox Path Inc. for peer-review and results were provided to Covance for inclusion in the final report (see Protocol Deviations for exceptions). After examination, slides were returned to Covance.

Statistical Evaluation

Levene's test (Levene, 1960) was done to test for variance homogeneity. In the case of heterogeneity of variance at $p \leq 0.05$, transformations were used to stabilize the variance. One-way analysis of variance [ANOVA (Winer, 1971)] was used to analyze body weights, body weight changes, food consumption, continuous clinical pathology values, palmitoyl CoA oxidase activities, and organ weight data (Week14 and 53 interim sacrifices only).

ANOVA was done on the homogeneous or transformed data. If the ANOVA was significant, Dunnett's t-test (Dunnett, 1964) was used for pairwise comparisons between treated and control groups.

Group comparisons (Groups 2 through 6 versus Group 1) were evaluated at the 5.0%, two-tailed probability level. Only data collected on or after the first day of treatment were analyzed statistically.

Survival and Tumor Analysis

Survival. Evaluations of trend and heterogeneity of survival data were performed using the Cox-Tarone binary regression method using the National Cancer Institute (NCI) Life Table Package (Thomas, Breslow, and Gart, 1977). Week 105 was treated as the end of the study in the NCI package for both sexes. Animals that were sacrificed at scheduled

intervals were censored in the analysis. Continuity-corrected one-sided tail probabilities for trend and two-sided tail probabilities for group comparisons were evaluated at the 5.0% significance level.

Nonneoplastic Lesions. Nonneoplastic lesions were chosen for statistical analyses if the incidence in at least one treated group (Groups 2 through 5) was increased or decreased by at least two occurrences over the control group (Group 1). The high recovery group (Group 6) was selected based on the incidence rate (%) if it was increased or decreased by at least two as compared to the control or high-dose (20.0 ppm) group. When there was only one incidence in the high-recovery and none in the other groups, that case was excluded from the statistical evaluation. These were analyzed by the Cochran-Armitage test for trend and the Fisher-Irwin exact test for control versus treatment comparisons (Thakur, Berry, and Mielke, 1985). One-sided tail probabilities for trend and group comparisons were evaluated at the 5.0% significance level and are reported in Text Tables 3 and 4 for males and females, respectively.

Neoplastic Lesions. Neoplastic lesions were chosen for statistical analyses using the same criteria as in the case of nonneoplastic lesions. The incidental tumors (i.e., tumors that were not assigned to be the cause of death of the animals by the study pathologist) were analyzed by logistic regression of tumor prevalence (Dinse and Lagakos, 1983). The logistic regression model included linear and quadratic terms in age (week of death), but thequadratic term was eliminated if there was a lack of convergence. The fatal and palpable (superficial) tumors were analyzed by Cox-Tarone binary regression method using the death time or the first palpation time (as applicable) as a surrogate for the tumor onset time. In the case of any particular tumor type where the study pathologist assigned the tumor in question being the cause of death of a subset of the animals and the rest of the animals were assumed to be dead of other competing risks, IARC-type (Peto et al, 1980) cause of death analysis was performed. Specifically, the subset of the tumors which were assigned to be the cause of death by the study pathologist was analyzed by Cox-Tarone logistic regression under life table techniques. The subset, which was considered incidental by the pathologist, was analyzed by logistic regression of tumor prevalences. Tumor types whose cause of death was undetermined, were treated as incidental for statistical evaluation. The score statistics and their respective variances from the above tests were then used to compute the combined evidence as described by Gart et al. (1986). If one tumor in the group belonged to one of the two categories (fatal and incidental) in a test was combined with the other category for the purpose of statistical

analyses. In addition, in the cases where there was lack of convergence for the asymptotic test of the logistic regression method, the exact probability of the significance was obtained by using LogXact-Turbo (1993) and combined with the probability of Cox-Tarone test, if necessary.

The benign and malignant neoplastic incidences were evaluated both separately and combined where appropriate. The criteria for combination were based on the work of McConnell et al. (1986). The incidences of multiple-organ findings such as hemangioma, hemangiosarcoma, lipoma, liposarcoma, fibroma, fibrosarcoma, leiomyoma, leiomyosarcoma, endometrial stromal polyp, and endometrial stromal sarcoma were counted by animal, not by tissue type. They were evaluated statistically if they met the selection criterion for the analysis. The statistical results for these cases may be biased because not all the animals were examined for every tissue. One-sided trend and pairwise group comparisons were evaluated at the 5.0% significance level and are shown in Text Tables 5 and 6 for males and females, respectively.

In the nonneoplastic analyses, animals sacrificed early (Week 4) were excluded from the denominators. In the statistical evaluations of the neoplastic lesions, animals sacrificed early (during or before Week 14) were discounted from the number of animals at risk. In the neoplastic analyses, the low- (0.5 ppm), mid-(2.0 ppm), mid-high, and high recovery groups that did not have complete histopathology examinations were excluded from statistical analyses.

In the text tables, the p-values under Group 1 (control) are for trend analysis and the p -values under Groups 2 (low), 3 (mid), 4 (mid-high), 5 (high) and 6 (high recovery) are for the comparison of that group versus the control group. Group 6 was also compared with Group 5, and the p-values for those comparisons are indicated in the text tables. Trend analysis includes Groups 1, 2, 3, 4, and 5 only. Ordinal dose levels 0, 1, 2, 3, and 4 were used in all analyses for Groups 1, 2, 3, 4, and 5, respectively. Continuity correction was done for all asymptotic tests.

The following notations are used throughout this report designating direction and significance of effects.

+ = Effect in the increased direction
- = Effect in the decreased direction
* = Significant at $p \leq 0.05$
** = Significant at $p \leq 0.01$
E = Exact permutation test
NA = Not analyzed

Record Retention

The raw data, documentation, records, specimens, protocol, and final report generated as a result of this study will be archived in the storage facilities of Covance-Madison. At least 1 year after submission of the final report, the Covance Archives staff will contact the sponsor. At that time, the sponsor may choose to have the aforementioned materials returned, archived for an additional period of time, or disposed of by Covance; a fee will be charged based on the archive disposition option selected by the sponsor. Raw data stored on magnetic media and the protocol, study correspondence, and the original final report will be retained by Covance. At least 1 year after submission of the final report, any frozen samples will be returned to the sponsor, retained by Covance, or disposed of, and a fee will be charged. Data generated by the sponsor will be archived in the sponsor's storage facilities.

Specimens, data, and reports for PCNA evaluation, BrdU immunohistochemistry and electron microscopy will be retained by PAI.

RESULTS AND DISCUSSION

Dose Analysis

Results of the homogeneity, stability, and dose preparation analyses are in Tables 1 through 3.

Several homogeneity analyses were conducted on each of the several mixes in an attempt to resolve issues related to the inherent variability and lack of sufficient sensitivity in the analytical method for measuring Perfluorooctane sulfonic acid potassium salt (PFOS; T-6295). Mean values of the homogeneity analyses for the pre-dosing mix done on March 18, 1998, ranged from 119-135% and 107-118% of the theoretical concentrations for the diets containing 0.5 and 20 ppm (PFOS; T-6295), respectively. Mean values of

the homogeneity analyses for the mix done on April 16, 1998, ranged from 96.2-122%, 98.5-107%, 97.6-101%, and 90.0-101% of the theoretical concentrations for the diet containing 0.5, 2, 5, and 20 ppm (PFOS; T-6295), respectively. Mean values of the homogeneity analyses for the mix done on April 22, 1998, ranged from 93.5-103% of the theoretical concentrations for the diet containing 20 ppm (PFOS; T-6295). Mean values of the homogeneity analyses for the mix done on June 18, 1998, ranged from 91.0-175%, 111-130%, 99.6-102%, and 90.5-97.0% of the theoretical concentrations for the diet containing 0.5, 2, 5, and 20 ppm (PFOS; T-6295). These results indicate that the mixing procedure produced a homogeneous distribution of the test material in the dose preparations; although variability generally appeared slightly greater at the lower dietary concentrations.

Stability analyses were conducted prestudy in an attempt to resolve issues related to the inherent variability and lack of sufficient sensitivity at levels in the analytical method for measuring (PFOS; T-6295). Results of stability analyses for the pre-dosing mix conducted on March 18, 1998, of samples stored for 28 days at room temperature indicated that the mean concentrations were 78.5, 76.7, 79.8, and 88.1% of the initial concentrations of 0.5, 1, 2, and 20 ppm, respectively. Results of stability analyses for the mix conducted on April 16, 1998, of samples stored for 33 days at room temperature indicated that the mean concentrations were 112.3, 119.6, 113.9, and 126.7% of the initial concentrations of 0.5, 2, 5, and 20 ppm, respectively.

The mean concentrations of the dose preparation analyses for all levels ranged from 44.4-635% of the theoretical concentrations (including the reassay and retention sample analyses). The overall mean concentrations within each dose level ranged from 102.3 to 108.7. Inherent variability and lack of sufficient sensitivity at low levels in the analytical method for measuring (PFOS; T-6295) resulted in homogeneity, stability, and routine analysis data that were in many cases outside of the standard limits of +/- 15%.

Observation of Animals

Survival and Clinical Observations. Clinical observations including mass observations are summarized in Tables 5 and 6; individual data are in Appendix 2. Adjusted survival data are illustrated in Figures 1 and 2 and summarized in Table 4; individual animal fate data are in Appendix 2.

Survival after 104 weeks of treatment was 22.0, 22.0, 34.0, 50.0, 45.0, and 27.0% for males in Groups 1, 2, 3, 4, 5, and 6, respectively, and 50.0, 30.0, 20.0 (after 102 weeks), 34.0, 52.0, and 48.0% for females in Groups 1, 2, 3, 4, 5, and 6, respectively.

There was a significant increased trend in survival that occurred in the males that and was due to significant increases in survival in mid-high (5.0 ppm) and high-dose (20.0 ppm) groups as compared to that of the control group. None of the other treated groups in the males revealed any significant differences in survival. No significant trend was noted in survival in females. There was a significant decrease in survival in the mid-dose (2.0 ppm) group and not in the mid-high (5.0 ppm) and high-dose (20.0 ppm) groups as compared to that of the control.

There were no clinical observations attributed to administration of the test material. The types of clinical observations noted are commonly observed in laboratory rats as they age on long term safety studies.

There was no effect of the test material on the incidence of palpable masses.

Body Weights. Body weight and body weight change data are illustrated in Figures 3 and 4 and summarized in Tables 7 and 8; individual body weight data are in Appendix 3.

Males given 20 ppm (Groups 5 and 6) had significantly lower mean body weights compared to animals in the control group during Weeks 9 through 37. During recovery the mean body weights for Group 6 males were similar to mean body weights for Group 5 males. Females in Group 5 given 20 ppm had significantly lower body weights compared to animals in the control group during Weeks 3 through 101. Mean body weights for females in Group 6 given 20 ppm were statistically lower than mean body weights for control females during Weeks 3 through 61, but their mean body weights became nearer to the weights of the control females when placed on recovery. At Week 105, mean body weights for surviving males were 98, 108, 103, 101, and 96% of controls for the low-, mid-, and high-dose groups (Groups 5 and 6), respectively. At Week 105, mean body weights for surviving females were 101, 107 (Week 101), 100, 86, and 105% of controls, for the low-, mid-, and high-dose groups (Groups 5 and 6), respectively. Overall mean body weight change was statistically significantly lower for males given 20 ppm diets for Weeks 1 through 15 and Weeks 15 through 29. Mean body weight change was statistically significantly lower for females given 20 ppm for Weeks 1

through 15 and Weeks 29 through 57 (Group 5 only). Mean body weight changes for males and females in Group 6 were significantly increased during the several weeks of recovery. Animals at lower dose levels occasionally had statistically significant decreases in body weight gain; however, these occurrences were inconsistent over time between sexes and were not clearly dose-related.

Food Consumption. Food consumption data are illustrated in Figures 5 and 6 and summarized in Table 9; individual data are in Appendix 4.

Although not always statistically significant, males given 20 ppm tended to consume less food during Weeks 1 through 24. Food consumption was similar for males given 20 ppm compared to animals given the control material during Weeks 28 through 104. Statistically significantly lower food consumption was noted for females given 20 ppm during Weeks 2 through 36. Food consumption for males and females was similar in all the other treated groups compared to animals given the control material.

Test Material Consumption. Test material consumption data are summarized in Table 10. Individual test material consumption data are presented in Appendix 4.

Animals were fed diets containing 0, 0.5, 2, 5, or 20 ppm T-6295. The amount of test material consumed by animals on a mg/kg of body weight/day basis was as follows.

Group	Dietary Concentrations (ppm)	Mean Achieved Dose Levels - Range (mg/kg body weight/day)	
		Males	Females
2	0.5	0.015 - 0.057	0.015 - 0.052
3	2.0	0.064 - 0.226	0.073 - 0.213
4	5.0	0.153 - 0.570	0.186 - 0.559
5	20.0	0.643 - 2.205	0.838 - 2.149
6	20.0	0.732- 2.336	1.047 - 2.160

Clinical Pathology

Hematology, coagulation, clinical chemistry, urinalysis, and urine chemistry data are summarized in Tables 11 through 29; individual data are in Appendix 5. The Pathology Report contains a discussion of the data.

Dietary administration of PFOS for approximately 53 weeks was associated with mildly higher urea nitrogen for males and females fed 5 or 20 ppm; mildly lower glucose for males and females fed 20 ppm; mildly to moderately lower cholesterol for males and females fed 20 ppm; and mildly higher alanine aminotransferase for males fed 20 ppm. None of these effects were considered adverse. The effect on cholesterol was no longer apparent after 104 weeks of treatment. There was no effect on hepatic palmitoyl-CoA oxidase activity.

Anatomic Pathology

Organ weight data are summarized in Tables 30 through 31; incidences of macroscopic and microscopic observations are summarized in Tables 32 through 41. Individual data are in Appendix 6. The Pathology Report contains a discussion of the data.

Terminal body weights in males and females at Week 14 were comparable between control and treated groups. At the Week 14 interim sacrifice, absolute and relative liver weights were significantly increased in the males given 20 ppm. In females given 20 ppm, only the liver-to-body weight percentage was significantly increased. Test material-related histomorphologic changes were limited to the liver in the males given 5 or 20 ppm and in the females given 20 ppm. The changes consisted of hypertrophy of hepatocytes in centrilobular areas in males and females, and midzonal to centrilobular hepatocytic vacuolation. The incidence and severity of the changes tended to be greater in the males.

At the Week 53 interim sacrifice, terminal body weights were significantly decreased in the females given 20 ppm. In the males, absolute and relative liver weights were increased in the group receiving 20 ppm. In addition, absolute and relative spleen weights were decreased in males given 20 ppm. There were no clear or consistent gross observations at the Week 53 interim sacrifice that could be attributed to the administration of the test material. At the Week 53 interim sacrifice, centrilobular hepatocytic hypertrophy and vacuolation was increased in incidence and severity in the males given 20 ppm. Generally, in the females given 20 ppm, only centrilobular hypertrophy was seen, and the change was less severe than that noted in the males. In addition, minimal to slight centrilobular hepatocytic pigment was found in the females given 20 ppm. There were no other histomorphologic changes that could be associated

with the administration of the test material. Liver findings in several unscheduled deaths given 20 ppm resembled those seen in animals sacrificed at Week 53.

At the terminal sacrifice, the livers of animals given 5 or 20 ppm exhibited a slight increase in macroscopic findings, including enlarged, mottled, diffuse darkened, or focally lightened. Hepatotoxicity, characterized by centrilobular hypertrophy, centrilobular eosinophilic hepatocytic granules, centrilobular hepatocytic pigment, or centrilobular hepatocytic vacuolation was noted in the animals given 5 or 20 ppm. An increase in eosinophilic clear cell altered foci and cystic hepatocellular degeneration was noted in the males given 2, 5, or 20 ppm.

The data suggests that the hepatotoxicity did not persist in the recovery-sacrifice animals.

In the unscheduled sacrifices between Weeks 54 and 105, animals given 20 ppm had increased hepatocellular centrilobular hypertrophy, eosinophilic hepatocytic granules, and centrilobular hepatocytic pigment were noted. Increased hepatocellular centrilobular hypertrophy was seen in animals given 5 ppm.

A significant positive trend was noted in the incidences of liver hepatocellular adenoma for males. This was associated with a significant increase in the high-dose (20.0 ppm) group over the control. The high-dose recovery (20.0 ppm) group animals in this case exhibited a significantly decreased incidence when compared to that of the high-dose (20.0 ppm) group. Significantly increased incidences were observed for thyroid follicular cell adenoma in the high-dose recovery (20.0 ppm) group when compared to either the control or the high-dose (20.0 ppm) group. There was also a significant increase in the combined (adenoma and carcinoma) thyroid follicular cell tumors in the high-dose recovery (20.0 ppm) group animals as compared to that of the high-dose (20.0 ppm) group. None of these cases were associated with any significant trend. Thyroid follicular cell carcinoma did not show any significant effect.

There were no other significant neoplastic findings in the males.

Significant positive trends were observed in the incidences of hepatocellular adenoma and hepatocellular combined adenoma and carcinoma in the females. These cases were associated with significant increases in the high-dose (20.0 ppm) group as compared to the control. All these tumors were incidental and noted at the terminal sacrifice. A

marginally significant increase for thyroid follicular cell adenoma and carcinoma combined was observed in the mid-high (5.0 ppm) group but not in the high-dose (20.0 ppm) group as compared to the control group. In fact, thyroid C-cell adenoma and thyroid C-cell combined adenoma and carcinoma actually showed significant decreases in the high-dose (20.0 ppm) group as compared to the control. There were significant negative trends in the incidences of mammary fibroadenoma and mammary combined adenoma and fibroadenoma. These cases were associated with significantly lower incidences in the respective high-dose (20.0 ppm) group when compared to that of the control. However, the low-dose (0.5 ppm) group animals for these cases exhibited significant increases over the control. A significant decreased incidence was found for the high-dose recovery (20.0 ppm) group in the incidences of mammary carcinoma as compared to the high-dose (20.0 ppm) group. There was no other significant group effect in mammary carcinoma. There was a marginal significant negative trend for the mammary combined fibroadenoma/adenoma/carcinoma. However, the low- (0.5 ppm) and mid-high (5.0 ppm) groups for this case exhibited significantly increased incidences over the control.

There were no other significant neoplastic findings in the females.

Cell Proliferation Results

There were no statistically significant increases in cell proliferation as measured by PCNA at weeks 4 and 14, or by bromodeoxyuridine (BrdU) immunohistochemistry at week 53. However, two out of five females in each of the mid-high and high dose groups showed a very mild, but biologically significant response (i.e. had a proliferative index that was twice the mean of the controls and greater than that of the highest control) at week 4. The cell proliferation response at week four was transient in nature as it was not observed at week 14, and was considered to be test compound-related.

Electron Microscopy Results

Liver samples were obtained from each of the 20 rats during necropsy at terminal sacrifice for examination by transmission electron microscopy (TEM). Liver samples were assessed for ultrastructural changes that may be related to chronic toxicity of the test material when administered in the diet. Electron microscopic evaluation identified mild to moderate changes related to treatment. Mild to moderate smooth endoplasmic

reticulum hyperplasia and minimal to mild hepatocellular hypertrophy were the prominent features found to be different between the high dose group and the control animals. Other changes included a slight increase in the amount of glycogen in treated animals compared with controls.

Characterization of Tumor Incidence Outcome

In males, hepatocellular adenoma was increased for trend ($p = 0.0276$) and pair-wise against control for the 20 ppm dose group (7/60 20 ppm vs. 0/60 control, $p = 0.0456$). Hepatocellular adenoma was not observed in the 20 ppm recovery group, which was significant compared to the 20 ppm dose group (0/40 20 ppm recovery group vs. 7/60 200 ppm dose group, $p = 0.0240$). Overall, the response in terms of hepatocellular adenoma can be considered weak at the 20 ppm dose level.

Thyroid follicular cell adenoma was increased pair-wise against control for the 20 ppm recovery group (9/39 20 ppm recovery group vs. 3/60 control, $p = 0.0280$). Although this finding is outside the range of recent historical control values in this laboratory, there were no other indications of thyroid abnormality.

In females, hepatocellular adenoma was increased for trend ($p = 0.0153$) and pair-wise against control for the 20 ppm dose group (5/60 20 ppm dose group vs. 0/60 control, $p = 0.0386$). Overall, the response in terms of hepatocellular adenoma can be considered weak at the 20 ppm dose level. The only hepatocellular carcinoma observed in the study was at the high dose. Hepatocellular adenoma/carcinoma was increased for trend ($p = 0.0057$) and pair-wise against control for the 20 ppm dose group (6/60 20 ppm vs. 0/60 control, $p = 0.0204$).

Mammary fibroadenoma was decreased for trend ($p = 0.0152$) and pair-wise against control for the 20 ppm dose group (11/60 20 ppm vs. 20/60 control, $p = 0.0235$).

CONCLUSION

The chronic toxicity and carcinogenicity of the test material, Perfluorooctane sulfonic acid potassium salt (PFOS; T-6295) was assessed following dietary admixture to male and female Crl:CD®(SD)IGS BR rats at dose levels of 0.5, 2, 5, or 20 ppm. Based on anatomic pathology findings in the liver, the no-observable-adverse-effect level for Perfluorooctane sulfonic acid potassium salt (PFOS; T-6295) is considered to be 2 ppm.

PATHOLOGY REPORT

SUMMARY

The purpose of this study was to assess the chronic toxicity and carcinogenicity of the test material, Perfluorooctane Sulfuric Acid Potassium Salt (PFOS) when administered in the diet to rats for at least 104 weeks. The test material was administered at dose levels of 0.5, 2, 5, and 20 ppm.

Dietary administration of PFOS for approximately 53 weeks was associated with mildly higher urea nitrogen for males and females fed 5 or 20 ppm; mildly lower glucose for males and females fed 20 ppm; mildly to moderately lower cholesterol for males and females fed 20 ppm; and mildly higher alanine aminotransferase for males fed 20 ppm. None of these effects were considered adverse. The effect on cholesterol was no longer apparent after 104 weeks of treatment. There was no effect on hepatic palmitoyl-CoA oxidase activity.

Terminal body weights in males and females at Week 14 were comparable between control and treated groups. At the Week 14 interim sacrifice, absolute and relative liver weights were significantly increased in the males given 20 ppm. In females given 20 ppm, only the liver-to-body weight percentage was significantly increased. Test material-related histomorphologic changes were limited to the liver in the males given 5 or 20 ppm and in the females given 20 ppm. The changes consisted of hypertrophy of hepatocytes in centrilobular areas in males and females, and midzonal to centrilobular hepatocytic vacuolation. The incidence and severity of the changes tended to be greater in the males.

At the Week 53 interim sacrifice, terminal body weights were significantly decreased in the females given 20 ppm. In the males, absolute and relative liver weights were increased in the group receiving 20 ppm. In addition, absolute and relative spleen weights were decreased in males given 20 ppm. There were no clear or consistent gross observations at the Week 53 interim sacrifice that could be attributed to the administration of the test material. At the Week 53 interim sacrifice, centrilobular hepatocytic hypertrophy and vacuolation was increased in incidence and severity in the males given 20 ppm. Generally, in the females given 20 ppm, only centrilobular

hypertrophy was seen, and the change was less severe than that noted in the males. In addition, minimal to slight centrilobular hepatocytic pigment was found in the females given 20 ppm. There were no other histomorphologic changes that could be associated with the administration of the test material. Liver findings in several unscheduled deaths given 20 ppm resembled those seen in animals sacrificed at Week 53.

At the terminal sacrifice, the livers of animals given 5 or 20 ppm exhibited a slight increase in macroscopic findings, including enlarged, mottled, diffuse darkened, or focally lightened. Hepatotoxicity, characterized by centrilobular hypertrophy, centrilobular eosinophilic hepatocytic granules, centrilobular hepatocytic pigment, or centrilobular hepatocytic vacuolation was noted in the animals given 5 or 20 ppm. An increase in eosinophilic clear cell altered foci and cystic hepatocellular degeneration was noted in the males given 2, 5, or 20 ppm.

The data suggests that the hepatotoxicity did not persist in the recovery-sacrifice animals.

In the unscheduled sacrifices between Weeks 54 and 105, animals given 20 ppm had increased hepatocellular centrilobular hypertrophy, eosinophilic hepatocytic granules, and centrilobular hepatocytic pigment were noted. Increased hepatocellular centrilobular hypertrophy was seen in animals given 5 ppm.

A complete discussion of statistically significant differences in the incidence of neoplasms may be found in the section entitles “Statistical Report of Survival, Nonneoplastic, and Neoplastic Lesions.”

METHODS

Six groups of Crl:CD®(SD)IGS BR rats were studied using the following study design.

Group	Number of Animals		Dietary Levels
	Male	Female	(ppm T-6295)
1 (Control)	70	70	0
2 (Low)	60	60	0.5
3 (Mid)	60	60	2.0
4 (Mid-High)	60	60	5.0
5 (High)	70	70	20.0
6 (High Recovery)	40	40	20.0

The animals in Group 6 were designated as recovery animals and were treated for 52 weeks, then placed in recovery for an additional 52 weeks.

During Weeks 4, 14, 27, and 53, blood and urine were collected for hematology, clinical chemistry, urinalysis, and urine chemistry tests from 10 animals/sex in Groups 1 through 5. Blood was collected for cholesterol and triglyceride determinations from all animals prior to the terminal sacrifice during Weeks 105 and 106 (Week 103 for females in Group 3) and the recovery sacrifice (Group 6) during Weeks 105 and 106. Blood films were also prepared for animals at the terminal and recovery sacrifices.

Five animals/sex in Groups 1 through 5 were sacrificed during Week 4; livers were collected and weighed. A portion of the liver was shipped to the sponsor for PFOS analysis and mitochondrial activity, a portion was shipped to Pathology Associates International (PAI) for hepatocellular proliferation rate measurements by proliferation cell nuclear antigen (PCNA), and a third portion was used for determination of palmitoyl-CoA oxidase activity. During Weeks 14 and 53, necropsies were performed on five and 10 animals/sex, respectively, in Groups 1 through 5. Surviving females in Group 3 were sacrificed and necropsied during Week 103 because of reduced survival. The remaining animals in Groups 1 through 6 were sacrificed and necropsied during Weeks 105 and 106. At necropsy, macroscopic observations were recorded, organ weights were obtained (Weeks 14 and 53), and tissues were placed in fixative as specified by the protocol. In addition, liver samples were collected for PFOS analysis (Weeks 14, 53, 103, 105, and 106), hepatocellular proliferation rate measurement [by PCNA at Week 14 and by bromodeoxyuridine (BrdU) immunohistochemistry at Week 53], and palmitoyl-CoA oxidase determination (Week 14). A section of duodenum was also collected at Week 53 for BrdU immunohistochemistry. At the terminal and recovery sacrifices, sections of heart and liver from 10 animals/sex in Groups 1, 4, 5, and 6 were preserved in 2.0% parafomaldehyde/2.5% gluteraldehyde in 0.1M phosphate buffer, processed, and embedded in epoxy resin for possible future electron microscopy.

At unscheduled necropsies for animals that died or were sacrificed because of poor health, macroscopic observations were recorded, and tissues were placed in fixative, but organ weights were not obtained. Microscopic examinations were done on selected tissues (adrenals, brain, eyes, kidney, liver, mesenteric lymph node, pancreas, spleen, testes, and ovaries) from the animals necropsied during Week 14 and on all tissues from the animals in Groups 1 and 5 that were necropsied during Weeks 53, 105, and 106. In addition, microscopic examinations were done on the tissues from animals that died or were sacrificed due to poor health. Macroscopic lesions, liver, lung, kidneys, pancreas, thyroid, testes, and mammary gland (females) were examined for animals in Groups 2, 3, 4, and 6 that were sacrificed during Weeks 103, 105, and 106. Sections of liver were stained with Oil Red O and examined from five terminally sacrificed males and females in Groups 1 and 5. Also, urinary bladder was examined microscopically from all terminally sacrificed animals in Groups 2, 3, and 4, and from all animals at the recovery sacrifice.

Statistically significant differences cited in the Results and Discussion section are based on comparisons between the control and treated groups.

RESULTS AND DISCUSSION

Clinical Pathology

Weeks 4, 14, 27, and 53. There were relatively few statistically significant or otherwise notable differences for clinical pathology results between the control and treated groups. Those differences that were the most consistent over time were considered to be associated with administration of the test material. These included mildly higher urea nitrogen for males and females fed 5 or 20 ppm; mildly lower glucose for males and females fed 20 ppm; mildly to moderately lower cholesterol for males and females fed 20 ppm; and mildly higher alanine aminotransferase for males fed 20 ppm.

There were no correlative microscopic renal findings for the minor change in urea nitrogen. The findings for alanine aminotransferase, and possibly for glucose and cholesterol, were likely associated with the histopathological findings of hepatocellular hypertrophy and vacuolation. None of the clinical pathology effects were considered adverse.

Of uncertain relationship to the test material were statistically higher urea nitrogen for males fed 2 ppm and statistically lower glucose for females fed 2 or 5 ppm at Week 53. These findings were not as consistent over time as those considered to be effects of the test material, and the magnitudes of these differences were very small.

All other statistically significant differences for clinical pathology results between the control and treated groups were considered incidental. Most of these differences did not affect animals fed the highest dose level, and none of these differences were consistent over time.

Week 103 (Day 719; Group 3 Females) and Week 105. As expected for rats of this age, the cholesterol and triglyceride results were extremely variable, especially for the males. Because of this naturally-occurring variability, the effect on cholesterol observed at earlier intervals was no longer clearly apparent. Although males and females fed 20 ppm had lower mean cholesterol concentrations than those of the other groups, the marked individual variability made it impossible to definitively identify a test material-related effect on cholesterol at Week 105.

The recovery males (Group 6) had a mean cholesterol concentration similar to that of the control males, but the recovery females had a mean cholesterol concentration that was similar to the females in Group 5. Once again, the marked individual variability for cholesterol obscured the significance of these findings.

Anatomical Pathology

Week 14, Terminal Body Weight and Organ Weights. Terminal body weights were comparable between control and treated groups. Absolute and relative liver weights were statistically significantly increased in the males given 20 ppm. In females given 20 ppm, only the liver-to-body weight percentage was significantly increased. The absolute spleen weight was significantly decreased in the females given 20 ppm, as was the absolute lung weight in females given 2, 5, or 20 ppm. Spurious, significant increases in left thyroid/parathyroid-to-body weight percentages were seen in females given 5 or 20 ppm.

Macroscopic Observations. There were no macroscopic observations that could be attributed to the administration of the test material.

Microscopic Observations. Test material-related histomorphologic changes were limited to the liver in the males given 5 or 20 ppm and in the females given 20 ppm. The changes consisted of hypertrophy of hepatocytes in centrilobular areas and midzonal to centrilobular hepatocytic vacuolation. The incidence and severity of the changes tended to be greater in the males.

There were no potentially test material-related lesions in the remaining tissues examined.

Week 53 Interim Sacrifice, Body and Organ Weights. In the females, terminal body weights were significantly decreased in the group given 20 ppm. Terminal body weights in the males were comparable between the control and treated group.

In the males, absolute and relative liver weights were increased in the group receiving 20 ppm. In addition, absolute and relative spleen weights were decreased in males given 20 ppm. Significantly decreased left thyroid/parathyroid weights were considered to be spurious due to the absence of a contralateral effect.

In view of the significant decrease in body weight for females given 20 ppm, significant increases in organ-to-body weight percentages for brain, kidney, liver, and spleen may be of no toxicological importance. Decreased absolute weights in the left adrenal gland and bilateral adrenal-to-brain weight ratios may also represent changes secondary to the body weight loss.

Macroscopic Observations. There were no clear or consistent gross observations at the Week 53 interim sacrifice that could be attributed to the administration of the test material.

Microscopic Observations. Centrilobular hepatocytic hypertrophy and vacuolation were increased in incidence and severity in the males given 20 ppm. Generally, in the females given 20 ppm, only centrilobular hypertrophy was seen, and the change was less severe than that noted in the males. In addition, minimal to slight centrilobular hepatocytic pigment was found in the females given 20 ppm. There were no other histomorphologic changes that could be associated with the administration of the test material.

Unscheduled Deaths Through Week 53

Large, mottled, or diffusely dark livers were noted in 2/3 males and 1/1 females given 20 ppm. There were no other gross observations that could be attributed to the administration of the test material. Microscopically, several animals given 20 ppm exhibited liver changes that were similar or related to those seen at the Week 53 interim sacrifice.

Terminal Sacrifice

Macroscopic Observations. The livers of animals given 5 or 20 ppm exhibited a slight increase in macroscopic findings, including enlarged, mottled, diffuse darkened, or focally lightened.

Microscopic Observations. Hepatotoxicity, characterized by centrilobular hypertrophy, centrilobular eosinophilic hepatocytic granules, centrilobular hepatocytic pigment, or centrilobular hepatocytic vacuolation was noted in animals given 5 or 20 ppm. An increase in eosinophilic clear cell altered foci and cystic hepatocellular degeneration was noted in the males given 2, 5, or 20 ppm. There were no clear differences in the Oil Red O stained sections between Groups 1 and 5.

Recovery Sacrifice

Macroscopic Observations. There were no consistent gross findings in the recovery sacrifice animals that could be attributed to the test material.

Microscopic Observations. The data suggests that the hepatotoxicity did not persist in the recovery-sacrifice animals.

Unscheduled Deaths Weeks 54-105

Macroscopic Observations. There were no consistent gross findings in the recovery sacrifice animals that could be attributed to the test material.

Microscopic Observations. Liver findings of the died-on-test or moribund sacrifice animals were generally similar to those seen in the terminally-sacrificed animals. Increased hepatocellular centrilobular hypertrophy, eosinophilic hepatocytic granules,

and centrilobular hepatocytic pigment were noted in the animals given 20 ppm. Increased hepatocellular centrilobular hypertrophy was seen in animals given 5 ppm.

Neoplasm Analysis - All Animals

A complete discussion of statistically significant differences in the incidence of neoplasms may be found in the section entitles "Statistical Report of Survival, Nonneoplastic, and Neoplastic Lesions."

Introduction

A peer review of the histopathology portion of the study entitled: 104-Week Dietary Chronic Toxicity and Carcinogenicity Study with Perfluorooctane Sulfonic Acid Potassium Salts (PFOS; T-6295) in Rats was conducted at Covance, Madison, Wisconsin, By Donald N. Kitchen, D.V.M., PhD of Colorado Pathology Services, Inc., Collbran, Colorado. The tissues had been previously examined and the data tabulated by pathologist, Dr. Richard Alsacker, at Covance.

Experimental Design

A summary of the experimental design for the study is presented below:

	Number of Animals		Dietary Levels
Group	Male	Female	(ppm T-6295)
1 (Control)[a, b, c]	70	70	0
2 (Low)[b]	60	60	0.5
3 (Mid)[b]	60	60	2.0
4 (Mid-High)[b]	60	60	5.0
5 (High)[b, c]	70	70	20.0
6 (High Recovery)[d]	40	40	20.0

a. The control animals received the basal diet only.
b. Five animals/sex in Groups 1 and 5 were sacrificed at Weeks 4 and 14 for hepatocellular proliferation rate measurements, biochemical analysis.
c. Ten animals/sex in Groups 1 and 5 were designated as interim sacrifice animals. These animals were sacrificed after at least 52 weeks of treatment.
d. Animals in Group 6 were treated for at least 52 weeks, then treatment will be discontinued, and the animals were observed for reversibility, persistence, or delayed occurrence of toxic effects for at least 52 weeks posttreatment. During recovery, the animals received basal diet only.

Colorado Pathology Services, Inc. Project Number: P-1934

Methods

The peer review as conducted consisted of two tasks. The first task was the complete review of all slides and confirmation of all diagnoses for 10% of the rats in the control and high dose (Groups 1 and 5) including the recovery (Group 6) of study 6329-183. The animals for complete review were selected by Covance and included the following:

— Main Study ---			
Males		Females	
Control	Group 5	Control	Group 5
C92503	C92753	C92866	C93113
C92505	C92757	C92867	C93115
C92510	C92761	C92868	C93124
C92513	C92762	C92869	C93125
C92514	C92774	C92871	C93133
C92518	C92775	C92873	C93135
C92541	C92776	C92874	C93137

— Recovery Animals 10% —	
Males	Females
C92821	C93181
C92823	C93182
C92827	C93183
C92833	C93184

Colorado Pathology Services, Inc. Project Number: P-1934

The second task consisted of a review of livers from all animals and thyroid glands and pancreas from all male animals, suspected target tissues.

Results

All the materials necessary for this review were readily available and well organized. Relevant in-life data and necropsy data were available to the reviewing pathologist. All slides required to be examined by the reviewing pathologist, were present and were considered to be of good quality. The quality of the histotechnique and the hematoxylin and eosin (H&E) staining were also considered to be good. No tissue artifacts were present that interfered with the slide evaluation and the stain provided good balance between nuclear and cytoplasmic staining. All slides were adequately labeled. Dr. Richard Alsacker the study pathologist, and Marcia J. Holland, histology supervisor, were especially helpful in providing the reviewing pathologist with materials and information needed to complete the peer review.

The differences noted during this review were examined and discussed by the study pathologist, the reviewing pathologist and the 3M pathologist (Dr. Marvin Case) utilizing a multiple headed microscope. All differences noted during this review were resolved with complete agreement concerning the final diagnoses.

Summary

The excellent organization of all materials prior to the arrival of the reviewing pathologist greatly aided and simplified this peer review. The slides were well identified, organized by task and of excellent quality. All differences noted during this review were resolved with complete agreement concerning the final diagnoses.

STATISTICAL REPORT OF SURVIVAL, NONNEOPLASTIC, AND NEOPLASTIC LESIONS

Methods

Survival. Evaluations of trend and heterogeneity of survival data were performed using the Cox-Tarone binary regression method using the National Cancer Institute (NCI) Life Table Package (Thomas, Breslow, and Gart, 1977). Week 105 was treated as the end of the study in the NCI package for both sexes. Animals that were sacrificed at scheduled intervals were censored in the analysis. Continuity-corrected one-sided tail probabilities for trend and two-sided tail probabilities for group comparisons were evaluated at the 5.0% significance level, as reported in Text Tables 1 and 2. Kaplan-Meier product limit survival curves are presented in Text Figures 1 and 2 for males and females, respectively.

Nonneoplastic Lesions. Nonneoplastic lesions were chosen for statistical analyses if the incidence in at least one treated group (Groups 2 through 5) was increased or decreased by at least two occurrences over the control group (Group 1). The high recovery group (Group 6) was selected based on the incidence rate (%) if it was increased or decreased by at least two as compared to the control or high-dose (20.0 ppm) group. When there was only one incidence in the high-recovery and none in the other groups, that case was excluded from the statistical evaluation. These were analyzed by the Cochran-Armitage test for trend and the Fisher-Irwin exact test for control versus treatment comparisons (Thakur, Berry, and Mielke, 1985). One-sided tail probabilities for trend and group comparisons were evaluated at the 5.0% significance level and are reported in Text Tables 3 and 4 for males and females, respectively.

Neoplastic Lesions. Neoplastic lesions were chosen for statistical analyses using the same criteria as in the case of nonneoplastic lesions. The incidental tumors (i.e., tumors that were not assigned to be the cause of death of the animals by the study pathologist) were analyzed by logistic regression of tumor prevalence (Dinse and Lagakos, 1983). The logistic regression model included linear and quadratic terms in age (week of death), but the quadratic term was eliminated if there was a lack of convergence. The fatal and palpable (superficial) tumors were analyzed by Cox-Tarone binary regression method using the death time or the first palpation time (as applicable) as a surrogate for the tumor onset time. In the case of any particular tumor type where the study pathologist assigned the tumor in question being the cause of death of a subset of the animals and the rest of the animals were assumed to be dead of other competing risks, IARC-type (Peto et al,

1980) cause of death analysis was performed. Specifically, the subset of the tumors which were assigned to be the cause of death by the study pathologist was analyzed by Cox-Tarone logistic regression under life table techniques. The subset, which was considered incidental by the pathologist, was analyzed by logistic regression of tumor prevalences. Tumor types whose cause of death was undetermined, were treated as incidental for statistical evaluation. The score statistics and their respective variances from the above tests were then used to compute the combined evidence as described by Gart et al. (1986). If one tumor in the group belonged to one of the two categories (fatal and incidental) in a test was combined with the other category for the purpose of statistical analyses. In addition, in the cases where there was lack of convergence for the asymptotic test of the logistic regression method, the exact probability of the significance was obtained by using LogXact-Turbo (1993) and combined with the probability of Cox-Tarone test, if necessary.

The benign and malignant neoplastic incidences were evaluated both separately and combined where appropriate. The criteria for combination were based on the work of McConnell et al. (1986). The incidences of multiple-organ findings such as hemangioma, hemangiosarcoma, lipoma, liposarcoma, fibroma, fibrosarcoma, leiomyoma, leiomyosarcoma, endometrial stromal polyp, and endometrial stromal sarcoma were counted by animal, not by tissue type. They were evaluated statistically if they met the selection criterion for the analysis. The statistical results for these cases may be biased because not all the animals were examined for every tissue. One-sided trend and pairwise group comparisons were evaluated at the 5.0% significance level and are shown in Text Tables 5 and 6 for males and females, respectively.

In the nonneoplastic analyses, animals sacrificed early (Week 4) were excluded from the denominators. In the statistical evaluations of the neoplastic lesions, animals sacrificed early (during or before Week 14) were discounted from the number of animals at risk. In the neoplastic analyses, the low- (0.5 ppm), mid-(2.0 ppm), mid-high (5.0 ppm), and high recovery (20 ppm) groups that did not have complete histopathology examinations were excluded from statistical analyses.

In the text tables, the p-values under Group 1 (control) are for trend analysis and the p -values under Groups 2 (low), 3 (mid), 4 (mid-high), 5 (high) and 6 (high recovery) are for the comparison of that group versus the control group. Group 6 was also compared with Group 5, and the p-values for those comparisons are indicated in the text tables.

Trend analysis includes Groups 1, 2, 3, 4, and 5 only. Ordinal dose levels 0, 1, 2, 3, and 4 were used in all analyses for Groups 1, 2, 3, 4, and 5, respectively. Continuity correction was done for all asymptotic tests.

The following notations are used throughout this report designating direction and significance of effects.

+ = Effect in the increased direction
- = Effect in the decreased direction
* = Significant at $p \leq 0.05$
** = Significant at $p \leq 0.01$
E = Exact permutation test
NA = Not analyzed

Results and Discussion

Survival. As indicated in Text Table 1, a significant negative trend ($p = 0.0005$) for decreased mortality occurred in for the males and was associated with significant decreases in mortality in mid-high- (5.0 ppm) and high-dose (20.0 ppm) groups as compared to that of the control group ($p = 0.0115$ and 0.0292, respectively). None of the other treated groups in the males revealed any significant differences in mortality.

As indicated in Text Table 2, no significant trend was noted in mortalilty in females. There was a significant increase in mortality in the mid-dose (2.0 ppm) group ($p = 0.0015$) and not in the mid-high (5.0 ppm) and high-dose (20.0 ppm) groups as compared to that of the control.

Nonneoplastic Lesions. The liver, pancreas, and thyroid in both sexes have been identified as appropriate to perform statistical analysis for nonneoplastic lesions.

As indicated in Text Table 3, there were significant positive trends in the incidences of hepatocellular centrilobular hypertrophy, liver eosinophilic centrilobular granular cytoplasm, and hepatocellular midzonal/centrilobular vacuolation ($p \leq 0.01$ for all the cases) for males. These cases were associated with significant increases in the high-dose (20.0 ppm) group ($p \leq 0.01$ for all the cases) when compared to those of the control group. In addition, there were significantly increased incidences in the mid- (2.0 ppm) and mid-high-dose (5.0 ppm) groups for hepatocellular centrilobular hypertrophy

(p = 0.0415 and 0.0000, respectively) and the mid-high-dose (5.0 ppm) group for hepatocellular midzonal/centrilobular vacuolation (p = 0.0024) as compared to the control in this sex. However, the male high-dose recovery (20.0 ppm) group animals in all these cases exhibited significantly decreased incidences over the high-dose (20.0 ppm) group ($p \leq 0.01$ for all the cases), implying that the effect may be transient (reversible) in nature. Significant positive trends were also noted for hepatocellular centrilobular pigment and liver individual hepatocyte necrosis (p = 0.0006 and 0.0106, respectively) in association with significant increases in the respective high-dose (20.0 ppm) group over the control (p = 0.0139 and 0.0224, respectively). A significant positive trend was detected for cystic degeneration in association with significantly increased incidences in all the dose groups as compared to the control ($p \leq 0.01$ for Groups 2 through 6 vs. 1, respectively). Furthermore, a significant positive trend without any significant group effect was noted for liver degeneration/necrosis centrilobular (p = 0.0132). Marginally significant increases over the control were observed in the mid-high-dose (5.0 ppm) group incidences for hepatocellular altered basophilic focus and liver coagulative necrosis (p = 0.0352 and 0.0351, respectively) and in the mid-dose (2.0 ppm) group for pancreatic interstitial fat infiltration (p = 0.0133) without any significant trends.

As indicated in Text Table 4, there were significant positive trends in the incidences of hepatocellular centrilobular hypertrophy and liver eosinophilic centrilobular granular cytoplasm ($p \leq 0.01$ for both cases) for the females. These cases were associated with significant increases in respective mid-high (5.0 ppm) and high-dose (20.0 ppm) groups ($p \leq 0.01$ for all the cases) when compared to that of the control group. Significant positive trends were also noted for hepatocellular centrilobular pigment and liver individual hepatocyte necrosis (p = 0.0000 and 0.0359, respectively). These cases were associated with significant increases in the respective high-dose (20.0 ppm) group (p = 0.0000 and 0.0500, respectively) when compared to that of the control group. However, the high-dose recovery (20.0 ppm) group animals in all the above cases exhibited significantly decreased incidences over the high-dose (20.0 ppm) group ($p \leq 0.01$ for all the cases, except for liver individual hepatocyte necrosis (p = 0.0329) implying that the effect may be transient in nature. A significant positive trend in association with a significant increase in the high-dose (20.0 ppm) group was found for lymphohistiocytic infiltration in the liver (p = 0.0080 for trend and 0.0038 for high-dose versus control). A significant positive trend was also noted for cystic degeneration in the liver (p = 0.0187). However, no significant group comparison was detected. In addition, there was a significant positive trend in the incidences of pigmented macrophage

infiltration in the liver (p = 0.0000). This was associated with significant increases in the high-dose (20.0 ppm) and high-dose recovery (20.0 ppm) groups as compared to the control (p = 0.0000 and 0.0147, respectively). However, the high-dose recovery (20.0 ppm) group animals exhibited significantly decreased incidences over the high-dose (20.0 ppm) group (p = 0.0383). A marginally significant positive trend was noted for Zymogen decreased granules in the pancreas (p = 0.0488). This was associated with significant increases in all dosed groups (p = 0.0093, 0.0011, 0.0329, 0.0127, and 0.0030 for Group 2 through 6 versus 1, respectively) when compared to the control. Significant increases were also observed over the control in the mid-dose (2.0 ppm) incidences of hepatocellular periportal vacuolation (p = 0.0358) and the low-dose (0.5 ppm) incidences of liver hematopoiesis extramedullary (p = 0.0.0352). However, no significant trends were associated with them. A significant negative trend was observed for hepatocellular hypertrophy periportal (p = 0.0026). This was associated with a significant decrease in the high-dose (20.0 ppm) group (p = 0.0127) as compared to that of the control The high-dose recovery (20.0 ppm) animals in this case exhibited significantly increased incidences (p = 0.0344) when compared to the high-dose (20.0 ppm) group. Significant negative trends were also noted for angiectasis and congestion in the liver (p = 0.0231 and 0.0451, respectively) and islet cell hyperplasia in the pancreas (p=0.0372). However, no significant group comparisons were found for these cases.

Neoplastic Lesions. As indicated in Text Table 5, a significant positive trend was noted in the incidences of liver hepatocellular adenoma for males (p = 0.0276). This was associated with a significant increase in the high-dose (20.0 ppm) group over the control (p = 0.0456). The high-dose recovery (20.0 ppm) group animals in this case exhibited a significantly decreased incidence when compared to that of the high-dose (20.0 ppm) group (p = 0.0240). Significantly increased incidences were observed for thyroid follicular cell adenoma in the high-dose recovery (20.0 ppm) group when compared to either the control or the high-dose (20.0 ppm) group (p= 0.0280 and 0.0121, respectively). There was also a significant increase in the combined (adenoma and carcinoma) thyroid follicular cell tumors in the high-dose recovery (20.0 ppm) group animals as compared to that of the high-dose (20.0 ppm) group (p = 0.0125). None of these cases were associated with any significant trend. Thyroid follicular cell carcinoma did not show any significant effect.

There were no other significant neoplastic findings in the males.

As indicated in Text Table 6, significant positive trends were observed in the incidences of hepatocellular adenoma ($p = 0.0153$) and hepatocellular combined adenoma and carcinoma ($p = 0.0057$) in the females. These cases were associated with significant increases in the high-dose (20.0 ppm) group as compared to the control ($p \leq 0.05$ for both cases). All these tumors were incidental and noted at the terminal sacrifice. A marginally significant increase for thyroid follicular cell adenoma and carcinoma combined was observed in the mid-high (5.0 ppm) group ($p = 0.0471$) but not in the high-dose (20.0 ppm) group as compared to the control group. In fact, thyroid C-cell adenoma and thyroid C-cell combined adenoma and carcinoma actually showed significant decreases in the high-dose (20.0 ppm) group as compared to the control ($p = 0.0336$ for both cases). There were significant negative trends in the incidences of mammary fibroadenoma and mammary combined adenoma and fibroadenoma ($p \leq 0.05$ for both cases). These cases were associated with significantly lower incidences in the respective high-dose (20.0 ppm) group ($p \leq 0.05$ for both cases) when compared to that of the control. However, the low-dose (0.5 ppm) group animals for these cases exhibited significant increases over the control ($p \leq 0.05$ for both cases). A significant decreased incidence was found for the high-dose recovery (20.0 ppm) group in the incidences of mammary carcinoma ($p = 0.0161$) as compared to the high-dose (20.0 ppm) group. There was no other significant group effect in mammary carcinoma. There was a marginal significant negative trend for the mammary combined fibroadenoma/adenoma/carcinoma ($p = 0.0482$). However, the low- (0.5 ppm) and mid-high (5.0 ppm) groups for this case exhibited significantly increased incidences over the control ($p = 0.0474$ and 0.0066, respectively).

There were no other significant neoplastic findings in the females.

COMMENTS ON THE DATA

Various models of calculators, computers, and computer programs were used to analyze data in this study. Because different models round off or truncate numbers differently, values in some tables (e.g., means, standard deviations, or individual values) may differ slightly from those in other tables, from individually calculated data, or from statistical analysis data. Neither the integrity nor the interpretation of the data was affected by these differences.

The units for the dose levels in the inlife summary tables are ppm.

The number of animals listed in the heading of the summary tables for clinical and mass observations reflects the number of animals assigned to each group at the start of the study.

The summary tables for clinical observations indicate the number of animals for which a condition was observed without regard to the reversibility, number of incidences/animal, or the length of time the condition persisted.

Only observations for each animal other than normal are indicated in the summary clinical observations tables.

Each animal with observations recorded as "Normal" throughout the study has the comment "No remarkable observations" indicated in the individual clinical observations tables.

The specific details for comments in the individual clinical observations tables that are indicated with a "C" can be found at the end of each group for each sex.

The level of severity for some clinical observations was not specified at the time of the observation and is indicated as <UNSPECIFIED> in the summary and individual clinical observation tables.

The day of initiation of treatment is "Day 1, Week 1." Body weight data are entered at the start of a study week (e.g., a body weight recorded on Day 1 is considered a Week 1 body weight, a body weight recorded on Day 8 is considered a Week 2 body weight). Body weight change data are calculated from the first day of the study week to the first day of the following study week (e.g., Week 1 values are calculated from Day 1 through 8). Weekly food consumption are calculated from the first day of the study week to the first day of the following study week (e.g., Week 1 values are calculated from Day 1 through 8).

COMMENTS ON THE DATA (Continued)

The values for summary and individual test material consumption are reported with more significant figures than is appropriate for the data due to limitations of the data collection and reporting software.

The comment "SPILLED" in individual food consumption data tables indicates that food consumption was not recorded due to spillage during the interval.

The comment "CNTMD" in individual food consumption data tables indicates that food consumption was not recorded due to contamination of the diet with urine or feces in the food container.

The comment "NOT TAKEN" in individual food consumption data tables indicates that the animal died before the end of the food consumption interval.

The comment "TECH SPILL" in individual food (water) consumption data tables indicates that food consumption was not recorded due to food (water) spillage caused by technician error.

Differences in the population size (N) in the summary tables for clinical and anatomic pathology are explained in the individual data tables or the code sheets.

Results of clinical pathology samples collected for animals sacrificed at unscheduled intervals appear in the individual clinical pathology tables for the next scheduled interval. These results are not in the summary tables and are not included in the statistical analyses.

Statistical analyses were not done when there were two or fewer values for a parameter.

COMMENTS ON THE DATA (Continued)

The calculation for individual test material consumption is:

Test material consumption =

$$\frac{\text{Diet Concentration} \times \text{Food Consumption}}{\text{Food Consumption Interval} \times [\text{First Body Weight of Interval} + (\text{Daily Body Weight Gain} \times \text{Day Factor})]}$$

where: Daily Body Weight Gain =

$$\frac{\text{Last Body Weight of Interval} - \text{First Body Weight of Interval}}{\text{Day of Last Body Weight of Interval} - \text{Day of First Body Weight of Interval}}$$

and: Day Factor =

$$(\text{Food Consumption Start Day} - \text{Day of First Body Weight of Interval}) + \frac{\text{Food Consumption Interval}}{2}$$

and: Food Consumption Interval =

$$\text{Food Consumption End Day} - \text{Food Consumption Start Day}$$

CODES, ABBREVIATIONS, AND UNITS

General Codes and Abbreviations
Codes for Clinical Pathology
Abbreviations and Units for Clinical Hematology
Abbreviations and Units for Clinical Chemistry
Abbreviations and Units for Clinical Urinalysis
Abbreviations and Units for Urine Chemistry
Codes for Anatomic Pathology

Note: The following lists of codes, abbreviations, and units are used by Covance. Some, but not necessarily all, of this information may be needed for this report.

General Codes and Abbreviations

WK	Week
N	Number of measurements in a group
Mean; MEAN	Arithmetic mean
CAM	Covariate-adjusted mean
SD; S.D.; STAND DEV; STANDARD DEV; sd	Standard deviation
*	Group mean is significantly different from the mean of the control group (Group 1) at $p \leq 0.05$
-; NA	No value; not applicable; not present
P	Present
C	Comment found at the end of each group for each sex
UNSCHED	Unscheduled
DISPATCH	Observations transferred from the inlife module of the data collection system to the necropsy module for reference during necropsy. Observations are duplicates of the last inlife observations.
TBW	Terminal body weight
#	Number
CO	Clinical observation

Animal Death Codes

1	Interim sacrifice, Week 4
2	Interim sacrifice, Week 14
3	Interim sacrifice, Week 53
T	Terminal sacrifice
D	Found dead
M	Moribund
U	First postrecovery sacrifice

Codes for Clinical Pathology

GENERAL CODES

NS	No sample
QS/QNS	Quantity not sufficient
NR	No repeat (sample volume not sufficient for repeat analysis)
FS	Fibrin strands
SC	Sample clotted
SH	Slightly hemolyzed
H	Hemolyzed
SL	Slightly lipemic
L	Lipemic
SI	Slightly icteric
I	Icteric
NF	Animal not fasted
U	Unscheduled/moribund bleed
DT/DOT	Animal died on test
DB	Died during bleeding
TJ	Technician judgment to repeat test
TE	Technical error (instrument or technician error that results in unacceptable data, e.g., unacceptable instrument output, sample spilled, entry of invalid data)
RE	Recording error (recorded incorrect data, e.g., wrong number, spelling error, incorrect date)
EE	Entry error (incorrect keyboard entry)
SE	Sampling error
PC	Platelets clumped
PD	Platelets decreased
PI	Platelets increased
PL	Platelets large
PA	Platelets appear adequate
CO	Color interferes with test
HB	Heinz bodies observed
PLASMO	Plasmodium
NO AGG	No aggregation
FR	Fractious
UTD	Unable to determine
NO COAG	No coagulation

Codes for Clinical Pathology (Continued)

RESULTS NOT INCLUDED IN STATISTICAL ANALYSES

Hemolyzed clinical chemistry or coagulation samples
Samples from animals at unscheduled intervals
Prothrombin times (PT) greater than 50 seconds
Activated partial thromboplastin times (PTT) greater than 110 seconds
Bleed times (BLETIME) greater than 30 minutes

CODES FOR BLOOD CELL MORPHOLOGY

The following scale was used to measure the degree of anisocytosis (ANISO), poikilocytosis (POIK), polychromasia (POLY), hypochromasia (HYPO), or basophilic stippling (BASTIP) or the presence of Howell-Jolly bodies (HJBODY), toxic neutrophils (TOXNEUT), or atypical lymphocytes (ATYPLYM).

Scale	Degree	Presence
-	Normal for the species	Not present
1	Slight	Rare
2	Moderate	Few
3	Marked	Moderate
4	Not applicable	Many

URINE APPEARANCE

Color						Clarity		Miscellaneous	
A	Pale	E	Amber	I	Black	J	Clear	M	Debris
B	Straw	F	Brown	P	Blue/green	K	Hazy	O	Feces
C	Yellow	G	Red	Q	Blue	L	Cloudy		
D	Dark yellow	H	Green	R	Orange				

Codes for Clinical Pathology (Continued)

URINE CHEMISTRY MULTISTIX® STRIP

Urine Glucose		Urine Ketone		Urine Blood	
-	Negative	-	Negative	-	Negative
+	100 mg/dL	+	5 mg/dL	+	Small
++	250 mg/dL	++	15 mg/dL	++	Moderate
+++	500 mg/dL	+++	40 mg/dL	+++	Large
++++	1,000 mg/dL	++++	80 mg/dL		
+++++	≥2,000 mg/dL	+++++	160 mg/dL		

Urine Urobilinogen		Urine Bilirubin	
-	0.2 mg/dL	-	Negative
+	1 mg/dL	+	Small
++	2 mg/dL	++	Moderate
+++	4 mg/dL	+++	Large
++++	8 mg/dL		

(1 mg = approximately 1 Ehrlich unit)

URINE SEDIMENT

Cells, Crystals, Casts, and Comments				Bacteria	
A	Amorphous urates	Q	Sperm	0	Not present
B	Amorphous phosphates	R	Fecal contamination	1	Few
C	Uric acid	S	Pinworm ova found	2	Moderate
D	Triple phosphates	T	Pinworm larvae found	3	Many
E	Calcium oxalate	U	Parasite ova found		
F	Calcium carbonate				
G	Granular casts				
H	Hyaline casts	0	Not present		
I	Cellular casts	1	1 - 5 per field		
J	Waxy casts	2	6 - 10 per field		
K	Unknown crystal	3	11 - 20 per field		
P	Mucous threads	4	>20 per field		

Abbreviations and Units for Clinical Hematology

Test	Abbreviation (Units)
Red blood cell count	RBC (E6/UL or $X10^6/\mu L$)
Hemoglobin	HGB (G/DL)
Hematocrit	HCT (%)
Mean corpuscular volume	MCV (FL)
Mean corpuscular hemoglobin	MCH (PG)
Mean corpuscular hemoglobin concentration	MCHC (%)
Platelet count	PLT (E3/UL or $X10^3/\mu L$)
Mean platelet volume	MPV (FL)
Reticulocyte count	RETIC (%)
Absolute reticulocyte count	RETIC (E3/UL or $X10^3/\mu L$)
Heinz body count	HEINZ (%)
Erythrocyte sedimentation rate	ESR (MM/HR)
Prothrombin time	PT (SEC)
Activated partial thromboplastin time	PTT (SEC)
Thrombin time	TT (SEC)
Activated coagulation time	ACT (SEC)
Fibrinogen	FBR (MG/DL)
Fibrin/fibrinogen degradation products	FDP (UG/ML)
Platelet aggregation	
Collagen	PAGG/COL (%)
Adenosine diphosphate	PAGG/ADP (%)
Alpha 2-antiplasmin	ANTIPLAS (%)
Bleeding time	BLE TIME (SEC)
Methemoglobin	METHGB (%)
Plasma hemoglobin	PLA HGB (MG/DL)
Myeloid/erythroid ratio	M/E RATIO
Estimated myeloid/erythroid ratio	EST M/E RATIO
White blood cell count	WBC (E3/UL or $X10^3/\mu L$)
Differential blood cell count	
Nucleated red blood cell count	NRBC (/100 WBC)
Corrected white blood cell count	COR WBC (E3/UL or $X10^3/\mu L$)
Segmented neutrophil count	N-SEG (E3/UL or $X10^3/\mu L$) and %
Band neutrophil count	N-BAND (E3/UL or $X10^3/\mu L$) and %
Lymphocyte count	LYMPH (E3/UL or $X10^3/\mu L$) and %
Monocyte count	MONO (E3/UL or $X10^3/\mu L$) and %
Eosinophil count	EOSIN (E3/UL or $X10^3/\mu L$) and %
Basophil count	BASO (E3/UL or $X10^3/\mu L$) and %
Anisocytosis	ANISO (-,1,2,3)
Polychromasia	POLY (-,1,2,3)

Abbreviations and Units for Clinical Hematology (Continued)

Test	Abbreviation (Units)
Poikilocytosis	POIK (-,1,2,3)
Hypochromasia	HYPO (-,1,2,3)
Howell-Jolly bodies	HJBODY (-,1,2,3,4)
Basophilic stippling	BASTIP (-,1,2,3)
Toxic neutrophils	TOXNEUT (-,1,2,3,4)
Atypical lymphocytes	ATYPLYM (-,1,2,3,4)
Aqueous white blood cell count (right eye)	R EYE (WBC/UL)
Aqueous white blood cell count (left eye)	L EYE (WBC/UL)

Abbreviations and Units for Clinical Chemistry

Test	Abbreviation (Units)
Glucose	GLU (MG/DL)
Urea nitrogen	UN (MG/DL)
Urea	UREA (MG/DL)
Creatinine	CREAT (MG/DL)
Total protein	T PRO (G/DL)
Albumin	ALB (G/DL)
Globulin	GLOB (G/DL)
Albumin/globulin ratio	A/G RATIO
Total bilirubin	T BILI (MG/DL)
Direct bilirubin	D BILI (MG/DL)
Indirect bilirubin	I BILI (MG/DL)
Cholesterol	CHOL (MG/DL)
Triglyceride	TRIG (MG/DL)
Urea nitrogen/creatinine ratio	UN/CREAT (RATIO)
Total lipids	T LIPIDS (MG/DL)
Phospholipids	P LIPIDS (MG/DL)
High-density lipoprotein cholesterol	HDL (MG/DL)
Low-density lipoprotein cholesterol	LDL (MG/DL)
Uric acid	UA (MG/DL)
Aspartate aminotransferase	AST/SGOT (IU/L)
Alanine aminotransferase	ALT/SGPT (IU/L)
Alkaline phosphatase	ALK PHOS (IU/L)
Gamma glutamyltransferase	GGT (IU/L)
Sorbitol dehydrogenase	SDH (IU/L)
Lactate dehydrogenase	LDH (IU/L)
Creatine kinase	CK (IU/L)
Amylase	AMYLASE (IU/L)
Lipase	LIPASE (IU/L)
Palmitoyl CoA oxidase	PCOAO (IU/G)
Calcium	CA (MG/DL)
Ionized calcium	ION CA (MG/DL)
Inorganic phosphorus	I PHOS (MG/DL)
Sodium	NA (MMOL/L)
Potassium	K (MMOL/L)
Chloride	CL (MMOL/L)
Magnesium	MG (MEQ/L or MG/DL)
Zinc	ZN (MG/L or PPM)
Strontium	SR (MG/L or PPM)
Iron	FE (UG/DL)

Abbreviations and Units for Clinical Chemistry (Continued)

Test	Abbreviation (Units)
Excess iron	EX FE (UG/DL)
Total iron binding capacity	TIBC (UG/DL)
Unbound iron binding capacity	UIBC (UG/DL)
Percent iron saturation	FE %SAT (%)
Plasma cholinesterase	CHEP (MU/ML)
Red blood cell cholinesterase	CHER (MU/ML)
Brain cholinesterase	CHEB (MU/ML)
Caudate putamen	CAUD PUT (UMOL/G)
Hippocampus	HIPPOCAM (UMOL/G)
Frontal cortex	F CORTEX (UMOL/G)
Cerebellum	CEREBELL (UMOL/G)
Bicarbonate	BICARB (MMOL/L)
Serum hemoglobin	SER HGB (MG/DL)
Serum bile acids	SBA (UMOL/L or MG/DL)
Fecal bile acids	FBA (UG/ML)
Average fecal weight	FCC WGT (G)
Fecal bile acids (calculation)	FBA (MG/Day)
Osmolality	OSMO (MOSM/KG)
Electrophoresis	
Albumin	E ALB (G/DL)
Alpha-1-globulin	E A-1 (G/DL)
Alpha-2-globulin	E A-2 (G/DL)
Beta globulin	E BETA (G/DL)
Gamma globulin	E GAMMA (G/DL)
High-density lipoprotein	E-HDL (%)
Low-density lipoprotein	E-LDL (%)
Very-low-density lipoprotein	E-VLDL (%)
Insulin	INSULIN (UU/ML)
Adrenocorticotropic hormone	ACTH (PG/ML)
Cortisol	CORTISOL (UG/ML)
Glucagon	GLUCAGON (PG/ML)
Triiodothyronine	T3 (NG/DL)
Thyroxine	T4 (UG/DL)
Creatine kinase isoenzymes	
BB	CK-BB (U/L)
MB	CK-MB (U/L)
MM	CK-MM (U/L)

Abbreviations and Units for Clinical Urinalysis

Test	Abbreviation (Units)
Urine volume	U VOL (ML)
8-hour urine volume	8 HR VOL (ML)
Specific gravity	SP GR
Urine osmolality	U OSMO (MOSM/KG)
Quantitative urinary/cerebrospinal fluid protein	QUAN PRO (MG/DL)
Urine protein excretion	PRO EXC (MG)
Urine chemistry Multistix® strip	
Urine pH	U PH
Urine protein	U PRO (MG/DL)
Urine glucose	U GLU
Urine ketones	U KET
Urine bilirubin	U BILI
Urine blood	U BLOOD
Urine urobilinogen	UROBILI
Urine reducing substances	U RE SUB
Microscopic examination of urine sediment	
Red blood cells per high-power field	RBC (PER HPF)
White blood cells per high-power field	WBC (PER HPF)
Epithelial cells per high-power field	EPITH (PER HPF)
Bacteria per high-power field	BACT (PER HPF)
Casts per low-power field	CASTS (PER LPF)
Crystals per low-power field	CRYSTALS (PER LPF1 or PER LPF2)
Urine appearance	URINE APP1 or URINE APP2
Comments	COMMENTS

Abbreviations and Units for Urine Chemistry

Test	Abbreviation (Units)
Urine volume	U VOL (ML)
Urine osmolality	U OSMO (MOSM/KG)
Urine creatinine	U CREAT (MG/DL)

Protein to urinary creatinine ratio	PRO/CREA (RATIO)
Urine protein excretion	PRO EXC (MG)

Codes for Anatomic Pathology

Code	Definition
	ANIMAL DEATH CODES
1-6	Interim sacrifices 1 through 6
T	Terminal sacrifice
U	First postrecovery sacrifice
V	Second postrecovery sacrifice
A	Accidental death
B	Death or sacrifice postaccident
D	Found dead
M	Moribund
P	Returned to stock
R	Unscheduled recovery sacrifice
O	Other type of unscheduled death
	MACROSCOPIC CODES
EX	Indicates that organ weight is excluded from calculations
NOT TAKEN	Organ weight not taken; explanation given in necropsy notes
MISSING	Organ missing or lost
UNSUITABLE	Organ technically unsuitable for weighing
AUTOLYTIC	Organ autolyzed and could not be weighed
EXCLUDE	Weight was taken, but was excluded from all calculations
	MICROSCOPIC CODES
Codes Prefacing Neoplastic Findings	
B-	Primary, benign neoplasm
M-	Primary, malignant neoplasm
N-	Metastatic neoplasm
I-	Locally invasive neoplasm
X-	Other neoplasm
Distribution of Findings	
Focal	
Diffuse	
Multifocal	

Codes for Anatomic Pathology (Continued)

Grades for Severity or Amount

1	Minimal - the least amount of change that can be observed with the light microscope
2	Slight - less than average amount of change, but readily discernible as abnormal
3	Moderate - the average amount of change that is expected for a lesion
4	Moderately severe (marked) - a marked amount of change with possible loss of function of the affected cells or organs
5	Severe - a great amount of change with probable loss of function of the affected cell or organs and frequently involves large areas of the organ

Other Microscopic Codes

TL	Total
P	Finding present
-	Finding not present
MN	Mean

TISSUE ABBREVIATIONS

Abbreviation	Definition
LN	Lymph node
GL	Gland
STOMACH, GL	Glandular stomach
STOMACH, NONGL	Nonglandular stomach
SALIV GL, MANDIB	Mandibular salivary gland
LN, ANT MES/PANC	Anterior mesenteric/pancreatic lymph node
AUDITORY SEB GL	Auditory sebaceous gland
LACRIMAL GLAND, EX	Exorbital lacrimal gland
HEMATO NEOPLASIA	Hematopoietic neoplasia
LACRIMAL GL, INT	Internal lacrimal gland
CAVITY, ABDOM	Abdominal cavity
SALIV GL,PAROTID	Parotid salivary gland
LN, TRACHEOBRON	Tracheobronchial lymph node
CATHETER EXIT	Catheterization site: exit site from the body
CATHETER ENTRANC	Catheterization site: entrance site into the vessel
CATHETER TIP	Catheterization site: tissues (vascular or extravascular) associated with the catheter near its tip

2/24/00	1	b	0.390	2.66	8.05	23.3
	2	b	0.405	2.18	7.48	26.0
	Mean	-	0.398 (79.6)	2.42 (121)	7.77 (155)	24.7 (124)
2/24/00[g]	1	-	-	2.35	6.18	21.4
	2	-	-	2.42	5.80	20.0
	Mean	-	-	2.39 (120)	5.99 (120)	20.7 (104)
3/23/00	1	-	0.240	2.38	8.05	25.0
	2	-	0.479	2.00	6.32	26.5
	Mean	-	0.360 (72.0)	2. 19(110)	7.19 (144)	25.8 (129)

Overall mean concentrations of each dose level ranged from 102.3 to 108.7.

b Below the limit of quantitation (<0.4 ppm).
c Each value in the parentheses is the percent of theoretical.
g Re-test
Overall Mean = $\frac{\text{Total of all means}}{\text{Number of means}}$

** END OF LIST **

APPENDIX 1

Protocol Deviations

Protocol Deviations

Protocol. Husbandry. Diet. "Certified Rodent Diet #5002, meal (PMI Nutrition International) *ad libitum*."

Actual Procedure. During the course of the study, for a total of 29 incidences, 24 animals were found without access to food. Food was provided when the limited access was noted. Comments regarding limited access to food are recorded in the data.

During single housing on April 13, 1998 (acclimation), temporary Animal No. 593 was not fed in.

Protocol. Husbandry. Water. "*Ad libitum*."

Actual Procedure. On April 29, 1998, during the a.m. room check it was noticed that Animal Nos. C92671 through C92690 (Group 3 males), and C92691 through C92725 (Group 4 males) did not have access to water due to a kinked water hose.

Protocol. Husbandry. Housing. "Individual (may be group-housed during acclimation)."

Actual Procedure. On May 10, 1998, Animal No. C92989 (Group 2 female) was found out of its cage during the a.m. check.

Protocol. Termination. Unscheduled Sacrifices and Deaths. "Animals to be sacrificed will be anesthetized with carbon dioxide, weighed, and exsanguinated."

Actual Procedure. At necropsy, Animal Nos. C92918 (Group 1 female), C92939 (Group 2 female), and C93038 (Group 3 female) were anesthetized with sodium pentobarbital instead of carbon dioxide. At necropsy, Animal No. C92621 received approximately 1.0mL of sodium pentobarbital prior to administration of carbon dioxide anesthesia.

A body weight was not taken for Animal Nos. C92566 (Group 1 male), C92687 (Group 3 male) and C92966 (Group 2 female) prior to necropsy.

Protocol Deviations (Continued)

Protocol. Postmortem Procedures. Tissue Preservation. "At the terminal sacrifice, sections of the heart and liver will be collected from 10 animals/sex/group in Groups 1, 4, 5, and 6 and preserved in 2.0% paraformaldehyde/2.5% glutaraldehyde in 0.1 M phosphate buffer. These tissues will be processed and embedded in epoxy blocks for possible future examination by electron microscopy.

Actual Procedure. At the terminal sacrifice, tissues were collected from 11 animals in Group 4 (females) for possible electron microscopy instead of 10 animals.

Protocol. Postmortem Procedures. Histopathology. "Lesions, liver, lungs, kidneys, pancreas, thyroid, testes, and mammary glands (females) from each animal in Groups 2, 3, 4, and 6 sacrificed at the terminal and recovery sacrifices will be embedded in paraffin, sectioned, stained with hematoxylin and eosin, and examined microscopically."

Actual Procedure. At the terminal sacrifice, one mammary gland mass was not collected for Animal Nos. C92927 (Group 1 female) and C93078 (Group 4 female).

At necropsy, the mass located in the inguinal region for Animal No. C92729 was not commented on or collected.

On July 13, 1999, a macroscopic lesion for Animal No. C92838 was not collected at the time of necropsy.

At the terminal and recovery sacrifices, parathyroid glands were examined microscopically from animals in Groups 2, 3, 4.

Protocol. Postmortem Procedures. Histopathology. "Slides of the pancreas from males found dead, sacrificed at an unscheduled interval, or sacrificed at the Week 14 and 53 interim sacrifices, terminal, and recovery sacrifices will be sent to Tox Path Inc. for peer-review and results will be provided to Covance for inclusion in the final report."

Actual Procedure. Results of the peer-review are not included in the final report. The results are on file with Covance.

Protocol Deviations (Continued)

Protocol. Experimental Design. Postmortem Procedures. "The following tissues (when present) or representative samples will be collected from each animal and preserved in 10% neutral-buffered formalin, unless otherwise specified."

Actual Procedure. Some tissues, required by the protocol, were not available for histopathologic examination. Missing tissues are listed with appropriate comments in the pathology data sheets for individual animals. Summary tables do not include them as having been examined.

These deviations are not expected to have affected the results of the study.

FINAL REPORT

Study Title:

104-Week Dietary Chronic Toxicity and Carcinogenicity Study with Perfluorooctane Sulfonic Acid Potassium Salt (PFOS; T-6295) in Rats

Author:

Peter J. Thomford, PhD

Study Completion Date:

January 2, 2002

Testing Facility:

Covance Laboratories Inc.
3301 Kinsman Boulevard
Madison, Wisconsin 53704-2595

Laboratory Study Identification:

Covance 6329-183

Sponsor Study Identification:

3M T-6295

FINAL REPORT

Study Title:

104-Week Dietary Chronic Toxicity and Carcinogenicity Study with Perfluorooctane Sulfonic Acid Potassium Salt (PFOS; T-6295) in Rats

Author:

Peter J. Thomford, PhD

Study Completion Date:

January 2, 2002

Testing Facility:

Covance Laboratories Inc.
3301 Kinsman Boulevard
Madison, Wisconsin 53704-2595

Laboratory Study Identification:

Covance 6329-183

Sponsor Study Identification:

3M T-6295

FINAL REPORT

Study Title:

104-Week Dietary Chronic Toxicity and Carcinogenicity Study with Perfluorooctane Sulfonic Acid Potassium Salt (PFOS; T-6295) in Rats

Author:

Peter J. Thomford, PhD

Study Completion Date:

January 2, 2002

Testing Facility:

Covance Laboratories Inc.
3301 Kinsman Boulevard
Madison, Wisconsin 53704-2595

Laboratory Study Identification:

Covance 6329-183

Sponsor Study Identification:

3M T-6295
