ASBESTOS IN AIR

On April 27, 1977 a survey was performed of your operations which use asbestos. Eight personal air samples were collected in the box car unloading and hydropulper areas. These samples were analyzed optically for asbestos fiber concentrations.

CONCLUSIONS

1. All samples indicated concentrations in the neighborhood of 0.2 fibers per milliliter over the eight hour work day. This is substantially below the currently recommended maximum concentration of 2.0 fibers per milliliter.

2. The primary sources of airborne asbestos fiber appears to be leakage from broken bags and dust from box cars. Some contribution may also be made by asbestos- containing slurry spilling out of the hydropulper and drying out on the floor.

3. Although the area in the vicinity of the #1 mixer was not sampled, it is anticipated that this operation generates much higher asbestos concentrations than the hydrapulping operation. This mixer should be used as little as possible and discontinued if not necessary.

4. Asbestos suppliers and plant personnel have been experimenting with various types of packing and shipping methods to minimize bag breakage and asbestos dust generation.

5. A review of medical controls indicates that all currently required medical controls are in effect. For your reference, a copy of our recommended medical controls is attached.

6. Because of the present uncertainty of the scientific community concerning airborne asbestos concentrations needed to present a significant risk of cancer, the recommendations contained in this report should be completed to assure that airborne concentrations are kept to the lowest practical levels.

ASBESTOS IN AIR

Medical Controls for Asbestos Exposure

At this time any exposure to asbestos fibers requires medical surveillance. The physician responsible will have to include the following components in his medical control program for workers concerned.

Preplacement Physical Examination

A medical and occupational history questionnaire with emphasis on the respiratory system and cigarette smoking.

A pulmonary function determination for Forced Vital Capacity (FVC) and Forced Expiratory Volume for 1 second (FEV_1). This testing may be done by an outside source or a spirometer can be purchased. A spirometer is the instrument used to measure pulmary function tests and the following companies can be contacted for information.

Ohio Medical Products
95 Cedar Lane
Englewood, NJ 07631

Warren E. Collins, Inc.
220 Wood Road
Braintree, MA 02184

Jones Medical Instrument Co.
200 Windsor Drive
Oak Brook, IL 60521

Vitolograph Limited
8347 Quivira Road
Lenexa, Kansas 66215

A 14 x 17 chest X-ray.

A physical examination.

The overall direction of this evaluation should be to identify the presence of existing pulmonary disability in the individual.

Annual & Termination Physical Examinations

The scope of these examinations should follow that of the preplacement physical examination.

Contraindications to having routine spirometry performed are:

1. History of coronary heart disease, angina, myocardial infarct, chest pain.
2. History of chronic middle ear disease, previous membrane rupture.
3. Restrictive lung disease requiring supplemental oxygen.
4. History of pneumothorax.

ASBESTOS IN AIR

RECOMMENDATIONS

1. Discontinue the use of #1 mixer for the processing of asbestos. If it must be used, it should only be used as a back-up system when the hydropulper is fully committed. In this case, the following should be accomplished:

   a. Inspect the exhaust system duct work and hood. Repair any damage and close all unnecessary openings.

   b. Remove accumulated dust in the hood and duct work with a vacuum system. A vacuum system is necessary to help limit the asbestos exposure to persons doing the cleaning.

   c. Assure that the ventilation system is properly balanced (see DISCUSSION Section of this report), providing a capture velocity of about 200 to 300 feet per minute. The transport velocity in the duct work should be a minimum of 3500 feet per minute.

   d. A program of routine evaluation and maintenance should be set up to assure the continued efficient operation of this hood. The capture velocity should be checked at least once per month if the system is used frequently.

2. Provide a counter-balanced cover for the hydropulper opening. This will prevent the slurry from splashing out of the hydropulper and contributing to the asbestos accumulation on the floor.

3. Instruct employees to discontinue dropping the cardboard separators on the floor of the box cars. These should be carried carefully into the building for proper disposal. Dropping them on the floor disturbs asbestos dust which has accumulated on the floor of the railroad cars.

4. The box car floors should be cleaned with the vacuum cleaner as soon as possible before the remaining bags are removed. This will help keep dust generation inside the cars to a minimum as bags are unloaded.

DISCUSSION

Because of the handling methods used, the nature of the asbestos used, and the high humidity in the hydropulping area; the airborne asbestos exposure in this area is considered controlled according to presently accepted standards. Since the bags are pulpable, they can be added directly to the hydropulper without being opened. The asbestos being used is a long fiber asbestos, with a significant moisture content. Hence, it tends to agglomerate in storage rather than produce a dust. This helped to reduce dust generation from broken bags. The high humidity in the hydropulping room helps keep spilled slurry from drying out and contributing to airborne dust concentrations

ASBESTOS IN AIR

DISCUSSION - Con't

On the other hand, spilled asbestos does dry out in box cars and visible dust was generated by the movement in and out of the box cars. It is therefore important that movement in this area be kept to a minimum and that the walking surfaces be vacuumed as often as possible while unloading.

The hood and duct work on mixer #1 was operated briefly and the velocity at the vertical slots was measured with an Alnor Velometer. This slot velocity was found to be between 400 and 800 feet per minute. The capture velocity (i.e. the air velocity at the point of dust generation) was difficult to measure primarily because of the high velocity of the supply air behind the operator station. This high velocity caused turbulence at the expected dust generation points and, therefore, made capture velocity measurements inconclusive.

In order to reduce this turbulence, the system should be properly balanced. In this particular system, I believe proper balancing can be accomplished by making sure that the volume of air provided by the supply system is less than or equal to that exhausted by the exhaust system. This will help minimize turbulence and improve the capture efficiency of the hood. If the hood itself can produce capture velocities of 200 to 300 feet per minute at all dust generation points, it may be possible to do away with the supply air entirely.

DATA

Pumps: MSA Model G Personal Sample Pumps

Filter Medium: Millipore AA filters

Sampling Rate: 2.0 liters per minute

Analyzed For: Asbestos fiber concentration

Method of Analysis: Fibers were counted optically with a phase-contrast microscope at a magnification of 400 diameters. A fiber is defined as a particle which is 5.0 microns or longer in length with an aspect ratio of greater than 3.0.

Recommended Maximum Concentration: 2.0 fibers per milliliter for an 8 hour time-weighted average exposure.

AIRBORNE DUST

On May 12, 1966, air samples were taken for talc, limestone and opalon dust in air at the pre-blend mixing platform. The results of this survey and our observations are summarized as follows:

CONCLUSIONS

1. Airborne dust levels during pre-blending charging ranged from 122 to 198 million particles per cubic foot of air; this was above the suggested threshold limit value of 28 million particles for mixture of mineral dusts.

2. Dust levels after pre-blending charging ranged from 36 to 72 million particles per cubic foot of air.

S. T. Wagner
Senior Industrial Hygienist
Loss Prevention Department

May 13, 1966

STW:oc

RECOMMENDATIONS

1. The pre-blenders should be enclosed as much as possible and a minimum capacity of 150 cubic feet per square foot of remaining open area should be provided.

2. A minimum duct velocity of 3500 feet per minute should be maintained.

3. Respiratory protection approved by the U. S. Bureau of Mines for pneumoconiosis dusts should be provided and worn until adequate ventilation is provided.

The pre- provided. Local exhaust ventilation control with a minimum capacity of 150 cubic feet per minute per square foot provided.

DISCUSSION

The results of air sampling showed that dust levels were far above the suggested threshold limit value for mixtures of mineral dusts during charging of the pre-blenders. There was no local exhaust ventilation and dust was generated during bag opening as indicated by the data sheets. Moreover, dusting continued until the liquids were added.

Local exhaust ventilation should be provided for the blenders and sufficient capacity is required to maintain an inward draft of 150 feet per minute through the open area. It is our understanding that the blender charging will be changed to bulk loading. Even under these circumstances local exhaust ventilation should be provided.

A general room fan was provided in the roof above the pre-blenders. It was observed that this pulled the dust past the breathing zone of the workers.

ASBESTOS IN AIR

On November 25, 1964, air samples were taken for asbestos at the slurry tank on No. 1 Machine. The results of this investigation and our observations are summarized as follows:

CONCLUSIONS

1. Asbestos in air did not exceed the hygienic guide of 5 million particles per cubic foot of air for silicates containing less than 1% crystalline silica.

2. The one-half percent moisture content of the package asbestos apparently prevents excessive dusting.

S. T. Wagner
Senior Industrial Hygienist
Loss Prevention Department

December 22, 1964

STW/kjs

DISCUSSION

The results of air sampling during charging of the slurry tanks in Machine Room No. 1 showed that dust levels ranged from 2.0 to 2.8 million particles per cubic foot of air. This was below the hygienic guide of 5 million particles per cubic foot of air for airborne asbestos dust. It appears that the one-half percent moisture content of the material was the controlling factor in maintaining low dust levels.

Local ventilation was not provided for the charging operation of the slurry tanks. However, if the moisture content is reduced, local exhaust ventilation would be required to control the airborne dust.

It would be desirable to improve the housekeeping conditions at the charging platform. It was observed that asbestos accumulations were on the floor and adjacent equipment. Periodic wash down of the platform with water would improve this condition.

DISCUSSION

The results of air sampling showed that the concentrations of asbestos in air were below the threshold limit value of 5 million particles per cubic foot of air as indicated by the Data Sheet. From the standpoint of good industrial hygiene practice, it would be desirable to provide an industrial vacuum cleaning unit to clean the floors, equipment and remove residual asbestos from the bag.

The threshold limit value was approached at the broke box where the bags were thrown after being dumped into the slurry tank. Visible airborne dust was observed when this was done. Moreover, it was observed that a broom was used to remove spilled material on the floor. For these reasons, it would be advisable to provide a vacuum unit and maintain contamination of the environment at a minimum.

AIRBORNE ASBESTOS DUST

On October 20, 1970, I sampled the mixing and rewind area for airborne asbestos dust. The results of my survey are as follows:

CONCLUSIONS

1. Airborne asbestos dust concentrations at machine #1 were below the Threshold Limit Value of 5 million particles per cubic foot of air.

2. The major dust concentration, 4.0 million particles per cubic foot of air, was at the slurry tank inspection port with the port open.

RECOMMENDATION

1. The inspection port slurry tank inspection port should be kept closed during normal operations.

Edward E. Fowler
Loss Prevention Department

DISCUSSION

For a regular eight hour exposure (forty hour workweek), the Threshold Limit Value (TLV) for asbestos in air is 5 million particles per cubic foot. If this level is not exceeded, the average employee should not show an excessive absorption of asbestos. Short exposure tolerance is not applicable to asbestos.

Air sampling results during charging and mixing of the slurry tanks at machine number 1 disclosed that asbestos dust levels ranged from 0.1 to 4.0 million particles per cubic foot of air. Since this is below the threshold limit value of 5 million particles per cubic foot of air, as outlined by the American Conference of Governmental Industrial Hygienists, it appears that the moisture content of the asbestos is the dust-controlling factor.

Local exhaust ventilation was not provided for machine number 1. However, if the asbestos moisture content is reduced, it is reasonable to expect airborne dust concentrations to be greater and local exhaust ventilation should be considered.

Due to the fact that air borne asbestos concentrations were higher at the open inspection port, it would be advisable to insure that this port be kept closed during charging and mixing operations.

CONGOLEUM INDUSTRIES
FINKSBURG, MARYLAND

ASBESTOS SURVEY

On February 23 and 24, 1972, I sampled for asbestos in air at numbers 1 and 4 slurry operations. The reason for the survey was to evaluate the possible asbestos exposure presented to your employees and to suggest the necessary controls. The results of the survey are listed below.

Conclusions

1. With the exception of one sample taken at slurry mixer number 4 operation, the Threshold Limit Value of 5 fibers/ml >5 μ in length was not exceeded.

2. The procedure for cleaning asbestos spills from floors and railroad cars should be changed.

3. The hydropulper throws wet asbestos into the work area.

Recommendations

1. Provide a cover for the hydropulper. (in process)

2. Provide a vacuum system to clean spilled asbestos from floors, work surfaces and railroad cars. (completed, but they need refined)

3. Do not throw empty asbestos bags from the number 1 slurry mixer operators platform into the waste cart. → rotating brush cleaning after each shift

4. Improve hygiene as pertains to care and storage of respirators.

5. Increase housekeeping efforts at both slurry mix operations.

Edward E. Fowler
Industrial Hygienist
March 29, 1972

EEF/bb

DISCUSSION

Instrumentation

Instruments used for collecting the samples were a Mine Safety Appliance Monitaire Sampling Pump and Millipore Filters. Samples were read on a phase-contrast microscope.

Standards

The Threshold Limit Value of 5 fibers/ml >5μ in length as determined by the membrane filter method at 400-450 X magnification (4 mm objective) phase contrast illumination was chosen as a standard. This standard can be found in Threshold Limit Values of Airborne Contaminants and Physical Agents with Intended Changes Adopted By The American Conference of Governmental Industrial Hygienists for 1971. The standard used can be found on page 34, notice of Intended Changes.

1. Hydropulper Cover

A cover should be provided for the hydropulper. When the asbestos slurry is mixed some of it is thrown from the hydropulper into the work area. A counter-weighted cover, kept closed except during loading operations should eliminate this condition.

2. Asbestos Spillage Control-Vacuum System

A vacuum cleaner system instead of a broom should be used to clean asbestos from floors, railroad cars, and work surfaces. It is worthwhile to note that the two highest sample results were obtained when the operators were sweeping for part of the sample time: The results were 5.5 and 4.5 fibers/ml (see data sheet).

It should also be noted that sweeping the floors with a broom created a visible dust cloud, which probably accounted for the higher sample results.

3. Dust Control-Empty Asbestos Bags

Empty asbestos bags at slurry mixer number 1 should be carried down the stairs and placed in the waste cart rather than thrown from the operators platform into the cart below. This may be an imposition on the operator, but it will considerably reduce the amount of asbestos that becomes airborne.

4. Respirators-Care and Maintenance

The following improvements in maintenance and care of respirators should be initiated:

1. A program to insure the frequency of changing the filters.

2. A program to insure that respirators are worn where needed.

3. Employee education as to proper storage of respirators and the importance of keeping the face pieces clean.

5. Housekeeping

Housekeeping should be improved in both slurry mix areas because asbestos is realatively light and easily becomes airborne when it is disturbed. Perhaps the best approach to improving housekeeping is to clean all spills as soon as they occur.

[illegible] Slurry Platform

[illegible] 1975

[illegible] Dodderer & W. Frank were alternating [illegible] of duty on the slurry [illegible] (i.e. 4 hours per shift on the platform)

Since Mr. Lloyd wanted a 2 hour [illegible] Dodderer volunteered [illegible] for 2 straight hours [illegible] done

---

[illegible] difference between timer reading [illegible] actual reading (114.16 vs. 118 mins)

C-E EASTWOOD

"THE PAPER BOYS"

1/24/75

Pump timer was found to be in error.

After being fully charged, the pump was run for exactly 300 minutes.

At the end of this time, the timer gave a reading of 263.4 minutes

$\frac{263.4}{300} \times 100 = 87.8\%$

$\frac{300}{263.4} = 1.13895$

To get correct time using timer, multiply the timer value by 1.139

10/28 · 50.05 mins on pump in 56.42 min

$\frac{50.05}{56.42} \times 100 = 88.7\%$

$\frac{56.42}{50.05} = 1.127$

Tests run 3 months ago
with OSHA ...
