Volume III of these Transactions, containing the Public Safety Sessions, the Education Division, and the Women's Session, is being mailed automatically to certain members of the National Safety Council who are believed to be interested in them. Any other member of the Council may receive a copy of Volume III without charge by requesting it.

National Safety Council

108 East Ohio Street, Chicago

HONORARY MEMBERS

Association of Iron and Steel Electrical Engineers

ROBERT W. CAMPBELL

OFFICERS (1928-1929)

HENRY A. RENINGER, President
E. W. BECK, Vice-President for Industrial Safety
GEORGE OPP, Vice-President for Local Councils
MILLER MCCLINTOCK, Vice-President for Public Safety
C. E. HILL, Vice-President for Public Relations
C. E. PETTIBONE, Vice-President for Finance
ARTHUR M. TODE, Vice-President for Membership
GEORGE E. SANFORD, Vice-President for Engineering
A. W. WHITNEY, Vice-President for Education
DR. C.-E. A. WINSLOW, Vice-President for Health
G. T. HELLMUTH, Treasurer
W. H. CAMERON, Managing Director and Secretary
HOMER E. NIESZ, Past President

EXECUTIVE COMMITTEE (1928-1929)

C. B. AUER, Past President
J. I. BANASH, ASSE-Engineering Section
E. W. BECK, United States Rubber Company
C. W. BERGQUIST, Western Electric Company
ANCIL D. BROWN, Syracuse Safety Council
W. H. CAMERON, National Safety Council
R. W. CAMPBELL, Past President
R. E. COLVILLE, Quarry Section
E. H. COTCHER, Automotive Section
CLIFFORD DAVIS, Memphis Safety Council
JOSEPH T. DAVIS, Attorney
L. A. DEBLOIS, Past President
MARCUS A. DOW, Past President
H. K. FERGUSON, The H. K. Ferguson Company
J. B. GIBSON, Power Press Section
G. T. HELLMUTH, Chicago, North Shore & Milwaukee Railroad Company
C. E. HILL, New York Central Lines
JOHN PRICE JACKSON, The New York Edison Company
WALTER G. KING, Past President
EMIL KOCH, Kansas City Safety Council
J. E. LONG, Steam Railroad Section

Seventeenth Safety Congress

D. FRANK LORD, Textile Section
 MILLER MCCLINTOCK, Erskine Bureau, Harvard University
 ARTHUR T. MOREY, Past President
 HOMER E. NIESZ, Past President
 GEORGE OPP, The Detroit Edison Company
 L. R. PALMER, Past President
 C. E. PETTIBONE, American Mutual Liability Insurance Company
 EDWIN PUGSLEY, New Haven Safety Council
 HENRY A. RENINGER, Lehigh Portland Cement Company
 E. J. RIEDERER, Delaware Safety Council
 G. E. SANFORD, General Electric Company
 FREDERICK E. SCHORTEMEIER, Indianapolis Safety Council
 C. B. SCOTT, Past President
 C. W. SMITH, Petroleum Section
 ETHELBERT STEWART, Bureau of Labor Statistics
 ARTHUR M. TODE, The Texas Company
 C. P. TOLMAN, Past President
 A. J. VANBRUNT, Public Service Corporation of New Jersey
 PAUL VAN CLEEF, Chicago Safety Council
 DAVID VAN SCHAAK, Past President
 H. M. WEBBER, Illinois Bell Telephone Company
 S. E. WHITING, Liberty Mutual Insurance Company
 A. W. WHITNEY, National Bureau of Casualty & Surety Underwriters
 W. H. WINANS, Union Carbide & Carbon Corporation
 DR. C.-E. A. WINSLOW, Yale Medical School
 J. M. WOLTZ, The Youngstown Sheet & Tube Company
 ARTHUR H. YOUNG, Past President

DIRECTORS (1928-1929)

WM. F. ARDERN, Safety Division, Milwaukee Association of Commerce
 C. B. AUER, Past President
 J. I. BANASH, ASSE-Engineering Section
 C. D. BARR, Birmingham Safety Council
 DAVID C. BAYLESS, Denver Safety Council
 E. W. BECK, United States Rubber Company
 C. W. BERGQUIST, Western Electric Company
 DAVID S. BEYER, Liberty Mutual Insurance Company
 J. M. BISSELL, Woodworking & Lumber Manufacturing Section
 HARRY R. BLAGG, Dayton Safety Council
 E. F. BLANK, Jones & Laughlin Steel Company
 W. H. BOYCE, Western Pennsylvania Safety Council
 W. R. BOYD, JR., American Petroleum Institute
 ANCIL D. BROWN, Safety Division, Syracuse Chamber of Commerce
 WELLS G. BROWN, Pontiac Safety Council
 S. C. BULL, Rahway Safety Council
 L. D. BURLINGAME, Providence Safety Council
 A. R. BUSH, Marine Section
 IRVING T. BUSH, Bush Terminal Company
 W. H. CAMERON, National Safety Council
 R. W. CAMPBELL, Past President
 C. L. CLOSE, United States Steel Corporation
 FRANK L. COCHRAN, Safety Bureau, Minneapolis Civic & Commerce Association

R. E. COLVILLE, Quarry Section
E. H. COTCHER, Automotive Section
H. L. CUMMINGS, Taxicab & Fleet Owners Section
A. D. CUTHBERTSON, Flint Safety Council
EDWARD DANA, Massachusetts Safety Council
CLIFFORD DAVIS, Safety Division, Memphis Chamber of Commerce
JOSEPH T. DAVIS, St. Louis Safety Council
L. A. DEBLOIS, National Bureau of Casualty & Surety Underwriters
WM. C. DICKERMAN, American Car & Foundry Company
ALEXANDER DIENST, Food Section
JAMES B. DOUGLAS, The Philadelphia Gas Works Company
MARCUS A. DOW, Past President
DR. LOUIS I. DUBLIN, Metropolitan Life Insurance Company
E. K. EASTHAM, Electric Railway Section
FREDERIC W. EASTON, Blackstone Valley Safety Council
W. H. ELAM, Nashville Safety Council
DR. E. W. ENOS, Madison County Safety Council
KENNETH L. FAIST, Paper and Pulp Section
ROBERT A. FAUST, Packers & Tanners Section
H. K. FERGUSON, The H. K. Ferguson Company
GEORGE T. FONDA, New York City
ALEXANDER FORWARD, American Gas Association
WALTER B. FRENCH, Hudson County Safety Council
J. B. GIBSON, Power Press Section
HON. CLARENCE R. GILMORE, Texas Council of Safety
WALTER A. GLEASON, Erie Safety Council
ERNEST P. GOODRICH, Consulting Engineer
S. GEORGE GRAVES, Grand Rapids Safety Council
DR. LEONARD GREENBURG, Chemical Section
HARRY F. GUGGENHEIM, The Daniel Guggenheim Fund for the Promotion of
Aeronautics
ISAIAH HALE, The Atchison, Topeka & Santa Fe Railway Company
G. T. HELLMUTH, Chicago, North Shore & Milwaukee Railroad Company
C. E. HILL, New York Central Lines
GEORGE HODGE, International Harvester Company
WM. L. HOGE, Louisville Safety Council
DR. F. L. HOFFMAN, Babson Institute, Inc.
E. J. HOWELLS, Decatur Safety Council
JOHN PRICE JACKSON, New York Edison Company
J. H. JENKINS, Dallas Safety Council
DANA E. JONES, Manufacturers Association of Erie
LESTER JONES, Wichita Falls Safety Council
CHAS. E. KANE, Employees' Publication Section
LAMBERT KASPERS, Evanston Safety Council
IRA V. KEPNER, Pennsylvania Salt Manufacturing Company
WALTER G. KING, Past President
EMIL KOCH, Kansas City Safety Council
W. M. KREGLOW, Lehigh Valley Safety Council
E. T. LAUBSCHER, Safety Council of Bexar County
R. M. LITTLE, New York Department of Education
J. E. LONG, Steam Railroad Section
D. FRANK LORD, Textile Section
MILLER MCCLINTOCK, Erskine Bureau, Harvard University
W. A. MCGONAGLE, Duluth, Missabe & Northern Railway Company
T. H. MCKENNEY, Illinois Steel Company

JAMES MADDEN, Paterson Safety Council
 A. G. MAGUIRE, Youngstown Safety Council
 MAJOR B. J. MARSHALL, Oklahoma City Safety Council
 H. T. MARTIN, Fisk Rubber Company
 GEORGE MARTINSON, Mining Section
 WM. E. METZGER, Detroit Athletic Club
 CHAS. J. MOORE, Longmeadow, Mass.
 ARTHUR T. MOREY, Past President

SEVENTEENTH ANNUAL SAFETY CONGRESS
NATIONAL SAFETY COUNCIL

Annual Meeting of Members

October 1, 1928

HOMER E. NIESZ, Chairman
President, National Safety Council

The Annual Meeting of Members at the Seventeenth Annual Safety Congress, National Safety Council, was called to order at ten-fifteen o'clock by the President, Mr. Homer E. Niesz, Manager, Industrial Relations, Commonwealth Edison Company, Chicago, Illinois.

PRESIDENT NIESZ: The Seventeenth Annual Meeting of the National Safety Council is now opening. Our deliberations will be started with the invocation by the Rev. Ralph W. Sockman, D.D., Pastor, Madison Avenue Methodist Episcopal Church, New York City.

REV. RALPH W. SOCKMAN: Almighty God, thou hast made us the heirs of all the ages; make us grateful for those visible and invisible forces which have fashioned this world in which we are living. We thank thee, our Father, for having brought us into the world in a land where life can be rich. We thank thee for having brought us forth in a day when life has become sacred.

We ask that that pioneer spirit which sought to make here a land where life, where body and mind and soul could be free and safe, that that spirit may be preserved. Grant us, oh God, in this countenance, so to capitalize the experiences of the past that we may make more rich the living and the present.

We thank thee, our Father, for that inventive genius which is making possible the machines of today. We thank thee that we can travel more rapidly and see more widely and live more deeply. But in the merchandise of all our speed and power, may life be kept safe; may we achieve the simple life in the midst of the complexity of our day. May we seek to keep the individual safe from the dwarfing pressure of the crowd. May we keep the minds of this land free from intolerance and bigotry. May we keep the bodies free from disease and accident.

Grant the deliberations of this Congress to be held in high level and noble purpose, and may its service go on bearing fruit, in the great cities and throughout the countryside of this land that we love, making richer the life, stronger the body, purer the mind.

We ask it in the name of the Master, Teacher and Thyself. Amen.

PRESIDENT NIESZ: This being a business meeting of the Council, the roll call is necessary, but as the Secretary has informed me there is a quorum present in person or by proxy, a motion to dispense with the calling of the roll will be received.

(Motion was regularly moved, seconded and carried that the roll call be dispensed with.)

PRESIDENT NIESZ: We anticipated having with us this morning the Mayor of New York. However, he was unable to come and has sent as his special represen

tative, to give the welcome of the city in his behalf, Mr. Thomas W. A. Crow, Assistant Corporation Council.

Address of Welcome on Behalf of New York City

By THOMAS W. A. CROW

Assistant Corporation Council, City of New York

It is a most unfortunate thing that our Mayor is unable to greet you here this morning. I come to relate to you his very deep, profound regret.

As you have probably read in the morning's papers, he is down in the City of Washington, where, as one of the counsel representing the City of New York in the 7-cent fare fight, he makes his first appearance before the Bar of the United States Supreme Court this morning. Were it not for that imperative and official engagement, I know he would be here and very glad to convey to you that which he has deputed me to do.

In speaking to me about coming here this morning, the Mayor said, "Tell the Congress, that to my way of thinking one of the most salutary and one of the most hopeful signs of our times is this: that in an age devoted to materialism, mass production, an age that is described as mechanistic, there is a large body of men and women who are moved with that very great objective, the conservation of our one great national asset, human life."

And he said, "We in the City of New York are most vitally interested in the work that they have already accomplished, in the work to which they dedicate themselves in the future, for in this city—and I think I may say with modesty, without any desire to boast, the greatest city in the world—we have all these problems that other communities have, but we have them on a larger and a more intense scale. Therefore, in this city, the problems that directly reach the question of life preservation concern us with a degree of intensity and application that perhaps, in our humble judgment, exceeds the situations as they present themselves in other communities."

So we, the people of the City, and the government of the City, greet you with a very warm interest on this occasion.

New Yorkers are sometimes referred to as the cliff dwellers, because we live in these great, high canyons along Broadway and the other streets, and we work and earn our daily bread in those vast centers. But after all, human nature in New York is exactly the same as human nature anywhere else in this glorious country of ours. We are not more or less provincial than any other people, and we are most eager to meet and to cooperate with anyone, with any group, with any organization that has for its objective the making of this world a better and a brighter and a safer place in which to dwell and live.

So it is my happy privilege; and it is a very great privilege, to convey to this Congress, the word of welcome by the Mayor of this City, the Hon. James J. Walker, has delegated to me to do.

I might say that in the last year or so we have had an almost envious stream of visitors from across the Atlantic, and the Mayor has in turn greeted each one, and to each one has presented the key of the city; and the last one to receive the key of the city departed from our city without returning the key. I might say he left the city unlocked, so you will find the city is wide open in hospitality, in interest, in cordiality.

And in closing, I might say (perhaps it is unnecessary for me to add)—Safety first.

PRESIDENT NIESZ: The next speaker will give us a welcome on behalf of the New York Safety Congress Committee. He is a graduate of Yale. He is vice-president of the General Motors Corporation, and is first vice-president of the National Automobile Chamber of Commerce. He is a director of the Lehigh Valley Railroad and many other large and successful organizations.

He learned the rudiments of safety in playing football against Harvard. He has maintained an interest in safety ever since, and his contribution to the cause is worthy of our praise and commendation.

It is a pleasure to introduce, Mr. Alfred H. Swayne, chairman of the New York Safety Committee.

Address of Welcome on Behalf of the New York Safety Committee

By ALFRED H. SWAYNE

Chairman, New York Safety Congress Committee; Vice-President, General Motors Corporation; First Vice-President, National Automobile Chamber of Commerce

It is my privilege and pleasure on behalf of the New York Safety Congress Committee to welcome the 17th Annual Safety Congress. May it be the greatest congress and the most profitable in life-saving accomplishment that the National Safety Council has ever held.

When the Safety Council accepted the cordial invitation of the Merchants' Association to hold its 1928 congress in this great metropolis, it was at once evident that considerable organizational work must be done to arouse public interest in accident prevention, stimulate attendance, and, in general, set the stage in a manner and to a scale appropriate to so large and important an event. We in New York, as you probably know, are vastly engrossed in our busy, everyday life; we are used to conventions and they are apt to come and go without creating a ripple on the surface. We are not indifferent, as some are disposed to think, but we are preoccupied. But the Safety Congress, it seemed to us, was far more than an ordinary convention: It was the culmination and review of a year's effort by the organized forces of the most intelligent and the most careless nation on earth to combat the evils wrought by thoughtless men; and it presented to the community in which it was held a rare opportunity to learn the habits and benefits of accident prevention.

And so we organized—first, the New York Safety Committee (which is the executive body) and later the New York Safety Congress Committee, which is the advisory and sponsoring body of which I have the honor of being Chairman.

The New York Safety Committee of the National Safety Council is composed of eighty of the leading safety engineers and experts in the metropolitan area, under the Chairmanship of Lewis De Blois of the National Bureau of Casualty and Surety Underwriters, a former president of the National Safety Council.

The work of the New York Safety Committee is described in a small leaflet. Time does not permit me to go into details, but I feel that in justice to its outstanding accomplishments in a short space of time and in the face of obstacles which are normal to the life and conditions of a great city I must cite a few of them.

An Inter-Fleet Drivers Safety Contest was organized; 420 firms entered their fleets of over 23,000 vehicles in the contest.

Safety material was sent to every public school principal, and many thousand safety posters and lesson outlines were distributed to the schools.

Twelve hundred sermon outlines were placed in the hands of New York ministers.

Four hundred thousand Safety Messages are being handed out by Boy Scouts to theatre patrons, and 200,000 safety wall-cards were placed in the homes through the courtesy of the Metropolitan Life Insurance Company.

Over 30,000 posters, stickers, car cards, and other advertising material were placed on public vehicles.

Special invitations to attend the Congress were sent to over 40,000 persons in the metropolitan area.

While the list of activities which the New York Safety Committee has pursued is neither long nor complicated, each one is characterized by the size and difficulty of the undertaking—conditions imposed by the vast area to be covered. And none of this great work could have been completed, even by such zealous and indefatigable volunteers, without the finest of cooperation by city and state officials, including the Mayor, commissioners of police and education, by prominent local bodies such as the Merchants' Association and other civic and trade organizations with which New York is so well provided, by the railroads, electric railways and other public utilities, by the great industrial corporations that are so deeply interested in the success of the safety movement, by the engineering societies, by the hotel men, and last but not least by the newspapers.

I wish that I might mention the names of all of the hundreds who have so generously contributed of their advice, time, efforts or money. It has been given freely that your congress might be a success and that the lives and limbs of human beings like ourselves might be spared the tribute to what we term "accidents."

On my own committee there are over two hundred of New York's most prominent and influential citizens. Philanthropists, captains of industry and finance, men prominent in civic affairs, presidents and chairmen of boards have gladly consented to sponsor this enterprise. It is, I believe, the most influential and representative committee that has been created since the Great War. Some of these men will attend the Congress; many will be deterred by their multifarious and exacting duties; but I know that when I welcome you to New York City and express the hope that your visit here will be enjoyed and will be profitable to you, to your great cause and to the City of New York, I voice not only my own heartfelt desire but that of every member of my committee.

The New York Safety Congress Committee and the New York Safety Committee, having prepared the way for you, now bids you welcome!

PRESIDENT NIESZ: On behalf of the National Safety Council, I desire to express appreciation and grateful thanks for the very cordial welcome given to us by the representative of the Mayor and by Mr. Swayne, chairman of the New York Safety Congress Committee.

It is indeed a pleasure and a privilege to have our Congress in this wonderful city and to be received with the cordiality and good fellowship which has characterized the greetings which have been extended to us this morning.

On behalf of the members of the National Safety Council, I thank these representatives for their welcome.

The President's Annual Address

By HOMER E. NIESZ

President, National Safety Council; Manager Industrial Relations, Commonwealth Edison Company, Chicago

Before I fulfill my final duty and render on behalf of your directors, executive committeemen and officers an accounting of their conduct of the affairs of your Council during the past year, permit me to exercise my highly valued privilege of extending a most cordial greeting to you—to members, representa-

tives of members, public officials, and guests,—all gathered here to attend the Seventeenth Annual Congress of the National Safety Council.

There can be no more convincing evidence of the real worth of the cause to which you have devoted yourselves, nor of the truly democratic character of the institution which you have created in its service, than the strikingly large numbers in which each year you come together to dedicate yourselves anew to the support of that cause and to determine how its service may best be advanced and enlarged.

For the third time we are meeting in the great metropolitan city of New York, and once more we are indebted to the leaders of this community, to the New York Safety Congress Committee, the New York Safety Committee, and others for their generous hospitality and preparations for our comfort and well-being during the progress of this Convention.

I am once more impressed with the constantly increasing interest in the great safety movement and with your clear understanding that only through the personal participation and cooperation of all members of the Council can the cause of safety be advanced as it should be and our organization take its proper and important place in the lead of accident prevention effort. Without such participation and cooperation the best efforts to those to whom you have entrusted the activities and management of your affairs could not have achieved anything like the same measure of success, and the safety cause would not be what it is today—a national movement of widest range and with practically unlimited possibilities.

Accident Records

Our national campaign for safety must continue to be based on facts. An examination of the trend of accidents over the past fifteen years discloses some facts which are indeed impressive. During that time practically every class of accidental fatality has decreased with the exception of those due to the automobile. Accident rates from burns, drownings, railroads, street cars, and other classifications show decreases of from 20 to 50 per cent. Smaller declines are found in the fatality rates from machinery, falls, and various other causes. In individual industries and groups of industries there are many notable instances of reductions. Striking evidence of the possibilities in such reduction is found in the Council's annual report of more than 2,000 industrial establishments, as well as in the notable volume entitled "Safety and Production" which reports the results of an exhaustive survey of the relation between accident prevention and production efficiency.

It is estimated that last year 3,000,000 industrial workers suffered lost time and 25,500 workers lost their lives through accidents. But if all of the industries in the United States had been as successful in their safety work as the 2,000 establishments that reported their records to the Council, 8,600 of these lives would have been saved and 400,000 lost time injuries would have been avoided.

It should be clearly stated, however, as a deduction from these recent statistics, that an unsatisfactory accident situation exists in many industries, especially in the smaller workshops. These small plants, so difficult to reach through general educational propaganda, present a real challenge to our resourcefulness and our continuous patient efforts for widespread acceptance of safety principles.

The 1927 records present the alarming situation of an increase in motor vehicle fatalities which is even greater in proportion than the increase in cars registered. It should be noted, however, that this increase in motor vehicle fatalities is smaller in those cities having community safety councils; and in

the cities where the best organized safety work has been done actual decreases have been secured.

Other public accidents have taken a toll of human lives during the past year numbering 20,000—an addition of more than 75 per cent of those caused by automobile alone.

Perhaps the most distressing group of accidents within our purview is the one occurring within the homes of our land—that haven of rest and security ordinarily considered safe. An exhaustive study of the available sources of information indicate the number of industrial fatalities.

While the facts on non-fatal injuries are meager it is estimated from the data at hand that there were at least 5,000,000 non-fatal home injuries last year. Knowing these facts is it not a challenge to our intelligence, our public spirit and our love for family and for our fellowmen? Shall we sit supinely by and let the slaughter go on unabated, or shall we accept our personal responsibilities, with a full realization of the pressing need for more organized safety work in all its branches?

Organization is necessary in this as in other fields of accident prevention, and I recommend the establishment of a Women's Committee or Division, whose most important function should be the determination and inauguration of means and methods of reaching the home-keeper and through her reduce home hazards and resultant accidents.

An interesting deduction from recent statistical data is that during the past five years the total accident fatality rate of children has been reduced while the adult rate has increased. It is well known that the most general and extensive safety activity carried on anywhere outside of the industries is the safety work done in and by the schools of America. Under the leadership of the National Safety Council's Education Division and through the efforts of other organizations working with the schools, especially through the efforts of school authorities, principals and teachers themselves, safety is now accepted as a natural and proper educational principle in thousands of American class rooms, and the record just cited proves that this work has been more than justified. If we can find a way of teaching safety to the adult population, especially outside of industry, to the extent that this has been done among school children, I believe we shall have solved a large part of our present problem.

A Review of the Year

The past history and achievements of the Council have been notable, and their narration would be but a repetition of previous presidents' addresses and other publications. I desire, however, to call your attention to some of the specific activities which have been inaugurated during the past year and are worthy of special mention. It has long been the policy of the Council to enlarge its field of usefulness as the opportunities occur and its finances permit, the possible projects usually running well in advance of the means to carry them out. Early in the year it was proposed to increase the service rendered to industrial members, and the first new service instituted was the publication in the NATIONAL SAFETY NEWS each month of suggested programs for safety committee meetings known as "Timely Topics for Safety Committees."

Recognizing the need felt by many industrial members for a medium to reach the individual worker as an aid in promoting interest in individual safety, a monthly magazine called *The Safe Worker* is now being published. It is furnished to members at cost and its popularity is evidenced by the fact that its circulation has already reached 125,000 copies per month and is rapidly increasing.

The inculcation in the mind of the worker of his own responsibility—the cultivation of a safety consciousness—is the most important factor in promoting safety and will bring to successful fruition, otherwise unattainable, the efforts of management, foremen, and safety organization in accident prevention. This little magazine, therefore, is an effort already proven effective in reaching the individual directly.

As a stimulus to life saving the Council has established during the year the "President's Resuscitation Medal," to be awarded to any one not eligible to receive other similar medals, who successfully restores breathing in cases of suspended respiration due to asphyxiation, electric shock or drowning, by the application of the Schaefer prone pressure method of resuscitation. This is supplemental to and not a duplication of similar medals awarded by the National Electric Light Association and the American Gas Association.

In recognition of the splendid safety work done in our largest industry and to encourage still greater effort in reducing accidents to employees, the Council inaugurated during the past year an annual award of trophies in a Steam Railroad Employees' Safety Contest. The first of these awards was made with appropriate ceremonies on May 21, 1928, to the seven Class I railroads having the lowest casualty rate for their respective groups arranged according to a man-hour exposure, and for the initial award the records for a period of from three to five years were included.

In order to make more effective the work of the Health Division, which has been active for several years, a Director of Health Service has been added to the staff, beginning September 1, 1928.

The study of industrial diseases, the health hazards of industry, their relation directly or indirectly to accident prevention and the furnishing of information not otherwise obtainable on industrial health subjects to our members are the chief objects for starting this new form of service under competent direction.

The choice of New York City for this year's Congress presented an opportunity for an experiment which has long been considered, namely, the establishment of a branch office. Its primary function was to assist with Congress arrangements and to experiment with other services to local councils and members with a view of determining whether such an office should be permanently established.

In the field of motor vehicle legislation and traffic control, the year has witnessed two major accomplishments, in both of which the Council has taken an active part. One of these is the completion of the model city traffic ordinance by a committee appointed by former Secretary Hoover and including numerous officers and members of the Council. The other is the preparation of an elaborate study and report of Traffic Signs, Signals and Markings by a committee of the American Engineering Council on which the National Safety Council was well represented.

Activities Continued

These are splendid examples of the sort of cooperative relationship for effectively prosecuting certain aspects of essential safety activities. An abstract has been published of the Uniform Vehicle Code, recommended for state adoption by the National Conference on Street and Highway Safety, and this abstract is proving of considerable value to those desiring to check up their present laws with the national model.

It would be an undramatic story to enumerate the posters, magazines, newsletters, safe practices pamphlets, and other publications distributed by the Council during the past twelve months. There is romance, however, in the

fast developing production and acceptance of this accident prevention experience. Two of the most significant activities during the past year have been the growth of our regional safety conferences and safety contests. Much has been accomplished by bringing together more than 15,000 people at these regional safety meetings held in various parts of the country. We have proof that many managers, supervisors, workers, public officials and others have received information and inspiration from these territorial meetings that they could not have received from any other source. The accident reduction achieved through the many safety contests has demonstrated that what is most needed in safety work is a popular incentive.

The Council has made progress during the year in mobilizing its latent forces for further analysis of the accident and health hazards of all processes and operations in industries. The completed study of the health hazards due to spray coating and the researches into the complicated problem of adequately safeguarding circular saws and annealing of chains are indications of what the Council can do to improve its service to industry. A start has been made by our Petroleum, Chemical, Rubber, Metals and Mining Sections in publishing sectional safe practices pamphlets, and other sections are ready to follow this leadership. Our ASSE-Engineering Section has organized sixteen committees of voluntary workers to study the accident hazards in miscellaneous industries. The policy of awarding medals in first aid and mine rescue work has been continued. Two new educational films have been completed this year. Continuous study has been made of the rapidly developing need for safety consideration in air transportation.

At considerable expense and through a well trained corps of men, efforts have been continued throughout the year to improve the community council activities and to organize new councils. There is not a city of 25,000 population or over in the United States that has not been reached by our field force with the offer of service to help organize the local effort to stop accidents.

Our public safety engineering staff has continued its community safety surveys and research work. Four of these surveys have been made during the year and research reports printed and distributed on the problems of parking as related to safety, on police traffic forces, and on traffic courts. The conduct of this work has been made possible through the continued monetary support of Mr. John D. Rockefeller, Jr., and other contributions.

Under the stimulus of the encouraging results I have already referred to our school work has likewise gone forward with the generous support of the National Bureau of Casualty and Surety Underwriters, and under the guidance of our vice-president, Mr. Albert W. Whitney. Our school memberships are increasing, as is also the circulation of our school magazine "Safety Education." Our school posters and lesson outlines have been used regularly in nearly 25,000 school classrooms in all parts of the country with beneficial results for both the present and future that can only be imagined.

Our Public Safety Magazine has taken safety information and encouragement to several thousand officials monthly; our large street safety posters have doubled in circulation during the year, and our first public safety film "The Verdict" has already won approval and will be shown at this Congress.

Public Safety

We are making continuous and intensive effort to arouse the interest of all kinds of community organizations, public officials, and others able to undertake the safety leadership of their communities. A special class of public safety membership and service has been developed during the year. The

number of non-industrial members is increasing but it must increase to a much larger extent to give us the contacts we need in many communities. I call upon every member present, especially the industrial members in small communities, to assist our headquarters' office to establish contacts with and give constructive service to the public officials and other public safety people in their communities.

Along with the development of a body of public safety members there goes inevitably the development of our public safety committee organization. I am happy to report that our Public Safety Advisory Committee has completed its second year of valuable service to the Council and under its general direction there are now functioning not only our Statistics Committee, whose work is so well known, but also an Engineering Committee and a Committee on Personality and Public Accidents, each of which is giving essential advice and supervision to our staff activities in these fields.

Publicity

It is gratifying to report that during the past year the prestige of the Council has increased with the press of the nation. Literally thousands of editorial observations have been voluntarily published by the leading writers of the United States whose attention has been called to our achievements by our reports, speeches and activities, and the accomplishments by members in the reduction of accidents everywhere. Although this city is approximately a thousand miles from the headquarters' office of the Council in Chicago, the daily papers in New York actually have printed more editorials about our endeavors than have the Chicago dailies. During the week of this Congress the newspapers and magazines of this greatest city in the world will be filled with reports, comments and pictures relating to this safety convention. I feel that this Congress owes its appreciation to the daily newspapers and to the trade, technical, and plant periodicals of America which have given unstinted recognition and support to the Safety Movement. The publications which are devoted to the industries of the nation have indeed been generous in their treatment of our efforts.

Industrial Sections

The officers and committee members of the industrial sections merit our continued thanks for the initiative and energy displayed in performing their duties since the last Congress. They are to be congratulated upon their success in achieving cooperative relations with the trade and business associations in their industries, for continuing the valuable monthly news-letters, for cooperative help in increasing the membership and in making preparations for the many meetings at this convention. The work of full time staff assistants in specific sections has now passed beyond the experimental stage. The value of the salaried secretarial work of the Petroleum Section, which continues to be supported by the American Petroleum Institute, should encourage each sectional organization to help finance similar specialties for all of the sections.

Conclusion

The personal volunteer work of the members of the Council, its officers and executive committeemen, section officers and the numerous committees deserve particular commendation. The managing director and his efficient staff at headquarters have administered the affairs of the Council in so capable a manner as to merit special recognition.

Our annual Congress includes in its diversified program many valuable contributions to the gospel of safety, which should provide inspiration for renewed efforts to achieve our objective—Universal Safety. Organization is the main spring of accomplishment in any line of endeavor and in the fullest use of this principle the National Safety Council can best extend its influence and usefulness. It must reach through the many organizations cooperating with it into every phase of life—the work shop, the schools, the home, the public places—in every community large or small, and must above all carry to the heart and mind of every individual the sentiment of safety.

This administrative year is ended with this Congress but the work of the Council must go on continuously and the united efforts of every man, woman and child associated with us in our glorious cause must be constantly exerted until, the safety millennium is achieved—the day whose sun will rise and set and rise again without an accident to mar the peace and happiness of our people.

PRESIDENT NIESZ: The next order of business is the annual election. The Executive Committee having appointed three inspectors of election, the Chair will appoint these men also tellers of this meeting.

This committee consist of: Mr. Austin P. Saunders, Chairman; Mr. F. C. Lynch, and Mr. Fremont Chester.

The next item of business is the reading and disposal of the minutes of our last Annual Meeting. As these minutes have been printed, a motion will be in order to adopt the minutes without reading.

(The motion was regularly made, second and carried that the minutes be adopted without reading.)

PRESIDENT NIESZ: We will now have the report of the Nominating Committee. Mr. W. J. Peacock, chairman of this committee, will present the report.

Report of the Nominating Committee

W. J. PEACOCK: Mr. President, complying with your instructions, we, the Nominating Committee appointed by you, with the approval of the Executive Committee, and as provided for in Section 4 of Article VI of the By-laws of the Council and as further provided by Section 5 of Article VI of the By-laws, present herewith the report of nominations for Directors to serve until the annual meeting in 1931.

The following list has been approved by the Committee and is submitted herewith:

Ernest P. Goodrich, Consulting Engineer,
175 Fifth Avenue, New York City.
Wm. E. Metzger, Detroit Athletic Club,
Detroit, Mich.
William Otter, Marsh and McLennan,
164 W. Jackson Blvd., Chicago, Ill.

The names of the following Directors whose terms expire October 1, 1928, are submitted for re-election:

David S. Beyer
W. R. Boyd, Jr.
C. L. Close
J. B. Douglas
F. W. Fisher
Isaiah Hale
Chas. E. Hill
Dana E. Jones

T. H. McKenney
H. E. Niesz
Lew R. Palmer
W. B. Pettibone
G. E. Sanford
David Van Schaack
J. M. Woltz

Very respectfully yours,
(Signed)

W. J. Peacock, Chairman
A. V. Rohweder
John Eib
G. A. Kuechenmeister
Carl L. Smith.

PRESIDENT NIESZ: There having been no other nominations received, under the provision of our by-laws, a motion will, therefore, be in order to close the nominations. May I have such a motion?

(The motion was regularly made, seconded and carried that the nominations be closed.)

PRESIDENT NIESZ: The nominations having been made in number equal to the vacancies to be filled, in order to save time, and there being no other nominations, a motion to authorize the secretary to cast the ballot for all members present in person or by proxy is in order.

(The motion was regularly made, seconded and carried.)

PRESIDENT NIESZ: The secretary has been instructed to cast the ballot.

SECRETARY CAMERON: The ballot is cast.

PRESIDENT NIESZ: I, therefore, declare the men, whose names have been read to you by Mr. Peacock, are elected as directors of the Council.

The next item on the program is the report of the chairman of the Resolutions Committee, Mr. Arthur T. Morey.

Report of Resolutions Committee

By ARTHUR T. MOREY
Chairman

Resolution of Thanks to the People of New York City

WHEREAS, This Seventeenth Annual Safety Congress of the National Safety Council in New York City promises to be the largest and most enthusiastic gathering of people interested in the prevention of accidents ever known in the history of the movement and the interest shown has been the most encouraging received to date, because of the wonderful cooperation received from the New York Safety Congress Committee, the New York Safety Committee, the Merchant's Association of New York, the press, the hotel men's organizations, other bodies of trade, technical and professional people and the most prominent civic, business and social leaders of the world's foremost metropolis, who have labored zealously to call the attention of the entire community to the importance of this convention and have spared neither time nor money to make this rally a success, and

WHEREAS, We, the members of the National Safety Council, gathered here from all parts of the United States and Canada and elsewhere, are thoroughly convinced that the inspiring interest and efforts contributed by these distinguished New York leaders have helped to make not only the people of this city but also the world think more about safety and have thus substantially helped the movement dedicated to the conservation of lives and limbs and property, therefore be it

RESOLVED, That a standing vote of thanks be extended to the City of New York, its public officials, various organizations and public spirited citizens who

have done so much to stage this great safety congress, particularly to Mayor Walker; Alfred H. Swayne, Chairman, N. Y. Safety Congress Committee; Lewis A. DeBlois, Chairman of the N. Y. Safety Committee; Willis H. Booth, President of the Merchants Association; the New York Police Department; Board of Education; American Museum of Safety the splendidly cooperating Press and the other distinguished supporters of this Congress, *the sincere thanks of the accident preventionists of America* who deeply appreciate the fact that the efforts of these benefactors have been a major factor in getting invaluable publicity and aid, through the metropolitan newspapers and press associations, which are relaying news of this event to papers throughout the world—through the broadcasting of timely safety messages via leading radio stations and numerous other forms of advertising *to the fact* that accidents do not just merely “happen” but are caused by certain circumstances that can in the main be controlled and eliminated, as conclusively proved by the reports, addresses of hundreds of speakers, exhibits and demonstrations, which feature this Seventeenth Annual Safety Congress.

Mr. Chairman, before you put that resolution to vote, I would also like to offer this one:

Resolution in Honor of the Council President

“Whereas, Homer E. Niesz has served the National Safety Council as President, during the past year with marked ability, faithfulness, and earnestness; and

“Whereas, Much of the credit is due him for the continuous success and expansion of the Council; therefore, be it

“RESOLVED, That the Seventeenth Annual Safety Congress, assembled in New York City, express to Mr. Niesz, by rising vote, its sincere appreciation of his service as President, of his helpful contribution to the cause of safety; and be it further

“RESOLVED, That the sincere gratitude of the National Safety Council be expressed in a similar manner to the Executive Committee and those other committees and workers who have labored so unselfishly and so well, and to our efficient and hard-working Managing Director, William H. Cameron, and to his splendid staff for their loyal development and successful effort in building up the remarkable progress of this great humanitarian movement.”

(The motion was regularly made, seconded and carried that the two resolutions be adopted.)

(The audience arose and applauded.)

MR. MOREY: Now, Mr. Chairman, I have two other resolutions to present. They are to the effect that it is the conviction of this Congress that a very large number of public accidents and industrial accidents can be prevented, and we want to put it in such form it can be broadcast to the whole world, to awaken those in industry and in charge of public safety to that fact, and to urge them to action. They are as follows:

Public Safety Resolution

WHEREAS, Last year, in the United States alone, approximately 70,000 men, women and children were killed and countless other thousands of persons were injured by accidents on the streets and highways, in other public places, on the sea, in the air, and at home, causing terrible pain and sorrow and an economic loss amounting to billions of dollars; and

WHEREAS, It has been conclusively demonstrated that most of these accidents could have been prevented through organized, cooperative efforts of those interested in the conservation of lives and limbs and property; and

WHEREAS, American leaders, concerned over the welfare of our people, are alarmed at this increasing toll and are determined that it shall be checked; therefore be it,

RESOLVED, That the members of the National Safety Council and others present at their Seventeenth Annual Safety Congress, pledge themselves to continue their endeavors to prevent accidents and recommend to all interested in this problem the following platform:

1. Immediate adoption of the accepted Standard Accident Reporting System in every state, city and town, that timely and accurate information may be obtained upon which to base accident prevention measures.
2. A comprehensive study of the traffic situation in each city; the necessary improvement of streets, revision of ordinances and regulations and the adoption of such traffic control measures as may be necessary.
3. Acceptance of the principle of uniformity in state and city traffic laws and regulations and in the design and use of signs, signals, and pavement markings and the support and cooperation of all interested organizations and officials with that end in view.
4. The elimination, as far as possible, of unfit and reckless motor vehicle operators, through the adoption of a driver's license law by every State.
5. Recognition on the part of both motorists and pedestrians of the rights and privileges of all users of streets and highways.
6. The furnishing of the necessary information to teachers, principals and superintendents of educational institutions so that they may give the needed instruction to the pupils under their guidance.
7. The widest possible publicity in newspapers and other publications for the specific ways and means of preventing accidents and the importance of personal caution.
8. Intelligent and impartial enforcement of reasonable laws and regulations which are intended for the control of the minority of the people who are responsible for the majority of accidents.
9. The organization and maintenance of a community safety council, committee or other group, in each locality, which should be non-partisan, non-commercial, cooperative, representative of all interests, created to mobilize the forces of public opinion and support officials in the performance of their duties.

Industrial Safety Resolution

WHEREAS, It is estimated that 25,000 industrial workers met untimely deaths and hundreds of thousands were injured while laboring in shops and factories last year, resulting in pain, grief, destitution, interruption of production and an economic loss of billions of dollars to both employers and employees; and

WHEREAS, More than 4,600 members of the National Safety Council have conclusively demonstrated that most accidents can be prevented through safety methods; and

WHEREAS, The conservation of lives and limbs and property is a responsibility which should be accepted by both employers and employees everywhere; therefore, be it

RESOLVED. That the members of the National Safety Council and others present at the Seventeenth Annual Safety Congress, assembled at New York City, Oct. 1-5, 1928, recommend immediate and earnest consideration of the following recommendations:

1. That both large and small employers make a regular and periodic inspection of their respective shops and factories, to ascertain how, why, when and where accidents occur and study ways and means of checking these accidents.
2. That employers maintain and analyze accident records, which are essential if they are to achieve real results.
3. That all employers safeguard, as far as possible, all dangerous mechanical equipment and revise hazardous manufacturing processes.
4. That employers impress upon their associates the importance of eternal personal safety efforts and the necessity of spreading accident prevention information.
5. That employers assist and cooperate with the National Safety Council and its affiliated community councils, federal, state and municipal officials and others engaged in accident prevention work.
6. That the inclusion of safety education in public, private and parochial schools, universities and colleges be encouraged by employers and employees.
7. That additional universities and colleges incorporate safety engineering in existing and future engineering courses.

AND, BE IT FURTHER RESOLVED, That those attending the Seventeenth Annual Safety Congress hereby express their deep appreciation to the thousands of employers who have been engaged in safety work, and also acknowledge their indebtedness to the millions of employees and to organizations, the press and the public generally for their support of accident prevention activities.

I, therefore, Mr. Chairman, move the adoption of these resolutions.

(The motion was seconded and carried.)

PRESIDENT NIESZ: We now come to a portion of the program which is of very special interest, as we are to have before us men who are prominent and well qualified to speak on the subjects they are to present.

The first speaker is a man who has been engaged in many activities of a civic as well as an industrial and business nature. He was president of Los Angeles Chamber of Commerce, later the Associated Chambers of the Pacific Coast, and still later became vice-president of the United States Chamber of Commerce.

And that is not all. In 1923, he became president of the International Chamber of Commerce. It is said that only the lack of communication and transportation prevented him from becoming chairman of the Interplanetary Chamber of Commerce.

In addition to these activities, he occupies the very responsible position of vice-president of the Guaranty Trust Company of New York. He is also vice-president of the Security Trust and Savings Bank in Los Angeles, a post which, it is said, he holds so that he can spend his winters in California.

Along with these activities and accomplishments, he has given time and attention to the cause of safety. In addition to this, he is serving as president of the Merchants' Association of New York City.

It is a very great honor and privilege to present to you, Mr. Willis H. Booth, of New York and Los Angeles.

The Humanics of Industry

By WILLIS H. BOOTH

**President of The Merchants Association of New York, Vice-President of
The Guaranty Trust Company of New York, New York City**

Shakespeare lived long before we had the labor problems of modern industry but he certainly must have had some similar labor problems of his own in mind when he observed, "If to do were as easy as to know what were good to be done" all sorts of wonderful things would have happened. The problem of the adjustment of human relationships transcends in difficulty and importance all other problems of industry.

When we accept the proposition that no two human finger prints are alike, we also practically accept at the same time the proposition that no two individuals are alike, so we are continually dealing with situations in which we do not have constant factors.

Two individuals may each possess all of the virtues that are humanly attainable and still not be able to get along with one another and so when we begin to talk about humanics in industry we are forced necessarily to generalizations. We can only reach, as the result of our studies, some ideas of the directions which should be taken, of the objectives to be reached, but the absolute method by which accomplishments can be registered is in each specific case largely a localized problem. Let us try to establish a little foundation for our thinking.

Last month in Glasgow, at the annual meeting of the British Association for the Advancement of Science, Professor E. B. Dailey asserted that millions of years ago Europe and North America were geologically united, but that they had drifted apart allowing the seas to flow between them and form the Atlantic Ocean. Professor Dailey's conclusion was drawn from an intensive study of the primary mountain systems of Europe and America.

Almost at the moment that Professor Dailey was publishing the results of his research, Secretary of State Frank B. Kellogg was returning from Europe after his consummation of the multilateral peace compact. Signed by fifteen nations and with every indication that its provisions will eventually be generally ratified, that document is now conceded a place in history as one of the great influences for world unity.

Between the prehistoric days of which Professor Dailey speaks and the modern times of Mr. Kellogg and his contemporaries, many influences have been at work. Racial characteristics and international disputes have produced gulfs between peoples greater than the oceans that separate continents. Wars have worked their havoc. Nation has risen against nation and discord, destruction and desolation have followed. It is a peculiar commentary that the very destruction born of man eventually teaches him the necessity of cooperation and provokes his efforts to influence the returning swing of the pendulum.

Industry has paralleled in the character of its history the other works that man has wrought. Industry's history has been one of strife, of conflicting forces, of chaos. But through all this trouble great progress has been made; undoubtedly even greater progress will be made in the future and as this progress will touch every phase of our national life, its permanent advancement will depend upon our ability to consider properly the human problem involved.

There is nothing new. All change, all development, all evolution, all progress is but the result of the operation of certain natural laws. The individual is the instrument through which these laws may be comprehended and employed.

The great material progress which you see around us and in which we glory had its foundation in individual thought. The human factor is the foundation of

it all. Certain inherent mental qualities exist in every man and are caused to develop in varying degrees of intensity and relativity. The dominance of any of the evil among these qualities tends to make of the man a destructive force; the man becomes a constructive influence when good qualities are dominant. But to some degree both destructive and constructive forces are necessary, just as the destructive forces which tear down the trees of the forest are necessary to the production of those commodities for which lumber becomes the raw material.

Let us be specific.

Not the least of these mental qualities which are the birthright of the individual is the instinct and desire to create. Industry is the product of the creative impulse of the individual. The first man conceived with his unaided brain and wrought with his bare hands the instruments that brought to him the necessities of life. As the boundaries of his little world expanded and crude competition came into being he devised improvements in method and product until barter and trade, the forerunner of our commerce, came into being. The contacts made in his journeys afield to trade his products for those of other men further enlarged his horizon and gave rise to competition. Competition brought aggrandizement and he, herding with others of compatible temperament and objective, unwittingly sowed the seed that, ages later, produced our towns and cities.

And so man struggled upward, forced by necessity to rely upon himself and use his individual inventive ability in the creation of those crude implements that have finally evolved into the wonders of our modern world.

The cumulative energy of this individual creative impulse produced in the years from 1750 to 1800 one of the greatest eras of invention that the world has ever known. During that period young James Watt invented the steam engine; Whitney, the cotton gin; Arkwright, the spinning frame; Hargreaves, the spinning jenny; Cartwright, the loom. History records approximately twenty other contemporary developments of lesser importance.

We can stop here and realize the effect which these inventions have had upon the progress of our own civilization and we can deduce from this experience one distinct factor which we must take to heart in our present problems.

The development of conditions in industry whereby the individual working in reasonable happiness and contentment may contribute to his tasks the maximum of inventive ingenuity is the first obligation of the employer, if our industrial activity is to continue to expand.

Stress is laid in this statement upon the development in the individual because there has been a distinct tendency in the development of our industrial situations to consider only labor in the group.

The introduction of machinery, carrying with it the opportunity for large scale production, and greater use of capital, was indeed a constructive development and contribution to our present day civilization. However, as is always the case with new situations, we overemphasized this mechanical importance, and this automatically tended to relegate to the background the importance of the individual in the resulting classifications of labor and division of industrial processes.

Through the nineteenth century there was a distinct disposition to consider man as an adjunct to the machine and we temporarily lost track of the fact that we were confusing cause and effect. The machine is the child of the mentality which created it and should in turn be its servant and not its master.

This attitude, no doubt, was the result of many conditions but the principal one originated within labor itself. Fearful that the development of machinery might result in the elimination of labor and resulting want and distress, labor organized groups to combat the inevitable advance of the machine era. In developing this perhaps necessary group antagonism to the forward progress of inventive ingenuity, the individual was subordinated to what was considered the welfare of the group. A philosophy based upon a minimum daily contribution in order that more labor

might be employed actuated the operation of these group movements, and so we had throughout the world this great combat between the power of inventive ingenuity and a labor philosophy which endeavored to restrict its operations.

At the same time, we were going through a particularly interesting change in the method by which industry conducted itself and this change has had a most important effect upon the human factor. In the advancement of our industrial era individual business has made way for the corporation and the individual owner or manager has been replaced by the corporate executive. This change in itself has produced a most constructive result in the relationships between the various companies and their workers. Obviously, the more enlightened and broad minded the corporate executive, the more intelligent are his considerations of the human problem.

By natural evolutions, therefore, in recent years we have stopped the swing of the pendulum in the direction which is making a man a mere adjunct to the machine. We have realized that dehumanization to the point where the personality of the worker has been subdued is of greatest possible disadvantage to the welfare of all people. In this new great industrial evolution more happiness has been brought to the masses of people. It is only necessary for us to continue our perspective for the progress to be genuine and real. Through it all the living conditions of the citizens of all enlightened nations have been steadily improving and are now more advanced than at any time in the history of mankind.

Our life today, with its automobiles and airplanes, its motion pictures and radios, its shorter working days and higher salary levels, could come to us only through the industrial influences here indicated. Our problem at this time in the relation of the human element in this industrial activity, is to promote, as we have earlier indicated, conditions by which and through which individual inventive ingenuity may continue to assert itself.

This first proposition couples itself automatically with the second. The object and the responsibility of all intelligent management is to develop conditions whereby all labor has the proper attitude toward its job.

Practically all industries now exist in a highly competitive social order and are forced by circumstances to survey every factor in any way connected with its operations. Of all of these factors, the human is the most important.

Competition has made it necessary for all industry to conduct a war against waste if it can hope to compete. Industry must make volume production its first and chief ally in this war, but as practical men we know that all efforts become fruitless unless properly supported by labor and they can only be so properly supported when labor itself has the right attitude towards its job.

Increased production demands larger markets. Our distribution is expanding in every direction. Almost instantly vast financial resources are transmitted from one corner of the globe to another. Geographical and international barriers to trade have been broken down. The world has become one huge market. Before we are aware of it, it may also become one large factory.

Generally speaking, the same quality of material, the same perfection in machine equipment, the same degree of refinement in methods and processes, are commonly available to all manufacturers. In the war against waste the forces of mechanics of industry work with a continually diminishing ratio of effectiveness.

But competition indicates that the struggle must continue and that a new ally must be found.

Our age of inventive genius, which has brought in its wake the very highest type of executive and managerial skill and intelligence, has brought our industrial leaders as a class rapidly to the conclusion that this new ally is embodied in the long buried potential creative impulse and ability of the workers in their plants. Much thought has been given and must be given, and much improvement has been made and must continue to be made, toward the devising of a method for

releasing this force first for the advancement of the individual industry to which it is devoted but more importantly for its contribution to the common social and economic good.

The trained executive knows that the human equation is of compelling importance if his company is to maintain its position in the field but what worries him is how he can keep his labor so minded toward its job that he obtains the best in service and inventive ingenuity. He knows that he must keep his labor reasonably happy if he would avoid the destructive forces of labor turnover and retarded production. How this can be done necessarily varies with every plant and with the type of employee. The important fact is that the modern corporation well managed is more human in its industry than any previous type of business.

In American industry in all of its ramifications and various signs we contemplate the whole gamut of labor from the non-English speaking alien to the college graduate and obviously the methods by which various types of labor might be made contented varies with each individual enterprise. At the same time, it is very hard to use the words management and employee, because management is in turn employed and oftentimes the directors of the corporations which select its management are in turn selected by stockholders who may possibly be employees of that particular industry, and the completeness of this circle emphasizes the primary consideration in all human operations. This consideration is the development of confidence, sincerity, absolute truthfulness and straightforwardness in both management and labor. These qualities above all others are appreciated by labor and are reflected in its attitude towards the industry. If management can get over to the human beings whose work it directs the fact that it is being at all times foursquare with them, the biggest part of the job is done. Humans respond to nothing so completely as mutual confidence, but they must engender it by personal integrity. This comes particularly true in large industries where we are forced to consider humans in the mass, where personal acquaintance in the nature of things is not always possible and where relations must be by understanding. The most outstanding characteristic of labor conditions in industry today is a sympathetic attitude displayed by management in every well ordered enterprise. Undoubtedly this offers the foundation for the better feeling which is the necessary basis of mutual cooperation.

At this point, there are a lot of details which we might well go into if time afforded. In the manufacturing industry the location of a plant is of primary importance. If commercially possible, it should be in a small community or on the outskirts of a large one so that light and air and conditions of living will greatly help the human problem.

Another is the petty boss standing between management and labor and oftentimes making the human problem more difficult for both by bad judgment.

The fact is that the philosophy among the more enlightened labor leaders is distinctly changing in character. That to which we have previously referred, based upon the subordination of the individual to the group and the minimum production of each employee in an imaginary protection of the others, has been replaced by a more enlightened philosophy based upon maximum production at low unit cost as a basis for high wages and more consuming power. This has changed the entire attitude of American business and is largely responsible for our present prosperous era.

Management is not now concerned with the cost of labor as much as with the cost of the unit of product. Labor realizes that increased production and lower costs afford greater business and higher wages. This philosophy now accepted by both management and labor has led both up to a more prosperous condition than has ever existed in industry anywhere within recorded history. The continuation of these conditions is based upon the proper development of the human factor for the very reason that as wages increase and hours of labor decrease,

unit costs can only be maintained or lowered by original conceptions of labor saving methods and these can only be found in the mind of the individual. Actually, then, in our human relations we are forced to return to the emphasis of the individual and to the hope that his development will respond to the advantage of the group. In future, the saving of the group will be in the intelligence of the individual rather than the saving of the individual by the mass power of the group.

In this great reservoir of inventive intelligence, found at a more average high plane in American labor than elsewhere, lies the continued prosperity of American industry. It is primarily a problem of human relations, operating with a guidepost of straightforward understanding. The solution will necessarily be gradual but intelligent effort will make it inevitable.

Colvin in his book "Labor Turnover, Loyalty and Output" says:

"No one is wise enough today to outline the precise way in which these problems will be solved. But no citizen who loves his country and his fellow men can shut his eyes to the impending changes or strive to prevent what the great majority deem progress."

The obligation to be straightforward, sincere and approachable rests just as much upon labor as it does upon management. Unquestionably they must both have the proper attitude towards the job and both must take pride in the work they are doing. Unquestionably labor will continue to expect its fair share in the profits of industry and there will probably always be difference of opinion on this point but each situation in its turn must be considered upon a basis of honest, sincere and straightforward cooperation. Entirely aside from welfare work, which is an outstanding consideration in modern business, every industry today is giving consideration to the question of wages and hours, to bonus systems; to profit-sharing and stock ownership. These methods are bound to vary in different industries and in type and will largely affect the attitude of managements toward the human problem. It is rather significant to observe that many of our industries which have been the most profitable are those which have taken the most advanced position in the consideration of the human factor. But the very fact that we have under discussion all of these various methods of increasing labor's participation, indicates clearly that modern management is alive to its problems and is approaching them as fast as it can with prudence. After all, the businesses must be made profitable or the problems will solve themselves automatically by the passing away of the industry in question. No plan will be fully successful unless conditions surrounding the tasks of men will in themselves attract labor to the job. Of course, this is not a hard and fast rule and depends upon the status of the labor market but in the long swing of years in which progress may be measured this rule will undoubtedly apply.

Granting that labor must have a proper attitude toward its job, the same is true equally of management. The voluntary cooperation of management is a hundred-fold more effective than the compulsory cooperation of management. Therefore, when we look at the human equation, is it too much to ask that the employer and employee both alike are sincere and honest in their mutual dealings? Is it not proper that this labor problem should be approached cooperatively as associates? The management is doing this continually in its interchange of thought through trade associations, engineering societies and other such agencies connected with other factors of the business. It is not too much to ask that management and labor as associates seek a common ground of understanding. The appearance of the more liberal labor leaders and so-called capitalists upon the same discussion platforms, the growing tendency to the abolition of the private offices, the growing ease with which executives may be approached by those under them are but the evidence that the search for this common ground is already seriously under way.

We are here today to discuss matters of safety. Does it not naturally occur to

us that therein lies perhaps the most important opportunity for developing this common understanding?

During the year ended June 30, 1927, more than 95,000 human beings lost their lives in accidents occurring in the factories and on the streets and highways of this country. In New York State factories alone almost 99,000 people were injured so severely that they received money compensation; 1,042 of those 99,000 died as a result of their injuries. These accidents, most of which, I venture, were preventable, cost New York State in excess of \$100,000,000. Charging deaths and permanent disabilities with a loss of 1,000 weeks each, injured employees were absent from work a total of more than 2,000,000 weeks.

Here is a condition, the relief of which demands the interest and effort of every human being, whether he sits in the president's office or works at a bench.

Here is a situation in which there can be no major controversy. The conservation of life and limb is of prime importance to both employer and employee, for death and disability cause disaster to both.

The solution can be found only in their combined effort; for divided they can accomplish but little.

Industrial safety is not a new subject. It is recorded that some thought was given to it in 1867. The problem of employees' relationships as a whole was considered as early as 1800 when Robert Owen, a Scotch mill operator, set up a paternalistic personnel program among his workers.

Robert Owen's effort was but the sowing of a seed. The harvest is contained in an ultimate civilization, the character of which we cannot conceive, but the fabric of which is being inevitably woven from the warp and woof of individual human thought and accomplishment.

The one outstanding fact is that our new standards of living have developed in the individual not only new capacities but new appreciations. This may not of itself make our so-called labor problem easier; in fact it may temporarily make it harder but it will ultimately introduce two factors which should have a distinctly stabilizing influence in our economic order:

1st—It should raise the level of education.

2nd—It should increase the per capita average of wealth.

These two factors should have a distinctly healthful influence in shaping the course of a democracy whose Government derives its authority from the consent of the governed. Possession of property is the best antidote for destructive socialism.

This unity of interest between industry and labor has increased as their productive capacity increases and a higher set of values for each in relation to the other follows in order.

The important fact is strikingly emphasized in this situation that these values must moreover be reciprocal if they are to attain their highest level.

The most casual survey of the field of industry reveals clearly that the employee who has a right attitude toward his employer usually makes the greatest progress personally and a group of such employees do so collectively. Only in an atmosphere of mutual understanding and interest, of cooperation toward a common achievement in the success of which all participate, can industry achieve its best results. We have learned many lessons in the past twenty-five years of industrial development, but perhaps none more important than the twofold lesson: first, by the employer, that high wages and protection of the human factor; and second, by the employee, that the development of mechanical power and mass production may combine to the greatest benefit of all concerned.

In this new appreciation of a common interest there need be no sacrifice of individual rights or ambitions which are the very basis of our social system. Paternalism toward employees is just as much out of place as communized ownership; self reliance must be developed as a primary virtue. Each party in this

new relation should stand squarely on his own feet, jealously protecting his own interests, but realizing fully how far that interest is one with his business partners. Ill advised charity is as much to be deplored as socialistic seizure of the other fellow's property. Each party to this relationship has important obligations to the other and each should recognize these just claims. The protection of life, of health, of productive capacity represents an obligation which is both humanic and economic. So also exists the obligation to protect property, the mechanical and financial organization of industry, as well as the human.

Progress in American industry is strikingly marked today by the dominance of a new psychology concerning industrial relations. Men, materials and money have combined in the development of our great resources and brawn guided by brain, wealth and labor directed by inventive genius and creative energy, have brought the United States to a foremost position in the industrial world. Each of these factors has its place of importance in industrial growth now as always. But today in sharp contrast with past industrial history we find a new controlling thought. That is the new appreciation of the importance of the human equation, of the economic as well as social value of its protection and conservation.

The golden age of English industrial supremacy following the Napoleonic wars and our own Civil war was largely founded on the exploitation of labor. The United States, as the world's new industrial leader, is basing its leadership on the cooperation of labor. England has been slow to make her readjustment to the new order and is seeing her former position occupied by others who see the wisdom of this new policy of reciprocal effort and understanding.

This new guiding thought is not formulated in pursuit of Utopian ideals. It is productive of the most practical results. First, it adds greatly to the productive capacity of the individual; second, it greatly increases mechanical efficiency and output; third, it increases the buying power of the consumer and raises the general standard of living; fourth, it greatly reduces labor turnover, the bane of all industry in its wastes and annoyances.

There is this further important consideration that must not be lost sight of in the development of this new thought, and that is that labor will naturally seek the substance and not be satisfied with the shadow in these new relations. Welfare provisions and social services will not satisfy in lieu of a fair participation in the earnings. Such efforts are fitting only when undertaken in addition to a just wage and bonus return in some form. Premiums for production above established minimums will go much further toward the establishment of industrial peace and the stimulation of industrial production than prize packages or medals.

In reviewing the whole field of industry, we may safely conclude that in these important respects intelligent self interest is guiding the way toward better standards of operation and a keener appreciation of the human values in industry and of the mutual rights involved. The ideals of peace toward which the minds and hearts of men are ever reaching may not yet have been fully achieved, but at least we are moving toward them, as such a gathering as this of today eloquently testifies.

PRESIDENT NIESZ: Mr. Homer L. Ferguson, the next speaker, is a graduate of the U. S. Naval Academy at Annapolis, and for some years after his graduation he continued to study the building of ships. A few years after that he changed his lieutenant bars for the unseen shoulder straps of a captain of industry, and that has been his job ever since.

For the past fifteen years he has been president and general manager of the Newport News Shipbuilding & Dry Dock Company, and he has retained his love for the sea and the things associated with it. He has taken a very intense interest in the safety movement and its development in industry.

It is a very great pleasure to me to present Mr. Ferguson.

Address**By HOMER L. FERGUSON****President, Newport News Shipbuilding & Dry Dock Company,
Newport News, Va.**

Not so many years ago I felt that safety work was largely waste effort, that after management had done its share to provide a safe place to work and met all of its legal obligations, it was then up to the men to take care of themselves. This was not on account of any lack or real sympathy for injured employees, but because it seemed a fairly hopeless task to make the careless careful about the one thing that most concerned them. My medical friends tell me that men of the soundest judgment in industry, finance or the professions, are apt to be quite childish about what is of greatest importance to them—their own health.

Accident hazards are undoubtedly increased by the speed and constancy with which we move about while awake. We are all sorry when anyone is hurt or killed, are glad that the injured man is properly compensated and his family made comfortable for the time being. The feeling of pity predominates. In an industrial plant, if a valuable piece of machinery is broken down or ruined by carelessness, there is usually a great deal of profanity and decisive action is taken to prevent a recurrence. The feeling of pity is quite apt to be absent.

My excuse for talking to you today is that I was drafted to discuss the question of industrial safety in a more general way at the first of your large meetings and feel that perhaps my experience may be helpful, as my ideas as to the value and efficacy of safety work have been changed.

For the benefit of those not familiar with shipbuilding, I would say that the Newport News Shipyard employs 5,000 men and has most of the hazards of industrial employment. There are machine shops, boiler, blacksmith and forge shops; iron, brass and steel foundries; copper, sheet iron and pipe shops; wood-working plants, ship sheds and furnaces; rigging loft, mold loft, shipways where hulls are constructed, dry docks and piers; probably twenty miles of railroad track, trucks, dozens of cranes of every description from three tons to one hundred and sixty tons capacity. The plant covers about one hundred and fifty acres. At our plant about thirty-five per cent of the men are colored, and these men do a large part of the stage building and rigging. We have found them rather less careful about getting hurt themselves and probably rather more careful about hurting any one else.

Our safety work started in a small way about fifteen years ago, with the appointment, and later the election, of a yard safety committee. This committee still exists, has regular meetings, with definite duties. Its members have the obligation to report immediately any unsafe practices or conditions, and may order emergency jobs of small extent done. In conjunction with the inspection provided by the State under the Workmen's Compensation Law, mechanical safeguards have been provided and applied and this work still goes on, although to a noticeably smaller extent.

Shortly afterward the Clinic was installed with nurses in attendance during working hours and a surgeon in attendance most of the time and always within easy reach. One of the chief values of a clinic in the plant is that minor injuries may be treated properly and quickly and infection prevented. This department is of great use, not only in the treatment of injury, but also in an educational sense. In a large plant, a clinic should have an X-Ray, for frequently small bones may be broken which otherwise would not be discovered.

The next step was the adoption of a definite employment and training program, with a physical examination for every new employee. In training men and boys for their jobs, the necessary instruction in safety is easily given. The record of our 200 apprentices for safety is excellent. A considerable contribution to safety is

made by the exercise of sound judgment in not placing men in jobs for which they are not suited by reason of their age, physical condition, or lack of training.

On account of the great risk involved in repairing vessels which have been carrying oil, it became necessary to have a certified chemist. We found a man who could do this work in addition to his other work and whose word is final as to the conditions of safety in or about tanks of an oil vessel, most particularly as to freedom from gas in such tanks.

We then took other natural steps in accident prevention, through the use of bulletin boards and posters throughout the plant, and the adoption of competitive methods as between the various departments. These steps were taken for the education of both supervisors and men and to create a spirit of competition. Every one can see these records daily, and there is apparently a keen desire on the part of the departments to keep their records clear. I would say, however, that the department causing an accident is charged with the accident, not necessarily the department of the man who is injured. The records of accidents are not only shown on bulletin boards, but are published monthly in a small plant publication. The rates of the various departments for order and safety are also shown in this publication. Organized safety campaigns with prizes are carried out once or twice a year—usually of a week's duration. In this connection, I would state that a clean plant where everything is kept in an orderly way, such as any good housekeeper or good industrialist should insist upon, adds considerably to safety.

We now have a full time safety engineer whose job is safety and nothing else, and who is primarily charged with the greater part of the safety work, keeping of records and the determination of the exact causes of accidents—and this means not only direct causes but indirect causes as well. Complete statistical records have been kept for years, and only from such records may sure advance be made.

Supervision is the key to safety work in a shipyard. We have adopted a plan of reducing bonus to a supervisor because of accidents to men under his care. In the case of serious or lost time accidents, a small court of inquiry is held at the clinic shortly after quitting time, and there appears at this meeting the superintendents and foremen of the departments involved, the employment manager and safety engineer, as well as the witnesses and the injured man if he can come. A report of the facts involved is made, and a copy sent to every one concerned. The effect of this is to create a real interest and to further extend the processes and benefits of education. It may be held that supervisors might give undue time and thought to this work. I do not agree with this view at all, as there is no reason why a man may not be a most competent machinist foreman and at the same time contract the habit of seeing and instantly correcting unsafe practices. Fortunately the human mind is one thing that can keep on growing indefinitely without getting too complete or too big. I am convinced that well directed and systematic effort in accident prevention will yield as large financial returns as will the same kind of effort applied in many of the other various fields under the control of industrial management.

Management finds in accident prevention that the interests of employer and employee are more nearly similar than in probably any other contact. The hurt man loses his time, his body is impaired in some way, even his life may be lost, and the employer loses valuable trained services, frequently sustains a direct money loss, has his labor turnover increased, and suffers that intangible but vital loss of morale.

Comparative records of industrial accidents may be more readily obtained than any other industrial records, and in this connection the records sent out by the National Safety Council are invaluable. The backing of the community is behind safety work, and practically every one believes in it after they become acquainted with it. It can not be turned over to hired men, however, no matter how competent

they may be as specialists. To further the laborious process of training and education constant effort is required.

At first it seems arbitrary to require men to wear goggles under certain conditions. We have come to the conclusion that the man with the record knows more about hazards than the man with a chipping hammer, and therefore insist that men in certain definite trades wear goggles, and in case they have to wear glasses of their own, goggles which go over their glasses are provided.

To illustrate that the problem of safety in an industrial plant is capable of breakdown and analysis like any other industrial problem, I have prepared for the benefit of such industrial engineers as may be interested, a brief statement of accident causes and prevention and responsibility.

Accident Causes

1. Failure of Mechanical Equipment
 - (a) structural Weakness
 - (b) Faulty Design
 - (c) Poor Material
 - (d) Abuse
 - (e) Lack of or Improper Safeguards

Accident Prevention

1. Engineering
 - Purchasing
 - Inspection
 - Plant Maintenance
2. Improper Methods of Doing Work
 - (a) Lack of or Insufficient Instruction
 - (b) Poor Supervision
 - (c) Improper Use of Tools and Equipment
 - (d) Workman Unsuitably Located to do Work Safely
 - (e) Physical Unfitness of Workman to do Work Assigned Him
2. Planning and Scheduling
 - Competent supervisors
 - Job Analysis
 - Intelligent Allocation of Labor
 - Selective Employment
 - Mental and Physical Examination
3. Individual Carelessness
 - (a) Recklessness—Chance Taking
 - (b) Lack of Forethought or Imagination
 - (c) Lack of Interest (absentmindedness)
 - (d) Improperly Clothed for Job
 - (e) Inexperience
 - (f) Horseplay
3. Safety Education
 - Thorough Training
 - Enforcement of Plant Rules

Safety Responsibilities

WORKMAN

- Health
- Suitable Clothing
- Safe and Efficient Performance of Duties
- Proper Conduct

MANAGEMENT

- Equipment and Tools
- Material
- Work to be Done
- Plans and Schedules
- Methods of Doing Work

Supervision
 Instruction
 Inspection
 Employment and Training
 Making and Enforcement of Rules
 Allocation of Help

There is a direct relation between accident prevention and any other industrial problem, both in the method of attack and the method of cure, and while we industrialists should always keep a proper sense of proportion, I would like to say for the benefit of those not already converted that as the result of many years of experience, I am satisfied that safety goes hand in hand with economical and high grade production, and the small cost involved is more than justified.

As a matter of fact, the principal problem involved is that of overcoming the natural resistance of the human mind to the entrance of a new thought. There will always be risks in industry. While it is a fine thing to have accident compensation, and it is a splendid sentiment that causes hospitals and charitable organizations to provide for the unfortunate, it is much more worth while to prevent accidents. When we can deliver to the owners a great ship, in whose construction and outfitting no workman has received an injury, I shall feel a very real pride in that achievement.

Annual Report of Managing Director

By W. H. CAMERON

Managing Director, National Safety Council, Chicago

To the Members of the National Safety Council:

During the past fiscal year 851 new members have joined the National Safety Council. A comparison of the total membership for the past two years shows:

Membership, July 31, 1928.....	4,638
Membership, July 31, 1927.....	4,359
Net Gain	279

The net gain in membership revenue was \$10,995.43. The total annual dues now being paid by 4,638 members is \$263,021.56, or an average of \$56.71 per member. The solicitation of new memberships through voluntary committees and in other ways has been continued unabated.

The NATIONAL SAFETY NEWS has gained in circulation and importance. The quality has improved and the number of special features and articles has increased. The minimum number of pages has been increased to eighty per issue. Two special issues were published during the year; the pre-convention issue of September, 1927, and the Chicago Congress Convention number. There has also been an increase in the number of extra copies ordered by members. The advertising doubled during the previous fiscal year and has considerably increased during the present fiscal year. The "Safety Exchange" and sectional articles have proved popular. Changes in typography and the use of more illustrations have improved the appearance of the magazine. The aim of the NATIONAL SAFETY NEWS is to provide practical information and to keep before safety workers a vision of the worthwhileness of their work.

The Safety Posters have been published regularly and steadily have been improved in quality. Four hundred and eighty posters were prepared during the year. This includes eight 17 by 23 inch posters and thirty-two 9 by 12 inch posters each month. More time and money have been spent upon their preparation and well known artists have furnished illustrations. The circulation has increased 27 per cent and the new varieties have emphasized the growing appreciation of

safety posters as an educational medium to lessen accidents. A 30-page catalogue of 252 selected posters was mailed to members January 1. Poster inserts for every package of posters were distributed on alternate months. Prizes were awarded to workers in contests for opinions on posters. The Council's street posters, distributed through community councils, have filled a need for continued education of the public in the safe use of the streets. The members and the sectional poster committees contributed generously to make this poster service possible.

The Safe Practices Pamphlets have appeared bi-monthly under the supervision of the Conference Committee of seventy-five safety engineers. Twenty-three of the series have been revised and reprinted during the year. Six new pamphlets have been produced. This "Safety Encyclopedia" now includes 99 separate treatises on the fundamentals of safety engineering practices. Two sectional Safe Practices pamphlets for the petroleum industry and one for the Rubber Section were completed during the year and thousands of copies distributed. New members are ordering complete sets of these pamphlets for reference purposes. One hundred and ninety-seven sets have been ordered by members during the fiscal year.

The Consultation Service has answered 7,010 requests for information. For the fiscal year ending July 31, 1922, there were 2,677 such inquiries. There is a marked increase year by year in the use of the facilities of the Library and Information Bureau. During the fiscal year 51,602 pieces of information were distributed in answer to 7,010 inquiries, including books, pamphlets, clippings, photographs, blue-prints, posters and similar material; 32,508 new pieces of material have been added to the Library files during the year. More exhibits were prepared for regional and national conferences than during any previous year. The information files have been systematically built up by the acquisition of up-to-date information on all phases of accident prevention, industrial health and hygiene, and allied problems.

Films and Slides have been in demand by members in increasing quantities. The five new stereopticon machines purchased last year for use of members have been in continual circulation and have justified the investment. The new film produced for the Chicago Congress, "The Handicap," met with the approval of the members, and six copies have been in steady circulation. A new public safety film "The Verdict," was produced during the year and six copies are now in circulation; a number of copies have been purchased by members and others. The list of motion picture films was revised and reprinted during the year.

The Safety Calendar increases in popularity as a medium for reaching the worker and his family, school children and the general public; 650,000 copies of the 1928 Calendar were distributed. The 1929 Calendar was ready for distribution June 1, 1928, and 160,000 copies have already been ordered by members. The information on the reverse side of the 1929 Calendar sheets refers to industrial safety and the primary relations of the worker to industry.

The 1927 Congress and Exhibit eclipsed every previous safety convention in attendance, number of speakers, exhibits and interest. The Transactions of that Congress were published in three volumes with complete alphabetical index. The sectional Transactions were also printed separately and the new method of distribution, allotting to each member one copy of the general meetings' report and the sectional report in which he is interested, seems to have met the full need of each member. The 1928 Congress program contains 80 pages.

National Safety Codes have continued to receive the careful attention of your committees and staff. Representatives of members of the Council are assisting in the formulation of 55 of the national standard codes. The Council is now sponsor or joint-sponsor for 14 codes. The Council continues to contribute toward the expenses of the American Engineering Standards Committee. Safety codes on Ladders and Stairs for Mines, and Underground Transportation in Metal Mines were approved during the year.

Editors of Employee Magazines have continued to receive a special service including original safety cartoons and accompanying stories. Other special material and assistance have been accorded members publishing employee magazines or contemplating the establishment of this type of publication. An attractive program has been prepared for the Annual Meeting of these editors at the New York Congress and the special feature in the NATIONAL SAFETY NEWS giving editorial advice to the publishers of employee magazines has been continued.

The Industrial Sections have been more active than ever. All of them have held Executive Committee meetings and have continued intensive service to the members within their groups. There has been an increase in the number of sections issuing monthly News-Letters. Many of the sectional committees have conducted energetic membership campaigns and performed invaluable service to fellow members by stimulating the furnishing of statistical data, material for posters and an interchange of safety experiences. There were twenty-four regional safety conferences during the year. Two thousand and eighty-nine plants contributed their accident records for 1927 and the tabulations have been printed in a pamphlet and distributed to the contributing members and others. Negotiations are in progress with the National Electric Light Association and the American Gas Association to contribute the statistical records of their members to the Council's annual report of its members. The officers and committees of the sections held a mid-year conference in New York City. The salaried secretary of the Petroleum Section has been continued through the generosity of the American Petroleum Institute. Three contests of members in the Paper and Pulp, Petroleum and Public Utilities Sections have been promoted and trophies will be awarded to the winners at the meetings of these sections at the New York Congress. Members interested in stopping accidents in the refrigeration business have organized a Refrigeration Section and will have their first meeting at the New York Congress. Two Petroleum Section Safe Practices pamphlets have been completed during the year, entitled "Pulling Oil Wells" and "Service Station Operation" also a Rubber Section Safe Practices pamphlet on "Compounding Materials" and thousands of copies have been distributed.

The ASSE-Engineering Section has participated in the regional safety conference as well as the Fifth Pacific Coast Safety Conference. Five research committees have been at work. The study of Wire Rope Attachments and Connections by two thesis students has been completed. Seventeen new sub-committees have been appointed to compile data on the best Safe Practices in sixteen industries. The two special laboratory research projects, Woodworking Circular Saws and Annealing of Chains, have made considerable progress and reports will be presented and discussed at the New York Congress. A report of the Committee on Elimination of Noise will also be presented and discussed. The amalgamation of the American Society of Safety Engineers and the Engineering Section, which took place at the Louisville Congress, has proved the wisdom of cooperation.

General Sections: In addition to the Health, Education, Engineering, Public Safety, Plant Publications and Employees' Benefit Associations, nineteen industrial sections have been rendering service to the members during the year.

Public Safety: The Advisory Committee of the Public Safety Division has held three meetings during the year. The Council has continued to assist the National Conference on Street and Highway Safety to accomplish its purposes by stimulating legislation based on the Uniform Motor Vehicle Code. The Model Municipal Traffic Ordinance, taken up by the Conference on our recommendation, has been completed and copies have been distributed. We have taken a leading part in cooperation with American Engineering Council, in standardizing traffic signs and signals. Much of the Council's activities for safety on the streets and in the home has been directed toward the formation and upbuilding of community safety organizations. The staff of the Public Safety Division has been increased during the year through the contribution by Mr. John D. Rockefeller, Jr., and an increase

in the appropriation made by the Council for public safety. The monthly bulletin, *Public Safety*, has been distributed to 7,000 public officials, automobile clubs, chambers of commerce and others, and the September issue will appear in a new and improved form. Twenty-six community traffic surveys have been completed to date. The 1928 statistical report, "Accident Facts—1928," was completed five months ahead of last year's report and distributed. An increasing number of communities and states are reporting to the Council their public accident experience and this information is being analyzed and interpreted for preventive purposes. The series of home safety addresses have been completely revised and reprinted. The Dash Board Card Service has been continued. Eight five-minute traffic lessons were printed in the NATIONAL SAFETY NEWS and later in pamphlet form. The result of a long study on the safety aspects of street parking eventuated in printing 3,000 copies of a pamphlet "Where Shall They Park?" The draft of a report on a study of "Traffic Work of Police Departments" is now in the hands of our Committee for approval. A monthly News-Letter has been started to public safety members. Many inquiries on public safety and traffic problems are answered daily. A committee has been appointed to investigate the relations of the individual to street and highway accidents and a laboratory investigation will be made under the auspices of our Personality and Public Accidents Committee. A summary of the Uniform Vehicle Code was printed recently and widely distributed. Posters and other material were contributed to the Boy Scouts for an overland trip. Special articles were contributed to many magazines and conferences were attended.

The Education Division has made progress through the leadership of Mr. Albert W. Whitney and the generous support of the National Bureau of Casualty and Surety Underwriters. Through the school magazine, *Safety Education*, field work, constant correspondence with many cities, attendance at educational conventions and other meetings and especially through the services of the executive secretary and field representatives the work has advanced. The school safety posters have been improved and a special service of a monthly poster and lesson leaflet distributed to 25,000 school rooms. A catalogue of sample posters was printed. Cooperation has been continued with other national bodies, such as the Playground and Recreation Association of America, the National Congress of Parents and Teachers and numerous others. This division was represented at the meeting of the National Education Association and other similar conferences.

Our Educational Publicity Service in the industrial and public safety fields has been considerably enlarged. Hundreds of news articles, special stories, seasonal safety lessons, photographs, charts and other propaganda have been published by numerous daily and weekly newspapers, magazines, trade, technical and class publications. Dispatches and feature stories have been cleared through the national news distributing agencies. Daily radio talks have been broadcast through a special service sent to more than 100 radio stations in different cities, at their request. Special material has been given to community councils and members for local publicity campaigns. Numerous periodicals have published editorials commending the Council's work. Our News Release Sheet Service is now sent to more than 1,500 newspapers and trade, technical and class periodicals. The Pictorial Mat Service is sent to 244 newspapers, on request. Among the national contests promoted during the year, were two "picture puzzle contests for boys and girls" and a "Safety photo contest."

Community Councils: Our intimate contacts by means of services to the community councils have been increased. There are now 57 affiliated local and state councils. These councils reach a population of 23,209,000. Twelve hundred volunteer committeemen are rendering service. The salaried staff aggregates 120 people and these councils are spending \$454,000 annually. The Council's service has been concentrated on existing councils but efforts are made to enlist the interest of other communities in local council activities. The director of this division of the Coun-

cil's service was transferred to the managership of the New York office and one of the field representatives was made the director of the division temporarily. The ten volume loose-leaf encyclopedia "Standard Practices for Community Safety Councils" has been kept up-to-date, and complete working standards have been continued for our field representatives. The monthly News-Letter of specific information to community council officers, with enclosures, has been continued. Two field representatives have given all of their time to the organization of and service to state and local safety councils. The second Summer Institute, lasting one week, was conducted for council managers and prospective managers. The Quarterly Conference of Managers was continued. The "Manual for Speakers" was revised, reprinted and distributed during the year. The service and experience of the National Safety Council and local councils on many recommended activities have been organized and prepared as memoranda.

External Relations: Friendly relations have been maintained with other institutions interested in safety, such as the American Red Cross, American Museum of Safety, Chamber of Commerce of the United States, Canadian Safety League, American Association of Industrial Physicians and Surgeons, the Safety Section of the American Railway Association, American Gas Association, the Safety Bureaus of the Insurance Companies, National Fire Protection Association, National Education Association, Joseph A. Holmes Safety Association, International Association of Chiefs of Police, Playground and Recreation Association of America, National Child Welfare Association, American Automobile Association, National Automobile Chamber of Commerce, Associated General Contractors of America, International Labor Conference of the League of Nations, the State and Federal Government Departments, as well as the American Engineering Standards Committee and the National Bureau of Casualty & Surety Underwriters. The Council has maintained its policy of cooperation with these institutions and has looked for opportunities for closer contacts with those leading the safety movement in their respective spheres of influence. A great many safety exhibits have been furnished on request for trade association meetings, etc.

General Activities: Many copies were distributed during the year of the completed report of the study of the health problem due to the use of spray guns. One thousand and sixty-eight bulletin boards have been distributed among members. A series of lectures and slides were completed for Engineering Colleges. A new pamphlet "Shop Safety" has been printed and is ready for distribution. Following considerable deliberation, a new service to members has been inaugurated through the publication of a new monthly magazine "The Safe Worker." Four issues have been distributed and the monthly circulation is now 125,000 copies. Another new service has been the printing in the NATIONAL SAFETY NEWS each month of suggested programs for safety committee meetings known as "Timely Topics for Safety Committees." A monthly News-Letter has been sent to members. Two new enterprises have been inaugurated to increase public interest in safety. One of these is the President's Resuscitation Medal. A number of these medals have already been awarded with appropriate ceremonies. Trophies were awarded to seven prize winners in a Steam Railroad Employees' Safety contest. A new industrial health division has been authorized and a director employed to commence work September 1. A branch office has been opened in New York City to assist with the Congress arrangements and to experiment with other services in the New York territory. The Council was represented at the quinquennial meeting of the International Labor Office, Geneva, Switzerland, and an elaborate exhibit was prepared for this meeting and left with the Labor Office for use at conventions in Europe. The new service department, to look after new members, has proved its value. The Council now prints all posters, as well as miscellaneous printing jobs. The new cost accounting and bookkeeping system has been adjusted and has now proved its worth. The entire offices of the Council have been rearranged and addi-

tional accommodations will be rented within a few weeks to take care of the increasing work of the headquarters. Personnel activities were formally inaugurated during the year, including committees on safety, fire protection, first aid, library service, exercise contest, and the bulletin board of the headquarters is changed every day.

Staff: The real staff of the National Safety Council is the membership, a large number of whom have contributed to the NATIONAL SAFETY NEWS, the safety poster service, the Safe Practices Pamphlets, the upbuilding and service of the sections, the Annual Congress, the film and slide collections, and all of the committees, both sectional and local. More than 1,000 persons now serve on these committees. The headquarters staff now numbers 82 persons. The leaders in this staff are:

William H. Cameron, Managing Director.
 Sidney J. Williams, Director, Public Safety Division.
 Julien H. Harvey, Manager, New York Office.
 Paul F. Stricker, Director, Territorial Councils Division.
 W. Dean Keefer, Director, Industrial Safety Division.

STATEMENT OF GROSS REVENUES AND EXPENDITURES

Fiscal Year Ending July 31, 1928

Gross Revenue

Membership Dues:

Active	\$263,811.66
Sales of Calendars, Pamphlets, Bulletins, Chauffeurs' Lessons and Miscellaneous Receipts	254,580.34
Contribution of National Bureau of Casualty and Surety Underwriters Toward Expense of Education Division.....	41,000.00
Education Division—Sundry Receipts.....	401.77
Public Safety Division—Contributions.....	54,057.77
Public Safety Division—Sundry Receipts.....	3,208.13
Gross Revenue, National Safety News, Advertising and Sales of Extra Copies (Dues from Council Members Not Included).....	40,520.28
Interest Earned (Bonds, Bank Balance, etc.).....	6,378.21
	\$663,958.16
Transfer from Reserve for Future Service to Members, Difference in Value of Investment Securities Sold and Securities Purchased.....	293.75
	\$664,251.91

Gross Expenditures and Disposition of Net Revenues

Annual Congress Expense.....	\$ 3,168.13
Annual Congress Exhibit	2,942.38
1927 Annual Congress Proceedings.....	17,120.71
Automobile Dash Cards.....	487.94
1928 Calendars	98,406.05
Chauffeurs' Lessons	87.20
Depreciation of Office Furniture and Equipment.....	13,660.42
Depreciation of Printing Department Machinery.....	3,207.23
Exchange	511.75
Territorial Councils and Field Work.....	39,030.34
General Bulletins	16,181.71
General Office Expense.....	6,469.53
Library Expense	794.34
Membership Solicitation Expense.....	13,388.05
Miscellaneous Publication Expense.....	3,550.77
National Safety News.....	56,731.05
Office Supplies, Printing and Stationery.....	6,688.82
Postage	4,705.05
Publicity	5,087.06
Rent, Light and Power.....	26,722.06
Safe Practice Pamphlets.....	2,310.94
Salaries of Officers and Staff.....	164,276.55
Sundry Activities	55,976.52
Taxes and Insurance.....	397.98
Telephone and Telegraph.....	2,509.66
Traveling Expense, Administrative, Including National Committee Expense	5,490.25
Loss on Exchange of Equipment.....	133.80
Sectional Activity Expense, Including Posters	20,824.30

Education Expense from Contributions of National Bureau of Casualty and Surety Underwriters.....	41,000.00
Education Section—Sundry Disbursements.....	401.77
Public Safety Division.....	40,544.70
New York Office Expense.....	3,682.37
	\$657,910.66
Transfer to Surplus.....	6,341.25
	\$664,251.91

We have examined the above Comparative Balance Sheet of the National Safety Council as at July 31, 1928, and July 31, 1927, and the accompanying Statement of Revenues and Expenditures for the year ending July 31, 1928, and have compared them with the books and vouchers and have found them correct.

ARTHUR YOUNG COMPANY,

Chicago, Illinois, August 13, 1928.

Certified Public Accounts.

ADJOURNMENT

SEVENTEENTH ANNUAL SAFETY CONGRESS
NATIONAL SAFETY COUNCIL

Annual Banquet

October 3, 1928

HOMER E. NIESZ, Presiding Officer
President, National Safety Council

HON. GROVER A. WHALEN, Toastmaster
Chairman, New York Mayor's Committee on Reception of
Distinguished Guests

The Annual Banquet of the Seventeenth Annual Safety Congress, held at the Hotel Commodore, New York City, was called to order at eight-twenty o'clock by the President, Homer E. Niesz, Manager, Industrial Relations, Commonwealth Edison Company, Chicago, Illinois.

PRESIDENT NIESZ: The starting of our program has been slightly delayed by the late return of some of our party who went out on a pleasure trip on a boat and remained sightseeing until long after dark, through no fault of their own.

My part of the program is very short, and I will proceed to do the things allotted to me and pass the leadership along into better hands.

I have a telegram from one of our associates in safety, which I would like to read:

"Montreal, Quebec.

"The members of the Board of Directors and the Permanent Committees of the Province of Quebec Safety League, in session at the regular fortnightly meeting, held last Wednesday, send you their sincere wishes for a successful and profitable Congress.

"It is hoped that the National Safety Council will hold one of its Congresses in Montreal at an early date."

The new Executive Committee will please take notice.

That telegram is signed, "J. C. Pettiguard, Chairman, Finance Committee and Acting Secretary."

I have also a telegram from Mr. R. B. Morley, General Manager, stating:

"Industrial Accident Prevention Association sends greetings to the Annual Congress of National Safety Council."

I have a telegram from remote Australia:

"Heartiest greetings from the youngest Safety Council in the world. We are with you in spirit and are sure to find inspiration in the work of the New York Congress for greater efforts in far-off Australia.

"Best wishes to you all, and may your tireless energies in this noble work be crowned with even greater achievements during the year to come.

"Horace J. Cook, Secretary,
National Safety Council of Australia."

There are many other telegrams and letters, but I shall not have the time to indulge on your patience to read them.

I have, however, a letter in which I know you will be vitally interested, because it is from the President of the United States:

"Nothing is of greater importance than the conservation of human life. Great strides to that end have been made by science, medicine, and surgery.

"For some years, earnest and intelligent efforts have been made to secure a greater degree of safety, but the annual toll from preventable accidents is appallingly high.

"Every well-directed movement to reduce this social and economic loss deserves the utmost encouragement from public officials and agencies and private individuals.

"It is my earnest hope that the Seventeenth Annual Safety Congress, to be held in New York City, on October 1 to 5, under the auspices of the National Safety Council, will be productive of still more effective organization, methods and enthusiasm, in the fight to increase the safety factor in modern existence.

"My greetings and best wishes go to you who will be assembled to consider these important matters.

(Signed) "CALVIN COOLIDGE."

I also hold in my hand a letter from the next President of the United States. Knowing that such a statement might well be challenged, I would like to say that I do not state this as a prophecy, but as an actual fact, because the letters I have are from the candidates of both the two main political parties.

The first letter reads:

"Your meeting serves a great human need. The universal establishment of safe conditions in our industrial plants, on our streets and highways, in our homes, is one of the highest responsibilities of public officials, of business executives, and of the individual citizen.

"Proper organization and proper measures to meet the growing complexities of modern life require changes of ideas and information. Through the Annual Safety Congress, which provides opportunity for searching discussion and record of opinion, the National Safety Congress renders a great contribution to these ends.

"I am glad to testify to the accomplishments of the safety movement. In industry the awakening of management to its responsibility for the safety of employees has not only saved human life but has had far-reaching effects in promoting a sound understanding between management and men.

"Without a doubt it has greatly contributed to the marked advance which recent years have witnessed in the producing industries of this country. Our railroads have done marvelous work in accident prevention. With the plans that have been worked out for improvement of street and highway traffic conditions, the attention now being given to the subject by official and organized bodies throughout the country and the encouraging results already attained in some localities, there is reason to expect a distinct and nation-wide improvement in this vital field.

"Modern science has given us many wonderful means for adding to the effectiveness of the individual and making life worth living. It is essential that we likewise apply modern methods for increasing the safety of our people. This you are doing and thereby greatly contributing to the well-being of the Nation.

(Signed) "HERBERT HOOVER."

The other letter reads:

"As Governor of the State of New York, I have been brought in contact with the accident prevention problem through the administration of the Compensation Act, Grade Crossing Elimination, the operation of the Bureau of Motor Vehicles, and in other ways.

"I have viewed with concern the steadily increasing number of accidents with their accompanying toll of life, injury, and destruction of property. The present situation, occurring in spite of the well-directed and earnest efforts of official and private agencies, demands our serious thought, our best plans for constructive action, and an intelligent, educational policy.

"The forthcoming Safety Congress, to be held in New York City, October 1 to 5, deserves the attention of our best minds. I believe that by directing public attention to the seriousness of the problem and by demonstrating that the majority of accidents can be prevented, the Congress is capable of doing much good.

"I sincerely hope that it will receive the attention it deserves. Loss of life and property through avoidable accidents is among the most regrettable of our national wastes.

"I send my best wishes for the success of the Congress.

(Signed) "ALFRED E. SMITH."

As the National Safety Council has already had its election, we know who our next President is.

I will read the names of the officers who have just been elected for the various offices in the Executive Committee of the National Safety Congress:

Vice President for Industrial Safety—E. W. Beck.
Vice President for Local Councils—George Opp.
Vice President for Public Safety—Miller McClintock.
Vice President for Public Relations—Charles E. Hill.
Vice President for Finance—C. E. Pettibone.
Vice President for Engineering—George E. Sanford.
Vice President for Membership—Arthur M. Tode.
Vice President for Education—Albert W. Whitney.
Vice President for Health—Prof. C. E. A. Winslow.
Treasurer—G. T. Hellmuth.
Managing Director—W. H. Cameron.

I have not given opportunity for any of the gentlemen to make a speech, much as they desire to do so. It remains, however, for the President-elect to give us his views, which will be those of the other officers who have been elected.

It gives me great pleasure to have as a successor for the coming year, as the head of your organization, one who has given many years of service to the Council, and who deserves the honors that have been tendered to him. I take great pleasure in presenting, Mr. Henry A. Reninger.

Address

By MAJOR HENRY A. RENINGER
Newly Elected President, National Safety Council

Having known the National Safety Council almost from its inception, its aims and ideals, I accept with a deep sense of responsibility the position of honor and trust as your president, appreciating fully the confidence your Executive Committee has imposed in me.

May I ask for your generous and constructive support toward all of the efforts and activities of the Council.

Placed on a firm foundation by our past presidents, executive committees and loyal workers, we have built up in a comparatively short time vast responsibilities. No longer are we promoting safety in industry only. The work now of the National Safety Council through its various sections, Local Safety Councils, committees, as well as individual personnel, touches every phase of life.

We are not only a National organization, but recognized internationally as the leader of the world in accident prevention work.

This summer I again visited the battlefields of France and was deeply impressed, after ten years of peace, with the hundreds of thousands of crosses in the poppy fields "over there." This was a terrible sacrifice of human life, but it was war.

Now, in time of peace, the annual toll in America due to accidents is 90,000 lives lost—an unnecessary sacrifice. After the experience of educating and training men for war, what a great satisfaction and happiness we have today in educating men, not to kill, but to save themselves and their fellowmen from needless destruction, pain and suffering!

The problem of the National Safety Council is the expansion of its present activities. Home, school and public safety programs must be more fully developed. This can only be accomplished, however, by an increased membership and income and through the generosity of public spirited citizens.

Speaking for your officers, Executive Committee, Board of Directors and Council Staff, on whose shoulders rests the responsibility of this great movement, we accept it cheerfully, knowing that we have your hearty and loyal support, as well as the enthusiastic cooperation of the thousands of other safety workers throughout the country, whose influence is felt in their own communities.

After these ten years in active safety work, let me assert there is no better use we can make of our lives than to dedicate them to the great cause of Universal Safety.

As your president for the coming year, it will be my endeavor to give you the best I have, gladly, knowing that I have you all with me in active help to make Safety understood and appreciated throughout our country—to carry on the noblest task that can be given to any man or woman—the saving of human life.

PRESIDENT NIESZ: Now it becomes my pleasant duty to turn the meeting over to the Toastmaster, who will conduct the affairs of this gathering from this time on.

The gentleman who will preside for you is well known in both public and business life. If I am correctly informed, he was secretary to Mayor Hylan more than ten years ago. He has served as commissioner of New York's Department of Plant and Structures, chairman of the Board of Purchases for New York City, and member of the New York-New Jersey Tunnel Commission. His regular job is general manager of the store of John Wanamaker, an institution which is modestly admitted, by its advertising manager, to be the greatest merchandising establishment in the world.

Among his other duties, our Toastmaster has been acting in the official capacity of chairman of New York's Committee on Reception to Distinguished Guests, and I know of no guests, as distinguished as those whom he has received have been, who are entitled to receive his attention more than this gathering of safety women and safety men.

I have the honor of introducing to you, Grover A. Whalen.

(Toastmaster Whalen took the chair.)

TOASTMASTER WHALEN: After listening to that introduction, I am quite sure that you must be surprised at the object that you see before you.

There are certain statements in the President's remarks that I concur with absolutely, and one of them is that the institution that I have the great privilege of being general manager of, is the greatest merchandising organization in the world. Ladies, please take note. (A very distinguished guest here just said that I have left out nothing but the address.)

The pressure of time is rather great at the present moment, and although I should like to talk upon the subject of safety, in which we are all so intensely interested, I shall have to forego this pleasure because of the fact that one of the speakers finds it necessary to leave very shortly.

However, there are a few things that I have noticed in the "*National Safety Noise*" that I should speak about. There is a statement here which runs something like this:

"New York, undisputed main stem of the western hemisphere, inspiration of writers and desperation of reformers!"

Do you know why it is the desperation of reformers? Because we are so lily-white here in New York we need no reformers.

Then it comes along and states that it is the finest place in the country to visit—on an expense account. You could even come here on a budget account and get away with it.

I am very sorry that His Honor, the Mayor, cannot be here personally to give you his own word of welcome, because there is no mayor in the world that could do it half as well as he can do it. And I am sure he would tell you, if he listened to what you read tonight from one of the telegrams, that he hopes that in your visit in New York you are finding just as great pleasure as you anticipate it will be in Montreal.

I am not going to lose very much more time in introducing the first number of the musical program. We have often heard of this young lady, who is familiar to us over the air, perhaps as familiar as anybody else in the country.

It gives me great pleasure to present, Miss Gladys Rice.

(Miss Gladys Rice, Prima Donna of "Roxy's Gang," sang two songs.)

TOASTMASTER WHALEN: I am sure we all enjoyed Miss Rice's rendition of those beautiful songs, and we wish to thank her for coming here.

The next speaker is a very distinguished gentleman, whom you all know. He is a man who is known very favorably throughout the country. We in New York are distinctly proud of him, because he represents a great people, and in the representation of those people, he has always found it possible to be a great citizen.

It gives me great pleasure to present to you a distinguished orator, a leader of his race, and one of the leading rabbis of the City of New York, Rabbi Stephen S. Wise.

Address

By RABBI STEPHEN S. WISE
Free Synagogue, New York City

I am rather doubtful of some of the things that have just been said by my friend, the Hon. Grover Whalen, in the light of the statement in your program:

"Grover, we are with you and ready to laugh at anything. Next we shall hear Rabbi Wise."

Mr. Chairman, Mr. Toastmaster, if this is a National Safety Council, my question is whether, if the next convention or congress of this body meets in Montreal, it will be safe for the Scotch?

I have fared rather unevenly tonight. On my way to this Congress, in the company of one of your officers, we were nearly wrecked in our taxicab. One of the waiters deposited most of the contents of the soup tureen on the back of my coat. And Mr. Whalen, in one of his friendly gestures, toward the end, placed the contents of his demi-tasse in my lap.

I was reminded of an experience that befell me some years ago. During the term of the incumbency of office of your distinguished chief, I was motoring, after a Sunday service, up to Pleasantville. You know, New Yorkers will hardly believe there is any place near this city which is a "pleasant ville."

I had to get there, make a speech at a luncheon, motor to Harmon and then take a train to Chicago. We had a chauffeur, sent by Mr. Lewisson, a very good chauffeur—but he ought to be the life president of the National Safety Council.

We motored at the rate of about twelve miles an hour, until I said to him: "Now see here, I want a bite of lunch, Mrs. Wise and I have got to get to the meeting, motor to Harmon, and get a train."

Well he is a Belgian, and my French is Parisian, and he couldn't understand me. Finally I said, "Look here! I know the police. Move!" Well, we moved.

He was going quietly along at the rate of about forty-five miles an hour, when we were hailed by a mercury on a motorcycle. Our chauffeur was thoroughly frightened. I said, "Just keep your seat."

I stepped out of the seat and said, "Thank you, Officer. I am very glad you stopped me. I was hoping an officer would, because I have got to go to Pleasantville. I am Rabbi Wise, and I want someone to take us along a little faster."

He said, "Certainly, Rabbi, step right along."

He motored with us for about ten or twelve miles. We never went faster than fifty miles an hour, and then he left with, "Thank you."

A few days later I met Commissioner Enright and told him the story, and he said, "Well, Rabbi, you were lucky. That must have been one of my Irish cops you put that over. You couldn't put that over on a Jewish cop."

What relation has a minister of religion to a safety movement? Well through religion, we priests of all churches try to assure safety hereafter. It is a great joy to be here tonight and to have part in this program, arranged under the inspiration of the National Safety Council.

Will you forgive me, if I say that I, a Jew and a Jewish teacher, have a peculiar right to occupy myself with and to engage your attention in, the problem of National Safety? For after all, the safety movement at its highest grows out of a conception which my fathers contributed to the spiritual treasury of humankind—the conception that human life is sacred, that human life is holy and inviolable, not only the immortal spirit of man, but the mortal vestment with which that immortal spirit for a time clothes itself.

The great movement on behalf of security and inviolability of life and person for humankind began with the teaching of my fathers, which has become a teaching of Israel and Christianity alike. Man was made in the image of God. "In the likeness of God, created He him." Well, that meant for all time that human life might not be violated. But there was something holy and of abiding sanctity in human life which it was the business of those who presided over the welfare of men, whether as kings upon thrones or as masters of industry, to safeguard, to cherish, and to conserve.

My own interest, as a churchman, in the National Safety Movement is bound up, not chiefly, nor least of all solely, I confess, with the economic aspect of the economic gains which are interwoven with the results of your great work. I venture to say that you represent a great moral and spiritual movement in two senses of the term, or rather upon two grounds. For one thing, you are teaching the irrevealable and unalterable truth of human responsibility

"Am I my brother's keeper?" was asked not by a man, but by a slayer of men—

the first destroyer of his fellowman, skeptically, cynically, fearfully asked, yes, and guiltily asked—"Am I my brother's keeper?"

The answer of your great movement is: I am my brother's keeper. I am to be co-guardian of my brother's life and will be as long as, and as far as, I have the power to safeguard and to make for the conservation of his life and welfare.

I would like to have emblazoned as the slogan of the great campaign you are waging, not the query, "Am I my brother's keeper?", but, "I am my brother's keeper." And I become my brother's keeper only when I recognize God made man in his holy and immortal image; and again when I accept the eternal truth that humans are brothers as well as fellow-keepers, brothers as well as employers and employees—brothers first and after that workers, employers, masters, employees, participants in the mighty creative industry of American life.

Gentlemen, there is one word that I want to say tonight, one word that I would have some of you, perchance, remember when I shall have done.

A few years ago, there was a great deal of cynical contempt, uttered oftentimes, and felt most of the time, touching the safety-first movement as if the safety movement meant that safety was to be the one, sole, dominant concern of the human race.

I should hate, I should loath, I should be ashamed to be seated at this board of the National Safety Council, if you declared that the great end of human life is safety, if the implication was that the business of man is to avoid taking risks.

But, after all, you and I know that life is full of risks, of human perils, which are unavoidable, of material dangers, of moral adventures, of spiritual temptations; life is full to overflowing with risks of every kind. And I have the right as an individual to take a risk, I have the right to incur perils. Ah, it is one thing to incur a peril or to take a risk, and it is another to inflict a risk. I have got the right to take every risk I choose within certain human limitations, provided that I have no responsibilities and moral and material liabilities; but it is another thing for me, as a master of industry, to decide that you, my employee, shall be subject to risks, risks which are avoidable, risks which are reducible.

I stress that word "reducible" for you know, gentlemen, better than I that every year the irreducible minimum is reduced further and further. You have found that. There is nothing that is as flexible as the irreducible.

And I repeat, Mr. Chairman ere I have done: I have the right to take risks. Everyone of us has, as individuals. But after all we are not individuals, save in a very small, limited area of our lives. We are social beings. Aristotle said: "Man is a political animal." He meant, of course, that men live, must dwell, together, and the richer and fuller life becomes the closer when knit together.

Shall we suffer a fellowman to endure, to be undone, to be overwhelmed by any risk which we may reduce or lessen or obliterate? That is the great problem of the National Safety Council.

Mr. Chairman, I come to you tonight, without authorization from the great heads of the churches of America. I can't speak for the heads of the Protestant and the Catholic Churches. But after all, I do speak for a great church, great not in its number of its communicants, but great in the influence, moral and spiritual, which it has exercised upon the human race. And in the name of that Testament which is cherished by Christian and by Jew alike, I tell you that you are performing a great moral and spiritual work. It is a work that has the sanction and the blessing of every church, including my own.

I come to you tonight, as it were, not to speak to you, but to invoke a benediction upon your great human-saving, ethical, spiritual task—national safety, safety for every American; safety, blessing for your and my America.

TOASTMASTER WHALEN: We must feel particularly pleased after listening to the address of Dr. Wise. I was sure that you wouldn't be disappointed in what he

had to say or in how he said it. He does so well always that we in New York look upon him as one of the greatest orators of all time.

The City Service Cavaliers will now entertain us.

(The City Service Cavaliers sang a number of songs.)

The "Three Cheers" will now present us with their original song, "Safety."

(The "Three Cheers" sang the Safety Song.)

TOASTMASTER WHALEN: It is rather difficult for any speaker to follow Dr. Wise, and I hope that you will extend to the next speaker the sympathy that he deserves in following such a distinguished speaker.

Your committee has been very fortunate to invite tonight a stranger, with whose presence you did not expect to be honored. We have here a former diplomatic officer of the Government of Norway, and he has now associated himself as the Port Captain of the Norwegian Steamship Company. He has given a great deal of his life and service to the work of safety, and he comes here with a full knowledge of the subject.

I ask you, if his English is not as good as you would hope it would be, that you be patient with him during his address.

Captain Olsen Talks

By TIMOTHY DAVID LINES

New York City

I did not think, when your very handsome Toastmaster asked me to come to this dinner, that I would have to speak. But I fooled him, I came prepared.

When your President introduced Mr. Whalen, he said he was to be toastmaster, and that he was personally known from one end of the land to another, and so on. But did you ever try to get tickets for any celebration here? No? Then I will tell you what they have to go through.

I have some Norwegian friends, and some Swedish friends too—of course, we don't get along together, but we tolerate each other! They said to me, "Captain, we would like to get a couple of tickets for the Lindbergh celebration."

I said, "All right. How do you get them?"

They said, "You have to go to the City Hall."

So I went to the City Hall, and I said to the man at the door, "Where can I get a couple of tickets for the Lindbergh celebration?"

He said, "You don't get them here. You have to go to the Municipal Building."

I went to the Municipal Building, and I said to the fellow there, "Could I have a couple of tickets for the Lindbergh celebration?"

He said, "You don't get them here. You have to go to the eighth floor of the Automotive Building."

So I went to the eighth floor of the Automotive Building and I said to the little lady there, "Could I see Mr. Whalen?"

She said, "What is your name?"

I said, "Captain Olsen."

She said, "Will you take a seat there?"

I said, "All right," and I sat down.

About thirty minutes later a great, big fat fellow came in there and said, "Is Grover in?"

She said, "Yes, go right in."

About half an hour later this man Grover came out and said, "Do you want to see me?" He was smiling, you know: and I told him who I was. He said, "I have no tickets. You go down to the Mayor's Committee."

I went down again to the Mayor's Committee, and I said to the fellow, "Are there any reservations for Captain Olsen?"

He said, "What do you think I am, an Indian?"

After about three or four days, I finally got two tickets—way out west some place! But I am not through with him yet. I have something else I want to tell. I want to tell you about what he did to me about three Sundays ago.

He said to me, "Captain Olsen, would you like to see a baseball game?"

Can you imagine a Norwegian going to a baseball game?

I said, "All right, I will go with you."

He took me up to the Yankee Stadium. I said, "What are you going to do here?"

He said, "You come in with me and watch the game. It is baseball."

I said, "Oh," and I went in and got in a little box, as I thought it was. And there was a hole and fellows were going down there.

I said, "What are they going to do?"

He said, "You watch for a few minutes."

I watched them throwing a ball here and catching it and knocking it with sticks and everything else. One fellow in particular had a padded chest and a mask on his face. There was a fellow with a megaphone who kept hollering.

There was a man behind me who kept pestering me and saying, "Captain!"

I said, "How do you know me?"

"Oh, I know you," he said, "I will bet you eight to five the Americans win."

I said, "I don't want to bet. You leave me alone."

Anyhow, after a while the players got out. One was up on the hill and there was one, two, three,—one here, and one there, and one, two, three,—and one there. (Indicating.) They had sticks in their hands and would take them and swing them this way and hit the foot there and hit the foot here. (Demonstrating.)

One fellow had a stick in his hand, and another fellow was squatted down (this way) catching. A fellow was throwing the ball and the man standing with the bat started arguing with the fellow.

Then I had to be bothered again. This fellow said, "I'll bet you eight to five they stay there."

Then another fellow came up, and it was Babe Ruth, a big fellow. He took a stick and struck the ball—Bang! you could hear him way from where I was sitting. He hit the little white thing, and if I may say it, he knocked it a hell of a ways.

It was way out in the field. A lot of fellows were sitting there, and everybody was fighting for that thing. Then another fellow got up, and he hit the ball, and he was running down. I said to Mr. Whalen, "What did he do?"

Mr. Whalen said, "He chased him home."

I told you I would get back at him, didn't I?

When I asked Mr. Whalen what this banquet was all about, he said it was a National Safety Council. Well I want to tell you, ladies and gentlemen, and distinguished guests here, that we, too, in Norway, are interested in safety and accident prevention.

For a long time the Safety Committee in Christiania, Norway, was in a quandary on account of automobile accidents. Everybody would come up with a device and say, "This will do," or, "That will do." One fellow wanted a fender bumper. It is placed on the fender of the car. Then the automobile driver can just drive down a big boulevard 40 or 50 miles an hour. Just picture this. A pedestrian walks across the street. The automobile hits him and stops instantly. Both of us reach out, grab hold of the body and lift it off the ground, without hurting the pedestrian one bit, and preventing a serious accident. That has been in use for the last three months in Norway.

One fellow, Captain Lawson—I spoke about the Swedes before—tried to invent an automobile with wings on the side that when you came to a bad part in the road

you could press a lever and lift the automobile up and go over the bad spot in the road.

"About two weeks ago, I happened to walk along Fifth Avenue at 42nd Street, and I never saw such chaos in my life and such a deplorable condition in traffic. My friend who was with me said, 'Don't worry, Captain. Don't you know, there are fifty-three people killed at this corner every day?'"

I said, "Why should the people in New York mind if they have fifty-three people killed every day? They have plenty more to kill."

If you will listen to me for just two or three minutes, I will tell you what we have in Christiansand. We have viaducts at our busy streets so that the pedestrian does not have to cross the street in the traffic. It is much safer. It is physically impossible for anybody to be hurt that way.

New York has plenty of money, why don't they try that?

Then we have the subway platform. We have what you would call a railing or fence. You just picture the subway across the platform, where people will be forced over on the tracks. Then there will be people going across the tracks and committing suicide.

The engineer is held responsible for everything. When his train is coming to the signal "stop" he gets out of the train, goes to the pillar, turns it, and down comes the railing, preventing anybody from going on the track. In the meantime, the guards of the trains open the doors to let the people in and out. Then when the car is crowded, he goes to the door again and locks it and up it comes. The door is locked, and he continues on to the next station, and thereby insures safety.

I did not intend to talk so long, but you have been kind and courteous to me, and I wanted to be kind and courteous to you.

I want to say one word in conclusion. My name is Timothy David Lines, and I am born and bred in New York. I thank you.

TOASTMASTER WHALEN: I told you that you would need to extend sympathy to the speaker who has just concluded. I am sure you agree with me.

You will hear next from a man who is well known to you all. He is a pioneer and organizer in the safety movement. He comes to us as representative of a great railroad—that has done much in safety work.

And while we are on the question of railroads, we have with us tonight, the president of one of the largest railroads in the country, and I think we ought to have the pleasure of having him get up and just bow.

President Patrick Crowley of the New York Central Railroad!

(Mr. Crowley arose.)

Mr. Crowley is one of those modest individuals that it is very difficult to get out on public occasions. -I want to congratulate the Safety Council on bringing him to this banquet.

The pleasure of introducing the next speaker is one of great personal pride, because I feel that he has made a great contribution to humanity in working in the interests of preserving the man power of the nation. And when we find men and women gathered together, as we all are, in a movement of this kind, and we have the pleasure of hearing from a man who has made such a distinct contribution to this cause, it gives us all a great deal of pleasure. It is a particular privilege at this time to introduce to you, Mr. Isaiah Hale, Superintendent of Safety for the Santa Fe Railroad.

Address

By **ISAIAH HALE**

Safety Superintendent, Santa Fe Railroad, Topeka, Kansas

The invitation which accounts for my inconspicuous appearance on this program was for a "Practical Safety Talk." A school girl was once asked "What is a

turlough?" She said "A mule." In explanation of her rather unusual reply he it noted that her mind had reverted to a time when she saw a picture of a soldier riding a mule, over the title, "Off on a furlough." She was therefore logical. So while I shall try to be practical, I hope you may be logical, that you may glimpse my points even though they may be somewhat vague.

For unusual reasons I shall repeat at this time a number of things said on former occasions which a favored few of you have heard, but I hope may have long since forgotten. Two prominent Englishmen were once dining with friends, and one of them offended the other by falling asleep while his friend was telling one of his favorite stories. When the sleeper awoke the other reproached him for going to sleep. "I wasn't asleep," he said, "I only had my eyes closed, and I heard distinctly every word you said." "I'll bet you were asleep" said the offended man, "and that you can't repeat what I said." "I'll take that bet," said the drowsy one, and to prove he had not been asleep he repeated word for word the story the other man had told. "You win," said the story teller, and paid over the money. Then the other man said, "I really was asleep and didn't hear a word you said, but I know that at this time in the evening you always tell the same story."

The man who has Safety for his subject is fortunate in that a large proportion of his audience, wherever it may be, is likely to be interested in his proposition. That expression reminds me that a Black Hand Society once wrote a quite wealthy man and told him that in event of his failure to leave \$25,000 at a designated place and time, they would kidnap his wife. The letter, by mistake, was delivered to a very poor man whose name happened to be the same as that of the rich man. The poor man replied to the threatening letter by saying, "I haven't any money, but I am interested in your proposition."

When given this assignment I was asked for the subject of my talk. I've heard a text defined as "a minister's self-starter." If mine serves no other purpose than to get me away from the dock on my short cruise, it will have done all that can fairly be expected of it. Looking ahead over the time covered by the length of your cigar I imagine an analysis of my talk, at its close, will show it to be not unlike a modern woman's dress, in that it will have touched everything but covered nothing.

As a preface I would pay all possible honor to that handfull of men, many of whom honor us by their presence here tonight, who met in Milwaukee about eighteen years ago with more of a vision than reason to hope it might ever be realized. There was no band music, no parade, they went into Milwaukee unheralded and came away unsung, but during the few short hours of their conference they gave to the appalling human toll of accidents its first serious consideration, and out of whose deliberations has grown more than merely one of the greatest humanitarian movements of all times; there has come also a humanization and a harmonization of relations as between employer and employee never before dreamed of.

I would do homage too to *this* army of men and women, and countless others not here tonight, who have "carried on" and who, each year, have been able to drop by the wayside some of the trials and discouragements of former years, and many of whom have accomplished the all but impossible, in spite of the apathy of their own managements.

The question of greater safety as the solution of an industrial problem that has existed since one man first worked with another, has been approached from many sides, but too often from an angle that permitted the fitful force to ricochet off into space without registering.

The Safety Movement, so called, has more than once been launched by a ranking administrative officer returning to his office from lunch, and saying to his assistant, "I lunched today with Smith, of Smith & Co., who tells me they have a safety organization. I think we ought to have one, too; we have a lot of injuries among

our men, and some of them must hear like the deuce. So I wish you'd go out and tell everybody to get up on their toes; that henceforth we are not going to have any more injuries. If we need to clean up a bit or even to put guards on a few machines here and there, I am willing to do that, but we do not want to do anything we can get along without."

Thus the "movement" is launched, and since my time is short, thus it died, or is slowly dying, because it never had the managerial interest and direction which alone would have made it a success.

Under the common law it is the duty of employers to provide a reasonably safe place in which men are to work, to provide reasonably safe tools, and to provide reasonably safe and competent fellow-workmen. Of far greater importance than any or all of these is the moral obligation of the employer to acquaint his employees with the known hazards of their employment, a long and arduous undertaking at the best, and one predestined to failure unless the directing officer is unafraid and unashamed to go before his men, at intervals, and earnestly and convincingly assure them of his wish to go hand in hand with them in working out their objective. Contrary to a too common belief, safety is not something that will ever boil up from the bottom; if it ever permeates the fiber of an organization it must percolate down from the top.

An other angle to the problem, a very important one, and one which, in turn, must have intelligent, forceful and continual supervision, is supervision by supervisors. Safety more than any other one policy sponsored by a management must rely on supervision, not alone for its advancement but for its very life. It is a hackneyed phrase, but no less true, that "a foreman is the key man." Not only what a foreman may say about safety in the presence of his men, but more important still, the manner in which he says it, will either breathe life into the Cause or bring about its early and complete collapse.

Too many supervisors think their principal, their only function, is to watch their men, to stand guard over them. One of the first duties of a foreman should be to feel and show an interest in their men. In our organization, for years I've daily told our supervisors that their first and most important duty is to give their men a right viewpoint on their relationship with the Santa Fe Railway. Failing to accomplish this after conscientious effort, to get rid of the man who cannot or will not tune in on the "home station;" or failing to accomplish it in any number of cases, to seriously take stock and see what is wrong with himself as a supervisor.

Quite as much as it is the duty of a foreman to teach a man how to hold a hammer or dump a wheel-barrow, it should be both his duty and his privilege to give his men higher ideals, to teach them not only their individual responsibilities but give them a fair understanding and appreciation of the rights of other men; and teach them to see in their jobs the best friend they have in the world, the friend that does more for them than all other friends combined;

To daily drive home with their men the thought that this idea of doing only what is necessary to get by is never doing quite enough;

That the secret of real happiness or success in life is not found in doing what one likes to do, but rather in liking what one has to do;

That it isn't enough for a man to be merely always doing something; he must be taught the advantage, to himself, of actually getting something done;

That two-thirds of promotion consists of motion, and that it is just as true in the accomplishment of promotion as in the spelling of it;

That a man should look upon his job as a stepping stone for today and not as a resting place for tomorrow;

That the limitations of a man are not the things he wants to do but can't, but rather the things he should do but doesn't do because of indifference or laziness, and if I might interpolate a personal observation right here it would be that the

greatest, and in many cases the only *difference* between a success and a failure in life, is *indifference*;

That no man can fairly expect recognition or advancement until he has earned it, but having earned it such recognition will come to every man;

That while it is easy enough for a small man to make a big job shrink, it takes a big man to make a small job grow, and there is not today in your organization or mine a single job that might not be made a bigger and a better job than it is, and that, too, by the very man who holds it, if he only had gumption enough to see it.

In this connection I am not at all in sympathy with much that is spoken today from the platform, from the pages of magazines and the daily press, that all men may be supermen; that what one man has done any or all men can do. To me it seems absurd to say that what some rare genius, Edison, Steinmetz or Marconi, has done, I might have done, even with diligent study. I believe much harm is done by spreading such fallacious ideas because occasionally some fellow will conscientiously try and fail, and following his failure will come a disappointment and a discouragement that cheat him out of the reasonable success that might have been within his reach. The point I would make is, there are few, if any, men who might not do more work and do it better than they are now doing it, if willing to pay the price of honest effort, and certainly no one is in quite so advantageous a position as a foreman to sell ambition to his men. The same feet that have carried me, and many of you, only to the top of a lowly hill, would have taken us to the top of a high mountain if we had turned in that direction and kept saying to them "Go on and on."

I no longer talk safety to our men in the way I did years ago, when I went about saying "Don't do that;" to the limit of my humble ability I am trying to boost the morale of our men; I am trying to increase their loyalty to their government, to themselves and to their job; I am trying to put into their minds and hearts an ambition to be somebody and do something worth while; and may I remind you that if *that* can be done, it will no longer be necessary to watch or stand guard over men.

Foremen are seldom or never eye-witnesses to injuries, but a far more important fact is they too often fail to see an injury in the making; they fail to see a workman doing something today which their experience ought to tell them will, if repeated, result in an injury on some tomorrow, and stop the practice before and not after an injury occurs. Following this thought, so firmly am I convinced that it is the exceptional supervisor who has even a reasonably clear understanding and appreciation of the responsibilities and privileges of foremanship, that I imagine when they were called into the "inside office" and told they were to be made a foreman, while some of them knew they had been struck by Opportunity, they did not know just where or why.

Later, and still in a daze and wondering what it was all about, I imagine they turned to a dictionary to learn what a "foreman" really is. Among other things they found a foreman is an "overseer;" all very interesting, but what is an overseer? Turning a few pages they found an overseer is one who oversees; following their quest they found that one who oversees is one who overlooks, and so from that day to this they have been overlooking things they ought to have seen.

Safety is not something a safety worker can ram down a workman's throat; if he could, getting it that way would not do the man any good. A workman must be taught by his foreman to want to believe in it; his conversion, if or when it comes, will come when he has had put into his heart the wish and the determination to pick up the banner as an honest-to-God crusader because he believes, in principle, it is right and just.

The one obstacle which more than another has impeded progress along safety lines is the disinclination on part of so many men to give the subject careful

enough thought and study to intelligently make up their own minds if worthy of their support—and therein lies the *real* obstacle, the constitutional objection on part of so many men to any effort so laborious as thinking seriously about anything. The remedy lies in the beneficent influence of their supervisors.

That reminds me that one of the problems of every large organization is the man who knows a lot of things that are not so. My observation on that is that the thing a man is down on is generally something he is not up on, and that would seem to open a wide and expansive field for such educational efforts on the part of a foreman as seems necessary. Failing to get constructive help from his employer, the workman often turns to the bally-hooers who are ever ready to tell him of the wrongs being done him; of his rights, "his inalienable and God-given rights as a liberty loving American citizen" * * that "all men are born equal," and a lot of rot of that sort. As for rights, *no man has any*, not until he has proven himself worthy; then, the sky is high and the horizon is wide. It may be true that all men are born equal, but men need to be taught it is their own fault if they remain that way. Every large organization has its bally-hooers, men who are sowing dissention and dissatisfaction; it should not be difficult to locate them because the man who is *against* something always talks louder than the man who is *for* something. The good of the service demands their early identification and conversion, or their removal from the service, because no man can think crooked and work straight.

I spoke awhile ago about the substantial friendship which ought to exist between a man and his job; I believe every workman should be taught to calmly and intelligently appraise his job in terms of its earning capacity. For instance, the man who is earning \$150 per month should be taught to realize he is earning 6 per cent on \$30,000; the workman earning \$200 per month, that he is earning 6 per cent on \$40,000, which is their employer's capital investment in them. Few men are as proud of their job or guard it as carefully as they would its equivalent in savings, yet the job is worth infinitely more—for several reasons. First, if a man is a square shooter, no one will ever take his job away from him, yet by some "dirty work at the cross-roads" he might be flim-flammed out of his money tomorrow; second, the workman who is earning \$150, for instance, can make it a \$200 job in a fractional part of the time it would take him to increase his savings from \$30,000 to \$40,000. Again, it is the supervisor who must teach his men these things if they are ever to know them. The most worthy of human achievements, what ought to be the greatest of human desires, is to be useful, and one needs not be a genius to be useful, because industry, faithfulness, integrity and knowledge of one's business will make a winner even out of an ordinary man, and the ordinary man must be taught to believe this.

It is high time managements began to realize the different levels of intelligence in men, and be more discriminating in taking new men into their service. Out of the 1,700,000 young Americans given a psychological test during the World's War, 70 per cent of them were given the mental rating of a child fourteen years of age, and 45 per cent of that number, or 31½ per cent of the entire total, were rated by our government experts as "morons," a moron being defined as "a person not mentally capable of complete self guidance." A man applies to one of you, looking for work; you take his chest expansion and note his back-muscle development, and if it compares favorably with a prize-fighter or wrestler you hire him even though he has not the brain capacity of a jumbo peanut. On the other hand, if you were considering the purchase of a piece of machinery at \$25,000 or \$30,000 there would be no end of conferences and analyses to make sure the new machine was worth its cost.

At intervals some chap tells me that a workman without influence "has no chance," not seeming to understand that a third person's "pull" is a puny thing as compared to a man's own inherent *push*; the poor nit-wits do not seem to realize

that the less one has the more there is to get; and the more there is to get, certainly the easier it ought to be to get something.

Managements need to remind supervisors and supervisors need to tell workmen that there are in this country 750,000 major executive positions paying up to \$100,000 per year, that there is a 10 per cent turn-over, 75,000 being vacated and filled annually; that 53 per cent of the pay-envelopes in America are for less than \$25 per week, and that out of our 42,000,000 wage-earners less than 4 per cent earn more than \$4,000 per year; and tell them too that only the fit survive.

There is too much self-complacency; it isn't to our credit that many of us have stuck in one job a long term of years; it is high time we realized that if we had been much account we would have been promoted a long time ago.

Roger W. Babson, recognized as an eminent authority on the subjects he discusses, said not long ago: "Only one man in fifty in America ever thinks; only one in five hundred ever originates anything, even an idea, that is worth anything to himself or anybody else; and at the age of fifty years, 53½ per cent of the male population of America are down and out, have quit cold, and are living on the bounty of relatives, friends or some charitable organization." Rather a sad commentary, I would say, on our much vaunted civilization and intelligence when we are told that at fifty years, at what ought to be the best years in any man's life, 53½ per cent of us are through. Do you know why these men have quit? They've quit, most of them, because they never tried; they never tried because they never cared, and they never cared because they never had the right sort of influence from men like you. Management involves responsibilities not always recognized, and direct supervision carries with it a stewardship of which only the exceptional supervisor has any conception whatever.

I would have you supervisors, be your title manager or straw-boss, go back to the job and be a supervisor, a leader of men in fact as well as name; I would have you earn, and earning get, and getting, hold the respect, the confidence and the friendship of your men; I would have you find them coming to you with their petty personal problems, that some day you may feel the cockles of your heart warmed by that thrill—comparable to which there is no other—the thrill that comes from reaching a helping hand to some poor devil who is in a rut, who needs nothing (and down in his heart wants nothing) quite so much as a pat on the back, a kindly word of encouragement from his boss, that he now too seldom gets.

Quoting something Van Ambergh, "The Silent Partner" once said: "The passing of an impressive number of summers and an equal number of winters have taught me a lot of things; they've taught me that other people treat me just about as I treat them; taught me that when I go out looking for trouble I always find it, and taught me too that the 'Golden Rule' is the sum total of all wisdom for getting on with the world." The Golden Rule is a biblical term; the American for it is "a square deal," and I want to say to you, Mr. Leader-of-Men, with all the emphasis I can give, it isn't the Golden Rule nor is it a square deal when we take flesh and blood and make out of it nothing more than a commodity at an agreed price per hour or day.

Some one has said that "too much of this world is run on the theory that one does not need road manners if one drives a five-ton truck," and by the same token there are far too many men in positions of authority who have yet to see any reason why they should be considerate of and kind to others, forgetting (if they ever knew) that kindness is a language even the deaf can hear and the dumb can understand. The manager or foreman who fabricates steel, builds or runs a railroad, makes cement, pumps oil or refines it, or does anything else, who does not undertake the satisfying and ennobling task of building characters among his men, presents a mighty sorry spectacle as a leader of men. I do not often turn to verse but one of Edgar Guest's seems apropos right here:

"Let me be a little kinder,
 Let me be a little blinder
 To the faults of those about me.
 Let me praise a little more,
 Let me be, when I am weary,
 Just a little bit more cheery,
 Let me serve a little better
 Those that I am striving for.
 Let me be a little braver;
 When temptation bids me waver
 Let me strive a little harder
 To be all that I should be.
 Let me be a little meeker
 With my brother who is weaker;
 Let me think more of my neighbor
 And a little less of me."

The wonderful appeal of the American Red Cross lies in their humanitarian service. They follow disaster everywhere; they bury the dead and comfort the bereaved, they nurse the sick, feed the hungry and clothe the naked. Though less spectacular, when properly understood organized safety has no less an appeal; its definite purpose is to set up and maintain such an orderly process that disasters, and their consequences, shall no longer be known in industries.

We hear much now-a-days about service; service is only a modern symbol for countless human virtues known to every generation since the beginning of time; service is a mother's solicitude for her children; service, in the long hours of toil our parents gave for us, was the hardships endured uncomplainingly, all these and a million others which only the Recording Angel will ever number; but service is the one thing which every man and every woman must put into his life and his job if he ever expects to take anything worth while out of either of them.

Success in life is not possible except through service; there is no open gateway to success; if it is ever reached one must climb the barrier, not often an easy thing to do. The great tragedy of life is that the multitudes go wandering through the years looking for a breach in the wall, for an easy way through, only to lie down at the end of the trail, weary and disappointed.

John Burroughs once said: "a man's life may stagnate as literally as water may stagnate, but just as motion and direction is the remedy in one case, so is purpose and activity the remedy in the other."

In every activity, catastrophe is only a step or two behind integrity and honesty of purpose, and if you will go with me and look under the hood of any failure stranded along Life's highway, we will find there unmistakable evidence that the man had used a substitute for common honesty and hoped to get by with it; yet today we all know any number of men who are dishonest—they are dishonest with themselves!

ADJOURNMENT

**SEVENTEENTH ANNUAL SAFETY CONGRESS
NATIONAL SAFETY COUNCIL**

A B C Session

October 4, 1928

R. F. THALNER, Chairman
Safety Director, Buick Motor Company, Flint, Mich

The A B C Session of the Seventeenth Annual Safety Congress was called to order at two o'clock by the chairman, R. F. Thalner, Safety Director, Buick Motor Co., Flint, Michigan.

CHAIRMAN THALNER: Gentlemen, we have two subjects this afternoon which are to be discussed, and those two subjects are to be treated from two different viewpoints. You men who are safety directors and engineers, you men who are foremen, plant superintendents and managers, have always been told about the two divisions of accident prevention work, the mechanical side and the educational side. Both of these viewpoints will be discussed today at this meeting.

The first one, The Part Mechanical Safeguarding Plays, will be discussed by a man who is very well fitted to undertake that work. I know that you are all going to enjoy listening to our first speaker, Mr. David S. Beyer, chief engineer, Liberty Mutual Insurance Company, Boston, Massachusetts. Without any further remarks, I present to you Mr. David Beyer!

The Part Mechanical Safeguarding Plays

By DAVID S. BEYER
Vice-President and Chief Engineer, Liberty Mutual Insurance Company,
Boston

The comment that we live in a mechanical age has been made so often that it would be bromidic to repeat it here. It is scarcely an exaggeration, although it may be a slight mixing of metaphor, to say of the nineteenth century infant that "the hand that rocks his cradle" is an electric motor, and that the stork which brings him into the world has rubber shoes and a fifty horse power engine. Everywhere we turn, in the home, on the street or in the office or factory, we are confronted with mechanical devices and so many wonders have been demonstrated before our eyes in recent years that our credulity is no longer taxed by any mechanical miracle.

When the laboratory of one of our large electrical concerns recently announced that they had produced a "Robot" or a mechanical man, who at his master's spoken orders would answer the telephone or turn off the electric lights, the story was widely printed in our newspapers but accepted by the public without much question. I know it is true for I have before me a picture of—shall I say, him, her, or it?

You will remember in the popular play which pictured the development of the

Robot, the mechanical servants finally became so powerful that they revolted and destroyed their masters. It is accordingly quite appropriate that we should turn on the spotlight and see whether these new servants are indeed being properly trained in the way of obedience and discipline, or are they getting out of hand and becoming a menace to our safety?

Of the great efficiency of the mechanical helper there can be no doubt. Most of us can recall the little old grandmother who knit our socks a generation ago. When we are told that one operator in a modern factory can turn out as many pairs of socks as 6,000 such grandmothers,* we realize that the machine is here to stay and the growing use of machinery is constantly adding to the importance of machine guarding.

Seriousness of the Mechanical Accidents

While the machine hazard varies with different industries, it is a substantial part of the whole cost of industrial accidents. For example in Massachusetts during the years 1918-20 inclusive, the 53,000 tabulatable mechanical accidents that occurred were 25 per cent of the total number, but they caused 33 per cent of all the days lost. In other words, the average mechanical accident is nearly half again as serious as the average non-mechanical accident.

This checks pretty closely with an analysis made by the National Council on Workmen's Compensation Insurance covering 27,000 separate inspection reports for plants located all over the country and employing about 1,700,000 persons, with accident payments of \$29,000,000, in which 36.1 per cent of the total cost was represented by mechanical accidents, divided as follows: Point of operation of the Machines 28.8 per cent; Moving Parts of Machines 1.9 per cent; Machine Drives 1.6 per cent; Transmission 1.7 per cent and Elevators 2.1 per cent. In the woodworking industry, (including carpenter shops, pattern shops, planing mills, etc.) as much as 60 per cent of the entire cost came from mechanical accidents; just about half the total cost of all accidents in these industries was due to accidents at the point of operation, in other words, the saw blade, jointer head, etc.

In the metal working industries the percentage of cost for mechanical accidents ran somewhat less, about 37 per cent for machine shops, and 23 per cent for foundries.

Construction of Mechanical Guards

Just a word about the construction of mechanical guards; if I were to say much on this subject I should feel like the young man when one of his friends said to him "I saw you with a new girl the other night."

He replied, "No, that wasn't a new girl; it was just the old girl with a new coat of paint."

I won't attempt to repaint the information on the construction of guards for you because that field has been quite well covered already. One can turn for such information to the excellent "Safe Practice" pamphlets of the National Safety Council, to the Standards that are being developed by the American Engineering Standards Committee, or to the various books on Industrial Accident Prevention (of which one by the writer of this article has just had its third edition printed).

In a paper presented at the Milwaukee National Congress in 1920 the writer summarized the important "Fundamentals of Safeguarding" as follows:

*See in *Industry* (June 19, 1926) published by Associated Industries of Massachusetts, an article by Colonel Charles R. Gow, entitled "Industry's Contribution to Human Welfare."

1. Make the guard strong so it will stand the necessary wear and tear.
2. Make it convenient so it will offer the minimum interference.
3. Use the material that is best suited to the particular conditions encountered. (Usually, metal, with wood where there are acid fumes, etc.)
4. Have the machine guarded by the builder or when it is installed if possible, but where guarding is done locally, have it done by some one specially trained in guard building.
5. Make all guards conform to insurance and state standards, so as to get the benefit of any insurance rate reduction and to avoid later criticism from state factory inspectors.

Those principles still hold good, but in looking them over now it appears that one more might well be added, that is,—

6. Design the guard if possible so that it will *increase* production.

Of course, it is not always possible to put on a guard that will actually increase production but at least a very strong effort should be made to so design and install it that it will not interfere with production; otherwise it will take a constant battle to keep it off the scrap heap.

Probably many of you are familiar with the very constructive work along this line that was done by our old friend Gus Kaems, and more recently by Louis Boraks, on the punch press operation, through the use of gravity or chute feeds.

I have before me numerous illustrations of guards which have produced substantial improvement in production such as the following:

Increase from 800 pieces per hour to 1,400 pieces with a reduction in cost from 6 cents per hundred to 4 cents per hundred—in short, 75 per cent.

Increase from 600 to 950 pieces per hour, with a saving of 2.3 cents per hundred—60 per cent.

Increase from 15,000 pieces per day to 50,000 per day,—and so on.

It is very fortunate that the trend toward higher speeds and increased production for the machine very often brings out mechanical methods of inserting and removing the stock, which will practically eliminate the hazard to the operator. Where you can get the production man fighting *for* the safety appliance instead of *against* it the battle is surely won!

Results From Mechanical Guarding

There is one question in connection with mechanical guarding in which I am sure we are all interested, and that is, what results can we actually expect from the installation of such safeguards?

I am sure every Safety Engineer on going into a large factory and seeing hundreds of machines with some mechanical hazard unguarded, must at times have questioned in his own mind whether he is justified in asking that they should all be guarded or not; particularly so when he is told that so far as anyone can remember, there has never been an accident on one of these machines.

To insist on these guards being put in seems somewhat like arresting a whole community and jailing the entire population in order to apprehend one or two potential criminals!

A few years ago this question confronted the safety man at every turn, and it was about as difficult to answer as the one which was put up to the school boy, when the teacher asked him why lightning never struck twice in the same place. He replied, "Because when it strikes once the same place isn't there any more."

It was pretty hard to show that an accident would occur in a given place until it actually did happen and then of course you couldn't prove that it had been prevented!

I remember how eagerly I used to gather up records of near-accidents, involving the use of a safeguard, to use as sales material on the hard-boiled foreman or superintendent who *had* to be shown, before he would agree to a new safety device. But it is getting easier every year to "sell" safety, because it is being recognized more and more as playing an important part in the modern production programme.

As many of you will remember, it is now more than fifteen years since the first Workmen's Compensation Act was passed, and we have a pretty complete history of accidents in several states from that time on. An analysis and study of the results since the passing of the Massachusetts Compensation Act, which I have just completed, brings out some very interesting facts on the part played by mechanical safeguarding.

Massachusetts affords an especially good field for such a study for several reasons.

It was one of the first states to pass a compensation act, and thus get complete accident reporting. It has had some of the most comprehensive statistical records of any state, extending back over a period of more than twenty years. It is one of the six or seven leading manufacturing states of the country, and its industries, among the most important of which are textiles and machinery manufacture, represent about the average exposure to machine hazards.

There are three state departments from which the necessary records can be drawn. The Industrial Accident Board classifies both the number of accidents and the days lost. The State Insurance Department keeps a complete record of the cost of accidents. The Department of Labor issues "Statistics of Manufacture" showing employees, payrolls, value of manufactured products, etc.

While these reports do not fully correspond in certain details such as the classifications of the various occupations, and they do not all have the calendar year division of time, it is possible to make comparisons between them that are approximately correct and that show the big outstanding changes that are taking place in the industrial accident situation.

The trend of compensation legislation in other states has been similar to that in Massachusetts, hence the results here may be taken as an example of what may be accomplished in any other manufacturing state.

This study is devoted chiefly to the nine-year period covered by the years 1917 to 1926 inclusive. (The reason for choosing this particular period is that the present method of accident classification in use by the Industrial Accident Board, which gives days lost as well as the number of accidents, was started with the year 1918, so a much more accurate comparison is possible for the subsequent years than for the ones prior to that time. The statistical information for the year 1926 was the latest complete year available when this study was made.)

While there have been many cross-currents and complex influences at work during this time, the years 1918 and 1926 both represent prosperous years of high industrial activity. The falling-off in business and other changes that succeeded the war had pretty well worked themselves out by 1926, so that it corresponds favorably in many ways with 1918.

In studying the statistics of these two years, the outstanding item of interest is a gratifying reduction of 23 per cent in the number of "tabulatable" accidents (those causing loss of time after the day in which the injury occurred) and a reduction of 28 per cent in the total number of days lost from these accidents. Still more pertinent to the subject we are discussing, is the fact that during the course of these nine years the figures show a reduction of 60 per cent in the *tabulatable mechanical accidents* and 54 per cent in the number of days lost from these accidents.

Tabulatable Accidents in Massachusetts
(From Annual Reports of the Industrial Accident Board)

1926 Reduc. Over 1918	372,000	378,000	750,000	770,850	170,908	941,758	1,691,758	
Per Cent Reduc.	58	19.1	28.5	51.8	9.2	28.2	28.3	

Total fatalities were reduced from 438 to 313, or more than 28 per cent, and fatalities due to machinery were reduced from 107 to 45 or a reduction of 58 per cent. (Total fatalities in 1912 and 1913 were 474 and 509 respectively.)

On the face of it this is certainly a splendid showing for a great industrial state with some thirty to forty thousand separate industrial establishments, and employing approximately one million workers.

We have had many excellent records of accident reductions in individual plants, but so far as I know, this is the first time that such a comprehensive record for an entire state has become available, and I think it is a very strong indication of the claims which many of our safety engineers have been making for a number of years as respects the importance of mechanical guarding.

We have heard a great deal of talk about the value of "safety education," and while I believe thoroughly that such work is an essential part of a comprehensive accident prevention program, I think there has been a tendency in some quarters to over-estimate its importance in reducing accidents.

The results shown by these figures would seem to justify that feeling, since although there has been an active campaign for safety education as well as mechanical guarding carried on throughout the state, non-mechanical accidents show a reduction of only 11 per cent numerically and 9 per cent in days lost. In other words, while mechanical accidents were being more than cut in two, non-mechanical accidents showed a decrease of only about 10 per cent.

This total reduction of approximately one-fourth in all injuries and the lost time resulting from them seems the more convincing when one notes the regularity with which it occurred from year to year over the entire period. It does not show rapid fluctuation from one year to another, which might be expected if it were due to some exceptional condition. Also it is noteworthy that the reduction was continued during the years of increasing industrial activity represented by 1925 and 1926.

Such large state-wide reductions sound almost too good to be true, even to an optimistic safety engineer. A number of cross checks were made, however, together with studies along auxiliary lines which would tend to throw light on the main issue, and these have all tended to substantiate the fact that these figures are approximately correct, and *do* represent an actual reduction in the frequency and severity of mechanical accidents particularly, and all accidents as well.

In the first place the thought immediately strikes one that industrial conditions have changed considerably since 1918, which represented almost the peak of our war activity. Have those changes altered the number of employees engaged in manufacture or the extent of mechanical exposure?

The answer seems to be that while there have been material fluctuations within that time, the year 1926, both from the standpoint of number of employees engaged in industry and from volume of production, compares closely with 1918, and that the mechanical exposure if anything has increased during that period.

A study of the payrolls reported to the Massachusetts Insurance Department shows a total of \$800,000,000 for the year 1918, compared with \$1,297,000,000 for the year 1926.

These are "policy year" figures, covering all Workmen's Compensation policies issued during the years 1917 and 1925 and expiring in 1918 and 1926, respectively. They really represent an approximate average for the two years. Over 91 per cent of all accidents reported to the Industrial Accident Board for this period were covered by insurance, so the figures on accidents and days lost correspond approximately to these payrolls.

The average yearly wages for the corresponding period taken from the statistics of manufacture of the Massachusetts Department of Labor and Industries shows an average wage for the first period of \$850.00 and for the second \$1,218.00.

These are average for the years 1917-8 and 1925-6, respectively.

If we divide these figures into the total payrolls it would show approximately 950,000 employees in 1918 and 1,050,000 in 1926, thus indicating that, if anything, the number of employees had increased in the latter year. The records show that while there has been some reduction in manufacturing employees, this has been more than offset by an increase in Contracting work, Clerical Office and miscellaneous classification, such as Chauffeurs, Stores, Stevedoring, etc.

Payrolls in Massachusetts

(From the State Insurance Department Reports, by "Policy Years.")

Year	1917 Millions of Dollars	1926 Millions of Dollars
Manufacturing Industries	496	556
Contracting Classifications—		
(Buildings, Foundations, Construction, etc.)—	40	99
Clerical Office and Salesmen.....	109	249
Drivers and Chauffeurs	19	30
Misc. Non-Manufacturing — (Stores, Restaurants, Theatres, Stevedoring, etc.).....	136	363
	800	1,297

The Clerical Office and Sales Forces should be spread through the other classifications, but no record is available as to how they are distributed.

The contracting employees more than doubled during this period and the accident hazard of the construction classifications is two to three times as great as that of the average manufacturing classification.

Extent of the Mechanical Exposure

Again, we may ask whether the reduction in mechanical accidents may be due to a reduction in the mechanical exposure; here also the answer seems to be reasonably conclusive that such is not the case.

It is difficult to measure mechanical exposure, but it is a well-known fact that during the past decade there has been an increasing tendency to supplant hand labor by power machinery and that seems to have occurred to a considerable extent in Massachusetts.

For example, there has been an increase in the number of electric kilowatt-hours generated in the state, from less than a million in 1918 to more than two million in 1926. The general "horsepower per worker," according to the country-wide reports of the United States Bureau of Labor Statistics, increased from 3.2 in 1919 to 4.3 in 1925, or 34 per cent.

The statistics of manufacture for Massachusetts issued by the Massachusetts Department of Labor show total value of products in millions of dollars in 1918 as 3,851, compared with 3,420 in 1926. While this represents a falling off in the value of products of 431 points, or 11 per cent of the total, it would seem that this reduction is considerably more than offset by a reduction in wholesale prices of 25 per cent (U. S. Labor Dept. Reports), which occurred during this period, so it is a fair assumption that the actual amount of products increased rather than decreased during this time.

The foregoing seems to indicate rather clearly that on account of the increase in production and the increased use of power, without any increase in the number of employees in manufacturing operations, there must have been an increase in the mechanical exposure.

"No Lost Time" Cases

The foregoing discussion has been based entirely on a consideration of the tabulatable accidents; in other words, those causing loss of time on a day following that in which the injury occurred. The close comparison between the reduction in days lost and the tabulatable accidents shows pretty clearly, however, that the tabulatable accident frequency is a fair measure of lost time and, therefore, of accident cost.

No detailed analysis by causes is possible for the "no lost time" accidents occurring during this period because, on account of their relatively trivial nature the Industrial Accident Board did not go through the large amount of work that would be involved in their tabulation.

It is probable that the majority of them were the minor cuts, bruises and abrasions which are necessary accompaniments of handling materials in all kinds of industrial operations. Since they only caused temporary loss of time during the day on which the accident happened, they are not of much interest in a study of this kind, although an investigation of them in the individual plant may be of value as indicating potential hazards.

The total number of accident reports, including these trivial cases, is a little lower in 1926 than in 1918, as is shown in the following table:

Total Accident Reports in Massachusetts

1918.....	170,718	1921.....	155,554	1924.....	164,746
1919.....	178,084	1922.....	139,611	1925.....	155,059
1920.....	193,600	1923.....	176,588	1926.....	162,239

What Has Been Accomplished in the Way of Reduced Accident Cost

Granted that accident frequency and lost time have been substantially reduced, the next important question is, was this reduction in accidents translated into reduced accident cost and did the employer receive the benefit of this reduction in return for his investment of time and money in safety work? Here again the answer is in the affirmative.

The 1926 accident cost per hundred dollars of payroll, excluding medical expense, shows an improvement over that for 1918 of 28 per cent (\$0.51 total, less \$0.128 medical or \$0.382 + 15 per cent increased benefits = \$0.459 anticipated cost, comparing with \$0.332 actual cost in 1926). This cost reduction corresponds closely with the improvement of approximately 25 per cent in lost time and accident frequency already described, and represents as nearly as can be determined the improvement the insurance companies should have enjoyed in their losses if the accidents had been reduced as outlined, and all other factors had remained constant.

(The annual medical expense mounted from \$1,091,519 to \$2,696,565, increasing from 22 per cent of the premiums in 1918 to 34 per cent in 1926. As against this there was some compensating gain to the insurance companies through the increasing level of wages, the amount of which is difficult to estimate since most of the gain from a wage increase is automatically absorbed by the higher benefits that result on account of benefits being based on wages.)

Now as regards the cost to the employers of the state:

The insurance rates collected in 1918 (1917 year of policy issue) averaged \$1.07 per hundred dollars of payroll (\$8,568,000 premiums divided by payrolls of \$799,844,000). In 1926 (1925 year of policy issue) the average rates were \$0.91 per hundred dollars of payroll (\$11,827,000 premiums divided by payrolls of \$1,296,931,000). This gives an average reduction of 15 per cent in the rates actually collected.

In addition to this rate reduction there were changes in the compensation laws between the year 1918 and 1926, increasing the benefits to injured workers by 15 per cent.

Massachusetts employers thus received an equivalent benefit in their insurance rates of 30 per cent, when the rate reductions and the increased benefits are both taken into consideration.

Every time the compensation laws are liberalized an increased cost results which the employers must ultimately pay in the form of increased insurance rates, unless this cost can be compensated for by savings elsewhere. Such changes in the laws were made in *twelve* out of the *fifteen* years that have elapsed since the original compensation act was passed in Massachusetts. These changes include an increasing compensation from 50 per cent of wages to 66 2/3 per cent, increasing minimum payments per week from \$4 to \$9 and maximum payments from \$10 to \$18; increasing total compensation from \$3,000 to \$4,500; reducing the "waiting period" before compensation begins from two weeks to seven days; extending the original two weeks limitation of medical expense, at the discretion of the Industrial Accident Board, and giving the employee free choice of his own physician, etc.

All these changes combined have more than doubled the present accident losses to the insurance companies, as compared with the 1912 cost level.

However, the average compensation rates in 1926 were only \$0.91 per hundred dollars of payroll, comparing with \$0.87 for the period of 1912-14 (Premiums \$9,490,000 and payrolls of \$1,098,808,000. See annual reports of Massachusetts Insurance Commissioner.)

The whole history of this movement, as reflected in these figures which have now for the first time been thoroughly analyzed and evaluated, reflects credit on the employers of this state as well as on the other agencies that have been working for improved safety conditions.

The passage of the Workmen's Compensation Act undoubtedly added much impetus to progress in this direction, through its effect in concentrating attention on the seriousness of the industrial accident hazard, on which only fragmentary and scattering information had been available previously.

The "Schedule Rating Plan" developed by the insurance companies in conjunction with the state insurance department, under which superior safeguarding in a plant was directly reflected in a lower insurance premium for the plant, was also an important factor, through the definite financial return which it offered the employer on the cost of safeguarding.

Massachusetts was one of the first states to pass a Compensation Act, and its record marks a very definite step in the progress that is being made in this country to provide more and more fully for the safety and welfare of its great force of industrial workers.

Summary

In summing the matter up it may be said that the foregoing study of Massachusetts accidents over a nine-year period would seem to show quite conclusively that there had been a reduction of approximately one-fourth in the accident frequency and lost time during these years and that this had resulted in a reduction of about 28 per cent in the accident loss cost. This cost saving has been about equally distributed between the employers in the form of a 15 per cent reduction in insurance rates, and the employees in the form of a 15 per cent increase in compensation benefits.

Accident prevention has unquestionably been one of the chief factors in bringing about this saving, and it is particularly gratifying to the safety engineer that the development of mechanical safeguards has been able, not only to offset the growing mechanical exposure over the past decade, but to bring about an actual reduction of at least 50 per cent in the accidents caused by machinery.

More important by far, than the reduction in money cost, is the indication that over a hundred lives are being saved each year among those who carry on the industries of the state, and in addition there are being eliminated yearly, 18,000 disabling injuries!

CHAIRMAN THALNER: Mr. Beyer, I want to thank you very kindly for your splendid presentation of this subject. At this time, if there are any questions to be asked of Mr. Beyer, I am quite sure he will be pleased to answer them.

I was extremely interested in the percentages with regard to the frequency and the severity of mechanical accidents; although 25 per cent of the number of accidents occur as a result of mechanical or machine failure, that 25 per cent causes a loss of 33 per cent of lost time. Consequently, it is quite important that that particular phase of our work be given strict attention.

The part that any safety program plays in a plant depends upon the sincerity of that program. It is utterly improper to ask men in your plants to work safely and be careful workmen without first having provided the protection which they deserve. It would be foolhardy to try to start any accident prevention program in a plant in any industry, unless your mechanical program was completed. Your mechanical program simply is a demonstration to your working force that the

management is sincere in its endeavors to eliminate accidents and they, of course, must take the first step.

Now, the other step is that of the educational part of the program. We often refer to it as being "The Other Seventy-Five Per Cent." We have heard of a number of means by which educational programs are put on and put across with good results. Today, that particular subject is going to be given to you by Mr. A. M. Williams, supervisor of safety at the Chrysler Corporation, in Detroit, Michigan.

The Other Seventy-five Per Cent

By A. M. WILLIAMS

Supervisor of Safety, Chrysler Corporation, Detroit, Mich.

The heading of this subject assumes the ratio of 75 per cent and 25 per cent between the educational and mechanical sides of safety as being correct.

This ratio has come in for a great amount of study during the last three or four years. It first came to my attention several years ago when I made a study of the accidents occurring in the company I am with. Since that time there have been some variations from the percentage but they have been towards a percentage of 90-10 rather than in the other direction.

If we accept the figures as correct then we should direct the bulk of our attention to the educational side of *Safety* or to manbuilding. With your permission I will coin this expression—"Safety is brains at work."

In our safety efforts in the past we have tried many things and the one we have made the least headway with is that of getting each individual employee to apply his own intelligence to his own *safety*.

If *safety* is to be successful and permanent I am convinced that we must train more highly the intelligence that we have in our shops. We must teach men to be alert, to protect themselves. We must develop or help our employees in developing certain mental capabilities that are becoming atrophied or shrunken up through lack of use.

If safety is brains at work what is the job?

What part of the brain is working?

What is it doing and how is it doing it?

When we get that far we usually stop. The skull is like a stone wall because it stops us and we would do anything rather than climb the wall to get a look on the other side and find out what is going on in there. This talk will not be technical so do not get uneasy.

I like to picture the human mind made up of parts just like our bodies—a muscle for this and a muscle for that purpose.

Let us consider the human mind as being made up of many parts the same as the body is made up of many muscles. We know that exercise of any given muscle will develop it, also that lack of use will shrink it up. It is fair to assume that the same occurs with various mental muscles. Of course there are no muscles in the brain but for the sake of clearness we will assume that up there inside each skull there are muscles that we think with and muscles that we file away this kind of knowledge or that and muscles that we execute this movement or that movement with.

The reason that I want to use the term "mental muscle" or muscles of the brain is to drive home the fact that the brain becomes strengthened by use just the same as the muscles do.

In our physical examination rooms the applicant for employment undergoes a rigid examination as to his physical development. If the muscles of the right shoulder are much smaller than those of the left it becomes apparent to the

examiner that this man has not used his right arm as much as his left. The left through use has grown strong and the right through dis-use has shrunk away.

Fortunately we have two arms to use in comparing but when it comes to that section of the man above the collar—his brain—we have nothing to compare with to determine just how—if at all—he has exercised it. We do not know whether or not the man has been developing those functions necessary to use in guarding against danger—against accidents.

We strengthen our lifting muscles by lifting and our thinking muscles by thinking. We strengthen our walking muscles by walking and our reasoning power by reasoning.

I am reminded of the story of Pete Pare.

Pete was a big lumber jack from the Canadian northwoods six feet, three or four inches and weighing some 250 pounds. According to the story, Jack Dempsey came to Toronto and offered \$500 to any man who would stay in the ring with him for three rounds. Through newspaper publicity this information drifted back through the backwoods to where Pete was employed. His friends and admirers begged him to go down and get this easy money. When Pete left for Toronto he took with him all of the spare change from the lumbering camp to put up on his side. A friend of his went along to insure fair play.

After the affair was over and the two came back to the camp it was up to the friend to explain to the boys just what had happened and he explained it in this way—"When Pete get in the ring we feel proud of Pete—great big arm, great big leg, strong and big. Jack Demp, we feel sorry for Jack—little arm—little leg. And Pete he make a pass at Jack Demp. and Jack he duck and Pete he make another pass and again Jack duck—then Jack made a pass at Pete and Pete, he no duck!"

Regardless of size Jack Dempsey had been taught to take care of himself and to protect himself from injury. That part of his brain had not atrophied through lack of use but had been strengthened. He knew what to protect himself against and was alert. On the other hand Pete had been trained in a kindlier environment. He had not been trained to protect himself every instant of time. True—there are hazards in his work but they have been pretty well guarded against and simplified through the proper annealing of chains, proper design of canthooks, toggle chains in loading logs, spiked skids, proper design of swamp-hooks, etc., so that Pete had had very little mental exercise in developing the thinking section of his brain.

He may have been a giant physically but he was far from being a giant in certain mental sections.

Our problem lies in presenting to the men those things that will develop the very section of the mind that Jack Dempsey's training developed. I don't want anyone to run away with the idea that I am comparing industry with the prize ring in so far as hazards are concerned—far be it. I am using the illustration to prove a point. I am using it as an acid test to prove the correctness of the theory. Interesting bulletins, pictures, etc., are all valuable in teaching safety, but Jack Dempsey had done more than look at pictures. There must be something in each bulletin that will make the individual think for a moment about his own safety and apply the lesson taught in the bulletin to his own case; when he does that he then exercises that section of the mind we are trying to reach.

Suppose we assume that there are three general departments of the brain—receiving or filing—reasoning or imagining—deciding or acting. A man may be well read. During his reading he has been receiving and filing. Some men do little else during their lives but read and study and make little or no application of the knowledge they have received and filed. Another man may be all action, still another only a dreamer or thinker.

I remember back to an old lumber jack who, when I was a boy, gave us an early lesson in safety. He said, "Boys when you hear timber crack watch out for yourselves because when one of these big trees comes down you must be somewhere else and be there quick. We can't tie all of them up so that they won't fall on you. You must use your heads and use 'em fast."

His gospel was "*Learn to think and think fast.*"

A man may read, but that may not make him mentally alert because it apparently does not exercise the right mental muscles. A man may tell another of some important event or a funny story but this does not necessarily mean that he did a lot of thinking about it and that he enlarged his thinking capacity at the time. A man may see a safety bulletin and not get any good out of it because he does not think about it.

The old lumber jack made us boys not only use the receiving departments of our brains but made us develop our thinking muscles by making us think. How did he do it? By appealing to our instinct of self preservation by letting us know we might be crushed by falling timber—pain and even worse might be the price if we were not alert.

In our spare moments we worked out plans of what we would do in case of a tree falling towards us. If it was close we were to run towards the butt or stump because it would be a hundred times easier to dodge it there than near the wide top which was fashioned like an immense fly swatter. If we were farther away then we were to run with the tree or the right or left depending upon other variables. We worked these plans out in the dirt.

The point is that in making these plans we taught ourselves to be alert. We were getting the most valuable safety training ever received. We were not only storing up knowledge to use in an emergency but were training our mental thinking muscles to act and act quickly in an emergency.

I have always felt that we are doing our best safety work when we are getting men to draw rough diagrams of what to do and not to do in any case of emergency. A great many times we hear of men who have exhibited wonderful presence of mind. In extreme emergency they made exactly the right move. After all when the facts were all brought out it was found that they had thought out or thought through and planned out the entire procedure long in advance of the happening—when it did come they merely carried out their original plans.

This brings to mind a story of Von Hindenburg. In his preparation for the defense of Germany. The story goes that for forty years before the Great War he spent a good portion of each year on his country's frontiers and in the swamps, lakes and hills of the countries beyond their border line. He studied the topography of the countries and made his plans of attack. In his imagination he would place his armies in every possible position and then plan against this and that emergency. When war finally did break out his plans were swiftly executed because they were merely a "carry out" of what had been planned years and years before. There was hardly an emergency that had not been thought through years before. The story of Von Hindenburg is also true in the life of U. S. Grant, in some of his important battles of the Civil War.

Safety is getting every man in industry to look his ground over in advance—to "Think about safety." To Exercise His "Safety Thinking Muscles" until they are as healthy and as quick to respond as the ball player's arm.

Against this background we have been doing certain work at Chryslers' for the purpose of developing this safety function in each employee's mind. We first decided that if we were to teach safety we must have some literature to use. We needed safety-first readers. And this called for rule books and the number of different trades involved and the wide range of hazards covered called for not only one rule book but many until today we have eight rule books covering our

eight major activities and two more in the making. The trades covered fell logically into these classifications:

1. Sheetmetal and Punch Press Rules.
2. Rules for the transformation of Castings, Forgings and Bar Stock.
3. Rules for Acetylene, Arc and Spot Welding.
4. Rules for Drivers.
5. Rules for Woodworking.
6. Rules for Maintenance Work.
7. Rules for the Handling, Storing, Transferring and Shipping of Material. etc.
8. Rules for Body Building.

In the preparation of these rules we have the greatest opportunity to start men thinking safety by securing their assistance in preparing the safety rule books.

Questionnaires were prepared for every employee and each questionnaire asked for the four more common causes of accidents in the trade on which he was employed. Many of the employees were unable to give more than one common cause of accidents on their work. The bulk of them however gave four. The questionnaire, when sent to carpenters, electricians, millwrights and other employees using ladders, brought out the fact that there are 31 common causes of ladder accidents.

These were incorporated in the rule books. I believe it is the most comprehensive set of ladder rules ever issued and it came entirely from the men on the job.

When these questionnaires went into the plant we noticed a marked falling off in our accident rate, proving beyond doubt that we are getting some real benefit from the thought being given to safety.

Editing and publishing these rule books was merely a technical job that took a little time and considerable money. The real job came in the practical application of them.

These books were first delivered to all of the employees. Each employee was informed that they were to be rigidly enforced and for his own protection he should familiarize himself with them, otherwise he might be disciplined or even discharged for a violation of a rule that he was not familiar with.

Fortunately at the time these rule books were passed out the labor situation was very favorable for a move of this kind because jobs were scarce and men were anxious to carry out the wishes of management in order that they keep their jobs. As soon as the rules were in effect, discipline followed and it was necessary in almost every department to discipline one or more individuals within the first few days. This was done in all cases, in a very kindly way, by explaining to an offender that we did not wish to keep in our employ a man who did not respect the company's rules. If we were satisfied from the man's attitude that he would respect them in the future and in addition to that assist in securing the respect of other employees, then we re-instated him. Other men more or less Bolshevistic in their make-up were not disposed to follow them. We found in these cases that the rule books were a real service in weeding out of our organization quite a lot of bad timber. All of this of course was with the old employees and did not hit the spot we were aiming at—that of the new and inexperienced employee. However, if we were to give rule books and a safety talk to the man at the time of writing him up for employment—and he were to find these rules ignored in the plant our case would be lost—it was necessary for us to start with the old employees.

Our plan for the new men now consists of contacting with the man on safety at least four times during the time he is being written up.

First: *The man who does the rough selecting at the gate* when the man is accepted tentatively, calls his attention to the fact that the company is interested in knowing his attitude towards Safety and the company's Safety rules.

Second: By the *physical examiner* who calls the man's attention to a few posters on the wall in the Physical Examination room, complimenting the man on his having all of his fingers and his freedom from scars, which are the evidence oft-times of carelessness, and his hope that employment with us will be free from accidents. He also emphasizes the subject of safety by picking up a copy of the rule book that would eventually be given to the applicant and telling him that if he follows the instructions it would be of assistance to him. By all means he should become familiar with all of the rules and not stop with one reading of the book, but read it from time to time after he goes on the job.

The third man's contact with him is the *write-up clerk* who assigns the badge number and gives him the Safety Rule Book and when he hands over the book mentions the importance of it and the fact that it represents the company's policy on safety and that every employee is expected to live up to them.

The fourth man is the *foreman* who asks the applicant for the book, fills out the receipt for him, has the employee sign it and then calls his attention to the fact that the rules are considered part of the man's trade skill. The foreman also explains that while the employee is undoubtedly familiar with a great many of the rules he should make sure that none of them are overlooked—he is expected to familiarize himself with all of them.

It is not so much what is said to the new employee as the *manner in which it is said* that impresses him with the importance of studying the rules and we find they are studying them.

After the man enters our employ—at intervals of say 30 days—we circularize the departments with leaflets, one going to each man. These are slightly larger than a pay check and are given to employees by the foreman. Each sheet carries two pictures that are technical, each showing the right way to do some job. The purpose of this is to bring the man's attention back again to rule book and encourage the reading of it at that time.

Then comes the Safety Committees. It is the Committee plan of stimulating interest in and thinking about safety—in short developing safety mental muscles.

At the present time our safety committees are made up largely of the foremen. These meetings are self inspiring to a great extent and result in keeping the foreman "on his toes" to follow through to the men with all of the educational material we can provide them with.

In our safety bulletins we find that we have passed the point where the inspirational picture is necessary—we are getting to the point where the men are asking for bulletins illustrating the right way to do some particular job. In the beginning of any safety campaign the inspirational pictures are about the only ones that can be used but as interest in the subject grows men become quick to tell us—"Aw bunk, you don't have to sell us on safety—but show us how."

The organization of safety committees is a very flexible thing and some form can be found tailored to fit any form of organization. It is while employees are working in safety committees that they are thinking safety, that they are drawing the plans in the dirt, so to speak, of what to do in case of emergency. They are the Von Hindenburgs and General Grants studying conditions before the unexpected happens.

They are developing their safety mental muscles.

While they are drawing these plans they see the possibility of a grinding wheel bursting and causing a serious accident. Before they are through with it they see that the grinding wheel is guarded. They catch the flaw in a fly wheel hub before it breaks. They see the new employee working on revolving machinery with his sleeves rolled down and correct this condition before the unexpected happens. They stop the reckless jitney driver before he injures himself or another.

They catch the unguarded man-hole opening in a floor before someone falls into

it and in a catastrophe such as an explosion we find them making their way to safety in order and not in panic.

As sure as the safety committee meets and considers accident prevention, just so sure will they bring to light mechanical conditions to be corrected, and if their interest in the safety committee work can be maintained long enough, the plant will be brought to mechanical perfection.

It is educational work, they are exchanging ideas, thinking about safety, and in so doing automatically taking care of the mechanical side of the problem.

Therefore it is in this work that we find our logical place of beginning. We might compare it with a famous paint advertisement—"Save the surface and you save all."

With "the other 75 per cent" of the Safety job, the educational side, at work we find if taking care of the mechanical side and doing it automatically.

CHAIRMAN THALNER: This subject has been very well covered by our good friend Art Williams, and I imagine there are going to be some questions.

I think it was the late Elbert Gary who said that there were three important words to us in running any organization, and those words were, Organize, Deputize, Supervise. And doesn't that bring us right back to the one point which Mr. Williams stressed in his paper, that of responsibility, placing the responsibility on the man's shoulders; giving him something to do? You never put over a community fund campaign unless you get your team workers in and give them something to do. Then, when the week has passed, each man has brought in his quota. Consequently, it is responsibility that is going to do the job we are after.

Another point which he stressed which rather interested me was that of "Right Thinking." I heard a speaker at one of our sessions a couple of years ago criticise our posters. He said, "You have a poster which portrays the idea that a man is thoughtless." He went on to show that while he was coming down the street in a taxicab, another taxicab coming from the right collided with his. Both drivers got out and started to argue about the trouble. This taxicab driver said, "I thought you were going to stop," and the other taxicab driver said, "I thought *you* were going to stop."

He brought out the point that both of those fellows, although they had an accident, were thinking. There was nothing thoughtless in their action, but they were thinking *wrongly*. That is why the idea of right thinking seems to me to be a very important factor in this educational program.

There is no doubt in my mind but what there is a wealth of material right here in this group with means and methods of attacking the educational program. I should like to hear from some of you gentlemen at this time as to what methods or policies you are pursuing to put across this very same program. I see Mr. McLain, of Pittsburgh out there.

MR. McLAIN (Jones & Laughlin Steel Co., Pittsburgh, Pa.): That is hardly fair, Mr. Chairman. I have been sitting here thinking of something else; I wasn't thinking rightly. There might have been an error just at that moment.

These A B C sessions and these thoughts that we bring out here of trying to get a man to do something and do the right thinking are absolutely the A B C's of all our safety work, in my experience. You have all reached conclusions. I met one of my closest associates at noon today, and I looked him square in the eye. I said, "I am going to ask you a question, and don't lie to me."

He looked up kind of funny. I said, "Have you heard a single new thing at the convention this week?"

He began to twist around a little bit, taking time to think about it. "I don't believe I have," he replied, "but I have heard some of the same old ideas put into so many different ways that I am going to go back and think they are new anyway!"

Here is an idea, Mr. Chairman, as old as this Safety Convention that began seventeen years ago—the training of these men to think for themselves. If it is in our own minds as safety engineers, we can think and lead others to follow. If we can't, we don't belong in that job of right thinking and careful thinking. I emphasize this one point, and I am rather childish about it. It is the giving of instruction to the men. You have heard me say before, some of you, that the average man, at least in the steel mills where I come from, has a mind that will rate somewhat under a ten-year-old child. I say the "average." I am not speaking of supervision.

We have a great deal of cheap labor, which of course accounts for it. If you go to Tony and say, "Tony, do you understand?" he is going to say "yes," because he thinks you want him to say that. He doesn't always understand, but he says he does. I have found, time after time, that we have fallen down by not talking to that man in the simple A B C language that he can understand. That is "right thinking" on the part of the foreman or man who gives the instruction. You have to do that if he is going to get this pick and shovel man or the average man to follow him in it. After all, if you can get a man to understand what you are driving at, what you want of him, nine out of ten men will do it that way. That is my little thought.

MR. THOMAS (DuPont Company, Portland, Me.): I have been very much interested in the talks that have been given here this afternoon. I have attended one of these A B C sessions every time that I could. You see, you can't attend more than one session at a time, and today is really the first time that I have heard the point stressed that safety education is really the kernel of the whole matter.

At my plant, we have a number of various machines and a number of various hazards. I will say this just as a matter of information. We started in 1920, and we went for three years without a lost time accident. In April, 1920, we had two accidents, both of which could have proved fatal but did not. They happened within a day of each other. Both of those accidents were absolutely due to the fact that the men did not think. One man was in a place where he had no business to be. Nobody expected him to be there, and he was hurt. The other man was working practically alone, and did an absolutely careless and reckless thing, without thinking. He was permanently injured, but it was not a fatality. I speak of those accidents for this reason: They were investigated by the management and by the safety committee, and after a thorough analysis of them, there was not a single man in that plant that blamed the company for either one of those accidents. They all saw that the company had taken every precaution that could have been taken, and yet the men who were injured stepped into the hazard thoughtlessly.

Since April, 1923, we have gone up to the present time without a lost time accident. That record is still continuing. I believe absolutely that the lesson learned from those two accidents by the men in the plant has been a great thing in promoting the present no lost time accident record. Every man in my plant is a safety man. If he were otherwise, he wouldn't stay.

I had the unfortunate experience of discharging a man who had been there two years. I had taken the matter up with him from the viewpoint of safety, but he would not absorb the idea. There was nothing else for me to do but let him go.

I made an investigation among the different foremen and so forth, to find out if the men in the plant really thought the company was wrong in discharging that man. I have yet to find a single man who does not agree with the management in the matter. That man did not belong with the crew because of his attitude on safety and lack of cooperation with other men. It is certainly true as we have

heard this afternoon that you must train the men to think. When you can get a thinking man, you have a safety man.

MR. WINTERS (U. S. Metals Refining Co., Carteret, N. J.): Mr. Chairman, speaking on accident prevention and making a man think, about three years ago we organized our accident prevention system. We followed the line of trying to determine ways and means of making men think and placing responsibility directly where it should belong. First of all, we organized what we call an "Accident Court." The court is presided over by the assistant manager. A safety engineer investigates all lost time accidents. The report which the safety engineer turns in to the court is based on an independent investigation. The foreman in the shop, of course, must also make out a report, which the department head signs and reviews.

For the first year or so, we found that a great many of our foremen tried to cover up accidents. The check-up which was made on them independently developed a point where those cover-up cases were detected. The foreman was shown he could no longer cover up any accident or the true cause of any accident. We keep a record of every foreman who has what we call a lost time accident. That accident is charged directly against him. There is a difference between an accident which is charged directly or indirectly. Where we can show that the cause of an accident has been through negligence or lack of safety instruction on the part of the foreman, we charge the accident directly against him. Where it is a matter of an ordinary accident which may occur in any department, such as a man's stumbling or slipping, or any hundred of other causes, the case is called "indirect" and that is charged against the department but *not* the foreman.

From our safety work, we came to the belief that the foreman is the man whom you have to educate to prevent accidents. That may not apply to all industries, but it certainly does apply to ours because we have at least a 75 per cent foreign element in our plant, a great many illiterates, and so forth.

You may say, "Why don't you get men who can read and write, or get better men?" That again depends on the geographical direction or location of your plant. If we were in a place where we could get all American labor, we wouldn't have that situation. We have to adjust ourselves according to the conditions as we find them.

What do we do after a foreman has had a number of those direct accidents charged to him? We have a foremen's safety school which is conducted every week. A number of foremen are picked out for the classes, and particularly those foremen who have the worst accident records in their departments. They have to attend the safety school. That is the place where they learn safety. Of course, those foremen who can't adjust themselves to conditions and stay with the safe majority, we have to let go. That is the final analysis. But we have absolutely found that we cannot place responsibility directly on the workmen themselves. We may stand in that position alone, but we have a system which works. I believe that any system that works is the right system on accident prevention. We must adjust ourselves to certain conditions as we find them. We hear of a great many places that say, "We have such a wonderful record, or no accident record." I am sorry that I can't say the same thing. We have accidents, but we are reducing them day-by-day and month-by-month—we are getting better. But, we have had a harder road to travel than the majority of people who have better conditions on the labor situation.

The spreading of propaganda on accident prevention is all educational. We have bulletin boards, safety rallies, departmental meetings, and so forth. But still, we maintain, that the foreman is the man who can put safety into your organization. We leave it entirely up to our foremen.

MR. HOPKINS (Hartford Insurance Company, Hartford, Conn.): Might I

inquire of the gentleman who just spoke, what his method of education for foremen might be? I am interested in that line.

MR. WINTERS: On the matter of educating the foremen, we have 114 foremen in our plants. We divide them into groups of 10. We have these foremen report to the safety engineer once a week for one hour. These meetings are held in a private office, where the safety engineer has a round table discussion with the foremen. He brings up the cause of a lost time accident right with the foreman who is responsible for it.

In addition, we have a plant magazine, that we call "The Safe Worker," which is sponsored by the National Safety Council. We add the necessary literature to this magazine which applies to our own problems. We give every foreman the benefit of five hours of this training or lecture work. We give the foreman opportunity to express himself as to whether he has any objection or whether there is any objection to our "attack," we might say; in this way, we create interest in the accident prevention work. We found that a great many foremen didn't know what it was all about before we started that system.

JOHN BEIT (Schwarzenbach Huber Company, New York): Referring to the gentleman who spoke previously about having no lost time accidents since 1923, I would like to know what kind of business they are in and how many men they employ.

MR. THOMAS (DuPont Company, Portland, Me.): The number of men vary from 35 to 75. I will say though, that the operation is the manufacturing of wood pulp for dynamite purposes. In addition, during the last four years, we have operated a sawmill. My company asked me whether I wished to assume the responsibility of a sawmill on our safety record in addition to the operation of the pulp mill, saying that the sawmill was more hazardous. Being under the same management and the same safety education, I said we would assume the education of those men.

I realize the number of men is not large, but when you figure we have gone eight years with only two lost time accidents, it means that those few men must be thinking pretty seriously of safety.

CHAIRMAN THALNER: That is a very good record, considering the classification of the work.

MR. FULTON (Standard Underground Cable Company, Perth Amboy, N. J.): May I ask what your lost time is?

MR. THOMAS: Lost time, according to DuPont regulations, means time lost away from work other than on the day of accident. If a man is injured in the morning, he may lay off for the rest of the day, but he must be back at the job on the following day, otherwise it is a lost time accident.

CHAIRMAN THALNER: That is the standard tabulation which is used by the U. S. Government. Are there any other questions?

MR. HAYES (Employers Mutual Life Insurance Company of Alabama, Birmingham, Ala.): Some of our insurance companies conducted a no-accident campaign last summer. As a method of getting employees interested in the safety campaign, they offered a prize of five dollars in gold each month for the best safety slogan submitted. Some of those plants have a large percentage of colored help, and you would be surprised to see the great number of safety slogans that some of these Negroes turned in, as well as other employees in the different cotton mills where most of them are rather illiterate. The results of that campaign were most gratifying. I thought I would offer that as a practical suggestion for getting the employees themselves, interested in the safety work.

CHAIRMAN THALNER: The next order of business, gentlemen, is the election of officers. At this time I will call for the report of the Nominating Committee.

Report of Nominating Committee

MR. McLAIN: Mr. Chairman, the President of the National Safety Council appointed three gentlemen, Messrs. Webb, Auel, and Heinrich, as a Nominating Committee to suggest officers for this section. It so happened that none of these gentlemen could be present this afternoon, and I have been asked to submit the findings of this committee. I offer to you as their report, these names:

For Chairman of this Section, George Opp of the Detroit Edison Company.
Vice Chairman, E. F. Blank, of the Jones & Loughlin Steel Company.
Secretary, Mr. C. D. Adair, of the American Rolling Mills.

I therefore move their nomination.

N. E. GREEN (Louisville, Ky.): I second the nomination and suggest that the secretary be instructed to cast one ballot.

CHAIRMAN THALNER: Is there any discussion? It is moved and seconded that the secretary be instructed to cast one ballot for the nominations as submitted. All those in favor signify by saying "aye;" opposed, "no." The motion is carried.

CHAIRMAN THALNER: The second part of this program has to do with "Accident Prevention in the Smaller Plants." I have gathered together a few figures which I want to give to you before going into that part of the program, which were taken from a report which U. S. Labor Commissioner Ethelbert Stewart has written in his monthly review of January, 1928. They are pertinent to the particular subject at hand today. Forty per cent of the establishments in the United States employ from one to five persons. Twenty-eight per cent of them employ from six to twenty persons. Nine-tenths of one per cent employ from 500 to 1,000, and one-half of one per cent employ 1,000 and over.

We all know of the accident prevention methods which are in vogue by the larger corporations of the country; they have special departments, the work is carried on in an efficient manner, and special emphasis is given to that angle of our industrial life. However, there are a large number of small plants, as shown here, who cannot afford to have a full-fledged or full-time safety department.

In spite of the fact that good records are being made by the large corporations, increases in accident rates are being experienced by the smaller fellows. The result is that we have a few plants doing a lot of good work, decreasing their rates, and we have a very large number of plants (practically 90 per cent), who are not having the same experience. Consequently, these two papers which are to be presented regarding the accident prevention programs for smaller plants should prove exceedingly interesting. We are to deal first with "What is a Good Industrial Safety Program in Plants Employing from 150 to 1000 Workers?"

This first paper is to be handled by Mr. Ralph E. Motley, who has charge of plant personnel and employment at the Atlantic Refining Company, Philadelphia. It gives me a great deal of pleasure at this time to introduce Mr. Motley!

What Is a Good Industrial Safety Program for a Plant Employing from One Hundred to One Thousand Men?

By **RALPH E. MOTLEY**

Director Plant Personnel and Employment, The Atlantic Refining Company, Philadelphia

I do not recall the name of that great philosopher, who, when asked the question "how long is a piece of string" answered that it was "twice the length from the center to either end," but I was tempted to use the same kind of reasoning when I first attempted to answer the question which is the subject of my talk.

Accordingly, using the same line of reasoning, the first answer that came to my mind was this; "a good safety program for a plant employing 100 to 1,000 men is

that program which will produce the desired results." But the fallacy in the reasoning behind both of these answers is, that while they both give you a general rule to follow which, unquestionably, is correct, it would be absolutely impossible to determine either the number of inches of which that string was composed or the component parts of the particular safety program in mind. So, just as we must actually measure the piece of string to arrive at our answer in inches, so must we analyze the subject of safety in order to arrive at our answer to the safety problem in terms of actual, tangible lines of procedure.

Before attempting to prepare any safety program which will give some promise of successful results, it is first necessary to analyze thoroughly the subject of safety, and arrive at the actual cause of accidents. To me, these causes seem to be of three general kinds, requiring three fairly distinct lines of procedure. Accidents may be due to mechanical, physiological, and psychological causes.

Under mechanical causes, we find such things as unguarded machinery, dangerous elevators, slippery floors, obstructed passageways, over speeded fly wheels, and other familiar causes for which the worker is in no way to blame. These causes have their cure readily at hand for the management which will apply it.

Under physiological causes we find such things as long hours of work, unhealthy working environment, inadequate lighting or ventilation, and monotonous or arduous tasks. The manner in which the worker handles himself or performs his duties is profoundly influenced by bodily conditions. A worker suffering from overstrain or worry or from excessive fatigue is not a safe person in the neighborhood of any accident hazard.

Psychological causes may be considered as ignorance, inexperience, carelessness, recklessness, and lack of plant discipline or supervision. To cope with these causes is not the responsibility of any one person or group, but of all persons and all groups. The most perfect mechanical preventive devices cannot substitute for personal caution and good sense.

If you please, we may translate these three general causes—mechanical, physiological, and psychological—into more workable terms, so far as our plant conditions and prospective safety program are concerned. Instead of the term "mechanical causes," we may substitute that of "fairness," and by fairness I simply mean the primary obligation industry owes its employees. This primary obligation is merely the providing of safe and properly protected tools and machines for the employees to work with. If this were conscientiously carried out in every shop and plant in the country, we could from this one cause alone notice a material decrease in accidents.

Suppose we replace the term physiological causes with the term "health," or rather the lack of healthful conditions. Too much emphasis cannot be placed on this group of causes. There is no denying the fact that inadequate lighting and ventilation, long hours of work, and monotonous or arduous tasks have a profound influence on bodily conditions which ultimately will render the employee more susceptible to accidents. This is a tremendous problem and one which cannot be solved or corrected in a day's time, but it is one which deserves very serious thought on the part of management. How would you like to work under the same conditions the lowest 30 per cent of the employees in your plant work under?

For psychological causes we may substitute "lack of education." A majority of the causes under this group such as ignorance, inexperience, etc., are the very essence of the lack of education. Do you have any method at all for instructing the employees in the kind of work they are to do, or do you depend upon their past experience in other plants to guide their actions? Education in safety can take many forms, some of which we will touch upon when we actually piece together our safety program.

In addition to analyzing thoroughly the causes of accidents, we must give serious thought to the human elements to be encountered and which must be corraled

before we can go ahead with our program. I have divided these human elements into four main groups; management, superintendents, foremen, and men. Any company which has not the vision to see the benefits to be derived, both for itself as well as its employees, from successful safety activities certainly is overlooking the paramount obligation industry owes its employees: namely freedom from accidents for themselves and their fellow workmen. If the management from the highest executive down is not head and shoulders behind the safety program, then the safety engineer might just as well take down his shingle and go on an extended fishing trip, because he will have far better luck catching fish than he will in reducing accidents. Sell the management first of all on the absolute necessity of an adequate safety program. If you do not have enough facts at hand to do the trick, the National Safety Council will only be too glad to put its entire resources in the form of safety experience and knowledge at your disposal. But sell the Management or your program will probably take a tumble.

The superintendents form the next group in line to be sold on safety in general as well as the particular program in mind. By superintendents, I have in mind those individuals, sub-executives, who have charge of a number of different operations in one department, each operation being in charge of a head foreman who reports directly to the superintendent. This arrangement would probably exist in an organization of 1,000 men, but most likely would not be found in an organization of 100 men. Just as the superintendent looks to the management for his orders and suggestions, so does the foreman look to the superintendent as representing the company, and he looks to him for guidance and advice. Consequently it is necessary that the superintendent be sold on safety in order that he may not interrupt the flow of guidance coming in the chain from the top link to the bottom.

The foreman is the key man in the organization. He is constantly in touch with the men on the job, and consequently is the logical man to be placed with the responsibility of instructing the new men on the job. It is a well known fact that in any new experience, the two points of greatest difficulty are at the beginning and the end of the experience, the foreman being the greatest of the two. Therefore, a most important opportunity exists when the new employee is introduced to the workplace. It is the foreman's job to introduce the new workman to the new work place, to instruct him in the exact manner in which the work is to be done, and to point out any hazards or dangers incident to the job. The foreman should make an example of himself as a 100 per cent safety man in order that the men under him may be encouraged and inspired to work as safely as possible. How can a foreman perform this gigantic task if he himself is not thoroughly sold on safety?

And now we reach the last of the human elements to be encountered; the last link in the chain of successful safety, extending from the highest executive down to the lowest man. "Man"—a conglomeration of flesh and blood, desires and emotions, senses and feelings, is certainly a puzzle to solve. But the puzzle must be solved before the greatest results can be obtained in any kind of activities, especially so in safety activities. Of course, it is unreasonable to suppose that a man can be analyzed as completely and definitely as can be a piece of stone or metal; although it is claimed by some that definite human qualities and characteristics can be determined by such things as the shape of the nose, the color of the hair and skin, the contour of the head, and so on. If this were the case, our job of successfully carrying on safety work would be completely solved by selection. But unfortunately such is not the case, and we must be content with more indirect methods. The result of the program will be determined by the effect on the workmen in the plant. They are the ones who have the accidents; the accidents are dependent to a large extent upon the general "safety atmosphere" created in the plant by the higher ups; the "safety state of mind" of the higher ups is largely moulded by the kind of men actually entrusted with the tangible safety activities, and the kind of safety activities they carry on.

"What Is a Good Industrial Safety Program for a Plant Employing from 100 to 1,000 men?" Having discussed the most important factors which must be carefully studied before preparing a program, I will now answer that question, not with the "piece of string" reasoning but based upon our own Company's experience and observations I have made in companies enjoying considerable success in safety activities.

Just as every nautical ship has its captain who is in command and who really is the guiding and executive power within his own bailiwick, so must the ship of safety be entrusted to the hands of one individual who plans and directs its course. The safety engineer is the name commonly applied to the individual. There are safety engineers, and then again there are people who are not, but merely have the title. This is not said with any disrespect to those worthy individuals who make up that class or group, but there are times when the man holding the job is any but the right type for that kind of work. Maybe the job was thrust on him; maybe he got the job because he liked the title; there are lots of reasons for this sad state of affairs, but the unfortunate part of it is that it exists in that vocation as it does in many others. The success of the safety program will largely hinge on the type of man holding down the job of safety engineer.

To my mind, a good safety engineer should be more interested in safety than any one in the plant; he should be on friendly terms with and have the goodwill of all the men in the plant. He should be honest, firm, fair, and have an understanding nature. He should have unusual energy, be a good leader, and a good talker. I am more and more convinced that unless he has acquired or developed this particular tool i. e. a good talker, he has overlooked one of his most effective approaches to the men. In addition to this, I believe he should have what Dr. Talbert, of Stanford University, terms "Intelligent Openmindedness," which he considers to be, "The refusal to take traditions for granted; the willingness to go contrary to the crowd if the crowd is wrong; the faith that there is an answer to every problem, and that if we haven't found the answer, that is no sign that it doesn't exist. In other words it is simply "Intelligent Openmindedness."

The importance of the safety engineer justifies the few minutes I have taken to express my idea of his qualifications. I realize that we will probably not find all these qualities in many men individually, but I do believe that we should endeavor to find men with as many of these qualifications as possible. The man may be from within or without the plant. I have not said anything about his technical training. Obviously this is very desirable.

To assist him in carrying out the safety program, he should have a committee or committees composed of the men of the plant. Whether these men come directly from the so called working men, or from the foremen, depends largely on the size of the plant and its own peculiar conditions. If the plant is large enough to justify a General Safety Committee and sub-committees, then I would most earnestly recommend that the General Safety Committee be composed of as high type men as possible. General foremen and even superintendents should be members of this committee. This gives the safety committee organization more prestige among the men than if this committee were composed of lower positioned men.

The sub-committees would then be made up of lower grade foremen and men in the plant. The committees should be changed often enough to inject new blood, and give as many people as possible an opportunity to serve. The effect is two-fold. The committees benefit by new ideas and the committee-men benefit from the experience they have gained by serving. The duties of the committee will also vary in different sized plants. The National Safety Council has a pamphlet covering this subject pretty thoroughly, and for that reason I am not going to go into it any deeper at this moment, but will touch upon it from time to time in connection with the rest of the program.

To my mind, education and publicity should play as important a part in the

safety program as any of the other agencies we have at hand; and this agency should be carried on from the executives down. Education should be of two forms; on the job, and in mass form. Separate meetings of superintendents and foremen, and rallies at which the whole plant is present are examples of the mass meetings I have in mind. Individual instruction by the foreman in the proper method in which the work should be done is an example of the education on the job. If the plant is large enough to include a group of sub-executives called superintendents, meetings of these individuals should be called by the manager of the plant at least once a month.

At these meetings, except where a special campaign is to be launched, definite phases of safety work should be taken up and discussed. But let me warn you of one thing; make sure that the person leading the meeting is thoroughly conversant with his subject and that he has the ability to put it across. Nothing will so nearly wreck the purpose of these meetings as a poor leader. The meetings should not be long probably fifteen to thirty minutes will suffice. Make sure you have something to tell them, and have the manager there to impress upon the superintendents the fact that the management is heart and soul back of the safety movement, and that it is looking to them to "bring home the bacon."

If for no other reason, these meetings find their justification in the fact that the individuals are gathered there for a definite purpose, that the definite purpose is the saving of life and limb, and that by virtue of the positions they hold they are the guiding power which will spell the success or failure of a realization of that purpose. The foremen's meetings should follow a day or two after the Superintendents' meetings. Each superintendent should call together his foremen, give them a general idea of what happened at the superintendents' meeting, review the accidents which may have occurred in the particular department during the past month, and discuss ways and means of preventing future occurrences.

Once every three months, an outside speaker should be obtained to talk to all the foremen at one time. The subject should deal with safety in general in order that the foremen may obtain some knowledge of comparable activities in other companies and throughout the country in general. Mass meetings for the entire plant should be held about every three or four months. The size and nature of the plant will determine just what kind of a meeting should be held. A high executive in the company, preferably one who is known to a majority of the men should make a very brief talk outlining the Company's attitude toward safety work, and giving them just praise for any good work which may have been done during the last period. If possible, have a band to play a few favorite numbers. Quite a few companies have bands of their own which can fit in very nicely in this respect.

The time of holding these meetings is a much debated question. It is my firm belief that unless these meetings are held during working hours when the men will consider them as part of their work, the greatest good will not be obtained. I know of several successful rallies which have been held in the evening, but these should, I believe, be confined to a gathering of the entire plant. A good time for the superintendents' meeting would be just after lunch, and from four-thirty to five, or the last half hour before the close of the working day, should be a good time for the foremen's meetings. If properly conducted, I can think of no more effective means of keeping the safety morale at its highest pitch than by just such meetings as these.

Posters unquestionably play an important part in any safety program. The poster is one form of advertising. Not so long ago I read a message on one of the placards in a street car which impressed me very much. I do not remember the exact wording, but the thought was this: "The true value of any advertisement is determined by the degree of confidence it creates. Building up that confidence on good-will is the principal purpose of advertising." When making up your poster program, bear that thought in mind. Select only those posters which will drive

the message home, and at the same time build up confidence in and good-will for the safety program being carried on.

Whether you should have a daily or weekly poster schedule in your plant, that you should decide. The National Safety Council not only will be able to help you on that point, being pioneers in the safety poster game, but they also have a very effective poster service which is designed to meet your needs. In addition to this there are numerous reputable poster and bulletin board companies throughout the country which most probably can help you in fitting this kind of safety advertising to the needs of your plant. But by all means, use some form of good poster advertising.

If your plant is large enough, you may wish to get out a little safety periodical. A little over a year and a half ago, we decided to get out a little safety paper in our own company. Immediate interest was aroused by allowing the employees to suggest names for the paper. From the numerous ones received, that of *The Siren of Safety* was selected as the one best fitting the magazine we had in mind. It started out as 5 by 7 inch eight-page paper, but it has met with so much favor by the employees and we have found so much use for it that it was increased to 12 and then 16 pages. Such a paper does not have to be elaborate, nor do you have to spend much money on it. We publish this paper once a month.

Some of us have a few things in common, and a few of us have a great many things in common; and it is on these things in common that we must depend to a large extent in our safety work. Perhaps the most outstanding trait peculiar to most of us is the "desire to excel." It may be in golf, it may be in swimming, it may be in one of a hundred or more things, but way back in the minds of most of us is the desire to excel in something. The seed is there, sometimes deep-rooted, and it only requires the proper kind of direction and cultivation to reap the rewards of a golden harvest. Competition can be used very effectively as a forerunner to this golden harvest. You should be the judge of just what form it will take. Whether it be individual, departmental, plant, or all of these, you won't go far wrong. Offer some kind of trophy or award for the winners and then keep this award or trophy everlastingly in front of the employees. Most companies with good safety records owe in large part their success to competitive schemes. Competition is the life of the party.

Whether you agree with me or not, I firmly believe that the subject of discipline should play an important part in the safety program. Most games and sports have definite rules and regulations which govern the actions of the players. Failure to observe those rules and regulations means a penalty; sometimes a severe penalty. If at the start of the race the runner gets off ahead of the gun, he is penalized so many yards; a fairly mild penalty. In certain kinds of track meets if the runner steps out of bounds, he is disqualified; a very severe penalty. Rules and regulations to a certain degree are as essential to safety as they are to the games and sports. The penalties should be the same; severe or mild depending upon the particular case.

Safety is no sugar coated pill to be taken and then forgotten. It should have enough sting and pep to be felt all the way along the digestive system. If safety can't be sold to the employees on the cooperative plan, then it should be sold to them whether they like it or not. It is for their own good. But remember this; give the worker a chance; give him two chances if necessary. Then if he just won't come through, there is only one remedy left. Have incorporated in your safety program certain definite rules and regulations regarding penalties, and stick by them. Safety is the cheapest and most valuable thing in this old world of ours; yet some people want to pay the price of an arm or leg before procuring a little of it, and some people won't have it at any price.

I realize that I have only skimmed the surface in attempting to answer the question "What Is a Good Industrial Safety Program for a Plant Employing from 100

to 1,000 Workers," but I have given you what I consider to be the most important factors. Summarizing, I believe that a safety program, to be effective, should be composed of the following ingredients:

1. Definite active interest in safety from the highest executive down.
2. Sound Safety Committee Organization.
3. Good Educational and Publicity Methods.
4. Attractive Competitive Features.
5. Proper Disciplinary Measures.

Since the proof of the pudding is in the eating, I am going to give you one example showing what has been accomplished by a safety program similar to the one I have explained to you. This program is not infallible—nobody's is—but I want to tell you what the company with which I am associated did in reducing accidents by following this program. Our company operates four plants, varying in size from 200 to 5,000 employees. The program at all the plants was practically identical. Compared with 1926, our company reduced lost-time accidents 42 per cent; days lost due to injury 71 per cent; fatalities 70 per cent; and one plant went eight months without a single lost-time accident.

When an accident happens, you can buy new wheels, new pipes, new machinery; but what about the worker's hands, his arms, his very life? That one thought should be sufficient to spur you on to greater accomplishments in accident reduction and prevention; and to establish and put into operation a safety program so thorough in every respect that it ultimately would banish from this earth industry's illegitimate offspring—accident.

CHAIRMAN THALNER: Mr. Motley, you certainly have covered it in a thorough, interesting and instructive manner. I assure you, I voice the sentiment of this meeting when I thank you very heartily for your presentation of this subject. There is one other problem, the problem of a safety program dealing with plants in which there are less than 150 workers. That would fall in the category of this 68 per cent of our industrial establishments employing from 1 to 20 persons.

Without any further ado, I am going to call on Mr. F. E. Town, superintendent of the Manitowoc Portland Cement Company, of Manitowoc, Wisconsin.

What Is a Good Industrial Safety Program in Plants Employing Less Than 150 Workers?

By F. E. TOWN

Superintendent, Manitowoc Portland Cement Company, Manitowoc, Wis.

In preparing to present my ideas of a good safety program in a plant employing less than 150 men, I found myself immediately handicapped when I learned that this phase of safety work was to stand in direct comparison with the program of safety for the larger plant; for obviously we have many points in common and much that is essential of the work in the large plant, is also of prime importance in the small plant. It is unnecessary therefore for me to dwell on fundamental requisites which are of common knowledge to all of us, but rather to mention briefly a few of the advantages which the work in smaller plants has, perhaps, over the more or less stereotyped program so necessary in large industries.

Let us observe the company's attitude toward its problems in the plant and the personnel of the company as well as its employees.

Processes, production methods and capacities, neither require nor permit a machine-like precision of methods. The employee does not lose his identity, but is known personally by the various heads of the business who have at one time themselves stood shoulder to shoulder with these same men at the bench or at the machines, or who have personally inducted the novice into the policies and

purposes of their little industry. And so one of the prime requisites of a successful Safety program, is that the management and its lieutenants each have a keen appreciation of the importance of safe practices being introduced and enforced in their plant, from the standpoint of the employee's welfare as well as from that of purely good business economy. He must believe in every phase of the Safety movement, lest the man in the tanks doubt the sincerity of his purpose, and fail to catch for himself the true significance of Safety and the part it should play in his own life. Especially is this important because very few small plants afford the services of a full-time safety engineer. The management's zeal and sincerity of purpose in the Safety program will therefore be reflected in the attitude of the employee towards these plans, and half of the main objective will have been accomplished.

The employee's attitude toward them, and his reaction to the purposes of the management, is of equal importance, and how best to awaken in him, and maintain a true interest in his own safety welfare, constitutes an ever present task. But how may this be done most effectively?

No game, no task, no undertaking of any kind, can possibly command the same degree of interest of the observer that is experienced by the one who actually participates in that activity himself. This is none the less true of the small plant safety work. If you would be sure that "Safety First" is a live issue in your organization, build a workable plan that may well carry the daily slogan, "Think Safety" into each employee's mind as he approaches each job before him. Give him a personal part in the safety work of his plant. Permit him and require him to assist in carrying out the details of the program, then help to visualize the results.

This calls for a specific plan, which can only be developed as the needs and operating condition of each plant require, or type of industry permit.

I have in mind a company, which from its inception, believed in the teaching of "Safety First" principles, but only dealt with generalities in their safety practices, and much to their chagrin and disgrace, every year brought an increasing number of accidents—and perhaps a fatality or two. At last the management decided it could tolerate conditions no longer, and calling a mass meeting, issued an ultimatum, which carried with it promises of the severest penalties, even to an entire change of personnel, if immediate plans were not adopted whereby a marked improvement should be effected in the accident records of the plant. Such drastic action was not without results of far greater benefit than had been anticipated, all of which were brought about by the adoption of such principles as I have already mentioned. A detailed description of their program will well illustrate such a type of a specific plan as might well be carried out in many small plants. Naturally it is built around a wide awake safety committee, which meets regularly once a week at an hour established as best suited to that plant.

The order of business would be about as follows:

- Roll call.
- Reading of minutes of previous meeting.
- Inspectors reports.
- Recommendations of Inspectors detailed.
- Reading of Safety suggestions.
- Safety suggestions discussed and detailed.
- Appointment of Inspectors.
- Appointment of recorder inspector.
- Report on work detailed previous meetings.
- Report of departmental meetings.
- Reading of accident reports.
- Informal discussion.
- Adjournment.

Every member of the safety committee is required to attend the meeting unless

excused. An attendance record is kept of all members, and the personal written excuse of all absentees is read.

The safety committee is made up of foremen and departmental heads and an office clerk for secretary. Nothing but matters pertaining to safety may be brought up at the meetings. The inspectors are chosen from men in the ranks—and picked by their foremen. The number of inspectors should be limited to only such a number as is required to handle the work properly, without too great an outlay of time. Their written reports are turned in for reading at the meeting by the secretary, though they are expected to be present at the reading of their reports.

Under "Recommendations of Inspectors detailed," the Safety suggestions of the inspectors are discussed, and if allowed, are made a part of the safety program, are numbered and members of committee appointed by the chairman to carry out such suggestions as soon as possible.

Safety suggestions which may be turned in by anyone in writing, through the medium of the safety inspector or the safety suggestion box are next read and discussed, and handled in the same way as the suggestions from the Inspectors.

The item of business covering the appointment of "Recorder Inspector" needs some explanation and refers to a method by which each employee may visualize the results of the concentrated safety effort in his department or plant.

Some means, such as the arrangement of a registering device like a clock, a thermometer, or an actual tally recorder is used, mounted at a central station or bulletin board in each department. A master calendar is displayed, perhaps near the entrance to the plant where every employee may see it on entering. A smaller, but similar one, is placed in each department. Some place on this master calendar, is shown the standing or number of perfect days elapsed since the last lost time accident anywhere in the plant, as of seven in the morning of the current date. Also on the face of the master calendar, or on a nearby bulletin, is posted the name of one employee from each department, who has been selected for that day to operate the calendar in his own department. His knowledge of his appointment is gained only by a close observance of the calendar as he enters the plant.

The duty of the recorder inspector, who is a member of the Safety Committee, is to check up the recorders of each departmental calendar after nine a. m., if another day has elapsed without a lost time accident, to be sure that the employee selected from each respective department has properly observed the master calendar and bulletin, and carried out his duty as instructed by the bulletin. His name may appear at frequent intervals, or otherwise, at the whim of those responsible for his selection, and it therefore becomes obligatory for each and every employee to observe the bulletins and standings *daily*, thus starting the day with a safety thought in his mind.

If the recorder inspector notes a failure of an appointee to properly perform his duties, such failure is reported to the chairman of the safety committee, who properly reprimands the offender and posts his name on the master calendar the next day, as a slacker in the cause of safety. A second failure of an appointee to show the required interest in his departmental calendar and the plant record, must be reported to the Plant Superintendent, who should take summary action by immediately dispensing with this man's services, or giving him time to think over his shortcomings on a vacation without pay.

Such penalties may seem severe, but the careless man who is absolutely not interested in your safety program, is both an expensive and dangerous man to have around, and how better can you test each employee for his zeal in the safety program of your plant.

Each department is supposed to have its departmental safety meeting once every two weeks—for questions, suggestions and very brief discussion of safety matters. This is presided over by the foreman of that department, who permits only safety

matters to be dealt with at that meeting. At the general meeting of the Safety Committee he reports on his departmental meeting, clearing up any questions that have arisen, or bringing in the new suggestions.

When accident reports are read, the injured man is brought before the committee at the first meeting possible, to state particulars of accident, and assist in fixing responsibility for same.

All discussion is brief and to the point. All reports are in writing to save time. Thus what seems to be a most lengthy procedure does not generally require more than an hour, and the meeting is never permitted to exceed an hour and a half.

Permit me now to return for a moment to the personnel of the operating force. Obviously enough, the small plant is never required to employ men in masses or large groups, but rather singly, or a few at a time. They may therefore be privileged to more nearly pick their men, take only the better grade of labor, aiming at the proper ages, experience and sobriety of habits when work is concerned, that will guarantee to the management a regularity in the performance of duty, and a maximum interest in the plans, whether they pertain to production or safety.

Insist on knowing the physical fitness of the new employee. At least have your plant physician check him over for major conditions, such as sight, hearing, heart condition and hernia, and record the doctor's findings—it will save many a worry later.

Acquaint the new man with the safety plans and purposes of your organization. Establish a safety code and explain it to him before he is permitted to work. Watch the new man—protect him—educate him—he constitutes the greater liability on your safety program; the greatest hazard to your safety record. Beware of the drifter—he has no interest in the welfare of your organization, nor the safety of his fellow employees. I would not place an embargo, so to speak, on any class of labor. All able-bodied men must seek honorable, legitimate employment if they would maintain their self-respect. But the man of your community with a wife and children should have greater consideration from you for your vacancies, than that man who has only himself to provide for, and his greater sense of responsibility, both at home and on the job, may guarantee for you a better safety record. Check up on all illnesses—they may be lost time accidents in disguise, or potential future accidents. Establish one or more first-aid teams—the more the better—well distributed among the departments. Competitive drills by them will build up an efficiency that will make their assistance indispensable in case of accident. Then rule that after the arrival of the first four "First-Aid Experts," all other men are to return to their work. It will surprise you how much this will benefit the injured and reduce production losses usually arising, through either the sympathetic or morbid interest of the fellow employees. The majority of the men in your plant should know something about producing artificial respiration, checking the flow of blood, applying emergency bandages for broken bones, and especially know how to pick up a wounded man and put him on a stretcher.

Maintain a well equipped first-aid room and see to it that it is used. Immediate attention to slightest scratches and cuts requires such facilities, and is one more step toward creating the safety habit. A carefully kept record of first-aid administrations will surprise you at the number of cases arising daily, and convince you that you have a large number of potential lost time accidents, unless these precautions are rigidly enforced.

Perhaps the greatest single requisite, therefore, in a well-planned safety program, is education. Just as one's life's education is never completed—so we learn as we progress in this business of saving lives and reducing suffering, that Safety education must be uppermost in our minds, to ever observe the new type of accident, and by proper analysis, gain the lessons that can be imparted to our committees, from the committees to the foremen, and from the foremen to the men in the ranks. By constant study, similar types of accidents can be reduced in number.

The greatest aid to education is statistics. Unless you know where your accidents are the most frequent, what kind of accidents are the repeaters, what class of men are the greatest offenders, you are indeed working in the dark. Unless you know how your own safety records compare with those of similar industries on a man-hours basis, both for frequency and severity, you will miss an incentive that can do more to promote a healthy safety standard than any other one device. As competition is the life of business and industry, so it may also become the main-spring that will keep the wheels of industry turning safely. For what department of a plant will not resent the insinuations that some other group is showing better records than its own, in any line of endeavor, and statistics properly compiled may show its own standing on safety matters as compared with any others, or possibly that of the entire plant, with the average of other plants of the same industry.

This spirit of competition, combined with a visible emblem of their objective will also command the support of each employee. The sight of our nation's colors never fails to arouse a stir and thrill of patriotism and loyalty within us, and so it seems that once we raise an emblem, pledged to the significance of a true and lofty purpose, the sight of it floating to the breeze arouses a somewhat similar thrill. And if that purpose be the maintenance of a perfect safety record, exemplified by keeping the safety pennant flying only as long as the record is unspotted, every employee will jealously guard that pennant, and make every effort to see that he is not the one to bring it down.

Much could be offered as suitable plans and programs of safety in the small plant, and perhaps in each case they would be more or less individualistic, but I think not least of all fundamental general requisites is the personal touch; and I am reminded of an impression which came to me one time in Chicago as I boarded the "Twilight Limited" for Detroit. It is a beautiful train—every car of nearly uniform design, the very latest ideas in furnishings and equipment, and all carrying the atmosphere of solid comfort, luxury and safety. A well-groomed porter waited at every platform to assist the passengers. The train officials stood alert, with a thought on the schedule of the trip, as the time of departure drew near. Busy men and women hurriedly sought their reservations, said farewell to a friend, sent a belated message, or settled themselves to read the latest issue of the daily news. On every hand one was made aware of the fact that he was aboard a popular high-class train, and felt a certain sense of satisfaction and security.

I chanced to look over on another track near by—and there stood another train, probably made up for a second section of the train I was on, as it had the same type of cars and equipment. But not a train official or employee, nor a passenger, was to be seen in or near it—it was simply an assembly of cars. It had no appearance of going any place—apparently not scheduled—no warmth—no life—no appeal to the imagination of the traveler—and what was the difference between the two assemblies of equipment? There was absolutely no difference except in the purpose—the schedule—the personal contact—the human touch. And since I was on my way to attend a state safety conference, the analysis of the thought brought to me a striking parallel to the comparison of the conditions in some plants with those in others.

That small company which cannot put the human touch into its Safety program and which will not establish personal contacts with its employees on at least one or two stated occasions each year in behalf of safety, such as through mass meetings or banquets, is destined to fall short of the true aim of its safety program. After all, to quote P. B. Juhnke in his splendid thoughts on Safety—"the end is that the workman shall live to enjoy the fruits of his labor; that his mother shall have the comforts of his arm in her age; that his wife shall not be untimely a widow; that his children shall have a father, and that cripples and helpless wrecks, who were once strong men shall no longer be a by-product of industry."

CHAIRMAN THALNER: Mr. Town, we have thoroughly enjoyed this paper, particularly so, because it has been delivered by a superintendent of a plant. We safety engineers get together and give our papers, but it does my heart good to have a superintendent or operating official other than a safety man come into our meetings and give his viewpoints and ideas on a safety program. We thank you, very kindly.

Now, is there any discussion which you want to bring up?

MR. GREEN (Louisville Car Wheel Company, Louisville, Ky.): I would like to ask the men here who represent plants of 150 men and under to please stand up.

(Eight members arose)

MR. GREEN: Will those who are in plants of over 100, but under 150 sit down? (That leaves 3.) Thank you, gentlemen. The reason I ask that is, when the first program was sent out for this National Safety Congress, I saw that we were to have this topic and then a discussion of plants having 150 men and under. Incidentally, I might say our own plant is under 100. I wrote to Mr. Cameron and told him the big problem, as I saw it, is the plant of about 50 employees and under. I don't know whether that bunch of statistics you have there, Mr. Chairman, gives the average of plants all over the United States or not, but I was shown by the Secretary of our Board of Trade, Government statistics which showed that the average number of employees in the plants is 42.

Now, of course, that means that a great many plants must be very much less than 42, as you have shown here in your figures. In four of the meetings I have attended at this Congress, the point has been brought out that, practically speaking, the large plants, the large employers, have gotten past this problem of safety; that is a thing of the past because they all believe in it and the managers and superintendents believe in it. But the fellow we have to go after is the little fellow like myself.

We have been working on this thing with the National Safety Council since 1916. When I got in it, if anybody had told me they could go a year without a lost time accident, I think I would have laughed at him, but we did that thing last year, and we have gone so far this year without a lost time accident. The point, though, that I want to bring out is this; when we go back home, we ought to get started on some kind of a program. I have been the vice-president of the Louisville Safety Council for some time, and I want to make that one of the features for the coming winter. We must interest the employers in the small industries in safety work. It doesn't matter whether the place is a foundry, paper mill, pulp mill, or what. The problems are the same. The small employers must be interested in the safety movement, and I think we are the fellows who have to do it.

MR. OLER (American Ice Company, New York): I happen to be an officer of the American Ice Company. We operate approximately 75 factories all over the Eastern seaboard, from Boston down to Washington. It is peculiar to our type of manufacturing that even though some of our plants occupy nearly a square block and are sometimes two or three stories high, still we will not employ in that plant over 50 men. I would like to ask if any gentleman here can give me (it is not necessary to take up the point here) any suggestions on how we can (we are compelled to operate our plants 24 hours a day on 3 shifts) effect a workable safety program in those plants? I can take his name, and I should be glad to get in touch with him later. It is a difficult problem.

GEORGE McLAIN (Jones & Loughlin Steel Co., Pittsburgh, Pa.): I shall be glad to get in touch with that gentleman.

CHAIRMAN THALNER: Any further discussion? I wonder how many of the representatives here employ from 150 to 1,000 workers; will you kindly stand up?

(About 17 members arose)

CHAIRMAN THALNER: How many employ over a thousand?

(Fifteen members arose)

CHAIRMAN THALNER: The fact that we have a count of this representation here may aid the committee for next year in formulating a program toward getting a man interested whom we feel should be more interested in safety work—the smaller manufacturers.

MR. GREEN: The other problem we have, of course, with the small man is to get him to attend these meetings. He feels that the expense of coming to the National Congress is more than he can afford. He may have 45 employees. If he comes from Louisville, the cost would be around \$125 or \$150. The expense per man is about three dollars. If we could sell the idea that three dollars a man per year for safety work is not very much, we may be able to reach him, but ordinarily it just looks like \$150 out of pocket, and he says he can't afford it.

W. W. WILLIAMS (Employers Reinsurance Corp., Kansas City, Mo.): It would be manifestly unfair to say that the small man, or rather the small plant, is a small plant because it has a small man at the head of it. But, from an insurance standpoint, gentlemen, it is the small plant that produces the bad losses. Their loss ratio is invariably bad. The larger plants, because of their greater facilities, greater capital, and possibly more brains, are able to get into the safety game, and get out of it as much as they possibly can. But the small plant, whether they have a small man at the head or not, is in a different position. If they have a small head, it will always be a small plant. They never will get anywhere in the matter of safety because that man hasn't the time even to think about safety. He is only two jumps ahead of the sheriff in trying to get his payroll together. He is really the man we ought to work upon. There are literally thousands of small plants employing from 10 to 50 men which have never made a move towards organized safety. There is where we should spend a lot of time and effort.

MR. GREEN: Some of these small plants do not have small men at the head of the plant. That is to say, that man is able to reason. There are some, of course, that we never are going to get. They are small and they are going to stay small. However, many of the other small plants are simply waiting for somebody to help them develop and grow up.

MR. GILMORE (Columbia Casualty Co., New York): The fact has been stated that you have a severe problem in the small plant. I think, if you will stop to reason, if you take the plant at the present time employing from five to ten men, you will find that it is an outgrowth of one man's brain; the man at the head of it is a man who has worked himself up through the trade. He has gotten a little bit of money together and has gone into business. He worked at the bench probably in the old days, when ship loads of fresh immigrants came over, flooding the labor market. Those were the days before the safety organization. That man still has the idea in the back of his mind that, "I always worked with an unguarded saw, I never had any guards on a punch press."

You run up against a lot of opposition in that respect. While that man may agree with you if you try to interest him in the subject, he has a mental reservation back of it. The men working with him also take the same attitude. I find in going around (my work takes me occasionally into different types of industries) that where it is an organized business with 10 or more employees, the condition is different. The men at the head of it, as a general thing, have some appreciation of what can be saved in dollars and cents by safety work. That business probably has grown over a longer period of years, and their experience has been greater. The larger the plant, the less opposition you get to any recommendation based on the sound knowledge of sound engineers.

CHAIRMAN THALNER: It seems to me that the problem of the small plant with regard to getting the man interested would be reflected to a certain extent in his bad experience. The time is going to come, or probably has come when, if he isn't interested in safety, through a bad experience, he will be forced to pay higher rates for his compensation insurance. Then he will wake up to the fact that he

should do something for accident prevention. Of course, that isn't the proper way to bring the thing about, because we know through experience that safety work is not only economical, but humanitarian as well.

If we can get this fellow interested, much gain can be made, through this representation here. When you go back home, see if you can't interest yourselves in one or two of these men, and through your local Safety Councils or your State meets or regional meets, bring them into contact with the subject to the extent that they will be thoroughly saturated with it. We undoubtedly can make some strides in attempting to solve the problem of the small plant.

ROBERT M. BOON (DuPont Co., Portland, Me.): One thing that interested me (this is the first time I have had the opportunity of attending these meetings), is the number of insurance men we have present here. I think we must face the conclusion that the greatest incentive in safety is an economical one. We can get ourselves into believing that we are doing this entirely for the altruistic or humanitarian side of it. We may pat ourselves on the back and grow a few wings on our shoulders when we get that idea; but I believe that safety first and safety programs are put on from an economical standpoint. There are so many insurance men present that I am led to that belief. They are interested in reducing these accidents so that the rates can be better. Some times the risk is so great on some of these plants that they can't take it. They want to reduce accident risk so that they can take insurance on a reasonable basis. I don't say they are here solely from an economical standpoint, but I think that is the first consideration.

After you get into this safety work, you will find it gets to be not a religion with you exactly, but it is something that gets right down deep into your hearts. The economical saving that we can stress, I believe, from the viewpoint of the small manufacturer, is what we need to get him interested. I don't think you will reach these men by preaching a sermon about doing good toward their fellowmen. I think if you show the small manufacturer the hard dollars and cents side of it, he will see that it is a good proposition to put a safety man in his plant. After you get him that way first, sooner or later, you may make him a disciple of safety.

MR. McADAMS (Columbia Casualty Insurance Co., Boston, Mass.): Of course, this may ultimately materialize into a debate between his point of view and the point of view of the insurance men represented unless we are cut off very shortly. Unfortunately, the example the gentleman cites is too frequently found among the employers of labor. I maintain nothing greater than to stress the fact that every man who has somebody working for him has a deep moral obligation toward that man, *irrespective* of the economic situation.

CHAIRMAN THALNER: Whether we consider it as economic or humanitarian, the fact that a man can earn a full day's wages is economic and also humanitarian. Is there any further discussion on the subject?

MEMBER: I do not think it fair or scientific to assume that the reason why the small plants produce the largest or worst accidents is because the superintendents or managers of small plants are less intelligent or less earnest about safety than the managers or superintendents of large plants. The manager of a small plant has duties for which specialists are hired in the large plants. He must be shown how to accomplish a safety program under different conditions. He therefore must be educated as to how best he can accomplish this work. I believe that is the object of these small plant meetings. I hope they will be continued. I might say, as representing eight small plants, that one of them has not had an accident for four years. We do not feel that we are small men, although we hold a small position.

ADJOURNMENT

*SEVENTEENTH ANNUAL SAFETY CONGRESS
NATIONAL SAFETY COUNCIL*

Group Plant Safety Supervisors Session

October 2, 1928

W. H. WINANS, Chairman

Manager, Industrial Relations, Union Carbide Company, New York City

The Group Plant Safety Supervisors session at the Seventeenth Annual Safety Congress was called to order at two-ten o'clock by the chairman, W. H. Winans, Manager, Industrial Relations, Union Carbide & Carbon Corp., New York City.

CHAIRMAN WINANS: We are going to change the order of the program slightly. Major Reninger has another meeting that he really must get to as soon as possible, so Mr. Hoyman has kindly consented to permit him to read his paper first; and we will have a short discussion immediately following it so that he can get away to the meeting of the Cement Section, which he has to attend.

Those of you who know anything about what the cement industry has done in recent years in promoting safety, and particularly what the organization that Major Reninger has been connected with has done, realize that some worthwhile things have been accomplished. I don't know just how much he is going to tell us but under the subject that has been assigned, it ought to be possible for us to get something from the experience of a large organization with branches operating over the country, that will help us put this game across. Without taking further time, I have the pleasure of introducing Major Reninger, of the Lehigh Portland Cement Co., Allentown, Pa.

Sowing Seeds of Safety in the Major Departments of a Company

By HENRY A. RENINGER

Special Representative, Lehigh Portland Cement Company, Allentown, Pa.

Twenty years ago safety in industry was practiced by very few concerns. Ten years ago the National Safety Council was becoming established and known. Many people, even at that time, felt that safety was a theory and not practical, but the Compensation Laws compelled them to make necessary revision in equipment and design, to guard the dangerous parts of machinery which had in the past been responsible for many serious and fatal injuries. Large sums of money were spent, and while accidents were reduced they were not reduced to the extent which had been looked for and we began to realize that the guarding of machinery

was not the most important part of safety work. The education of the executive, department heads, superintendents, foremen and employees, was the big problem.

In giving you this informal talk I, perhaps, am bringing out some of the problems that I ran up against in my own organization, but I believe they will be of interest, for it will give you a general idea of what group plant supervisors are up against in a fair sized corporation, with plants scattered in various parts of the country.

We had more or less carried on safety work and had organized committees in 1915. From 1916 to the end of the war there was no general supervision of the work, but the safety committees functioned and did certain jobs, as protecting and guarding machinery and complying with any rules and regulations issued by the insurance company or State inspectors. However, the results had been more or less unsatisfactory and after the war, upon my return, I was told to carry on this work and organize it and see whether we could not cut down the toll of accidents which cement plants were then having.

Perhaps the simplest way to get a department started is for the president of the corporation to issue a letter to all departments and plant superintendents, announcing the creation of a safety department and instruct all departmental heads to cooperate. By so doing all officials know that this work is approved by the head of the organization. From then on it is the duty of the safety director to sow the seeds of safety among all departments and persons directly affected by this new program. It means that the Safety Director must keep a full and complete record of all accidents and the cause of the same; that he must put this information in such shape that it can be read by the chief engineer, the executive officials of the company, plant superintendent and department heads.

Sowing seeds of safety can be done in many ways and I don't believe that just the sending of reports to these various officials is the best means of bringing this to their attention. Personal contact with the various department heads and executives, the telling of the story of an injury to an old employee or the fact that an employee was killed, leaving his wife and several children to be taken care of by others.

Naturally the treasurer or comptroller of a company will be interested in safety from the financial standpoint and reports showing cost of accidents, cost of compensation insurance, etc., will interest him because that is his particular duty.

After years of experience we are able to compare one year's cost with another and where you show a saving and accumulate a surplus they will begin to realize that safety is not a fad but is a real saving.

I think you men have all had that same experience, that it was pretty hard to get the treasurer or the controller interested in safety; and when you brought up a bill for \$300 or \$400 for some certain thing for the safety department, they very often questioned whether it was a worth-while expenditure. However, after you can show them these reports of several years' experience and where your insurance premium is coming down and your compensation is coming down, then the treasurer or controller begins to sit up and take notice.

How can we interest the principal departments in a big organization? The Engineering Department, for instance, I find that the material of greatest interest to the Engineering Department is reports and charts showing accidents, days lost; also man hours and days lost per 100,000 man hours with a curve showing production.

A ten-year report that has just been worked out showing all these figures has proven very interesting not only to engineering but to all departments. However, reports of this kind do not mean very much to sales, traffic, advertising, and they must be reached in a somewhat different way. Our Engineering Department ap-

preciates reports and charts and it is also the duty of the Department of Safety to keep them advised on any new laws and regulations in various state departments; to furnish them with copies of any new codes. Our Engineering Department receives a copy of every Safe Practices Pamphlet issued by the National Safety Council, and we find that they make use of these safe practices many times in the designing and construction of new buildings. We also keep them advised in regard to anything new in the way of fire protection and fire prevention. Any new inventions that will improve the safety of any machinery in use are also furnished to the department.

Operating in nine different states, we take very particular care to keep in touch with the different factory laws and Department of Labor laws that may affect in any way our plants, and particularly to see that the engineering department gets a copy of these laws. We furnish them with copies of any new codes.

We take it upon ourselves to see that they are furnished with anything new, whether it be a newspaper clipping or an advertisement from a magazine that may be of interest. We shoot that down to the vice president and chief engineer who, I am glad to say, takes a very keen interest in all of this work.

In regard to the Purchasing Department, we also try to keep them advised of anything that is new and the Engineering and Purchasing Departments work with the Department of Safety in seeing that new machinery being purchased has all the proper safeguards. Any help that the safety engineer can give to any of these departments is appreciated, and after gaining the confidence of these departments you will be called in from time to time to make recommendations.

The Traffic Department's interest and cooperation was aroused through the report of the Safety Department showing the number and bad order in which cars were received at the various plants and which were hazardous in unloading. Every accident, where a man is hurt in unloading cars due to faulty equipment, is referred to the Traffic Department, and this report, through them, is forwarded to the railroad. By having our Traffic Department take an active interest in this work we find that the rolling stock coming into our plants from the mines is in better condition than ever before.

Up until we started this particular means of keeping them advised of accidents, they never did show any great interest in the safety department; and it was really through the vice president and general traffic manager, who came to me and wanted to know why any dealings with railroads in this particular line were not taken up with the traffic department, that we got their interest. He said, "We will do it. We will be glad to do it, and it is our place to do it." I was perfectly willing to shoot the stuff over to him and they handled it from there on, I am glad to say, very satisfactorily.

The Sales Department, in many ways, has no connection with the Safety Department. They are employees who are not exposed to the hazards of a plant and their main job is in selling. However, they recognize the Safety Department for the simple reason that every employee's registration card must be made out and sent to the Department of Safety, who also handles personnel records. Interesting bits of information are sent to them from time to time. Every salesman on the road driving a car was furnished with a set of Safe Driver's Practices, with a letter accompanying the set advising them that, at the request of the vice-president, this was being forwarded to them for their information and study. All accident reports, of course, are handled by this department and all minor injuries to office employees are treated in the department; all departments call upon us in emergency cases, whether sickness or accident.

We are called in from time to time to help them out. Many times we have taken over the matter of funeral arrangements and things of that sort, where these different employees, no matter in what department, call us in and ask us for advice, and we are only too glad to give it to them.

The sales department about three months ago organized a class of student salesmen, put them all through a training course, and part of the course now consists in sending these men out into material dealers' yards. They seem to feel that a salesman, by visiting the various material dealers' yards, will be better able to help the dealer talk on the subject if he knows just how a material dealer's yard is run. So today we have 20 men taking a two-months' course in various yards throughout the United States; going in there and reporting at six or six-thirty, and working as a laborer in the yard, loading or unloading lumps, breaking cement or anything else.

When the class of student salesmen were about ready to go out on the road and to spend a certain number of weeks in dealers' yards, the Sales Department asked our help and to talk to these men on the hazards they would run up against in the material dealers' yards. We were only too glad to give them a forty-minute talk, and found all of the salesmen very much interested in the subject, so much so that many of them have written in for further information on the subject of safety, fire prevention and housekeeping in yards.

The handling of all accident reports for the salesmen on the road has tied in these men, with the result that, from time to time, this department is able to render a service here or there for them and receives due recognition.

The personality of the safety director must be such that he is on friendly terms with all officials and department heads and he must take advantage of every opportunity to tell the officials interesting stories of things happening in and around the plants. This must be done in such a way that it does not become tiresome. He must have at his fingers' ends the facts and figures—number of man hours worked, number of man hours lost, cost in dollars and cents; also the amount of savings. He must remember at all times, however, that these various department heads have problems of their own. The superintendent and manufacturing departments have their daily problems and safety is just another one that is added to the burdens which they already have; therefore, he must sell this idea in a way that will bring them to feel this job is one that must be done, not under compulsion, but because they have been shown it is of benefit to them in their production work. He must not assume the attitude that he can command attention and conformities to the rules, because the chief executive has issued an order that safety must be carried on—if he does he will not get very far.

I attribute my success to personal contact with the superintendents, with the department heads, with the foremen, and I believe that all the work that has been accomplished in our own organization has been due to our getting around and meeting with the foremen, sitting down and talking to them and going over that old story that we hear; getting to know them and finding out what is on their minds, and letting them know that the boss is interested and that you are going out 200, 300, 400, 1000 or 1500 miles just to see them from the main office. I believe that is the one thing that has helped us as much as anything.

The chief engineer, the chemical engineer and the sales manager are not hired to help the safety director—they are hired to work out their own problems and carry on their own work, but it is necessary that the safety director so interest them in his department that they will be only too glad to work along with him.

Sowing seeds of safety is like sowing seeds on a field with a very high wind blowing. They do not always land where they are intended to, but are scattered sometimes to the four winds and many times take root and grow where least expected.

There is no question in my mind that the safety director has one of the most difficult jobs in a company. He must show the Sales Department that safety helps them in selling the product; also the Advertising and other departments that it is helping them in their work.

Accidents are expensive and they do not make profits for the company. Many companies do not know the cost of accidents because they do not keep accurate records, but where these costs are known and by safe practices accidents are prevented, the work of the Safety Department is shown to be a benefit to the company in a financial way and its recognition is assured.

When a report can be shown where a plant was spending from five to ten thousand dollars for compensation, medical and hospital each year for a period of five years, and then for the following five years a report shows they only had three lost-time accidents, with one compensation case, with the saving running into tens of thousands of dollars, all department heads will sit up and take notice.

Reports should be made interesting, simple, and not tiresome. If they do become tiresome they will not be studied.

There is no question in my mind but that in every organization we have different problems—different types of department heads to handle, and every safety director must work out his own problems. Every safety director must be a lifter, not a leaner. It is his job to be of help wherever possible to any department at all times; the less favors he asks and the more help he can give, the better his reputation with the various departments.

I never had any order issued by the president of our organization, but when I came back from the Service and reported back to the company, they gave me a desk and chair and said, "There is your office. This safety work seems to work out all right; it went along during the war and it helped some. We don't know anything about it. Now, there's your corner. Go to work." Those were the only instructions that I ever had in the work we have built up, and the work that we have accomplished has just been a gradual building up of this department which, by picking up the odds and ends that you find in a corporation—such as fire prevention, fire protection, personnel, reports on labor turnover—has become a self-insurer in most of our plants. The safety director, to my mind, has an opportunity of building for himself in any organization, if he is willing to work and keeps his eyes open. If he just goes along the line of least resistance, he will not get anywhere. You can't force safety down the throats of your department heads but you must interest them and be of service to them. Regardless of whether it be called the department of safety, welfare, industrial relations, or what not, let it be a "service department" for any and all departments covering almost everything; and if you once can give them a service in one line, you can gradually draw in safety and get them interested.

CHAIRMAN WINANS: Thank you, Major Reninger. It is very obvious from the approach which the Major has made to this subject that it is assumed that those of us who are here are confronted with the problem of accident prevention in branches of a main office organization. His paper has gone at the proposition from the standpoint of getting the general departments which come in touch with all branches, all working toward the same end.

We will take five minutes, if you want to use it, for discussion of this paper or for questions at this time. If you don't use it, we will go to the next paper.

DONALD SHAW (Hercules Powder Co., Wilmington, Del.): I would like to ask the Major if any attempt is made on his part to show his directors or his management the indirect costs? For instance, you show the direct costs, but are you beginning to make a study of the indirect costs in line with the study recently made by the Travelers Insurance Company?

MAJOR RENINGER: We are doing that, but we don't have enough information to make it worth while over a period of only one year. However, as time goes along, I think we can accumulate more data to make it pretty worth while. You

know it is pretty difficult to show the executives the total cost of accidents or the total cost of labor turnover or the actual saving that you can effect through your safety work. We do know how much we have saved each year on our compensation insurance but we can't say just how much we have saved in other ways, such as labor turnover and machinery spoiled, and things of that sort. We are trying to get that information, however, according to Heinrich's way of keeping track of it, of the Travelers.

G. A. ORTH (American Car & Foundry Co., New York City): Mr. Chairman, Major Reninger made reference to the attitude of the sales department in his safety work. I just happen to have a letter in my pocket from the sales manager of our concern, and I think it is quite appropriate that I read it to you. It is food for thought, I think, for everybody here. This letter is addressed to me and reads:

"Permit me to express my appreciation of the fine showing the safety department has made in the minimizing of accidents in our shops.

"Aside from the humanitarian feature, which of course is the big consideration, everyone realizes that a smooth running organization and continuous performance is productive of the best results in the time of delivery, as well as in the maintaining of the lowest possible labor costs, both of which are of vital importance in our work of selling the company's products.

"In these days of keen competition, every little detail has its bearing in the awarding of business and were we to suffer a delay on a contract, due to some accident in the shop, it would work to our detriment when that customer was next in the market for equipment, if indeed they did not penalize us for the delay in the delivery of that particular order.

"Any reduction that is shown in the cost of accidents naturally has the effect of reducing our production costs, better enabling us to meet competitive prices and provide work for our shops.

"As stated above, we are fully appreciative of your past efforts and wish to assure you that every member of our sales organization is interested in the work. If there is, at any time, anything that any of us can do to advance the cause of safety, we will be only too glad to do so.

(Signed) Vice President in Charge of Sales."

CHAIRMAN WINANS: The next subject is to be presented by Mr. M. G. Hoyman, Staff Superintendent of Service, Kimberly-Clark Company. We have all heard a good deal about what Kimberly-Clark has accomplished in safety and I know it will be of a good deal of interest to hear from Mr. Hoyman as to how it has been done.

How We Keep Safety at Work in Our Distant Plants

By M. G. HOYMAN

Staff Superintendent of Service, Kimberly-Clark Corporation,
Neenah, Wisconsin

Several pulp and paper mills of the Kimberly-Clark Corporation are located within twelve miles of the general offices in Neenah, Wisconsin. Another group of mills may be called "distant plants." One mill in this group is 130 miles from Neenah; another mill is 700 miles away; another mill is 1,400 miles away.

My frank opinion is that the administration of safety work in a number of outlying mills differs but little from the administration of safety work in a single mill or in a number of mills situated near each other. Each mill has its own risks and problems. Before safety can function in any given plant a program must be built around the plant's needs.

There are few devices or procedures specifically designed for "Keeping safety at work in distant plants." The fact that some of our plants are separated from others by many miles has not been a large determining factor in our choice of safety organization and safety methods. Nevertheless, we feel that our safety organization and methods have been successful in keeping safety at work not only in our near by, but also in our distant plants.

Therefore, I shall describe some of our safety methods which seem to work particularly well in our distant plants. I shall point out all their characteristics which are results of the distant location of the plants. Then I shall attempt to generalize upon our experience. I hope that from these remarks and from the ensuing discussion you may get some ideas on adapting our findings to your own needs.

Before describing our safety work in distant plants, we might see how well that work has succeeded in reducing frequency and severity of accidents. The proof of the pudding is the eating. Allow me to give you some data upon safety results in a mill which is 130 miles from our Main Offices.

During the four years, beginning with 1914, this mill had an average of 105 accidents per year. As a result of these accidents an average of 1,401 working days were lost each year. During the four years beginning with 1924 this mill had an average of only 11 accidents per year. As a result of these accidents an average of only 593 working days were lost each year. The days lost in the later period were less than half the days lost in the earlier period despite an increasing pay roll.

The progress of safety in this mill may be shown in another way. During the four years beginning with 1914 there were 16 accidents per year for every 100 men on the pay roll. During the four years beginning with 1924 there were but two accidents per year for every 100 men on the pay roll.

During the four years beginning with 1914 the lost time caused by accidents in this distant mill amounted to two days per year for each man on the pay roll. During the four years beginning with 1924 the lost time caused by accidents amounted to but one day per year for each man on the pay roll. During this ten-year period the accident frequency rate was cut down to about one-eighth (12 per cent) of its original value. The accident severity rate was cut down to less than one-half (47 per cent) of its original value.

In another large mill the last decade has seen the accident frequency rate reduced to 11 per cent of its original value and the accident severity rate reduced to 36 per cent of its original value.

What are the safety devices and procedures which have accomplished these results in our Distant Plants?

One of our favorite devices is the safety contest. The contest is serviceable in creating the proper feeling and attitude in the employees. The contest develops that group emotional state in which each man in the mill feels himself participating in a big worthwhile campaign. The contest itself does not produce lasting results. Emotional states quickly wear out. However, with employees stimulated by the contest, the safety director can build permanent safety foundations.

Our contests are not forced affairs. The contest is not put on until some mill or department is anxious for it. Contests are arranged only on request. Usually the contest is suggested by some department or mill that feels pretty strong in safety, and is looking for a fight with some other department or mill.

The fact that mills participating in a contest are many miles apart is no handicap. We maintain interest in safety in distant plants by a rather elaborate system of bulletins. These bulletins bring each mill in close contact with other mills. Early in our safety experience we found that it was necessary to have some definite information as to progress made in safety work, and as to the results obtained from specific action taken. Adequate information on safety progress in all units of the company is the key to keeping safety at work in distant plants.

We first had a weekly bulletin. This bulletin merely gave information on the number of accidents in the different mills each week. We have constantly added to the information contained in the bulletin so that it now shows the names of all departments, the foreman of the department, the number of employees in each department, the frequency of accidents, the days lost from each accident, and the cause of each accident.

These bulletins are posted in each department every Monday morning. Each superintendent receives one. Bulletins are exchanged between all plants in the company and a bulletin from each plant comes to the central office each week.

When the contest is at its height we frequently use the telegram to broadcast the standings of the competing mills. A typical telegram reads thus: "Niagara had an accident, Alfred Gercu, construction laborer, while getting off truck wrenched knee, lost one day, Tuesday, June eighth."

At this point I would like to ask two questions. Why is it that mill managers, mill owners, insurance companies, doctors, and social workers were the originators of safety campaigns when they were not the people who were getting hurt? Why is it that the workmen who lose their eyes, their hands, and their lives seem to be least concerned about accident prevention?

We think that the answer is this: The mill manager, mill owner, insurance company, and doctor are so situated that they see accidents in the mass. The individual worker personally comes in contact with few accidents. We have found that the greatest single factor in reducing accidents is to give to the average worker the mass-view-point of accidents. When he sees accidents not only as an industrial problem but also as a personal problem it is surprising how soon he becomes interested in safety work.

One of our most effective safety devices we call the "One Hundred Year Safety Man Award." During the last five years this device has been used with success in all our mills, and with especially great success in our distant mills.

The essence of the "One Hundred Year Safety Man Award" is this: By working safely a certain number of man days, every man in a department from superintendent to sweeper receives a brand new five dollar bill.

To illustrate: There are 310 working days in one year. One hundred men working one year would work a total of 31,000 man days or 100 man years. The five dollar award is made when the "Safety Man" in the department is 100 years old. For instance, a department of 100 men working safely one year, or a department of 50 men working safely two years, or a department of 200 men working safely one-half year would receive the award. Deductions are made from the age of the "Safety Man" for accidents and for days lost.

We have tried to keep this "Safety Man" award from entering the ranks of commonplace things by making a great deal of it. We close down the department for five or ten minutes to make the award. We have an official of the company speak briefly congratulating the men on their fine record.

We make no secret of the fact that safety means profit for the company as well as profit for the men. We explain to the men that by working safely they help us to carry our compensation insurance. Five hundred dollars is a low premium to pay on the safety of 100 men for one year.

A certain construction crew at one of our distant mills affords a good illustration of the effectiveness of this plan. In the days before the plan was adopted this crew had many accidents. After the plan was adopted this crew made the then unheard-of record of going four calendar years and receiving the prize four consecutive times without a single accident.

I said "construction crew," which you construction men all know is rather a dangerous term to use. I just received a report, before I came down to this meeting, of a department that became eligible for this award. It was the fifth consecutive time without a break. If there are any paper mill men here, you

will understand what I mean when I say a Groundwood Department, where they grind up the wood. There are all the way from sixty to eighty and ninety men, and sometimes even as many as one hundred, engaged in that work. Five consecutive times took them over five years.

Our safety suggestion system is another device which helps to keep safety at our distant mills. Excellent safety suggestions have been made by employees. A man whose suggestion is adopted acquires the sense of company citizenship. He feels that he is a part of the company as a whole even though he is employed in a plant which is a thousand miles from other plants.

I know that happens to be the problem of a great many people; that is, how to get safety suggestions carried out and have the suggested repairs made. We probably went through the same thing that many of you have. A man makes a suggestion down in the mill to his foreman, and if the foreman sees fit to carry that out, well and good. If not, he tells the man, perhaps, to forget it, or at any rate he forgets it, and a good safety man is spoiled in the making and becomes discouraged.

We overcome that somewhat by getting out a safety suggestion form. It is made out in triplicate. Every foreman carries a book of these. Our Council representatives have a book and we have some books in boxes put around through our mills on purpose to keep these in, so they might be available to the men. The idea is that if a man comes to his foreman and makes a safety suggestion, it is the foreman's duty, which he well understands now, that he is to take out his book and make out this recommendation or suggestion in writing, giving the man a copy of that to show that he has made it out; keeping one in his book, and sending one to our "Service Department." The man delegated to that work in our service department goes over the suggestion with the foreman and the man who originated the suggestion. This service man, if he deems that the suggestion is worth while, is authorized to write out an order to have that work done. If they find that it is not feasible, he is instructed to inform the man, giving him the reason why. Until we worked out that scheme, we had the same trouble that a good many of you have in getting Safety suggestions carried out.

Safety cannot be kept at work either in outlying or in nearby mills without the intelligent cooperation of the foreman. It is not the foremen's function to arouse emotional interest in accident elimination—that is done by the contest. It is not the foremen's function to educate the workman in the causes and results of accidents—that is done by the bulletins. It is not the foremen's function to give a monetary reward for safe work—that is done by the One Hundred Year Safety Man. It is the foremen's function to unite safety and work. Safety must not be looked upon as a thing separate from work. Safety is a method of working, a method which in the last analysis is under the control of the foremen.

We put the safety responsibility squarely up to the foremen, especially to the foremen in distant plants. These foremen feel that accidents are their own fault. We do everything to encourage that feeling.

I have touched upon here only those safety devices and procedures which in our experience seem to have been successful in "Keeping Safety At Work In Distant Plants." I have not mentioned our methods of introducing the new man to the job, and training him in safety ways. These things and all the other orthodox elements of personnel administration obviously do their part in "Keeping Safety At Work In Distant Plants."

CHAIRMAN WINANS: Thank you, Mr. Hoyman.

With your permission, we will ask you to keep your notes of the questions you would like to ask Mr. Hoyman—I know you have some—until we have given the other two men scheduled on this program a chance to present their side of the

story, and then we will come back, go after Mr. Hoyman on his subject, and Mr. Beck and Mr. Lundrigan on theirs.

At this time I will ask Mr. Ed Quesnel, of the Commonwealth Steel Co., to take care of this next item on the program, which is the election of officers for this section.

E. G. QUESNEL (Commonwealth Steel Co., Granite City, Ill.): Mr. Chairman, Ladies and Gentlemen: You heard your Chairman request a discussion on Item No. 3 on the program, Election of Officers. This is a rather unusual departure from our previous practices. Those of you who have been attending previous Congresses know that we have not been electing officers. They have been appointed. The section has been unusually successful. Our meeting today testifies to that point. Those in the front, if they will turn around, can see how successful it really is. It is not the largest, but I think it is one of the largest in attendance at the Congress.

In previous years the officers have been appointed by the National Safety Council staff; subjects have been assigned and speakers secured, but the section has become so important and so valuable to industry at large that they feel that it should be self-supporting and that even more interesting subjects could be selected if officers were elected by this section who were identified directly with group plants and who could pick out subjects which would be interesting to the largest number. So that they have this year asked us to take up the reins and elect our officers.

Just a word in regard to the duties of these officers. They will have no committees to appoint; they will have no sectional meetings during the year to arrange for. The sole purpose of these officers will be to get up as strong a program for the next Congress as possible. So, in order to start it off, the President of the National Safety Council, Mr. Homer Niesz, appointed a Nominating Committee for us. These gentlemen are Mr. John Gibson, Chairman, of the Western Electric Co., Mr. George E. Sanford, of the General Electric Company, and Mr. T. O. Messenger, of the American Can Company, all very splendid gentlemen whose judgment we can rely upon for picking first-class men.

If Mr. John Gibson is present, will he please come forward and give us the nominations for Chairman, Vice Chairman and Secretary.

Report of the Nominating Committee

JOHN GIBSON (Western Electric Co., Chicago, Ill.): Mr. Chairman, the Nominating Committee has had several hectic sessions which have culminated in a harmonious selection of three individuals whom the committee now wishes to place in nomination as follows:

Chairman of the Section—Carl B. Auel, Manager, Employees Service Dept., Westinghouse Electric & Mfg. Co., East Pittsburgh; Past President, National Safety Council.

Vice Chairman—R. T. Barker, Director of Health and Safety, Western Electric Co., New York City.

Secretary—R. E. Colville, Manager, Insurance Department, U. S. Gypsum Co., Chicago, Ill.

Mr. Chairman, I move that the report be accepted.

(The motion was seconded by Mr. Ernest W. Beck.)

ASSISTANT CHAIRMAN QUESNEL: Is there any discussion? There being none, all those in favor of this motion will indicate by saying "aye;" contrary "no." The "ayes" have it, and these gentlemen are elected to their respective offices.

Is Mr. Auel in the room? (*No response.*) Is Mr. Barker in the room? (*No response.*) Is Mr. Colville here?

Gentlemen, this is Mr. Colville, the Secretary.

You can anticipate a very interesting and instructive session next year, I can assure you.

CHAIRMAN WINANS: Our next subject will be handled by Mr. John Lundrigan, Industrial Superintendent of the International Paper Company, New York City.

Status of the Group Plant Safety Engineers in Industry

By JOHN LUNDRIGAN

Industrial Superintendent, International Paper Company, New York City

MR. LUNDRIGAN: Mr. Chairman, Ladies and Gentlemen: I would very much like to discard this prepared speech and devote my time to some of the things that seem to me particularly important, that I have noticed or that came under my observation during this Congress so far. Unfortunately, or perhaps fortunately for you people, it is printed and I guess you will have to take it as it is. As a matter of fact, it is made up very largely of the actual rules and regulations under which the International Paper Company carries on its organized accident prevention work. I might add here that it is only what we call the Magna Charta or Constitution. In other words, it is the minimum of the company's requirements by actual, positive rule and regulation, under the sanction, approval and order of the executive management of the company. It is necessarily uniform because of this element of distance which enters into our plants, situated, as they are, from the gulf of the St. Lawrence to the lower part of Louisiana and extending somewhat into other parts of the country.

I want also to explain that those rules are not the caprice or whim or theory of any individual or set of individuals. A good many people give me a large part of the credit for having been their author, and everybody gives me all of the criticism for the things they don't like about them. As a matter of fact, when we undertook organized safety work, we had been somewhat fed up with the sentimental side of the question. We all believe in that. We were participants in, and probably leaders in, the general discussion of the need for getting rid of accidents and illness as well. We all know that until it became a plain, every day matter of actual money cost, it was a good deal in the same category that the weather was, in connection with Mark Twain's famous remark; that is, a good deal talked about but not very much done about it. Therefore we decided that the only place to prevent accidents was on the job where the accidents occurred, and the only people who could do the trick were those who were in authority and operating on the job.

We also recognized that there were opportunities for keeping step with not only the old industrial conditions that were exacting their toll of human suffering and cost, but with the tremendous advance in means of transportation power and operation, which required that they be given help, that they be furnished with necessary, positive information as to what constituted a hazardous condition and what constituted a bad practice, and some reasonable method of getting rid of it. Therefore we decided to virtually make this activity a part of the company's executive management and just as positive a part of the operating management of each individual plant of the company, no matter where it was located.

In another thing we have been most fortunate, namely, that we have not only had the benefit of the wise counsel and leadership and sympathy of men like our president, Mr. Graustein, and his predecessor, Mr. Dodge, but we have had their positive encouragement in the matter of spending real money where it was necessary. Of course we believe and we know that we have shown them over and over again, in plain facts and figures, that we have returned that money not once but several hundredfold. So that with us, so far as its operation is concerned, it is a plain every day cost proposition and it is so treated in our organization.

I know of no better way to define our judgment of what should be "The Status of the Group Plant Safety Engineer in the Organization with which he is connected," than to reproduce practically verbatim regulations under which our company operates this part of its business. Our plants are so large in number, widely separated, with a large variation in number of employees and product, that we consider it fairly representative of both a large industry and a group of separate small industries. In other words, we believe our plan can be applied to any type of industry, number of plants of the same industry or groups of plants of various industries in the same localities.

The character of our business as indicated, requires both general and local supervision of this work, including uniformity of method, reports, etc., so far as any part of the plan applies to its individual units. Our general supervision not only checks up and compiles a record of individual performance, but acts as a clearing house for education, information and cooperation of the whole. It might be well to explain here the industrial superintendent is responsible for many other personal activities of our company, in some of which he acts more or less independently, reporting to the executive responsible for that feature of the company's business, whereas in the matter of accident prevention and its auxiliaries he is in practice an executive.

In the case of the local plant or individual unit, the general policy of our company is to consider the plant manager as the International Paper Co. in his jurisdiction, subject, of course, to rules, orders and practice laid down by the general management, so that we locate the authority and responsibility of the plant safety supervisor as being the direct representative of the plant manager in carrying on this work at the plant. So far as his relations to other department heads at the plant are concerned, he is rated neither above nor below any of them. In our judgment the two features that must be entirely divorced from his work are dictation on the one hand and subordination on the other.

The following rules govern this entire organization:

The Safety Organization shall consist of:

- General Supervisor of Safety and Sanitation
- Local Supervisor of Safety and Sanitation
- Local Safety Committee
- General Supervision Committee

The local supervisor of safety and sanitation shall be stationed at the mill, under the direction of the manager or superintendent. Included among his duties shall be the following:

I must stop here to explain that phrase "or Superintendent." When those rules were written eleven years ago we had small individual plants where the title of the man in charge was Superintendent, in order that this might apply to those plants as well as the larger plants where the fellow had a larger title of manager. Hence we had to repeat that phrase, "Plant Manager or Plant Superintendent." We want to get into your mind the fact that no matter what plant it might be, great or small, there is no one in authority or control between the safety man at the plant and the man in executive charge.

1. Keep informed on all national and state laws dealing with safety and sanitation in the territory where the Mill is located.
2. Recommend the installation of safe-guards wherever, needed. Inspect and report on the condition of all safe-guards, danger signs and absence of proper lighting of any part of the plant or premises.
3. Report all dangerous conditions, wrong and unsafe practices, lack of cleanliness of plant and premises to the mill manager or mill superintendent.
4. Look after proper disposal of the plant of waste and reusable material.

5. Report on improper, insufficient or wasteful lubrication in any form, including overheated bearings.

6. Act as Secretary of and keep a record of all proceedings of local safety committee meetings.

7. Call attention of department foreman to dangerous and unsanitary conditions or wrong practices and arrange for the elimination of these conditions; either through the department foremen, or personally supervise the work if ordered to do so by the mill manager or mill superintendent.

8. Report all conditions that might have resulted in an accident had there been employees in their usual place, such as fallen material, broken supports, etc.

9. Make frequent inspections of all mill departments and premises. During such inspections he may be accompanied by the superintendent or foreman of the department inspected. He shall be accompanied by the department superintendent or foreman in charge of a department where an accident occurred, when making investigation of such accident.

10. Personally accompany all persons who, from time to time make regular or special inspection of plant, including Labor Departments and State Factory Inspectors, Compensation Insurance Rating Boards, and special inspections in connection with fire, boiler, fly wheel, elevators and other forms of insurance carried by the company. Make memoranda of any wrong conditions called to his attention by such inspectors or inspections.

11. In cooperation with department superintendents and foremen give special and continuous attention to observation and instruction of new employees. When directed by the mill manager or mill superintendent he shall arrange to keep a list of applications for employment and of employees available for transfer from one Department to another, which information shall be available to each department superintendent and foreman.

12. He shall keep a separate file of all reports, documents and information dealing with safety and sanitation, including general and special instructions, mill accident history; literature permanently assigned to his mill; and all correspondence in connection with the general subject of safety and sanitation.

13. He shall be in charge of and responsible for the safe keeping proper circulation, and display of all safety literature, including posters and bulletins, together with their movement from one mill to another as may be directed by the manufacturing department.

14. He shall make such reports, as may be now or hereafter required, to the mill manager or mill superintendent and through him to the manufacturing department.

15. He shall keep an accurate list or card index setting forth: Name, date of employment in such position and salary of the local supervisor of safety and sanitation, and the plant nurse where one is employed.

The name, occupation and actual or approximate period of service with the Company of each member of the local committee. This record is to be kept up to date and corrected according as there is any addition or change in any of the positions named. The original is to be sent to the New York office and a copy kept in the mill safety files.

16. Whenever any construction, installation, replacements or repairs are being carried on in or in connection with any part of the plant or premises by any person, firm or corporation other than the local Mill Management, all of the foregoing duties and responsibilities of the supervisor of safety and sanitation shall apply so far as maintaining safe conditions, the prevention of accidents and making proper recommendations and reports to them, are concerned.

All reports or recommendations made in connection with the foregoing shall be in triplicate, one copy to go to the Mill Manager or Mill Superintendent, one to the person in charge of the work and one to be filed by the supervisor of safety

and sanitation. Regular accident reports shall be made on Form 339 of all accidents that occur in connection with the foregoing operations and shall have noted on them the name of the employing person, firm or corporation in order to distinguish such accidents from those occurring to persons in the employ of this company.

Whenever for any reason there is no safety supervisor assigned to or on duty at a mill, the mill manager or mill superintendent will arrange for the making of all reports and keeping of records designated herein, the same as though a safety supervisor were on duty.

The local safety committee shall consist of the mill manager or mill superintendent, as chairman, the local safety supervisor, as secretary, the resident engineer, all department superintendents and foremen, plant nurse and one or more workmen from each department. The workmen's representatives on this committee may be selected by the employees in that department.

Should the employees fail to select a representative for any department, the mill manager or mill superintendent may designate a representative to serve for such department until one has been selected.

In addition to the foregoing each of the special traveling inspectors representing the manufacturing department shall be considered to be members of the local safety organization at each of the mills whenever they are personally at such mill. They will be expected to call the attention of the mill management and safety organization to any hazardous condition or unsafe practice that comes within their knowledge and, in addition thereto, take up and discuss such conditions together with recommending remedies for them at any regular or special meetings of the local safety organization.

Mills or divisions having separate units at a distance from each other should have a local safety committee for each. The mill manager to be chairman and the safety supervisor secretary of all local safety committees.

At least one regular meeting shall be held in each calendar month of which minutes shall be kept in such a manner as to be available for reference at any time.

The duties of the local safety committee shall be as follows:

1. To discuss all dangerous and unsanitary conditions or wrong practices coming within their knowledge and to make recommendations for remedying same.
2. Review and investigate accidents that have occurred, and make recommendations to avoid their recurrence.
3. Discuss and make recommendations on accident prevention and general safety and sanitation.
4. Assist in putting into practice recommendations made by the manufacturing department, including the circulation and distribution of educational matter having for its object accident prevention.

The general supervision committee shall consist of the general supervisor and all local supervisors. The general supervisor shall be chairman of this committee.

Meetings of this committee will be held at the various mills of the company, alternating so that a meeting will be held at each mill in turn. The local supervisor at the mill at which each meeting is held will be the secretary of such meeting and shall keep the minutes thereof in such manner as to be available at any time.

The meetings as far as possible will be arranged by general localities or River Divisions. It shall be the duty of visiting supervisors to inspect the plant in connection with the local supervisor.

All suggestions made by employees whether members of a committee or not shall be made known to the mill manager or mill superintendent and the general supervisor and local supervisor of safety and sanitation.

It was necessary to clarify or make more easily understood the foregoing rules for which reason the following memoranda becomes virtually a part of them:

Suggestions in addition to any other instructions on the subject of installing and operating an organization for mill and premises, safety and sanitation.

1st—The individual designated as local supervisor must understand that one of his principal functions is to work toward more harmony and cooperation between the local managements themselves, and between them and the mill employees. He is neither above nor below the standing or authority of Foreman, except as specific duties are prescribed.

The most important point that both the manager and supervisor must keep in mind is that his duties relating to safety and sanitation take precedence over other duties he may be assigned to, in order to relieve both of the excuse that such matters were deferred owing to press of other duties or responsibilities.

2nd—He should become familiar with all existing laws relating to sanitation and safety in the state where he is located. He should be put on the mailing list of state department, charged with enforcement of same, which can be done without cost by making application. He should become personally acquainted with the State Inspector and accompany him on all inspections. This also applies to inspections of all kinds by representatives of insurance companies or other interests.

3rd—He should become thoroughly familiar with the structural and other conditions of the plant equipment and premises, and personally acquainted with the employees particularly those who are leaders or officers of the employees' organizations, and when non-English speaking help is employed, men who can speak their language and English as well. The importance of this lies in the fact that the vitality of the workman's safety committee, and the securing of suggestions from employees will depend largely on the interest taken by the local supervisor along these lines.

4th—It is of equal importance that he establish a working system and friendly cooperation with all department Foremen, and Headmen below the grade of Foremen.

5th—It is vitally important that all reports, recommendations, suggestions or criticisms, scrupulously avoid anything of personal feeling or bias, a good way to overcome or avoid this, where any individual or set of individuals appear to be directly affected, is to talk the matter over with the parties directly, pointing out the necessity for remedying or changing the condition then existing, when it often will be found that instead of having to report an individual, he will probably concur in your action. This does not apply to violation of laws, rules or agreements, as such are distinct matters calling for discipline, except when certain things have been a common practice, good judgment must be used in doing away with same, usually by order or personal act of the Mill Manager.

6th—Keep in mind that cleanliness of plant and premises is of great importance in reducing the causes for accident, sickness and loss of waste material.

It may be found the present facilities of the plant and premises are not adequate, or are not of the proper type or location for taking care of new, used or waste material, or the raw material and supplies used in our manufacturing operations. The remedying of these conditions so far as possible, or at least making recommendations to that end, is a very important part of the duties of the Local Supervisor.

7th—Improper or insufficient lubrication is not only costly from the standpoint of excessive use of lubricants, but very often more costly owing to overheated or burned out bearings causing breakdowns, and sometimes accidents to employees. Careful inspection of lubrications in all parts of the plant should be made frequently and at irregular periods, and all wrong conditions called to the attention of the man or men in responsible charge, as well as included in the written report of the supervisor.

8th—In cooperation with the foremen concerned, advice and instruction to new

employees and old employees who do not appear to fully understand the correct method of doing the work assigned them, is a very important part of the duties of the Local Supervisor. It will often occur that foremen have not the time to devote to this work and it may be of such character that the Supervisor is not sufficiently familiar to do so himself; in such cases he should cooperate with the foreman in securing some other employee to instruct inexperienced men.

It will be found many times that help employed for a specific position or duty are not fitted or qualified to perform the work. When this is the only objection to such employee, it may be there are other departments or occupations where he could be acceptably employed. The local supervisor should keep informed on this subject so that a transfer might be affected, instead of as is often the case dismissing the individual and possibly having the same experience with the next new employee secured to fill the vacancy.

The same principal should always be applied when it is necessary to reduce help on account of low water or other conditions, that is, permanent help who are competent and willing to transfer to other departments during temporary shut-downs, should be so transferred instead of new help being hired. To accomplish this it is necessary that complete knowledge of the labor requirements of all departments be in the hands of some one who will take the initiative, as we know oftentimes the workman laid off takes it for granted there is no other employment for him, and does not always return when his department resumes operation, which means you have lost a more or less experienced employee and are likely to have to break in an inexperienced man in his stead.

9th—Owing to the fact that the supervising inspector will be making continual inspections, which will necessarily take him to all parts of the plant and premises, we are of the opinion he can at the same time perform the duties and make the reports now done by the fire inspectors, and at the same time and for the same reason act as an inspector of lubrication, making such reports on that subject as are now or may be hereafter required.

10th—Whenever in doubt as to whether or not a particular condition should be reported, include same in your report.

11th—Each mill has a copy of Bulletin No. 77 of the New York State Department of Labor on accident prevention, which is also helpful in this work.

12th—Suggestions, recommendations and criticisms are always in order, so do not hesitate to make them, as future instructions and additions or changes in plan of general and local administration will depend very largely on them.

13th—Desk room should be provided for the local supervisor with facility for the creation of a local unit for an industrial library, made up of the various laws, rules, regulations, and publications, on the subject of sanitation and safety, that may now or hereafter be available.

14th—The establishment of the safety and sanitation organization, and the duties of any person connected therewith, in no way alters or interferes with any regulation between this company and its employees, neither does it in any way change the system of discipline.

While the rules make some provision for cooperation in the employment and location of help, a few years' experience taught us the necessity of adding what we term an "Employment Service" and because of its direct connection with accident prevention and health promotion, we couple its administration with that of the accident prevention work. In other words, the same individual is in charge of both.

The rules governing our "Employment Service" follow from which it will be noted, the same principal is applied as in the accident prevention work. The man in charge neither hires nor fires. His mission is to provide sources from which to draw new employees and to cooperate in proper location or transfer of those already on the payroll:

Beginning January 1, 1924, all mills shall establish an employment service for the purpose of providing for a more adequate supply of labor and diminishing the labor turnover.

Where local Supervisors of Safety are employed they shall administer the details of the service, including the keeping of the records, except that (with the approval of this Department) the mill manager or mill superintendent may designate some other employee to do so where conditions make it advisable.

It shall be the duty of the one in charge to keep in constant touch with the department superintendents and foremen both as to the immediate and future needs for help and as to the possible reductions in help in each of the mill departments.

He shall furnish each new employee with a copy of General Instructions No. 14—RULES and General Instruction No. 74—SAFETY ORGANIZATION, instructing him particularly as to the safety provisions, including first aid and nursing service provided at the mill.

He shall personally introduce the new employee to the department superintendent or foreman, advising as to whether or not the new employee claims experience in the work he is to do, and in either case recommend to the department superintendent or foreman that he be given adequate instructions as to the nature and hazards of the occupation.

When an applicant is not hired and desires to be considered for future employment, he shall make a record of all the information the applicant is willing to furnish, on Form No. 287 "Application for Employment and Record of Service," the same as though the applicant were actually hired, including whether he will be available when a vacancy occurs or whether he will accept a position other than that applied for, entering the acceptable occupations by name on Form No. 287.

Form Letters (see Mill Form Instructions No. 304) shall be used to notify such applicants of a vacancy when it occurs, accompanied by an addressed stamped envelope for reply.

The Employment Service shall have up to date information available to both applicants and employees covering at least the following subjects:

1. Rates of wages paid by this company for each occupation the applicant is willing to accept.
2. Up to date lists of boarding and rooming houses, with locations and actual or approximate rates for weekly board, for rooms and for meals.
3. Means of transportation and fare back and forth from the principal points in the mill town or vicinity to mill.
4. Location and rental cost of various types of dwellings.
5. Location of schools and kindergartens, including denominational schools.
6. Location and denominations of churches.

When for any cause the number of employees in any department is reduced the Employment Service shall keep informed as to whether other employment is available at the plant.

When employees are laid off for any reason, their address shall be determined and recorded on Form No. 287, so that when vacancies occur in any occupation they are capable of filling, immediate communication with such employees will be possible.

Generally speaking, when additional help is needed, former employees (not dismissed for cause) shall be given preference, particularly residents in the mill locality and those having dependents. When this supply is exhausted local and out of town waiting lists shall be utilized.

In filling occupations above the classification and rate of common laborer, persons then in the Company's employ shall be given preference by being transferred thereto when they possess the necessary qualifications; such qualifications shall usually be based on the recommendation of the Department head under whom the

employee is working and that of the Department head where the vacancy exists.

The Employment Service shall not in any way supplant control of method of employment as it now exists. Its main function is to provide for important additions thereto and it shall cooperate with the department superintendents and foremen and others of the supervising force.

The records and other information connected with the Employment Service must be kept in such a manner and so located that they will at all times be easily available to the department superintendents and foremen for their information and use.

From time to time we gradually installed a plant and community nursing service which now exists at all of our pulp and paper manufacturing plants and except at the smaller ones provides for a separate nurse for community service as well as the service at the plant.

The immediate direction of this service is looked after by a supervising nurse from the general staff and so far as the local plants are concerned, while there is no question of jurisdiction that can be raised between the Local Safety Supervisor and Plant Nurse, it is not only understood but a practical fact, each of them is expected to and do work in cooperation with the whole system as herein outlined.

The original plan was put into practice in 1917 and added to as herein mentioned. The mere fact that we have never had any occasion to take any important provision out of the plan must indicate to you that we consider it the best we are capable of devising and I believe it pretty fully defines the questions we have been asked to answer here.

MR. LUNDRIGAN: I realize from the length of time that it has taken to read this lengthy document, that you think this is a somewhat complicated proposition and requires a tremendous organization to carry it on. I just want to reassure you on this fact in the presence of probably fifty supervisors of the International Paper Company and the lady who has charge of the nursing service of the company, and I might add also the lady who has charge of all of us and keeps track of the records. They are all in the room. Therefore I must watch my step in stating this proposition and I want to assure you that not one single person was added to the pay roll of the International Paper Company's organization to carry this work on, and it does not involve any greatly complicated machinery. It was just a matter of consolidating things that everybody had a little hand in doing. It was simply a matter of centering all the information so that all the information flowed through one channel.

I want to make a little comment on this word "engineer." To the man in the street an engineer probably means a fellow who drives a locomotive; maybe it means the fellow who drives an automobile. Of course, if it does, we hadn't better be proud of that type. But I believe the better informed man looks upon the term "engineer" as meaning a man who has nearly all to do with the designing of structures, machinery, power, and their operation; in other words, inanimate things; whereas, if I understand the vital point in this whole matter, it is the successful dealing with human beings. And while a man might be an engineer without any handicap to him and do this work, I say that the best engineer in the world can't do it unless he has got a lot of horse sense and human sympathy mixed up with it.

That is the point I wanted to make, so far as the title is concerned; and it is the very reason why the International Paper Company did not use the term "engineer" in designating the man in charge of this work. However, we believe, in fact, we know that the men we have designated to carry on this work have got common sense enough, and in this document they have authority enough, to enlist, and they do enlist the active service and the friendly cooperation and all of the volunteer help they can get from engineers and all classes of trained or informed

persons. So we have no reflection whatever on the engineer except this one thought which I want to leave with you, which doesn't happen to be in the paper and may be a little bit foreign to the particular subject assigned me.

It will be a wonderful thing for the human beings who suffer accidents, and for society and business which pays for accidents, when we can get a little more positively into the minds and into the practices of the engineer the need and importance and operating value of specifying safe construction in the structures and designs that he is furnishing to the public and to industry. Those of you who have practical experience in plants know that the usual practice today is to purchase a piece of machinery or a piece of equipment and then tear your maintenance crew apart building guards around it; whereas if you had specified that, had your engineer designed that, in his original proposition to the manufacturer, the manufacturer would have been very glad to comply.

CHAIRMAN WINANS: Thank you, Mr. Lundrigan.

Now we will give Mr. Beck a chance to go the last lap on this. Mr. Ernest W. Beck is Supervisor of Safety of the United States Rubber Company, which at the present time is operating something over thirty plants, with something over 30,000 employees.

The Elements of a Successful No-Accident Contest

By ERNEST W. BECK

Supervisor of Safety, United States Rubber Company, New York City

It is generally known that the majority of our accidents are not due to mechanical or physical conditions, but to the human factor. We can see and handle the mechanical and physical hazards, but the human problem is not so easily solved. There are no two of us alike, therefore, we must give this human problem our serious thought and try many different means and methods to solve it. The average individual likes competition, and we should take full advantage of this element when promoting and maintaining an interest in safety. No doubt, the success of the large number of No-Accident Contests being conducted today is due to the friendly spirit of competition that is aroused on the part of the contestants.

It is surprising the large number of safety contests that are being conducted throughout the country today. Large industrial companies, I believe, took the initiative, and showed what could be accomplished. We now have several of our industrial sections and a number of trade associations conducting well organized safety contests. The New Jersey Department of Labor and the Industrial Commission of Ohio have started a statewide inter-plant safety contest. There is no question but that a well organized safety contest will accomplish a great deal of good and justify many times over the small expense of time and money. Inasmuch as this is a meeting of group plant safety supervisors, I am going to talk on the subject assigned to me as applied to the large company operating several plants at distant points.

There are many different kinds of contests, some lasting for a twelve-month period and others conducted for a week or a month. However, there are certain common factors and I will do my best to outline certain elements which I believe enter into any successful no-accident contest.

Plan All Details in Advance

In order for a No-Accident Contest to be successful, all of the details must be well planned in advance of the contest period. Make sure that you leave no stone

unturned, for it is surprising how many embarrassing questions may arise if your plan is not complete. Consider every possible factor and consult several others in the organization who may be concerned.

When a large company is about to start a contest, circular letters in the form of questionnaires, suggesting a No-Accident Contest should be sent to each plant. Tell the factories that the contest is their party. Ask them for their ideas and get as many suggestions as possible from all, but do not depend too much on getting enough ideas from your subsidiary plants to make your contest a success. My advice to the safety supervisor is to draw up his complete plan and then where possible apply the best suggestions received.

Decide on the most appropriate time to conduct the contest. There are certain periods of the year when such a contest can be handled more effectively than at others. The summer months are a poor time. I believe the best period of the year is May, October or November. When the plant has an unusual peak in its production is a poor time to start as the supervisory force who can make or break a contest are usually very busy. Of course, it is obvious that all the plants in a large company should conduct their contest at the same time.

After laying out your plans it is very essential that you should draw up a budget covering in detail each activity that you expect to carry on; such as printing, prizes, posters, etc. The purpose of a budget is to secure an appropriation to carry out the plans for the contest.

Sell Executives on the Idea

Before submitting your budget for approval, you should gather a few facts and figures that will assist in placing before your executives the advantages to be gained by conducting such a contest. Give a few illustrations if necessary of what others have done, and if you have conducted a No-Accident Contest before, give a few facts and figures of what was accomplished. Arrange for your president or your general factory manager to send out a general letter to all plants, announcing the contest, and encouraging cooperation on the part of all.

Safety, in order to receive the proper support, must be sold to the management. Management is accustomed to dealing in figures and it is surprising how simple a job it is to sell safety to the busy executive by showing him a well prepared set of accident figures. By all means keep accurate records and when you get them, use them.

Responsibility of the Central Safety Office

The central safety office should advise the local plants well in advance of complete plans regarding the contest. All printed material should be in the hands of the local plant committee several days in advance, so that they may plan their own method of distributing, handling and posting same. The central safety office should stay out of the picture as much as possible, so that the plant may conduct the contest according to its own ideas—following, of course, the fundamental principles laid down by the central office. It is very essential that the central safety office organized an efficient system for reporting all accidents.

In order to make the contest as fair as possible, a large group of factories may be divided according to the number of employees or to the nature of production.

The Importance of a Local Committee

Have a local committee organized at each plant. This committee will head up the campaign at the factory; think up and carry out the various ideas suggested and stimulate interest during the period of the contest. Be sure to select the right person as chairman of this committee, as so much depends upon him.

Encourage the subsidiary factories to promote original ideas. It is surprising the number of good ideas that will originate through a local safety committee and can be carried out at their point. So often these ideas cannot be carried out at another plant, due to the nature of production, location of factory, type of help employed, etc. The factories get a big "kick" out of some special idea they may put over. It is advisable to advertise among the other plants the special stunts that all factories are carrying out. If possible, get photographs for future use.

Outstanding Contest Feature

Among a large number of things that you do during the period of the No-Accident Contest, it is advisable to have some outstanding stunt—such as a picture contest of some kind; a puzzle or a written contest, which will arouse the greatest interest on the part of all men and women. Give prizes and have the contest open to wage workers only. The idea of featuring a special scheme is to encourage every one to participate. If you just go out to reduce your number of accidents, you never know how much effort, if any, was exerted.

It is essential that proper judges be selected in advance of beginning of contests. The local plants have a splendid opportunity here of getting some good local publicity by having as judges of their contests about three prominent men in the community in which the factory is located. We have had as judges at our several factories the following type of men:

- Mayor of the town.
- Deputy Commissioners of Labor.
- Presidents of local business associations.
- Representatives of the local press.
- Managers of local safety councils.
- The Clergy.
- The school superintendent or principal.
- The Chief of Police.
- Fire Captain.

Of course, you should also have a few judges for deciding the grand prizes in the contest. Such judges should be nationally known, and men who have won their spurs in the field of accident prevention. For the contest which we conducted last year—we were fortunate in securing three past presidents of the National Safety Council to serve as judges: namely, Arthur H. Young, Louis De Blois and Walter King. I believe the judges should not be employees of the company. This holds true especially when selecting the judges for the grand prizes. Keep the work for your judges at a minimum as the best judges are busy men.

One of the most successful elements in our No-Accident Contest was the large amount of excellent local publicity that we received—especially in the smaller towns where we operate. The local merchants entered into the spirit and placed posters in their windows. Large banners were stretched across the public highways, announcing to the public that a No-Accident Contest was in progress. The local newspapers printed daily articles and in some cases, we had several half pages and even a full page ad donated by the local merchants. The subject was mentioned in the schools and in the churches, and of course, was talked of in the homes. I cannot overemphasize the value of general local publicity. You all remember this same element of publicity was very effective during the Liberty Loan drive. Every safety man should consider himself a sales manager and an advertising manager. He has the finest commodity in the world to sell, but like other commodities, it has to be advertised and preached about if he is going to sell his goods.

Feature a Special Stunt Every Day of Week

During the period of the contest, it is necessary that the interest be maintained. This can be done by having a special feature for different days or weeks. One day could be "Fire Day," at which time you could hold a fire exit drill and also have a fire brigade drill, demonstrating the use of fire extinguishers, and have a fire inspection at the plants. Another day could be "First Aid Day." A demonstration of the Schaefer Prone Pressure Method of Artificial Resuscitation could be given. You could have a day for signing "Safety Pledges"; also a "Home Safety Inspection Day." Another period could be devoted to speakers. Have a day or a week for safety inspection of the plant. Have a safety slogan for each day. In other words, don't let the interest drag.

One of the best methods of putting over the safety message is the use of safety motion picture films, even better than a good safety talk. I believe you can appeal to the eye much better than you can to the ear, and you are leaving a more lasting impression as each one draws on his own imagination and applies the picture to his own experience and living conditions. The story in the motion picture also goes over big among the foreign help, especially those who may not understand a well prepared safety address.

Post Accident Records

Daily records of accidents and results of other activities during the No-Accident period should be given extensive publicity. In addition to giving the plant executives and supervisory force an up-to-date record of all results accomplished, be sure to post records on the bulletin boards about the plant. The employees should be kept advised of the results being accomplished. This can be done in many ways. When possible show results in the illustrated manner, by thermometers, clock dials, automobile races, and the like.

Encourage competition between departments and plants. Men and women are like grown up children. They like to play and enjoy competitive games. We should take advantage of this characteristic and encourage competition between departments and also between plants. It is surprising the amount of good that can be accomplished by encouraging healthy competition.

Among a large number of companies participating in a No-Accident Contest, you are sure to have some factories showing more interest than others. You will find yourself busy with the active factory because they are keeping you advised of what they are doing, while the factory that is not doing very much is not taking much of your time. You should watch this situation closely and endeavor to stimulate the interest of all factories by telling them just what the other fellow is doing. Endeavor to get the interest of all departments and plants. It is usually the department or plant that shows the least interest that needs your attention the most. Give your accident statistics wide publicity in your organization in such a way that they will cause the negligent to do better and further encourage those who are doing good work.

The foreman can make or break a No-Accident Contest. If he is lukewarm and shows a lack of interest it is to be expected that the men under him will feel the same about the matter. In order for a No-Accident Contest to be successful, the foreman must take a personal active part. He should give out the material personally; he should speak to his men about the contest and if he takes his part seriously and conscientiously, the contest will be a success.

Hold Safety Meetings

Of course, it is necessary in any well organized safety contest to hold meetings. When conducting such meetings, be sure that the big boss is there, in fact, he

should always have a few words to say on this subject at any safety meeting. I have heard of factory managers and superintendents who said that they were too busy and did not have the time to be present and speak at a safety meeting. Such factory managers are passing up an excellent opportunity to put over safety at their plant. As a matter of fact, they may not know it, but their very absence hurts the safety movement at their plant as the employees, foremen and others are going to do their own thinking and in the majority of cases, they will think that the factory manager is not interested enough in safety to be present.

Accident prevention is a responsibility of management. In large plants, we may have safety experts, but if the *big boss* at the top *does not come out* for safety and *does not* pass the word down the line and does not do *what he can* to sell the safety idea, *we are not* going to accomplish the desired results. Safety meetings should be held on company time and I believe should not last over one hour. At such meetings accident records and the results accomplished should be mentioned, together with a story of what the other fellow is doing. The meeting should be snappy, unusual experiences should be mentioned, and the meeting should close with the feeling on the part of all that it is possible to do even better.

Use National Safety Council Posters

Something in advance of the contest period, draw up a form for all factories to fill out, recording the number of safety bulletins wanted and the kinds desired. This selection should be made from an analysis of the accident causes. Be sure and order plenty of National Safety Council posters. You might arrange for a home made bulletin contest. Suggest that you also print safety slogans on large signs three feet by seven feet. They can be read the full length of the yard or shop.

I stated at the beginning of my talk that the highest executives in the company should send out a letter asking all plants to cooperate in conducting the No-Accident Contest. While the contest is in progress, it is advisable that follow-up letters be written by factory managers, superintendents and foremen, encouraging the continued effort on the part of all and thanking them for their cooperation in the past. Such letters not only stimulate the interest of employees, but I believe help to further sell safety to the supervisory force signing such letters.

Presentation of Prizes

Prizes should be given as soon after the close of the contest as possible. Have one of the higher executives present the trophy and take pictures of the occasion for publicity in local and trade papers. When prizes are given for the best replies in written contests, I believe it is advisable to give special recognition to factories turning in the greatest number of replies in proportion to the number of their employees. My reason for saying this is that a large plant may exert a great amount of energy to get all of its employees to respond to a request, and may not win a prize,—while the smaller plant with only a few employees may win a prize.

We have purchased an additional prize as an honorable mention on account of the excellent work which a particular factory had done. Do not skimp on the prizes as it is poor economy. A successful No-Accident Contest will not only pay for itself many times over, but so often accomplishes things that money cannot buy.

There are a large number of trophies that may be given as prizes, and they vary from loving cups to gold pieces. For three years the company which I represent has given large bronze plaques artistically designed, which were hung up and required very little attention. We believe this is better than giving a

loving cup or some other article that needs periodical attention or that soon wears out. Two years ago we tried out a scheme of presenting the original oil paintings, photographs of which are used on the National Safety Council calendar. These paintings were very well received by the factories winning them. They were placed in a glass case with special illumination over the frame,—and hung in a conspicuous place where all the employees could see them. They are a beautiful piece of art and tell a safety story.

Four of these trophies were presented by the U. S. Rubber Co. to winners in its 1927 Annual Safety Contest.

When your contest is all over and the prizes have been awarded, I believe it is advisable to write the complete story for publication and distribution to all the employees. Show a large number of photographs of prize winners and safety rallies taken at factories. Publish the results accomplished. All this stimulates further interest.

Secure Comments and Criticism

At the close of your contest, I believe it is a good plan to write to all factories and ask for their comments and suggestions on how to improve the contest when conducting it again. Ask several questions, and it is surprising what you will learn even after running contests for several years.

There are many other elements, but time does not permit me to mention them all.

When conducting safety contests, where you want the employees to know and

follow the details closely, it is advisable to have as few rules as possible. Avoid complicated formulas and if possible, say nothing about frequency and severity rates. As the employees become educated to figuring accident rates and using formulas, more details can be used. The basis of conducting safety contests varies. Some people use the best severity rate,—others the best frequency rate, and some both. Some plants arrange for the largest reduction in severity and frequency rates,—while others take the longest period without a lost time accident. There are a few who use other adjusted methods.

United States Rubber Company Formula

The formula which the United States Rubber Company uses is quite different from any which I have seen, but it is designed to accomplish the same purpose.

Before explaining our method, I would like to state that if I were starting a safety contest in a company among factories where little or no safety work had been done, I would most certainly start with a simple plan, such as the best frequency rate.

In a large company like ours, where the subject of safety has received attention for many years, the various factories object to using a frequency rate alone or a severity rate alone, and some of our factories have objected to the use of both, so in order to satisfy every member of our large family, we have drawn up what might appear to many to be a very complicated formula, but the "proof of the pudding is in the eating."

We have made but one change in our safety contest formula during the last five years, and that change pertained to death cases only.

We agreed that four factors should enter into our contest, namely, severity rate, frequency rate of lost time accidents, frequency rate of all accidents and a cost factor. We do not use the cost per \$100 of pay roll, as there is quite a fluctuation in the wage rate at our several locations. The wage rate in South Carolina is quite different from the rate in Michigan or Massachusetts, so we use the cost per 1000 man hours worked, which gives us the cost per exposure to accidents. After settling upon these four factors, we of course, realized that they did not carry the same importance and should not carry the same weight in determining a safety contest formula. Consequently, we weighed them as follows:

Severity	50%
Frequency (lost time)	25%
Frequency (of accidents)	5%
Cost per 1000 Man Hours Worked	20%
	100%

We have a complete simple manual covering all accidents and compensation records, so it is not difficult for us to get an accurate record of the number of accidents, days lost and cost involved. All factories, of course, use the standard manual and a record of every accident that happens at any of our plants is sent to a central office, where the final records are compiled and recorded.

You will note in our formula that 5 per cent is the maximum weight for all accidents. Our reason for placing this so low was to not discourage the reporting of minor cases. A factory in our contest can double its number of minor accidents and yet not be penalized more than 5 per cent. We find this low rate works out very well and the factories appreciate our keeping it low as we will always have a number of minor accidents and we should not discourage the reporting of minor accidents by placing a heavy penalty on them.

The United States Rubber Company contest is based on the percentage of improvement shown during the current year over the average experience for the past three years. The factory showing the highest percentage of improvement wins the prize.

Our compensation paid for injuries has steadily declined in spite of the more liberal laws which have been enacted in practically every state where the company's factories are located.

This contest has brought about some wonderful results, in fact, it has surpassed our expectations as during the last five years we have shown an improvement over each of the preceding years. The following table shows the percentage of improvement each year over the average experience for the previous three years:

Improvement for Company as a Whole—Year 1924	7.22%
Improvement for Company as a Whole—Year 1925	12.54%
Improvement for Company as a Whole—Year 1926	10.95%
Improvement for Company as a Whole—Year 1927	29.02%
Improvement for Company as a Whole—First 6 Months 1927	32.44%
Improvement for Company as a Whole—First 6 Months 1928	43.42%

As time goes on our contest will become keener and keener as all factories will be trying to show an improvement over a good record. We have been surprised to see some of the factories with very good past records come through with an improvement.

As time is limited, I have purposely avoided mentioning the details of our contest formula, but if any one present would like to have our method explained in detail, I have come prepared to place in his hands the complete story. At the close of this meeting, I will be pleased to give anyone a typewritten story of our

method. Or you may write to me for a copy of same at my New York Office, 1790 Broadway.

Don't think that a No-Accident Week or a safety drive will inject enough enthusiasm into the workman to last six months or a year. It is not the spasmodic outburst of fireworks, a brass band and a big splash that will accomplish the desired results.

All these methods mentioned, and many others, have their place, and if seriously carried out, will have a certain favorable effect in selling safety to the man on the job. But those of us who have devoted several years to the cause of accident prevention, know it is the every day plugging away that counts in the long run.

Presentation of trophy to the Passaic, N. J., plant, U. S. Rubber Co.

CHAIRMAN WINANS: Now the fun begins. It is going to be your chance to do some of the talking and we will take half an hour for it if you want to.

Now we will go back to the first subject which was presented by Mr. Hoyman and give you a chance to ask him questions on his subject, "How We Keep Safety at Work in Our Distant Plants." Is there any comment or question on that subject?

W. C. REIRLING (American Tar Products Co., Chicago, Ill.): I would like to ask Mr. Hoyman whether they give any compensation or prizes or awards for accepted suggestions from a suggestion box?

MR. HOYMAN: No, we do not.

CHAIRMAN WINANS: Why?

MR. HOYMAN: The reason probably is because we never thought that that was the desirable thing to do. On contests in a few individual cases we have given prizes for a slogan or for a suggestion but not for the suggestion of the regular Safety type that I spoke of in my paper.

MR. REIBLING: I think it is a very important point. We want to give money prizes in proportion to the saving. We have seen a certain danger in giving money to men who make suggestions. For instance, if they save us by a new process or new method or new device \$10,000 a year, we like to give them \$1,000, say, for that, but there has been so much objection to it and so much danger in starting a thing like that that we are very anxious to get suggestions on it.

CHAIRMAN WINANS: Is there any other experience on this question of money awards for suggestions that are accepted?

MR. WHEELER (Union Carbide Co., Niagara Falls, N. Y.): We ran a contest on suggestions at our Niagara Falls plant and we got very good results on it. We had over 1,500 suggestions in one month. The contest was open for one month, and you would be surprised to see all the things that were brought in. It was very educational and very good for the men. There was money paid for those suggestions in our contest.

EDGAR G. QUESNEL (Safety Engineer, Commonwealth Steel Co., Granite City, Ill.): I have two questions here which I would like to ask Mr. Hoyman. First, do you find any tendency on the part of the branch plants to conceal a bad record?

MR. HOYMAN: That is rather a difficult question because if you found a tendency of course you would try to curtail it. You know, as well as I do, that the dividing line between a lost time accident and one that is not a lost-time accident is subject to considerable variation, depending upon the person who decides that. In other words, if you arouse a considerable interest in safety or safety records in your plant, of course you are going to have men work with injuries which very likely are important enough or severe enough that in other plants they would lose time.

In answering the question, however, I don't believe that we have noticed any tendency toward concealing accidents, because in order for a man to work in our plant we have either nurses or doctors on hand at all times and every accident of any description whatsoever is reported. A very hard penalty is placed on a man who conceals a scratch; for instance, if it becomes infected later on, it very likely will cost him his job. We go according to the doctor's experience as to whether a man can work or not.

CHAIRMAN WINANS: What is your experience on that, Mr. Beck, in your contest?

MR. BECK: I have been very much pleased with some of the questionable cases that have come up as the result of our contest; in fact, a year or so ago we had one of our prize winners change their figures, which you can see might be possible with a case that might develop into a permanent partial disability; and the particular manager of that plant wanted it distinctly understood that he did not want that prize unless he was entitled to it. I think there is a very fair spirit among our factories on that score. They may question some of the smaller lost time cases, but when it comes to the big questions of right or wrong, I think that they don't want credit unless they are entitled to it. Then again, it is so easy for us to catch it. We have close supervision. We have a very complete manual of accident and compensation cost figures, and so forth, which they have to follow closely, and they certainly don't want to have it understood that they didn't play fair. We all like to play fair and we like a man who does play fair.

CHAIRMAN WINANS: Mr. Quesnel, do you want to comment on that yourself?

MR. QUESNEL: My thought in this connection was that in any accident safety contest there are a certain number of cases that must be estimated. If you have a close contest where two or more plants are running close together, would there be any tendency on the part of one plant to underestimate the extent of injury in order to lower its experience? For instance, a man is injured. You estimate that he will be off eight weeks. At that time it may look to you as though eight weeks would clear up the case, but later it develops that there is going to be some perma-

nent disability, such as stiffness of the fingers, or whatever the injured member might be, which would involve an additional loss. Would there be a tendency on the part of that plant to send in a revised figure or allow its previous estimate to stand, and should they win a prize on a close margin, and if this addition might make them lose it, would there be a tendency on their part to say nothing about it? That was my thought.

O. D. FREDERICK (Dirkes Lumber & Coal Co., De Queen, Ark.): What are you going to do when the manager doesn't even know of these injuries? We had a case in 1926 of a large sawmill employing 700 men, operating the entire year without a lost time accident, and they were awarded the prize. Six months later we had some lawsuits on our hands and we found out that the men were making up "pots" and giving it to the injured party in order to keep him from reporting the accident. In 1927 their record wasn't so good and this year it is very bad. Of course we are discouraging that as much as possible. That is a point on which I would like to hear if someone else has had any experience in that line.

HAROLD MOORE (Willis-Morrow Co., Elmira, N. Y.): I would like to ask if in any safety contest that you are running whether it is necessary for you to consider the extent of a permanency on a finger? We are out to prevent accidents. Does it matter from the point of view of an accident whether a man's finger is cut off at the first joint or the second? The accident is the same and we are trying to prevent accidents, so that in a safety contest it seems to me that the permanency should not be regarded at all.

There is another point. Let us take this question of hernias. That is always cropping up. In the case of a hernia you may have some predisposing condition with a man which may make the usual eight weeks totally inadequate to cover the lost time. Should you or should we in running a perfectly fair safety contest penalize that department where a hernia is sustained, where you have a permanency or an extended disability which has nothing to do with the case itself at all but is dependent upon it?

CHAIRMAN WINANS: Mr. Moore, may we take that up when we get to Mr. Beck's paper as to the rules of the contest? Mr. Beck has his formula here and we will take that up as a part of that general subject. We are talking now about keeping safety work up in the distant plants. Is there any question on this point that Mr. Quesnel brought up, of a tendency to misrepresent the records?

V. D. SUTTON (Postum Co., Battle Creek, Mich.): Mr. Hoyman said, in answer to Mr. Quesnel's question, that they penalized the man who had a trivial injury which later developed seriously. How do you penalize him?

MR. HOYMAN: We have a very strict rule that every accident, no matter how small, must be reported to the foreman and to the first aid room. The first occasion like that very likely would be a warning; on the second occasion we would lay him off. With the facilities that we afford for every accident to be reported and taken care of by having nurses in the plant full time, there is no excuse, and we accept none, for not reporting accidents of any description, no matter how small.

J. W. MYERS (Standard Oil Co., New York City): I would like to ask Mr. Hoyman whether that One Hundred Year Safety Man is weighted according to the hazard of the department?

MR. HOYMAN: No, it is not, excepting by the fact of only as to size of the department. Otherwise as to the hazards in the various departments we do not recognize that.

MR. MYERS: Doesn't the department with the relatively small hazard cash in on an unfair share of the prize money then?

MR. HOYMAN: That may be. I described in my paper a construction department or maintenance department that had gone four consecutive years. The thing that I was trying to prove there was that the hazards in the various departments cannot be judged by what a man might think about the hazards. The work is just as

safe as the man who is doing it makes it. In other words, the so-called hazardous work is not where our accidents happen, because the man who is familiar with that fact, who knows or thinks that that is supposed to be dangerous work, is more careful in consequence and is hurt a fewer number of times than our fellow who is walking around and drops something on his foot in non-hazardous work.

MR. MYERS: Mr. Chairman, we would like to hear from Mr. Beck on the question of hazard rate.

CHAIRMAN WINANS: Mr. Beck, will you please give us the allowance for variations in hazard in your different plants and departments as outlined in your contest formula, when we come to you.

Now, gentlemen, are there any other questions to ask Mr. Hoyman?

L. A. LADOWSKY (Pullman Co., St. Louis, Mo.): Don't you think a safety supervisor is better than just relying upon the foreman? You say, Mr. Hoyman, that you don't have a paid safety supervisor in your department. Don't you think it would be better to have a safety supervisor who would take care of those things and not rely upon a foreman for that?

MR. HOYMAN: What I said was that we have no safety man, engineer or supervisor, who puts in full time on that. We have a man in our "Service Department" who takes care of the safety work along with other duties. These things on safety naturally come to him, but he is not a full-time safety man.

CHAIRMAN WINANS: Are there any other questions for Mr. Hoyman?

J. J. WELINGTON (Brown Co., Berlin, N. H.): I would like to ask Mr. Hoyman if they have nursing service for the three eight-hour shifts?

MR. HOYMAN: No; perhaps I misinformed you there when I said "full time." We have our foreman trained in first aid to the extent of night service and facilities available for taking care of nights and a foreman to whom they must report everything that they take care of.

J. C. CAMPBELL (Reserve Gas Co., Clarksburg, W. Va.): Mr. Hoyman, under suggestions, I would like to know how you handle them. You say you make them out in triplicate. Who acts on them? Also do you have anything that is hazardous reported immediately?

MR. HOYMAN: I take it that what you are trying to find out is how we get action on safety suggestions. I said the foreman must make it out because he is in the line of authority and things should come through him. The so-called safety man that I spoke about, who works part time on that and to whom these suggestions come, in investigating the suggestion determines as to how soon that should be done; and he in turn in making out his requisition states their either "immediate action" or "can wait for some time." By the way, that goes back to our main office and the manager puts his okeh on it, which means that he also is informed, and it goes through as written.

CHAIRMAN WINANS: Mr. Hoyman, do you want to say anything in your own defense before we close your part of the story?

MR. HOYMAN: I don't know. I hope I don't need any defense. However, the things that I enumerated are only a small portion. I was trying to give you a little picture of just a few things that you might want to use and on which I would be glad to give you further details in a personal talk with you. I believe I can make myself more intelligible and even appear a little bit more intelligent in talking to one person rather than in talking to a crowd.

CHAIRMAN WINANS: Now Mr. Lundrigan will take the stand. His subject was, "What Should Be the Status of the Group Plant Safety Engineer?" How many of you disagree with the idea of close central office control over your plant safety operations? You don't need to tell me. I want you to tell him. If you have any questions to put to Mr. Lundrigan or any comments, this is your opportunity.

J. W. MYERS (Standard Oil Co., New York City): Mr. Chairman, I didn't quite understand what I thought was going to be the main point of his paper. Do the local plant sanitary inspectors or safety inspectors report direct to Mr. Lundrigan, or does his line of authority go through the management?

MR. LUNDRIGAN: As I understand the question, the gentleman wants to know whether the local safety supervisor is a part of the general office organization at New York or a part of the local plant safety organization. Is that it?

MR. MYERS: Not exactly. I want to know whether the local safety man reports direct to you or whether you act in an advisory capacity through the management.

MR. LUNDRIGAN: He reports direct to me through his plant manager. We refuse to read a report that his plant manager hasn't signed.

MR. MYERS: Do you give orders to him direct?

MR. LUNDRIGAN: His orders are the written rules of the company.

MR. MYERS: If you think some change should be made in a safety code do you order that thing done or do you recommend it to be done to the management and the management orders the safety man to put it into effect?

MR. LUNDRIGAN: Those orders are printed instructions of the International Paper Company, and have virtually the authority of the president of the company. He, of course, isn't bothered with the detail of their application or carrying out. They are printed as "General Instruction No. 74," for instance, signed by the International Paper Company. They are a part of the operating policy of each local plant, just as the question of blowing the whistle at a quarter to seven is a part of it, if that is what you are getting at.

MR. MYERS: I don't think you have quite answered my question. Do you have a direct line of authority through your local safety man?

MR. LUNDRIGAN: Through the local manager to see that he carries out those rules and makes the report required under those rules. We check him up constantly. We have two traveling supervisors, both of them are in the room, whose principal duty is to study the weekly reports of the safety supervisor.

MR. MYERS: If you want to correct a condition do you make a recommendation or do you issue an order?

MR. LUNDRIGAN: If we want to correct a condition provided for in our rules or a condition that has been recommended by the safety committee at the plant and approved by them, or a condition that we have found at the plant that comes within our rules, we ask the mill manager why he hasn't done it. The mill manager is the sole authority; he is the International Paper Company, as I tried to say, in the territory where he operates, in so far as our organization is concerned. We issue a supplementary instruction in which we say to the mill manager that he must endeavor to meet the date of a local safety committee meeting at which he should personally preside, unless of course he is ill or on his vacation or something of that sort, when common sense governs, and the man in authority takes his place. He is the chief executive and chairman of our local safety organization. He is positively controlled to the minimum of responsibility and performance by these written rules which I realized were somewhat tiresome reading.

Those rules, as I said before, or intended to say, are virtually prepared and approved of by every plant manager, every safety organization in our company, before they are ever put into authoritative form, so that a favorite expression, challenge or boast, or whatever you want to term it, of those of us who go out from New York is to say, "Those are your rules. You said they would work. You went farther than that and said that they would help you; that you wanted them, and you now have them and we are here to see that you live up to them." Then we go still farther and we say that we can personally come into the plant and apply any one of those rules or any supplementary instructions connected with them, not only without any difficulty but to the betterment of your condition and

particularly your cost. That is our position and of course it sounds somewhat egotistical, boastful, and so forth. We seldom have to use it, but if we ever do have to, so far after eleven years of performance we have been unanimous in proving that we were right.

DR. ETHELBERT STEWART (Commissioner, U. S. Bureau of Labor Statistics, Washington, D. C.): Mr. Chairman, the statistics we get from all industries of all sorts, wherever this matter comes up, show that about 85 per cent of the accidents occur to men who have been less than 30 or less than 60 days on the job, and an enormous percentage occur to the men who have been two and three days on the job. All of these companies have a high labor turnover. What do you do with the fellow who comes in and can't read your rules? The single manager in your shop can't get hold of every new man who comes up and teach him what to do; and after all haven't you got to have some scheme by which you can reach your accident rate that comes from the turnover, and must not that come from the bottom instead of from the top?

MR. LUNDRIGAN: I thank you, commissioner, because you gave me a chance to finish reading a part of my report.

Here is the answer: Beginning January 1, 1924, all mills shall establish an Employment Service for the purpose of providing for a more adequate supply of labor and diminishing the labor turnover.

Where the local supervisors of safety are employed they shall administer the details of the service, including the keeping of the records, except that (with the approval of this department) the mill manager or mill superintendent may designate some other employee to do so where conditions make it advisable.

It shall be the duty of the one in charge to keep in constant touch with the department superintendents and foremen both as to the immediate and future needs for help and as to the possible reductions in help in each of the mill departments.

He shall furnish each new employee with a copy of General Instructions No. 14. Rules and General Instruction No. 74, Safety Organization, instructing him particularly as to the Safety Provisions, including First Aid and Nursing Service provided at the mill.

He shall personally introduce the new employee to the department superintendent or foreman, advising as to whether or not the new employee claims experience in the work he is to do, and in either case recommend to the department superintendent or foreman that he be given adequate instructions as to the nature and hazards of the occupation.

When an applicant is not hired and desires to be considered for future employment, he shall make a record of all the information the applicant is willing to furnish, on Form No. 287 "Application for Employment and Record of Service," the same as though the applicant were actually hired, including whether he will be available when a vacancy occurs or whether he will accept a position other than that applied for, entering the acceptable occupations by name on Form No. 287.

Form Letters (see Mill Form Instructions No. 304) shall be used to notify such applicants of a vacancy when it occurs, accompanied by an addressed stamped envelope for reply.

The Employment Service shall have up to date information available to both applicants and employees covering at least the following subjects:

1. Rates of wages paid by this company for each occupation the applicant is willing to accept.
2. Up to date lists of boarding and rooming houses, with locations and actual or approximate rates for weekly board, for rooms and for meals.
3. Means of transportation and fare back and forth from the principal points in the mill town or vicinity to mill.
4. Location and rental cost of various types of dwellings.

5. Location of schools and kindergartens, including denominational schools.
6. Location and denominations of churches.

Does that answer your question?

DR. ETHELBERG STEWART (U. S. Bureau of Labor Statistics, Washington, D. C.): How many languages do your employment men speak?

MR. LUNDRIGAN: In the United States we think we can point somewhat with pride to the efforts that we make to Americanize and educate our help. We have in four district schools today, that started the day after Labor Day, a Labor Accident Hazard Course being taught at the expense of the International Paper Company, and in one or two instances it took a year to induce the Board of Education to permit it.

CHAIRMAN WINANS: Thank you very much, Mr. Lundrigan.

It is Ernest Beck's turn next. There have been a couple of questions asked already. The first one was about the weighting of the accident hazard.

MR. BECK: In any well planned safety contest it is necessary to have a set of rules; you must have a set of standards. When you are operating 30 factories in 12 different states, you have got the compensation laws of all those different states which you might think would disturb you in operating a contest, but it doesn't. We accept the standard scale of time losses as agreed upon by the Industrial Accident Boards and Commissions and the National Safety Council, and that is what we base our contest on.

It makes no difference whether I lose that finger or this finger. I am not so much concerned with the number of days that the man may stay out when he loses this finger or that finger. In some cases he may come back within 10 days after losing all of that finger, while another man may be out two months with that finger. We charge 600 days, or whatever it may be, for that finger, regardless of where it happens, when it happens or how it happens, because it is a loss to society of the right index finger, and that is the standard procedure in all 12 states in which we operate. You have to do that or you won't get anywhere, because you are going to have one plant say, "We have a clever doctor. He gets the men back in 15 days after the loss of an index finger." In another plant the doctor isn't so good and he takes a couple of months. As a matter of fact, the one man may not be in as good health as the other man. You must have a set of rules to govern you.

I believe your hazards are already determined in the base rate. If you take the average experience over the previous three years and hit an average, I think you have got the hazards at that particular plant pretty well weighted. Then, you see, you have another year on which to show an improvement on that particular average, which is a three-year average. We have plants where we have more women than men, where women stand and make footwear. We have plants where men stand at heavy motors and conveyors, handling motors weighing 500 pounds. After three years of exposure in that plant where we handle heavy motors and conveyors, we are bound to have more disability than where we have women working on light-weight footwear. But over the three years' average the factory with a bad experience has to try equally as hard to improve its experience because it has a high rate and it takes a big percentage of reduction to show a large percentage of improvement.

While I am talking on that score, the proof of the pudding is in the eating. In the five years that we have been conducting our contests, I have been dumb-founded to find each year that we have shown an improvement over the previous three years' average.

These are the figures:

In 1924 we showed 7.22 per cent improvement; in 1925, 12.54 per cent improvement; in 1926, 11 per cent improvement, and in 1927 we showed a 29 per cent improvement over the average previous three years, each year of which showed

an improvement over the previous three-year period. For the first six months of 1927 the improvement shown was 32.44 per cent and for the first six months of 1928 it was 43.42 per cent.

CHAIRMAN WINANS: That's fine. We have no opportunity for more questions if we are going to close this meeting on time and if it runs any longer you are going to say so.

DR. ETHELBERT STEWART: I would like to make one statement. I am not sure that this is true but it sounds like a good many other things that I know of, that are true. A railroad company in a contest was accused of having cut off a man's leg and put him in a chair and it took two men to wheel him down so he could be a watchman at a crossing and it wouldn't be counted as a lost time accident.

Just how much do you protect yourselves in these contests against the schemes of the fellows who are going to get the premium for winning the contest?

CHAIRMAN WINANS: I believe, Commissioner Stewart, Mr. Beck's previous answer covered that, namely, that the established schedule for permanent disability penalties applies throughout all of their plants and they can do the very thing you illustrate and still the penalty would go against that plant for the permanent disability caused by the loss of that man's leg. So I think the incentive for misrepresentation there is removed.

Are there other questions?

C. W. SCHEIHING (Oxweld-Acetylene Co., Newark, N. J.): Mr. Beck says to get a contest started that you must have it well planned in advance. We all know the foreman is the key man in the plant. In what way does Mr. Beck educate the foreman so that the contests go over efficiently?

MR. BECK: The president sends out a letter declaring the contest, which goes to the factory manager who in turn sends out a letter, and then there is a committee appointed and they organize the plans and work with the foreman, and the thing just grows.

(At the close of the session Mr. Ernest Beck displayed a number of lantern slides, illustrating safety trophies and scenes at safety rallies, some of which are reproduced with his paper delivered earlier in this session.)

SEVENTEENTH ANNUAL SAFETY CONGRESS
NATIONAL SAFETY COUNCIL

Special Session For Industrial Executives and Engineers

October 3, 1928

ROBERT ADAMSON, Chairman
Vice-President, Bank of the United States, New York City

The Special Session for Industrial Executives and Engineers was called to order by Mr. Charles P. Tolman, Consulting Engineer, 111 Broadway, New York City.

MR. TOLMAN: Gentlemen, it becomes my pleasure to open this meeting on behalf of the National Safety Council and to introduce the chairman, who will preside during this session. Before doing so, I would like to say that this meeting, in my opinion, is one of the most significant meetings held during this Congress.

For a period of seventeen years, the National Safety Council has been steadily developing the cause of the prevention of accidents. The movement started out of the bigness of heart of a group of men, but as it developed it proved to have a broader and deeper meaning from the standpoint of industry.

For a long time, accident prevention was regarded as more or less of a charitable, kind-hearted thing to do. We all know that executives are not privileged to extend charity in the name of their stockholders. Not until it became known that safety activities are a necessary feature of good management, profitable to management, and that the failure of adequate safety activities means bad management and loss of profits, did it become possible for the industrial executive to do as an executive that which he wished to do as a man.

This meeting, largely of business executives, in a city which is the executive city of the United States, is today significant of the importance of this movement in industry and in banking and in all of those things that go to make up the economic structure of our country. It is a particular pleasure to me to introduce as Chairman to preside over this session, a man who has had extensive governmental activities, and who is known as one of the leading bankers of this country, Mr. Robert Adamson, Vice-President of the Bank of the United States.

CHAIRMAN ADAMSON: It is a very great pleasure to me to address a meeting of the National Safety Council, because it recalls a delightful experience of a good many years ago when I was officially connected with one phase of the work which you are doing. During that time I had the pleasure of attending two of your Congresses. It is remarkably significant to see the wonderful growth in the attendance, in the interest and in the comprehensive breadth of the subjects you are discussing, since the last time that I sat in at one of these Congresses.

Mr. DeBlois told me that I was the second banker who had ever presided at one of these functions. I don't know whether that would be regarded as a good thing for the safety movement or not, because last night I heard a story illustrating the general character of bankers. A man applied for a position in a kitchen of a hotel. They asked him among other things whether he could shave ice or not. He replied, "I ought to be able to because I was formerly private barber to a banker."

I leave it to you to judge whether it is in the way of progress to have a banker as one of your speakers.

For many years I was the head of the Fire Department here in New York City. One of the most interesting things to me, and one of the most constructive things we were able to do was the work which we undertook in the way of fire prevention. It was comparatively a new subject at that time and we encountered great indifference and great apathy. We found it was a work of education. But one of the most significant things that I found, and it is a fact that applies to the work which you gentlemen are doing, was this: that the greatest number of fires did not occur in the places of greatest hazard, in the places where combustion was the easiest to start. The figures showed that the smallest percentage of fires occurred in the highly dangerous but well regulated industries, and that the great majority of the fires occurred in the homes of the people, where with the proper education and care they were preventible. That was a difficult matter to reach, because you couldn't reach it by enactment or ordinance. It was a matter of education, and that we undertook to do as well as we could.

I notice that a great deal of emphasis is placed in your literature on the word "accident." Strictly speaking, I think there is no such thing as an accident, because the things that we call accidents are merely the working out of the law of cause and effect. The great majority of those accidents are due to the human element. It seems to me that it would be an awfully good thing if we could coin a new symbol for this word "accident" which might bring into it an implication of the responsibility of the individual, because so many of them regard an accident as merely an act of Providence or something that they can't prevent. If you could find a word that would imply the human responsibility, you might do a great deal to correct the mental attitude toward this great subject.

Of course, the economic side of this question is one of vast importance. You only need to read the line on the first page of your prospectus here, saying that the economic loss in this country from accidents is five billion dollars a year. That is a stupendous thing, and when you say this you merely state a part of the problem, but a very great part of the problem which is before your Congress to solve.

I was encouraged when I read the other day the program for this convention, and saw how fully almost every phase of this subject has been covered. I know the wonderful progress that has been made along those lines. It can be solved only by the expert and by study and by education.

One of the most encouraging signs, too, along this line is the recognition, the growing recognition of industry of the importance of this subject. Your budget and the amounts of money which are now being spent by industries to prevent accidents is the most eloquent evidence of that.

I think that the cause of safety can be congratulated on the fact that in these industries there are many able, splendid men who are devoting their time, energy and thought to the solution of this problem. There are a great many in that work because they love it. I found in my contact with them that those men were devoted to this subject. When you get men who work with that enthusiasm and devotion and self-sacrifice, you are going to get somewhere in the solution of the problem.

This afternoon the program is going to follow along the lines of a given subject. Each of the four speakers here is to discuss, as an expert, some phase of that

subject. They are going to create for you a mosaic along that line, each one contributing to some part of it. It is planned that at the end of the speeches we are to have the discussion. It was thought better not to interrupt the continuity of their addresses by having the public discussion as the speeches proceed.

For the handling of the public discussion which will follow these speeches, the committee has thoughtfully provided an associate chairman, who is an expert along these lines, as I am not. I have great pleasure in presenting to you, as the first speaker, Mr. H. W. Heinrich of the Travelers Insurance Company.

The Origin of Accidents

By H. W. HEINRICH

Assistant Superintendent, The Travelers Insurance Company, Hartford, Conn.

An undertaking of great scope and value—such as the prevention of accidents undoubtedly is—depends largely for its success upon the soundness of the basic principles upon which rest its necessity and its method of operation.

We have long since passed the stage where the necessity for preventing avoidable accidents that result in death and physical injury needs defense. The mutilation of flesh and the spilling of blood are violations of nature; they are blots upon the perfection of a peaceful and industrious existence. Humanity bids up to prevent accidents. Even those skeptics who have argued that accidents should be considered an inherent part of profitable industry, seem to have been silenced by the discovery that accidents affect profits to a material degree—a discovery that resulted from the substantiation of the theory that the total cost of accidents to the employer is at least five times the visible cost as measured by payments for compensation and medical treatment.

We are not upon so firm a footing, however, when we analyze the basic principles which govern our methods of procedure.

I would like to make use once more (but perhaps in a different sense) of the oft-drawn simile between the prevention of accidents and the prevention of disease.

Necessity largely determines the sequence of action by the medical fraternity in treating a patient. Three steps are always considered and quite generally taken.

First—the immediate and outward evidence and result of the trouble is treated. For example, the flow of blood is stopped, the fever is reduced, the heart action is stimulated, and so on.

Second—the cause of the trouble (as shown by the diagnosis) is removed, if possible. If climate is at fault, a change is prescribed. If failure of organs to function caused the ailment, these organs are treated accordingly. In a broader sense—as in the case of fevers and plagues—wholesale action is taken, such as by quarantine, by oil treatment of swamps, by fumigation of ships, and so on.

Third—the patient is fortified, if possible, against recurrence; diet is prescribed to build up the system to reduce susceptibility, or exercise is recommended where it will assist in warding off a repetition of the trouble.

And so, too, with accident prevention we have the same three steps to take. Of course, we must treat the injury which is the *result* of the accident. Of course, we should guard against recurrence, if possible, by fortifying the patient—by which I mean providing goggles, gloves, leggings, and other protective devices, installing guards on machines, and taking other appropriate action to correct dangerous physical conditions; *but above all*, as in the case of bodily ailments, it is vital that we find and treat the *cause* of the trouble—in this case the cause of the accident. This, to a regrettable extent, we are not doing today.

We confuse the injury with the accident in our search for cause. We confuse causes and types and are therefore misled in our corrective action. The sequence

of events when an injury occurs is as follows: First, the cause; second, the accident; and third, the injury. Let me illustrate.

A person slipped and fell and sustained an injury. At the time he slipped and fell he was carrying an object of such size as to interfere with his view of the walkway surface, and as a consequence misjudged the location of the first step of a flight of stairs. Trucking and elevator facilities were provided for the transportation of these large objects, and the employee had disregarded instructions. Referring again to the sequence of events that exists in connection with all accidents, we have in this particular case first, the cause, which is non-enforcement of instructions; second, the *accident*, which is the slip and fall; and third, the injury, which is the result of the accident. Prevention of such accidents as this is obviously possible only through the determination of the *cause*. It helps us but little to assign this accident to an erroneously named cause—such as “slips and falls” or “contusions.” Nevertheless, this is just what is being done generally throughout industry. It is true that “slips and falls” is a cause. It is a cause of the *injury*, however, but not a cause of the *accident*, inasmuch as the *accident itself* is the slip and fall. It cannot but be obvious, therefore, that we, as accident prevention engineers, when referring to causes in connection with accident prevention, must above all things have in mind the cause of the *accident itself*.

This is so simple a fundamental that it must come as a shock to hear the statement made that industry in general is not now assigning accidents to true causes. You may perhaps doubt that this is actually so, and it may be interesting for you to check or test the validity of this statement. If you care to proceed along this line, I would suggest that you begin at your own plant and see just how far you have gone in the way of assigning accidents to *real causes*, keeping in mind that the cause of an injury is not the cause of an *accident*, and keeping in mind also that types of injuries, location, nature of injury, name of machine upon which the accident occurred or the department in which it happened, and other incidentals of this kind are not causes of accidents. You may also be interested to the extent of making a further check of the statement that I have made, which can be done by a brief study of national, state, and city tabulations of accidents and their causes, or by a study of data upon accident causes as provided by individuals and organizations throughout the country.

We are gathered here in a common cause and, needless to say, a worthwhile cause. We want results. We want to make progress. We are earnest in our desires. We spend much time in the discussion of ways and means to create and maintain safe working conditions. We use known hazards as a basis for our discussions, but we lack specific information bearing upon the relative severity of these hazards one to another. We are not even sure that the situations into which we inquire themselves actually produce accidents in great number. All we know is that accidents do happen and that hazards exist. We work faithfully and hard and are making commendable progress: but in a measure we are working in the dark—feeling our way along—retarded in our efforts to accomplish real and speedy results by the fact that we are not concentrating upon known causes and major issues.

Inasmuch as we do not know actual causes we, perforce, cannot know effective remedies. We know that education is good, and we apply it. We know that morale is a factor, and we work at that to some extent. We know that unguarded machines and other physical conditions present hazards, and we try to guard them; and we do other things of this kind that are worthwhile and that should be continued. Nevertheless, our efforts cannot bring the results that we desire until we know what we are doing and where we are going and have means to check our progress. These things can only come about through actual knowledge of accident causes and through what follows as a natural result, and that is, actual knowledge of effective remedies.

Criticism of the kind of accident prevention methods in general use at present, although friendly and sympathetic, is nevertheless non-constructive unless followed by something else. Progress has been made. Through painstaking research Travelers engineers have proved to their own satisfaction (and I believe it can be said to the satisfaction of others) that 98 per cent of industrial accidents are actually preventable, that 88 per cent of all accidents are due to supervisory causes, and that 10 per cent of accidents are due to physical causes; and they have determined what these causes are. Because the existing system of reporting accidents has not been so planned as to provide reliable data upon real causes, the task has been made difficult. We have, however, been able to obtain the complete stories of 75,000 individual accidents, and the results of an analysis of them have proved interesting and instructive. This is shown graphically by the accompanying chart.

Charting the Causes of Accidents

The circle at the top represents 100 per cent of all industrial accidents. The small black wedge, in the upper part of the circle, represents 2 per cent of all of these accidents that under practical working conditions may be termed unpreventable. The remaining white portion of the circle is the 98 per cent of all accidents that are actually and practically preventable. From this circle run two lines, right and left. The one at the left leads to a blank rectangle representing 88 per cent of all accidents that can fairly be assigned to causes other than material or physical. The smaller black rectangle at the right shows the 10 per cent of accidents that are truly caused by unsafe physical conditions.

Both lines converge at the bottom to a single point indicating the root-remedy. I have shown as a secondary root-remedy the employer-executive who has it within his power to enforce proper supervision—and, of course, to provide physical protection. Going still further, I have indicated in the lower rectangle that the employee is a root-remedy—as of course he is. An employee need not go to work in a physically unsafe plant, and if he is the proper type he may safely perform his work even under unsafe conditions and without proper supervision.

We all know, however, that it is not practical to expect the average employee to be perfect in these respects. He must be guided, supervised, instructed, and watched over. The employer-executive, however, can through the exercise of the very methods that promote production, efficiency, economy, and plant profits, control industrial accidents through the elimination or amelioration of actual basic accident causes, such as those listed in the following chart. There are seven items under supervisory accident causes and also seven items under physical causes.

These are noted in the graphic chart above described; and in further explanation of this chart the following points may be emphasized:

1. Both supervisory and physical causes may be controlled by the employer. It is apparent that in the last analysis the employee also may avoid accidents, even though he is exposed to unsafe conditions.

2. Accidents due to mechanical or physical exposures should be assigned to causes in the supervisory group, where the foreman had authority to install or maintain guards. In such cases we consider that the chief cause is laxity in supervision. By following this line of reasoning, we arrived at the total of 10 per cent shown in the "physical" group. As ordinarily analyzed, we found the physical total to be 25 per cent.

3. The value of analysis by the causes listed in the chart, as compared to the existing method of allocation as slips and falls, eye injuries, and others, is apparent. It permits concentration upon the things that count. It directs attention to supervisory responsibility or to physical hazards, both of which are controllable.

4. In supervisory item 2, we refer to *chronic* poor judgment, ignorance, and lack of skill, since *temporary* inability in these respects sometimes applies to properly qualified employees and would therefore be more likely to come under items 3, 4, or 5.

5. Terms such as carelessness, poor supervision, and improper selection of employees, have deliberately been omitted because of ambiguity.

6. An unpreventable accident (one of the 2 per cent group) may actually be due to one of the causes listed in the chart, yet the circumstances may prohibit assignment as a preventable case.

7. Some of the causes appear to overlap (unskilled and ignorant, for example) yet there are occasions when an accident is clearly chargeable to only one of the items, consequently all causes have been included in the foregoing list. Contributory causes should be shown as of secondary importance.

8. The necessity for brevity permits merely a condensed outline of causes. If the intent of each item is understood, however, the list will be found to be complete within the limits of practical application to existing industrial organization.

All the Conditions Should be Under Control

An employer will hardly deny that in a properly operated plant all of these fourteen conditions should be under the control of himself and his supervisory staff; and it also is apparent from a study of these conditions that they may be controlled by the very methods that are now used by employers generally in effecting economy, efficiency, greater production, and increased operating profits.

In addition to the humanitarian reasons for safety work which, in themselves, should be (and are) all-sufficient to compel us to eliminate preventable accidents, we know that these accidents cost industry approximately five billions of dollars annually. We have therefore a well-rounded-out incentive to our efforts. Without question, the frequency and cost of accidents in industry can be reduced speedily to 50 per cent of their present volume. I have said, however, that this reduction will come about chiefly through the recognition of the principles herein advocated, and I emphatically recommend the revision of present accident-prevention practices. I urge that the term "accident cause" be clarified; that a more systematic and determined effort be made to obtain the complete story of accidents from which the real causes may be more readily determined; that we set up a list of probable accident causes such as I offer you today (or another list, if a better one can be found); that we establish in our plants the practice of assigning accidents to such causes; and, finally, that throughout the various plants in industry and in the individual city, state, and federal bodies, we work out a uniform list of real causes and rearrange our method of tabulating accidents by causes, so that industry may have the benefit of nationwide data to which it may turn, to find and correct the predominating conditions that cause the industrial accidents of today.

CHAIRMAN ADAMSON: Gentlemen, it seems to me that your committee has been as happy in the wording of the topics to be discussed as it has been in the choosing of the speakers who are to discuss them.

We pass on in logical order to the next subject which is a part of this general subject, "Safety and the Individual." And to discuss that, we have a gentleman who needs no introduction to you. He was for many years supervisor of the fire prevention activities in the great Du Pont industry. He is an author of a very interesting work, "Organizations for Accident Prevention." He is a Past President of the National Safety Council. Since leaving the Du Pont organization, he has become widely identified with the whole safety field. In fact, we might say that he is a post graduate of the college of safety and conservatism. I have great pleasure in introducing as the next speaker Mr. L. A. DeBlois.

INDUSTRIAL ACCIDENT CAUSE ANALYSIS

Safety and the Individual**By LEWIS DeBLOIS**

**Director, Safety Engineering Division, National Bureau of Casualty and
Surety Underwriters; Past President, National Safety Council;
Chairman, New York Safety Committee**

I shall begin, not where Mr. Heinrich left off, but at a different point. I think you will find, however, that I shall come out on the same road eventually and that together we shall carry the subject along further, stopping for the other two speakers who are to follow us.

There have been in the past few years two outstanding contributions to accident prevention knowledge. One of them is not well known, at least in this country; the other, I fear, is not well recognized. The first is the work done by Miss E. M. Newbold for the British Industrial Fatigue Research Board and published as Pamphlet 34, "A Contribution to the Study of the Human Factor in the Causation of Accidents."

What Miss Newbold did was essentially this: She set up machinery for collecting the first-aid accident case experience of approximately 9,000 factory workers in relatively stable groups in ten different industrial undertakings. Some of them were men and some were women—but within each group all workers were subject to relatively the same hazards.

First-aid reports were the subject of the study because the period was not sufficiently long to permit the accumulation of sufficient data on lost-time accidents. Since every first-aid report was considered, you will see that the study was based on frequency and not on severity. There were 16,000 first-aid cases reported in the periods of observation which varied for the different groups from a few months to two years. The actual distribution of these reported cases among workers was then compared with the theoretical.

Most of you might conjecture, I think, that accidents in a given group would be fairly evenly distributed so that there would be a general averaging up of these unfortunate occurrences. This, however, is not necessarily the case. If accidents follow the laws of chance; that is, if we assume that accidents are solely chance occurrences, and if no one accident affects the occurrence of any other accident; that is, predisposes the injured person to a second accident, in very general terms the distribution should be, roughly: One-third of the persons in the group should have no accidents, one-third should have one-third of the accidents and the remaining third should have the remaining two-thirds of the accidents. This is a very crude method of expressing the working-out of a precise law, but it will suffice here.

Miss Newbold's observations of the distribution of accidents among individuals indicated in every case a marked deviation from what would be expected if accidents were chance occurrences. She found that a much larger proportion of persons than normal had no accidents, while a very small proportion had many more accidents than was to be expected. This latter class were the so-called "accident-prone." Let me add, also, the interesting fact that these accident-prone people seemed also to be those who reported oftenest to the first-aid stations and hospitals for minor sickness treatment.

If you stop to think about it, we in this country have reached, in a general way, about the same sort of conclusion about personal accident proneness. In regard to automobile accidents, for example, we admit that there is a small group of reckless chance-takers who cause most of the trouble. At the same time, we admit the existence of a very large group of drivers who operate their cars with no—or relatively few—accidents.

Now let us leave the British researches, retaining in our minds, however, the fact that it has been proven that an extreme accident proneness exists in a small proportion of each industrial group, and consider the second of the two outstanding contributions to accident prevention knowledge, which is, I think, our American experience in no-accident records.

We have been interested in no-accident competitions chiefly as a means of increasing interest in the safety movement; we have regarded as wonderful some of the no-accident records that have resulted; but have not we very largely missed the deeper lesson contained in this experience? I shall not take your time to give examples of conspicuous no-accident records, for our safety literature is full of them. They are to be found in all sorts of industries, in all sorts of plants and, naturally, for varying lengths of time. In terms of man-hour exposure, which is, of course, the proper basis for comparison, we consider that a half-million man-hours constitutes a significant record. From that figure, records go up to ten million man-hours, which is the highest I know. During these no-accident periods, there are no lost-time accidents.

What are the lessons to be derived from our American no-accident experience? First, let me say that I have studied a great many, but have never known one to occur except after months and sometimes years of painstaking, consistent effort. These no-accident records are not accidental; they are the result of human endeavor, and are accomplished only in plants where the entire personnel, from the manager to employees, is united in a determined effort to wipe out lost-time accidents.

Secondly, these records have been made in a wide variety of industries and sometimes in the face of extremely hazardous industrial conditions, foreign labor, high labor turnover, antiquated equipment, lack of safety devices, and, in fact, of practically every obstacle with which the safety man has to contend, except only lack of sympathy in the executive management of the plant. This latter is an obstacle which inhibits the making of a no-accident record.

The third point is the perfectly obvious one that during no-accident periods, not only are there no *avoidable* accidents, but those accidents which we have heretofore been pleased to call *unavoidable*, cease also. This is a paradox to which there is but one answer: there is no such thing as an *unavoidable* industrial accident. Mr. Heinrich, in his analysis of accidents, tells us that two per cent are unavoidable. If you ask me how about earthquakes, typhoons and hurricanes, I shall simply say that they cannot properly be termed *industrial* accidents.

We may now bring together the conclusions from Miss Newbold's researches in England and those derived from American experiences. On both sides of the water there is belief in an individual susceptibility to accidents; in other words, a varying degree of accident proneness varying, if you please, within wide limits—from zero to sixty, or higher. Our no-accident experience in this country, however, shows that each worker's individual accident proneness, no matter at what figure it started, becomes zero during a no-accident period and remains zero as long as the period continues. It seems probable, therefore, that the accident proneness of all men can be made equal or relatively so. This, in fact, is just what a no-accident effort accomplishes. In other words, we discover an ability to control individual accident proneness, almost without knowing that we were doing it.

You can see at once that this places our problem of industrial accident prevention on an individualistic, educational basis. If we are to succeed in national accident prevention, we must learn how to make mass effort reduce individual accident proneness to zero, not only within the industrial field, but among motor drivers, school children in the schools, people in the home and elsewhere.

Let us then turn back to our no-accident experience and see what it is that we actually do. Of course, during these periods we stop accidents. That is obvious.

But what is going on? What is the process in respect to each of these individuals at work in the factory in question?

I think the answer is so simple that we may have missed it. I am inclined to believe that it is nothing more complicated than the destruction of an old set of ideas (concepts) and their replacement by an entirely new set. We eradicate the old idea of accidents sent in upon our lives by God, by Providence, by "luck," by "chance," misfortune, or by whatsoever or howsoever you wish to speak of it or personify it. We commence to recognize that the accident, however sent, is humanly controllable. We recognize that the time has come for controlling it. That is all.

I do not know what may have happened to you as a child, but I escaped punishment many times because Mother said to Father, "Don't punish him; it was only an accident." There you have it: accident=excuse. We have grown up with it. It has been part of our lives. We spare men from the gallows or the electric chair because "it was an accident." Implicitly believing it to be something sent in from the outside and beyond our control, we have made it the excuse for anything and everything. But we are discovering now that, after all, it is within our control, so that accidental homicide practically becomes murder in greater or less degree. With the growth of the safety movement and the enactment of compensation laws, we lost the old defense of assumption of risk, fellow-servant and contributory negligence; we now lose the great human defense of "accident."

We have taken the groups of men in our plants and have sold them what we call safety, which is the "preventivity" of accidents. Incidentally, we have helped them to learn how to prevent accidents. We have placed behind their effort a body of public opinion which catches up the most reluctant, slow-to-act man in the plant and says to him, "We do not care whether you share our belief, but you must prevent accidents in this plant. Otherwise you will spoil our record, and woe to him who causes an accident and undoes what we as a group have set out to do." I have seen men who have broken these records go out the gate for the last time. It has happened in many, many plants.

Mr. Heinrich stresses very properly the great importance of accident analysis and the discovery of true cause. I see another great value in it, which is the value of the investigation as an educational means. If safety committees and safety inspectors will do what Mr. Heinrich has recommended here today, they will be undergoing the finest form of self-education in accident prevention. It is applicable also to the superintendent and to the manager of the plant. There is no better way to learn that accidents are preventable, that they are not mere misfortune, than by digging in to find their basic causes.

We have had trouble in reaching and selling the small plant manager an active interest in safety work. Although some good records have been made in small plants, the record of the average small plant is far from good. The attitude of the small plant operator may be expressed by his saying to the insurance or state inspector, "Safety first is all right. I am for the movement. But we don't have accidents here. We haven't had an accident in the last two or three years. I suggest you go across the street to Bill Jones' biscuit factory, where they have a thousand men and a lot of accidents. I've only twenty men and they've been with me for the past twenty or thirty years. We don't have accidents."

The truth is that he does not know whether he has a bad accident record or not. He sees too few accidents to alarm him. If this is true of the small plant, how much truer of the single individual! In all seriousness, I ask you how many accidents a year it takes to make an unsafe man and how few to make a safe man? You are safety engineers and executives interested in accident prevention. Do you know? Do you know when your men individually are safe, accident-free men? Do you know what the standard of comparison should be? How many years of

accident-free record should you have to render you eligible to the title of a "safe man"?

Let us figure it roughly. There are thought to be about ten million time-losing accidents a year in this country. In round figures, there are one hundred and twenty million people. We may assume that forty million have no accidents; forty million have 3,333,000 accidents; forty million have 6,666,000 accidents. If eighty million people have 10,000,000 accidents, it does not mean that one in eight has an accident. I may be only one in twenty—which keys in pretty well with our ideas of accident frequency, though it should be remembered that we have included children and women. At any rate, I arrive at the general conclusion that if I have not had a time-losing accident myself for five years, it may not mean anything at all—next year I may have three or four!

In this safety movement, you and I and the National Safety Council and everybody else have been trying to sell safety to the individual very largely on the basis of making him realize that he is a hazard and is likely to be injured. Against this is his own personal experience of years in which no injury has occurred. There is an internal resistance to our sales argument because the individual's experience (in nineteen out of twenty cases) appears to deny the truth of our statements that he is in danger. There is another basis, however, upon which we can sell him very well. We already employ it to some extent. We can sell him in the belief that his brother, his fellow employe, is in danger of being injured. He may not have seen himself injured, but he has certainly seen other employes injured. Sell him then an unselfish interest in their welfare and the realization that to help them he himself must set an example of safe conduct.

And, finally, may I point out that if we adopt this attitude of unselfishness in our teachings and in our conduct, it will soon cease to be an attitude and become our belief. Through it we can make of this safety movement the greatest humanitarian and altruistic movement that the world has ever seen—with one exception: the spread of Christianity. Indeed, it will be a movement of applied Christianity. I have always believed that the success of the safety movement came only through unselfishness and, to a certain extent, through self-sacrifice. I believe now that our future success in making it truly effective lies in our ability to believe and spread the belief that each man is in truth his brother's keeper.

CHAIRMAN ADAMSON: The next branch of this afternoon's subject which we are to hear discussed is "Safety and Production." We are to hear from a well qualified expert, a gentleman who is an engineer and distinguished in his profession. He is a Past President of the American Institute of Electrical Engineers and is the present President of the American Engineering Council. He belongs to many prominent engineering societies. He has had an active experience not only in engineering but his particular field of work has been in the management of industrial organizations. He is a combination safety engineer and engineering expert. I take great pleasure in announcing to you as the next speaker, Mr. A. W. Beresford.

Safety and Production

By A. W. BERESFORD

President, American Engineering Council, New York City

Purely from the basis of reason it is evident that the creed of the safety engineer—A safe plant is an efficient plant—is well founded.

That the reduction of personal hazard should automatically increase performance rates is evident. That the decreased interference of the unforeseen with orderly procedure must result in added hours of such increased performance is

equally evident. The accuracy of the reasoning is obvious and has resulted in the acceptance of the conclusions, but there has been little or no data to determine the degree in which the correlation made itself evident in the industrial fields.

A beginning was made toward collecting such data in the report entitled "Safety and Production" by American Engineering Council, and made possible by the National Bureau of Casualty and Surety Underwriters. There is no thought to quote that report save to say that the conclusions, as might be anticipated, justified the creed and put some measure of fact behind the theory enunciated. That added data over wider fields will emphasize these conclusions and amplify the proof seems certain. We therefore stand in the position of having expended considerable amounts of money and effort to demonstrate the existence of a relation already accepted, and question may well arise as to the justification for such expenditure.

This justification lies in the frequency with which facts and relations are accepted, but accepted without realization—without instinctive incorporation in the consideration of the problems of which they are a part. Anything which promotes that instinctive incorporation is of value; and the conclusions evolved by methods of reason, and their importance may, by physical picturing, be presented in a way which more definitely fixes them in the mind and results in realization and use. Actual data transforms the abstract generalization into concrete fact.

Today therefore, it may be stated as a fact and not as a generalization that in the industries thus far examined, efficiency in production goes hand in hand with betterment in safety record, and that this condition exists in major degree.

That this betterment in safety performance is an end to be sought and sought diligently is a tenet of modern thought, quite aside from any economic benefit that may result. Plain considerations of humanity demand it and, with the past record of accomplishment to indicate the possibilities of future performance, will continue to demand it.

It is a fair statement that that which intelligent public opinion demands and continues to demand, will ultimately come to be. There is therefore no reason to doubt that this demanded betterment in safety performance in industry will surely be attained, either through the understanding effort of industry, or failing that, through compulsory measures. The records accruing from understanding effort make evident what can be accomplished, and nothing short of that accomplishment will be accepted.

But added to the humanitarian pressure there is the provable economic consideration that this betterment, intelligently obtained, not only costs nothing but pays dividends; and where betterment is not in evidence it can be assumed only that there exists lack of realization of the fundamental conditions or lack of understanding of what is necessary to attain it.

It will be attained only by the exercise of the same procedure which must be employed to obtain any desired industrial advance, for instance, high production rates.

The desire for high production rates is bred of economic pressure, personal gain or professional pride. It is effective when it becomes the animating impulse of the operating head of a concern and receives his continuing intelligent attention and effort. He instills it in his immediate subordinates, leads them in the measures necessary to accomplishment and rewards them in the degree in which there is accomplishment. With them he evolves the plans to secure it, and with their help he builds the organization essential to the carrying out of those plans. He continually fosters within that organization the morale which binds it into a unit whole with a single major purpose and keeps alive the incentive to achievement.

Through personal contact and report he is continually in touch with that achievement. He is acquainted with the problems which arise daily and knows and appreciates the men and the means through which those problems are solved.

In the minds of no one contributing to the final result is there left any doubt as to his aim or his willingness fully to cooperate in the attainment of the desired end.

Betterment in safety performance requires the same procedure. Primarily the operating manager must possess a keen desire for accomplishment. This desire he must press on his lieutenants. He must show that continuing interest in the attainment of the end which will leave them in no doubt of his earnestness of purpose. He must plan with them to the desired end and must with them evolve the organization and measures to accomplish it. By personal contact and report he must know the progress in accomplishment and the men and means responsible for that accomplishment. There must be no doubt in the mind of anyone in the organization of his attitude toward the work undertaken, his vital interest and his willingness to cooperate. As in all other activities only such singleness of purpose will be effective. A mere concession that the work is desirable and a consent that it be carried on will accomplish little,—no more in fact than would a similar half-hearted attitude toward the securing of high production rates.

If then there be found in any concern a progressively deteriorating condition in safety accomplishment, or even a merely negative or permissive attitude toward betterment, no conclusion is possible other than that the operating head of the concern is either content to permit recurrent casualties, or does not realize, or is unwilling to assume his responsibility toward reduction of those casualties.

But whether due to lack of realization or unwillingness, the responsibility is his, and to his account must be charged the happenings, certain to occur, resulting not merely in loss of money, but in human disablement in varying degree and even in loss of life. No one else can adequately initiate and maintain effective the measures essential to their reduction.

Legal responsibility there may not be, for only in minor degree can the problem be solved by statute, but morally he must personally accept the burden.

This is true because more is required than the mere provision of safeguards required by law or for which reductions in premium are allowed. These are effective in degree but are wholly effective only when there is created and maintained in every individual in an organization a habit of mind which regards safety as a primary requisite to efficient operation, and which accepts the individual's responsibility to contribute to that end. Such a mental habit can be created and maintained only by the recognized leader, and then only if he himself possesses it.

To summarize: Betterment of safety performance is inevitable. It will come through the operation of one of two forces, viz.: Public opinion embodied in statute plus the economic pressure of increasing premiums, or the realization by management of its responsibility. The first will be slow, irritating and expensive. The second may be rapid, promotive of harmony and profitable both to management and man. To attain these results however, there must be complete understanding and acceptance of the fact that betterment is a function of the individual, not of the mass, and a function of every individual in the mass.

What is required is the acquisition by each workman of a mental habit which without conscious mental process recognizes hazard and impels him to avoid it, the acquisition by each supervisor of a sense of his daily and continuing responsibility to guard against hazard and to detect and emphasize the instances in which avoidable risk is taken, and in the management, the understanding acceptance of the direct and continuing responsibility of each individual therein. These things are as true for the small company as for the large.

The materials and methods for creating such a habit of mind have been developed and are available, but the vitalizing spark which makes and keeps them effective is the belief and sustained effort of the operating head. In this as in all else the organization mirrors the man who leads it. As he thinks and does, so will it think and do.

Once convinced of his sincerity and active interest there will develop in the organization through department-chiefs, superintendents and foremen, to the man at the bench and the laborer in the yards, an understanding cooperation which accepts the value of safety appliances and recognizes the hazard to all which lies in their neglect and the consequent justice of penalty for that neglect; which breeds intelligent analysis of existing conditions and measures and eliminates—not merely the accident, which frequently is only a symptom of an underlying condition—but the condition itself.

There is ample proof in the report of American Engineering Council, and in the experience of those plants in which betterment in safety performance has been attained in high degree, that these statements are true.

CHAIRMAN ADAMSON: As the final contribution this afternoon before our general discussion, we are to hear a talk on the subject of "Safety and Labor Relations." Those of you who are familiar with the early history and development of the National Safety Council know very well who the next speaker is to be. He early won distinction as the safety leader in the Fall River Shipbuilding Company. He won a national reputation because of the results which he obtained there, and he became a leader in the safety movement.

He was instrumental in the formation of the Boston Safety Council. He took an active part in the history of the National Safety Council. He is at present assistant to the president of the Bethlehem Steel Company; the Manager of the Industrial Relations Division of that company. I have pleasure in introducing to you, Mr. Joseph M. Larkin.

Safety and Labor Relations

By J. M. LARKIN

Assistant to the President, Bethlehem Steel Company, Bethlehem, Pa.

I have been asked to speak on the subject of safety and labor relations. Obviously such a broad topic cannot be adequately discussed in the short time at my disposal. I will therefore attempt to emphasize one phase of this subject which I believe has particular bearing in helping us to see in a new light the important economic position which good safety and good labor relations have come to have in business. I refer particularly to the necessity of doing everything we can to assure to workers steady jobs, in order that their living standards may be protected or even improved and their buying and saving power uninterrupted in the best interests of the community at large.

At the outset let me say that in no other country and during no other era have safety and labor conditions been as sound and wholesome as in America today. Greater emphasis is being placed on safety and accident prevention work than ever before. The results of these efforts are that industry is today a safer place in which to work; workers, collectively and individually, are more cognizant of the safety factor in their daily occupations. Furthermore they have come to realize the economic importance to themselves and to their company in avoiding accidents.

Such results as these are possible only because of the fundamental improvement which has been brought about in labor relations generally. Cooperation in industrial relations as a whole has brought with it a greater measure of cooperation in direct safety efforts. The economic side of safety has become a factor of greater consideration without disturbing the interest in accident prevention from a humanitarian standpoint.

There is generally a better thinking on the part of workers themselves. They have come to have an enlarged viewpoint toward each other and industry, they are

less provincial and are seriously concerned about the prosperity of business as a whole because they realize their stake in it. This is due largely to the enlightened educational work that has been done by industry in imparting freely to the labor force facts about the conditions of the business, to the generally sound policy of public relations we find in industry today, and to the larger participation workers have come to have in their companies and the better things in life.

I think I may safely say that workers have come to realize that their own interests are best served by having others prosper. After all this is but a part of the general trend of the times which is exemplified by a changed thought among business leaders themselves. They have ceased to take a certain quiet consolation in the fact that their own particular company is better off than the other fellow's and have come to realize and appreciate that the troubles of another industry are their own troubles.

This healthy situation which exists generally among business leaders and in labor circles is indeed one of the most hopeful signs for an enduring period of amicable industrial relations and the safety movement because of its unselfish aims has played an important part in bringing about these desirable conditions.

We find today that even in spite of the immigration restrictions and in spite of a reasonably high level of productivity, there is actually an ample supply of labor. Moreover the efficiency with which industry is being carried on today has made it possible to release from the old to the new industries an ample supply of labor. This efficiency has been brought about largely through the increased productivity of labor.

This increased productivity has had its greatest growth during the last five or six years. It has been brought about by four outstanding developments. First, there is the item of capital expenditure through which mechanical devices, electrification, larger units, changed methods and processes have come about. Second, there is the item of improved management. Third, there is the item of increased efficiency on the part of labor itself. Fourth, there is the item of a steady reduction in accidents and other wastes with the resultant gain in working time and increased earnings and purchasing power of the worker.

By and large, we are getting a better quality of labor today. Workers are more intelligent—the school requirements of the country are helping in this regard. There is a better feeling in labor circles. High wages are generally paid and management is exerting every effort to maintain these levels. Shorter hours are worked. The men are working less arduously than formerly and all of these factors have tended toward increased individual output coupled with better safety performance. Then again the extended experience formerly required to perform certain operations has been thrown to the winds until today we find that most jobs in our plants can be filled by new men under relatively brief training periods. So industry generally today is in the position of being able to obtain without difficulty sufficient labor of the type that lends itself more easily to rapid training in safe and efficient practices.

Naturally we ask what has become of the workers released as a result of increased efficiency and newer methods in the older industries. Have they left the community or are they idling away waiting for an opportunity to be employed? Not at all, they have largely become absorbed in industries which greater buying power of labor generally has helped to create.

The experience of one particular community which is probably typical of many others reveals that many of these released workers are now employed in an automotive manufacturing plant; in the many garages that have come into existence; in the scores of filling stations and automotive supply houses; in manufacturing radio equipment; manufacturing modern household utensils; in public improvements, including highways and bridges and a host of other lines created and maintained by the buying power of the workers.

The community I have just mentioned is essentially a one industry center in that the large majority of its population is directly dependent for a livelihood upon one large company. It might be expected that the reduction of 3,000 workers in this plant during the last seven years would to some extent reduce or retard the growth of the local population or that there would exist severe unemployment. The facts are, however, the population has increased by 28 per cent and there is no perceptible unemployment.

Fortunate it is, therefore, as a corrective of that greatest of all evils—unemployment—that the purchasing power of the people generally is opening up new lines to afford employment to those being separated from their former industry. Then again many of the separations are among those older in years whose needs are less than those of the younger men with families, and the pension plan which is quite general in industry is helping to take care of these men who have been permanently released. As indicating the economic importance of these plans, Mr. A. H. Young estimates that annual industrial pensions alone paid throughout the United States amount to over \$50,000,000.

Another factor that has helped to smooth adjustments between the old and new industries is the generally high saving power of the wage earner during this time of employment. This has been encouraged by savings plans, stock distribution and other facilities for thrift and investment which have aided employees in tiding them over from one industry to another. And industry itself is equipped today to be of service in this field by turning the efforts of its employment department from recruiting to placement on the outside.

The growing use of the automobile by the worker has had a tremendous beneficial effect upon the general labor situation. It has largely solved the fundamental problem of transportation for the worker and has greatly widened his working area. He no longer is at the absolute mercy of the neighboring employer for work, but the whole territory for miles around is now his to explore. And the employer too, has benefited, it has solved for him many of the major social conditions which a hoarded labor force around the plants always presented.

I have cited better management as one of the factors responsible for better labor relations. This generally includes a closer and more scientific administration of the payroll.

The efficiency of the employment department is now measured less by the speed with which it can recruit labor than by the aid that it can give management in avoiding the hiring of unnecessary people by transfer and other measures of labor conservation.

This increased care by management in administering the payroll is due largely to a desire to fortify the buying power of labor by holding to present wage levels in spite of decreasing commodity prices and the need for reducing manufacturing costs.

One of the aims of management in this respect is to obtain stability of employment and full-time wages for those employed. The organization of industry on such a basis that provides steady employment at full-time wages has become recognized as a sound policy from the standpoint of both the worker himself and of the company which employs him, and right here is where safety plays perhaps its most important role in the field of labor relations.

The necessity today for the high purchasing power of labor previously referred to becomes more significant in view of the fact that industry is organized on a mass production basis and this naturally requires mass buying. Perhaps this is one of the most important trends in the economics of this labor situation and in every labor policy today this element is basic. The ability to buy by the greatest number is of uppermost concern to the entire business world. Our industries have ceased to function solely or mainly to supply the needs of the wealthy classes. These needs would not be sufficient to maintain even a fraction of our present

productive capacity. It is, therefore, imperative that we have a high and sustained buying power by the masses of the people including the wage earners. Industry generally is alive to the value of high purchasing power for its workers and has adopted the policy of paying high wages. These high wages coupled with the decline in living costs over the last few years have been a most powerful factor in extending markets and increasing the standard of living of workers. It is, therefore, evident that accidents as they affect this buying power are of greater concern today than ever before and that their elimination is not only desired but urgently required.

Often overlooked is a further contribution by industry toward the purchasing power of labor through certain personnel activities that it has quite generally adopted. Among these activities is the practice of making up to employees a substantial part of losses in wages, that would otherwise be sustained through sickness and accidents, by the payment of relief and insurance benefits and workmen's compensation. This policy usually has been thought of from the standpoint of its advantages to the workers alone. Its importance as a means of helping to sustain purchasing power and thereby benefit general business has not been fully appreciated.

The most important contribution to the present state of affairs is that which is due to the cooperative relationship now generally existing between employers and employees. To reach the present basis industry has passed through several more or less clearly defined cycles: The first, of comparative indifference to the worker's relationship to the company which employed him other than as a cog in the machine; the second, realization on the part of labor of its economic power and consequent conflict with capital by reason of the fact that their mutual interests in industry were neither seen nor understood; the third, an enlivened interest on the part of management in the human side of business and on the part of the workers in the prosperity of the business in which they are engaged.

The third, or cooperative phase, is manifested on every side today. Indeed the company which is not striving for good relations today is the exception.

Safety is wholly non-controversial; it is beneficial to employee and employer alike and has no negative values. It is perhaps the happiest medium through which may be expressed the mutuality of interest of employees and employers. Organized safety work began more than twenty years ago, and in my own industry largely under the inspiring example of the United States Steel Corporation it stands as a beacon light of progress. One of its prime factors has been the work of the safety committees, composed of workmen or of workmen and foremen and this was really the first widespread demonstration of mutuality of concern and purpose on the part of employers and employees in American industry. This evolution into the present era of cooperation is not a haphazard result. It is definitely the joint product of the management group in American enterprise acting with intelligent labor leadership and is perhaps the most conspicuous and constructive accomplishment of employee-management relations.

How closely safety is linked with this development is seen in the similarity between the technique of safety work and the technique of good management. Foremost industrial leaders today view safety as much a part of the day's work as any other manufacturing problem.

Industry cannot operate efficiently and leave out safety, nor can business properly consider safety without relating it to the whole picture of the responsibility of plant operation in the most economical and efficient manner. We have in the past continually stressed the importance of reducing accidents mainly from a welfare or humanitarian standpoint. I do not fear that we will ever take a backward step in this regard, but let us in the future give our safety or accident prevention work a new stimulus, let us consider it as an important factor in our whole program of greater manufacturing economy.

The accident prevention movement can have a tremendously beneficial influence on general business, every accident that is avoided not only benefits the workman from a physical and monetary standpoint but it results in a direct contribution to general business. I know of an accident prevention campaign recently inaugurated that in the course of only nine months resulted in a saving to employees in wages alone of nearly a million dollars and the savings to the company are also substantial. Without detracting in any way from the broad humanitarian aspects of this work does not a consideration of the economic aspects of what this million dollars means in sustained purchasing power, in providing steady employment and keeping the wheels of industry moving furnish a new measure of appraisal of the important place which safety holds in the sphere of labor relations.

Good safety is necessarily a component of good labor relations and good labor relations spell safety in a much larger sense than as applied to mere accident prevention.

He would indeed be a brave man who would attempt to place an absolute economic value on the development in good labor relations in American Industry over the last decade or two, but it is a certainty that the wise attitude of cooperation and conciliation generally existing between management and labor in this country has been one of the most powerful factors in helping American Industry to achieve the leadership which it enjoys today. If we would know what might have been all we have to do is to examine the records where such cooperation has not existed to see the full effect of conflict, misery, economic suffering and business stagnation.

Good labor relations mean the safety and security of our social, economic and political well-being. It follows, therefore, that those who are bending their efforts to rid industry of the waste occasioned by accidents are engaged in a work that is essential to economic progress.

CHAIRMAN ADAMSON: It was a very thoughtful provision of your committee to arrange that when the point was reached in this discussion where some authoritative knowledge of the questions was needed, that an associate chairman should take charge. The gentleman who is now going to take over this meeting represents an organization which is an outstanding concrete example of safety as applied in a great industry. His industry is a notable example of what can be done not only economically but in other aspects by the intelligent, thoughtful and human application of safety principles. I know that you are going to be glad to hear now from the associate chairman, Mr. Arthur T. Morey, general manager, the Commonwealth Steel Company.

ASSOCIATE CHAIRMAN MOREY: Will Rogers has written that if we elect him President, we shall laugh with Washington and not at Washington.

The founders of the National Safety Council had in mind a democratic organization in which groups could get together and confer about their experiences and cooperate to attain this great objective of safety, which at that time was thought by many to be impracticable.

These gentlemen who have talked to us today have not come to talk at us but with us. We haven't come to be told; we have come to confer together.

I hope that we may have quite a discussion from the floor of the points brought up in these various papers. Mr. Heinrich, for instance, says that a wider study of classification is necessary in the elimination of causes. He also said that we have talked too much about types and that we need to study more about the causes. He says that 98 per cent of accidents can be prevented.

Mr. DeBlois sounds a note, the finest we have ever heard in our Congress, that all accidents are preventable. What do you gentlemen think of that proposition?

You have the floor. Do you accept the proposition that all accidents are preventable?

SIDNEY ASHMAN (Ludlow Manufacturing Company, Ludlow, Mass.): I would like to ask Mr. Heinrich if a particular example of an accident is within his accepted two per cent. A brakeman of experience, in boarding a car, strains his back. What is the cause of that accident?

MR. HEINRICH: From the very limited details given about this accident, it is impossible to determine the cause or the answer. In my talk I tried to make the point clear that it is necessary to get a complete story of an accident. If we don't know under what conditions a brakeman boards a train, we don't know very much about it. If we do know the complete story, why then we have a better opportunity to determine the answer.

MR. ASHMAN: The accident I had in mind occurred when a locomotive stopped to take on water. Before the locomotive started, the brakeman from the roadbed, which is in good condition, stepped up to the saddle and took hold of a bar as he climbed to the side of an ordinary freight car. Every bolt was tight. The brakeman was entirely in good condition, sober, and had no history of a previous back injury. That is all the data that I have. I am unable to determine the cause of that accident.

MR. HEINRICH: May I suggest a remedy without necessarily giving the particular answer that you want. If you set up a list of probable causes and you are able to eliminate every one of those causes, then most certainly I would agree with you that the accident was unpreventable. If, for instance, you know that instructions as to proper boarding of trains had been issued and were enforced in this particular case and that the employee obeyed those instructions, then one of your probable causes is out. If you know that he was physically fit, then another of your probable causes is out. If you know that there was no unsafe practice involved, no defects in equipment, that there was no improper planning of operation, then another cause is out. In other words, if you go right straight through the list and no one of those causes exists, then of course the accident is practically unpreventable.

MR. DEBLOIS: Looking at it from another angle, it is a common experience of a safety engineer to have the manager of a plant (for instance) who is being initiated into safety for the first time, approach him in this way: "Well, Mr. Safety Engineer, I want to go over these accidents with you. How do you prevent this? How are you going to prevent that? How are you going to prevent this other thing?" My experience with industrial accident reports is that after reasonably thorough examination into the causes of the accidents, you have to set aside about one-third and say, "I don't know how to prevent them." Here is what I have always said to plant managers: "Mr. Smith, I don't know how to prevent this accident of a back strain, or this accident where a man broke a leg when he stepped off an eighteen inch platform. I can, however, tell you this: That if you get safety going in your plant, our experience is that those accidents and all the other types of accidents stop." The best I can say is that the men themselves prevent them; and the back strains, which I have noted are somewhat epidemic, go along with the rest of them; they disappear. It can be done.

CHAIRMAN MOREY: Isn't our sense of the unavailability of an accident somewhat the measure of our own limitation of progress? Just a case in point. I remember very well, as you no doubt will also, when woodworking machinery was the most murderous of all to operate. I presume if a discussion like this had taken place ten years ago, I could have stood on the floor and said, "Now, how could you avoid such and such an accident in the pattern shop?" But since that time, our thought has risen, our understanding of the problem is much better and we have made many inventions and improved conditions so that instead of having

accidents we now have large safety records. I was down in a shop some little time ago, a new shop with 100 men in it, and they have gone 1,302 days without a lost time accident; while in another shop where they also have about 100 men they have gone about 700 days without a lost time accident. It seems to me that our sense of the unavailability of accident is only a measure of our own false limitation in the progress of our understanding.

D. S. FIRTH (Standard Accident Insurance Company, Detroit, Mich.): Mr. DeBlois, in support of his theory that all accidents are preventable, apparently uses the no-lost-time records as proof of his theory, while Mr. Heinrich includes, I believe, minor cases as well as major cases. Mr. DeBlois refers only to the major or lost time cases. Therefore, perhaps in the final analysis, there may not be a great difference of opinion between them.

In analyzing accidents, is it your thought, Mr. Heinrich, that minor accidents should be given the same consideration as major accidents, and if so, should they be analyzed individually or by groups according to type or immediate cause? Considering the apparent high frequency of so-called minor accidents, it would appear almost impossible economically to analyze the cases individually and thoroughly, and my thought is that perhaps if you do include those accidents to be analyzed that treatment according to groups by type or immediate cause would be the proper method of approach.

MR. HEINRICH: Mr. Firth has given me a very good opportunity to talk on another point that was not included in my paper. He asked this specific question: Whether or not in the analysis of accidents we should give equal consideration to minor accidents and major accidents, and whether there is not too much work involved in the consideration of all accidents if they are on the same basis?

In my opinion there is no such thing as a minor or major accident. There are such things (mark this well) as minor injuries that result from accidents. If we are in the business of preventing accidents, it is the accident that we are interested in, and not just the result. We are misleading ourselves again, because any accident has the potentialities of producing a serious injury. We have, of course, serious injuries and major injuries. An employee who drops an object 30 times may miss his foot 29 times. He may hit his toe the 30th time and on the 31st time he may crush his instep. In each one of those 31 or 32 cases you have the same accident. And yet, we are in the habit of taking the crushed instep as a measure of our accident prevention work.

And so, my answer is that there is no such thing as a minor or major accident—though there may be minor or major results from accidents.

As regards the economy involved in that, I believe from experience, that you are chasing a will-o'-the-wisp. If you set up a proper organization and eliminate them one by one, you will have no difficulty in cost involved in analyzing all accidents properly.

MR. BLUNT (Valentine & Company): We had quite a problem as to minor injuries, so many in fact that we were quite up against it. Mr. Heinrich's article came out in the *National Safety News*. I read it over. I immediately set the ball in motion to analyze not only our serious accidents but also our first aid accidents. We have, since that article was published, investigated, just as the article states, basic and physical causes and all the rest of them. We have been following those through. I can't give the results exactly. We have been trying to eliminate the small first aid cases that have been a bugbear in our plant. Here is one accident where a woman, coming downstairs, stumbles and sprains her ankle. That time it was not a minor accident, though before that, such results had been minor.

I was interested in telling you that we are trying to see if there is any relation that we can arrive at by following this scheme of Mr. Heinrich's through. We are

not only doing it on the major but on the minor, or simple, accidents. In this way we believe we will head off the major results of accident causes.

MR. DEBLOIS: I would like to pick up a point right there and illustrate it with an example, which at the same time may serve to show that Mr. Heinrich and I are not apart on theory at all. We are looking at the thing from different points of view.

Tripping on the stairs. There were a number of cases in one of the DuPont plants of accidents to girls tripping on the stairs and spraining ankles. The accidents were prevented by studying the cause. The cause wasn't high heels. The prevention was brought about by putting in an addition to the lunch room. They tripped because there was not enough lunch room seats for everyone and the girls hurried to get a seat.

SAMUEL J. STEINMANN (Indemnity Insurance Company of North America, Philadelphia, Pa.): About a year ago, my company instituted a service for the purpose of reducing accidents of all kinds. We took into consideration all accidents, the so-called minor and the major. For the past year, I have put all my efforts on the analysis of accidents. Recently, I concluded an analysis of a risk out in the Middle West, where in getting the cause of injury, I found that 39 per cent of the accidents would come under the flying object class; 32 per cent of those, of the total accidents, were eye accidents—one of the accidents did cause the loss of sight in one eye and there is a probability of removal of the eye. The cause of injury was the same in that case as in many of the other accidents, a flying chip, which brings out the point that all accidents should be considered.

This particular concern had a good safety committee, and the management was behind the safety movement. The safety committee in the investigations brought out one point, namely, that proper goggles were not provided. Another point brought out was that there appeared to be a lack of cooperation on the part of the supervisory force. I personally believe, as Mr. Heinrich does, that the real cause of those particular accidents was physical and supervisory, which could be controlled by the management.

I think if we go along in that particular line, we will make some progress in accident prevention work. We have talked too much about lost time accidents when the minor accidents have the same potential possibilities.

CHAIRMAN MOREY: Just as much instruction in a near accident as in a major.

B. G. DOOM (Electrical Metallurgical Company, Glen Ferris, W. Va.): I want to accept and defend if possible the position of Mr. DeBlois that all accidents are preventable. I believe it fully, and I believe there are just two elements entering into that problem which we must consider. It is a question of physical conditions and a question of mental attitude. I believe that in the case just cited, of the individual who was injured on the locomotive, that if that whole circumstance should be thoroughly analyzed, we would find that either the physical conditions were not safe and right or that the mental attitude of the individual was not right. If the physical conditions had been just right, had been safe, and if the attitude, the mental attitude of the individual, had been that of thoughtfulness and care, he would not have had the accident; there would have been no injury.

That, in my opinion, is the whole problem as to how to accomplish our end. We must make the physical conditions safe and we must maintain the proper attitude of mind on the part of the management and the workers, so far as it is possible. I contend that it is possible, and I want us to continue working along these lines until we realize the goal.

CHAIRMAN MOREY: Mr. Heinrich spoke of a man who accidentally dropped something 29 times and the 30th time he had some bad luck and it hurt him. I think that might have been bad luck to him, but that was pretty poor supervision, it seems to me.

JOSEPH SULLIVAN (Phoenix Furnace Company, Duluth, Minn.): I would like to bring out one point that Mr. Heinrich made, physical and mental causes. In analyzing a couple of accidents just recently, the result of the analysis showed that it was a mental cause. The point I want to bring out is: How are we to discover mental causes? To me, that is one of the hardest analyses to make, to put down a mental cause. An employee can come down to the plant in the morning, he could have had domestic troubles, not of a serious nature, but just enough so as to upset his whole system, and his industrial attitude is concerned for the rest of the day. How are we going to approach that man to find out if he had any minor domestic trouble that was the cause of that accident?

CHAIRMAN MOREY: I would like to speak on that point. (By the way, I didn't mean to confine the discussion to Mr. DeBlois paper and Mr. Heinrich's paper. Mr. Larkin brought out how safety was the entering wedge to better conditions, and because of those better conditions we knew our men better.)

It seems to me, in getting at mental causes, there has to be the finest cooperation in an organization; if we have a benefit association, for instance, or a visiting nurse. We have found that our visiting nurse gets pretty close to some situations, closer than we would get. If the safety committee in the plant, the foreman, the superintendent, those who come in contact with the man, his own fellow workmen, hear of some condition not good for the man, they should counsel him and report it. I think it takes vigilance on the foreman's part. The safety committeeman should catch a lot of those things.

I think lots of times, too, we don't pay enough attention to tendencies. We have seen this in our plant, and it is one that has been very hopeful to me, because we have discovered that the first carelessness does not usually produce an accident; sometimes it does, but it is very infrequent. It is the repetition of careless practices, under the human law of averages, it seems to me, that produces accidents. That is our answer to the no-accident effort. I believe if we study more closely and nip careless practices in the bud, we are going to get a whole lot closer to our no accident records.

MR. DEBLOIS: May I ask the gentleman this question? Let me take as an instance a small plant of the DuPont Company; 350 people in seven years had one time losing accident. Do you suppose for a minute that among those 350 people, men and women, during all that period of seven years, there were not literally thousands of mental conditions predisposing to accidents—worry, domestic rows, all sorts of things of that kind, which we can't possibly discover? How do you know that you and I today haven't some mental cause of disturbance on our minds? Yet we rise above it here. And so in the plant, it seems to me, the individual, when he has sufficient interest in accident prevention and has learned to establish safe habits of doing his work, rises entirely above those mental causes.

I don't think we have to know those mental causes. I think we have to get the right attitude and the right habits in the men and the mental causes will take care of themselves.

J. E. LONG (Delaware and Hudson Company, Albany): I think in a few of these discussions and suggestions we might well put it in this way: We have been insisting on safe practices in doing work, the right ways of doing work, but fundamentally we should at first create the incentive to doing work safely. It is all very well to superficially ask the man to do the work in a certain way, but until you have enlisted his interest, his active cooperation, his enthusiasm in the safety records, he will not get at the fundamentals, he will not get the actual performance that we desire.

E. B. PATTON (N. Y. S. Department of Labor, New York City): Mr. Heinrich at the beginning of his talk pointed out that there were many accidents which could be prevented. I presume because of the difficulty of analyzing the employee situation, he has transferred his attention to the employer and has reached the conclu-

sion that 98 per cent of the accidents can be prevented. It is extremely gratifying to have an insurance representative take that point of view. I think on the whole it is a fair one. I think Mr. Heinrich will agree that a great part of that 98 per cent which can be prevented by the employer, could also be prevented if you could bring the proper influence to bear upon the employee. I don't believe for a minute that these no-accident records could ever in the world be achieved through employer effort alone. It was because of the pressure brought to bear upon the employee that these records were achieved.

CHAIRMAN MOREY: Absolutely it is the employee who is a very large factor in producing results. We should bring him all the education and enlightenment we can.

C. M. STAVE (Globe Indemnity Company): It seems to me, that most of us in the insurance companies who have been accustomed to dealing with these analyses covering accidents in large numbers, almost on a daily basis, have become in the habit of dealing with accidents in matters of frequency and severity. It seems to me that some of this discussion on the question of minor and major accidents falls in that classification of frequency and severity. I think there must be some insurance men here who are thinking just about the same thing I am now and have probably had the same experience. When a large number of accidents come in as a report or analysis of some risk experience, we are rather inclined to say, "Oh, well, they have a large frequency rate but the severity is low." From my own personal experience, I agree with the man who says that every accident, no matter how minor the effects may be, the result of that accident should be considered a serious potential accident or a potential serious accident.

I came across an experience just a short time ago that is concrete evidence of what I have in mind. Any man who has ever worked in a shop has gone through the experience sometime or other of having a splash of oil in his eye. I doubt if one of us here today has ever had anything serious result from that accident. Just a short time ago, I ran into a case over in Pennsylvania, where a man received nothing more startling than a little splash of oil in his eye. The last thing I heard about that case, due to some peculiar local condition of the man himself, he was in the Wills Eye Hospital about to be operated on. It seems to me that the way to remedy the local conditions that creep up later in the so-called minor injuries, that often, very often develop in the serious injuries, is the matter of physical examination before the employee is put on the payroll.

CHAIRMAN MOREY: As a matter of prevention of causes, have we anything to say on the matter of physical examination?

J. H. MEIGS (Western Union Telegraph Co., Boston, Mass.): I have to do with maintenance outside and inside the plant. In 1922, we had 86 accidents. We have about 500 employees, outside men. We started, as we thought then, a pretty strong accident prevention campaign. We reduced them from year to year. Last year, we had 22. This year, so far, we have had nine. We report every accident. We make up reports on every accident, regardless of whether it is a minor accident or not.

We carried on quite an extensive campaign in accident prevention. We carried it on in this way: When we had an accident, I went out personally and interviewed the man, after the report was sent in. I talked it over with him. Oftentimes, if it was a serious accident, I talked it over with him in his home. I know most of the people and go to their homes. We get out a letter each month and send it to each employee in his salary envelope, giving the name of the employee who had the accident and how it was caused and what could have been done to prevent it. In addition, we send each employee a blue print each month, one being issued for each group of men in the New England States, and the cities in the New England States where we have accidents to two or more men have a circle on the blue print. The name of the supervisor or foreman that these men report

to, is shown over the circle. If John Smith has an accident, we put his name in there. If he doesn't have an accident that month, we show just a blank circle. We carry that blue print on through the year, so that at the end of the twelve months, it shows all the accidents that a certain foreman had. If he had no accidents, he just has a round circle. If he has had no accidents in the last three or four years, we give him a circle within a circle.

CHAIRMAN MOREY: Do you put the name of the injured man in?

MR. MEIGS: We send it to every man that has an accident. As a matter of fact, it has brought about good results.

We send out a yearly letter, showing the accidents we have had during the month. We have reduced on the outside, our male employees, down, as I said, to 22 last year and 13 this year.

We are carrying on the same force of men. We hold safety first meetings. We sit down in a tool room or workshop and just talk safety first. We talk about safety methods and accident prevention. We talk over the accidents we have had and how they could have been prevented. If a man is with us fifteen, twenty or forty years, like a lot of our men are, his salary card shows every accident he has ever had, a lost time or any other accident. They try to keep out of the circle, as they term it. The men call each other's attention to any unsafe methods in practice. The foremen who have anywhere from 12 to 25 men, when they come in at noontime or at night, asks the men, "What do you think of today's work? Have we carried it on in a safe manner? Have you any suggestions to make?" The men are free to express their opinion. We have them feel and understand it is nothing against them at all. We don't allow the foremen to hold anything against the men. We ask them to bring out these points.

CHAIRMAN MOREY: I would like to interrupt you there to put this point to the meeting: What is the thought of you men on publishing the name of the man who had the injury? Is that good practice?

B. H. WEEKLEY (U. S. Sheet and Window Glass Company, Shreveport, La.): We started out something on the line that the brother is talking about now. The first thing we did was to find out from the employees themselves whether or not they would care to have their names posted in case of an accident. Out of about 500 men, there were but two that objected. We have done some good work along that line.

MR. KEATING (Manufacturers Casualty Company): I would like to say that we have one large risk embracing six states, and before we used the names on the bulletin board we also put it to a vote. We found that among those 3,000 employees there was not one unfavorable vote to having a man's name posted on the bulletin board for having an accident. It has been productive of wonderful results, in that the various departments, as they are divided for competition, are very jealous and zealous that their names do not appear on the board.

MR. MEIGS: I would like to go one step further on that. We have on the inside, as most of you know, large offices in all the large cities. In Boston, we must have 1,700 or 1,800 people working in one office. They are composed mostly of girls and women. We had cases where girls and men would fall down the steps and sprain their ankles or sprain an arm or get a broken arm. We found upon investigation that it wasn't due to the high heels so much as it was due to the treads on the steps that had become worn. We went and replaced those worn steps. In addition to that, where we had quite a large number going down the steps, such as at ten o'clock, at noon-time, at three o'clock and five o'clock, one employee would be appointed to supervise those people in going down the steps. If she saw them running down or jumping or walking in an unsafe manner, she would call their attention to it. We have reduced those accidents to a minimum. I haven't heard of one in years, that is since 1922.

CHAIRMAN MOREY: I would like to leave this thought with the meeting and put it in the record, that our sense of an unavoidable accident is but the measure of the limitation of our own understanding. I think that is a natural conclusion from Mr. DeBlois paper.

W. S. CLARK (American Mutual Liability Company): The gentleman from Minnesota brought up a very pertinent question on the mentality of the man pertaining to accidents. There was one step he missed, and that is, what do you do with the man when you find out he has family difficulties?

CHAIRMAN MOREY: We have found that our personnel department has been able to remove a great deal of that condition of thought, of worry. We have helped settle family quarrels, and we have assisted men to go to the hospital to get cured. We have helped them leave and go to a better climate. We have sent them home when we didn't feel they were in a fit condition to work. We did everything we had the wisdom to do to help the particular case. Of course, no two cases are alike.

I think the delightful situation is coming in industry where instead of the relation of master and servant we shall enjoy a more friendly relationship. We are all friends, cooperating together to carry on the business. As we get that friendly interest in each other, we will do everything we can to help in whatever our problem is, financial or otherwise. Lots of men worry about financial things. We have a loan fund without security. We will loan men money to take care of their affairs and keep them out of the hands of the loan shark. It may be sickness; whatever the need is, we ought to, as friends, do our best to help him overcome that particular trouble.

W. C. REIBLING (American Tar Products Company, Chicago, Ill.): I studied our accidents all year. I found that during the period in which our business was dull we had no accidents, while we always had a few accidents when we were busy or rushed. The point I want to bring out is this: We must get down not only to the cause, not only the apparent cause, but the fundamental cause. What is the cause of those accidents? I don't think the sales department should crowd us with unnecessary rush orders. I think that is very fundamental.

ADJOURNMENT

**SEVENTEENTH ANNUAL SAFETY CONGRESS
NATIONAL SAFETY COUNCIL**

General Round Table

October 4, 1928

GEORGE OPP, Chairman

Safety Engineer, Detroit Edison Company, Detroit, Mich.

The General Round Table Session at the Seventeenth Annual Safety Congress, was called to order at two-fifteen o'clock by the chairman, George Opp, Safety Engineer, Detroit Edison Company, Detroit, Mich.

CHAIRMAN OPP: We are very happy to have you in attendance today. This General Round Table Session is one that has been added to the recent programs for the purpose of clearing certain general or miscellaneous items that each and every safety man, executive or otherwise, in attendance might have on his chest. It gives a chance to swap ideas, a chance to get together with those of other groups and other trade sections to have an opportunity to review with them their problems and your problems.

We are today very happy indeed to have Miss Ruth I. Stone as the opening speaker on this program. Miss Stone has been very active in industrial work in women's organizations and now has a splendid record established in the organization in which she now works. We are very happy indeed to have Miss Stone here today to speak to this General Round Table Session upon her subject.

How Safety Looks to the Worker

By RUTH I. STONE

Chief of Women's Personnel Department, Operating Branch, Hawthorne Works, Western Electric Co., Chicago.

If I were to put to you the question that was put to me, "What does the worker think of safety?" I think your answer would be: "The worker thinks safety is a damn nuisance." Of course, I can't tell you that; your committee wouldn't invite me to come down and say that to you.

I do take issue with your answer, which I am quite sure down deep in your heart you would have given me. I am quite confident that the worker does not think that safety is a nuisance, with the adjective omitted. He feels about safety quite as you feel about the traffic problem. Safety in itself is quite right. You don't quarrel with a traffic cop that picks you up and puts a ticket on your car; you don't quarrel over the fact that he is saving your life and that he is saving you perhaps an injury to your family. The thing that makes you quarrel, the thing that makes you mad, the thing that makes you swap stories the next morning, is not that he was trying to save you, not that he was rendering society a service, but the fact that he caught you trying to slip something over.

That is exactly the way the worker feels about safety. We have no objections to having our fingers saved and our lives saved and our eyes saved. It is awfully inconvenient at times to have to abide by all the rules you have laid down.

I have no right to speak for every worker; I have no right to speak for any large number of workers. In order to get an opinion on the work of safety, I sent, through the cooperation of four other concerns in Illinois, a questionnaire and asked them to give it to their gang bosses who were first line organization people, who would know what the organization thinks of safety.

I am going to follow very closely what they answered, because I not only think it is interesting but I think you will find it very helpful in your own safety programs to know what the worker thinks. These questionnaires were sent out and distributed and the gang boss was asked not to sign his name to it. Some did sign their names, and those I threw out. I got 197 answers unsigned, which I feel we have a right to assume is the person's real opinion of what the worker thinks of safety.

Do Guards Retard Production?

The first question was: "Do guards slow production?" I imagine that you would say, as a majority of our men said, "Yes." More than half said that guarding did not slow production. There were those more cautious who said that temporarily guards did. Others said that guards did slow production slightly. There were others who said that some kinds of guards do slow production.

I left a space for remarks, and on the remarks there were some very illuminating things. Here is one: "Some at first, until the operator becomes used to it. Not after proper instruction." Another one reads: "Through conversation with my operators, I found that where an operator is accustomed to using guards and wearing goggles they cannot work without them." Another one said, "Not if designed for the particular job. An operator can be trained to work with a guard." I think out of that we can interpret that guards do slow production, which means that you have got to be careful in the kind of guard you give us to work with, whether that guard is the very best guard to go on that particular machine and whether it covers the hazard of that particular machine.

The second question was: "Are guards worth while?" Of course, you would expect a vast majority to say, "Yes." There were some carefully-minded, more exact-minded people who said that some people do think that guards are worth while. There were five who felt that guards were unnecessary. One man just felt guards weren't worth while at all. These are some of the answers: "Some of the operators think that the guard slows them with their work." Here is another one which hits my sex particularly: "It seems to be the general consensus of opinion that such safety measures as hairnets, goggles, etc., are unnecessary and reduce the attractiveness of the individual operator."

I would like to add a word there. I am afraid you gentlemen don't understand our psychology, the psychology of the woman worker. I am afraid you gentlemen don't appreciate how we feel about spoiling our personal appearance. Are guards worth while? I have seen dozens of guards that were not worth while and so have you. I visited not long ago a factory which was beautifully guarded. It was one of the nicest factories I have ever had the privilege of visiting. All the girls were wearing cloth caps. I asked the man who was taking me around the factory, "Why are the girls required to wear these cloth caps?"

He answered me, "That is the first safety measure we put in. Fifteen years ago those girls were required to wear those cloth caps. It is the first thing we tell a girl when she comes in."

Cloth caps were necessary fifteen years ago when the machinery building was unguarded and when the shaft ends were exposed. They are required to wear those

cloth caps now because the girls fifteen years ago wore them. There isn't any rhyme or reason for having cloth caps on those girls at present.

I must tell you a story about one of our own department supervisors. Of course, we do change styles in our hair, and that is confusing to you gentlemen. First we wear long hair, and that is one kind of a hazard; then we bob our hair and that is another kind of a hazard; and then we decide to let our hair grow and that makes an extremely different hazard.

It is hard. I grant you, for you to keep step with our styles or hair dress. It seemed necessary in one of our departments not long ago for the girls to wear hair bands. They were effective for six months, and then the style changed in hair and they were totally ineffective. I made a plea that we remove the hair bands, which have always been a source of contention, at least, between the operators and the management. I got the men to admit that the present hair band on the girls was not worth a tinker's darn, but they would not take it off because they wanted to be able to report to the management that they were doing all they could for safety. If there had been an accident, they wanted to be covered by the fact that they were equipped with some kind of guard. They also felt, and this was probably true, that it was easier to shift the kind of a hair band if the girls had to wear something, than to have them taken off in two months or less.

If I could only send you home with the thought of not putting too much stress on non-essential things—I know it has been difficult for you to keep up with the passing style show—if I could only persuade you to evaluate your guards, I am sure it would go a long, long way toward your selling to us the things that are more important.

The Problem of Dress Regulation

We come now to the third question. "If the company did not supply this equipment of hairnets, gloves, etc., would they attempt to safeguard themselves?" They said just as vehemently as you would, "No." There are the reasons, which are pretty logical. "No, it is quite difficult to have them wear these articles at the company's expense." You all say "Amen" to that. "No. I did when I first started for the company. I only had them on for two days." No. The first answer you would get would be, "They cost too much." I think those are perfectly honest answers which you would agree with.

The fourth question was: "Do your operators help safety by suggesting guards and safety equipment or safety measures for performing your operation?" I think you safety men may take a great deal of credit to yourselves when we find that unanimously, over 100 of the 197 answers I received said that the employees did make suggestions; only 38 said they didn't; some said a few operators would make suggestions. One discouraged gang boss said, "I never heard of such a case yet." Another one said: "Yes, and if no provisions were made for safeguards you would soon hear about it." I think that is very, very encouraging for you because it is encouraging to know that you have been able to arouse an interest. It is also good psychology. You have made the employee think of the hazards of their own occupation and you have made them make suggestions. Any psychologist in education will tell you that it is the thing you wish to do that is the thing you can do well. If you can make your employees wish safety, then there is no problem to solve as to how to make them careful.

The fifth question was: "What proportion of your people do you think pay any attention to the safety posters and bulletins?" There were a great variety of answers, as you would, of course, expect. Seventy-four of the 197 felt that less than ten per cent pay any attention to the posters and bulletins. The great bulk

of them, ninety of them, felt that between 75 and 90 per cent of the people did pay attention to the posters and bulletins. Twenty-six optimistic souls said that 100 per cent of their employees pay attention to the posters and bulletins.

These are the comments: "All pay attention because the posters are attractive and easy to look at, but only a few benefit by them." Another said, "They attract considerable attention when actual photographs are displayed. They do not think anything of bulletins." Another: "Very few, because posters do not bring safety home forcibly enough to them; it should be done by lectures."

Modern Safe Practices and Those of 10 Years Ago

The next question was: "Is it easier to get your people to follow safe practices now more than it was ten years ago?" Of course, the bulk of the people said "Yes." Of the 197, 184 said "Yes" unanimously with very few comments, because ten years ago there was little to the safety campaign. Four people made no comment at all. Four discouraged supervisors said "No." One man said, "Very much so, because it has been driven into them by continuous lectures." Another one said, "Yes, because through posters the idea of safety is constantly before them."

That may be of some use to you in planning your publicity campaign.

The last question was: "Do you think this safety business has been overdone?" Of the 197, 136 said "No;" 24 said "Yes;" and 27 said, "Some of the operators do think that safety has been overdone."

Let us now go back to my original premise. I said that it was not the question of safety, not the spirit of safety with which we are making our quarrel, but it is your interpretation and the way you enforce your safety ideas on us that make it difficult for you to handle and difficult for us to avoid accidents. Let me read from the original sheet, because the comments of these gang bosses are very illuminating and also, I am sure, will mean much to you. "I do not think operators have any idea as to whether safety is overdone or not." He is an honest soul. "The safety program has been a wonderful thing for the operator." He also is an honest soul. On this one, I wish you could see the handwriting and the spelling: "My opinion of safety is great. I make it my business at seven-thirty every morning to go to each and every one of my operators asking how they are, look at their tools, and tell them to watch their step for the safety of us all, and I repeat the same oration in the afternoon. Safety First all the time." The next one reads: "As a general rule, no. They look upon it as they would education of any other form, thus their interest in the matter is rather apathetic." I wish I knew what company and what department that intelligent answer came from. Remember, these are all gang bosses. I have no idea what company it came from.

This one, I think, is a very great lesson for us all: "A lot of minor injuries are not reported because of the department attitude toward them. In an attempt to keep a good record, a certain amount of fear of consequences is instilled into the minds of the people who will take a chance rather than report an injury and get a bawling out." I wonder if you talk to your people who are injured just as the traffic policeman on the corner bawls you out when you pass a traffic sign? I think it is very difficult for the safety director and for the safety man whose job depends on making work safe and reducing those abominable statistics, lost time and otherwise, to always remember that the pressure is being put on production and "we" are between the devil and the deep blue sea as to whether to take a chance and do the thing we think is going to increase our production or whether we should take the narrow and straight path and have the feeling all the time that the foreman is going to jump on us because we haven't produced what we should.

Listen to this one: "They will cooperate if some attention is paid their suggestions."

Are you as a safety person, merely doing the spectacular thing of putting up beautiful posters and a great deal of talking like the gang boss who repeats his oration every afternoon, or are you actually doing the thing and are you paying attention to those invaluable criticisms that come from us who know the job far better than you as a safety man can possibly know it?

Preaching vs. Practical Action

"The worker thinks that there has been too much preaching to him and not enough practical action on the part of the employer." I don't have to make any comments on that.

Remember, there is no one who is quite so critical of the thing that you are doing and the methods by which you do it as those of us who are working on piece work and those of us who are trying to meet our production schedules. If your work is all preaching for the benefit of the impression it is going to make on the management and you are not practicing for the benefit of the employee, there is no one going to catch you so quickly as we are, and there is no one going to be so harsh on you and say that the whole safety program is "bunk." You and I know and the workers know, organized labor and the other organizations that helped pass the compensation laws must have known that if they fined the employer who had unsafe condition it was the one way to make him provide safe conditions in which to work.

Do we think that safety is a damn nuisance? No, but we often feel that your thoughtless and unsympathetic attitude of imposing and interpreting safety for us in our working conditions is a nuisance, and therefore we don't always pay attention to it.

CHAIRMAN OPP: Now, gentlemen, some of Miss Stone's remarks throw out a challenge to those of you who may have a difference in opinion on the questionaire that was circulated by Miss Stone. This is your opportunity to make comments of your views, to ask her further questions, if you desire; in other words, the question is now open for discussion.

J. F. GREEN (Safety Engineer, Western Cartridge Co., Fulton, Ill.): We have in our employ about 2600 people, 800 or 900 of which are women. Most of those female employees have to run machinery of one kind or another. A big majority is on a piece work basis. All of them are instructed not to put their hands around dangerous parts of the machine. Some of them do so. The trouble we have on our hands is to persuade those female employees of the dangers involved in wearing bracelets, finger rings and so forth. Every once in a while the question comes up and some female employee says: "This is my engagement ring; I wouldn't take it off for anything." Another employee might say: "This is my wedding ring. I absolutely refuse to take it off." I just wonder what method Miss Stone would use to take care of a conflict like that.

MISS STONE: This question of personal appearance is a very delicate subject. It is a most tender point.

I can't conceive of a job that requires the removal of a wedding ring. I can conceive where it might be advisable for the woman who wears an engagement ring to take it off on some operations. It seems to me that it is possible to point out here too that it is dangerous to that precious ring if she wears it to work. I think it needs a woman to tell her that. I agree with you that sometimes they take advice from a man quicker than they will from a woman. I admit that women are not very reasonable creatures. It does seem to me that when a thing is obvious it ought not to be difficult to get that girl to see your point of view.

The question of hairnets is an entirely different matter, because as I said on Tuesday morning to the Power Press Section, we women are in the marriage market. She is far more concerned in being successful in the marriage market than you are in the marketing of the product she is making. Therefore, she does not wish to do anything that might spoil the marcel that she had put in during the week.

I realize, gentlemen, it is very difficult for you to understand our psychology, and it is very difficult for us to understand you. When you want to make an impression, you all get into the identical kind of an outfit. When we wish to make an impression, we get something entirely different because we don't wish to look like anybody else. That, of course, is the difficulty in putting girls into uniforms. I am not committed to putting girls into uniforms unless under very unusual conditions. I feel we have no more right to complain about the kind of clothes or necktie you wear than you have to complain about the kind of clothes we wear.

We this summer had a girl come to work without any stockings. I told the foreman to tell the girl that it is quite the thing at the present moment to go to dances without stockings and to go to the bathing beaches without stockings but it has not yet been the style to come to work without stockings; that the company is very conservative and when it becomes the style we shan't object at all.

C. H. DAVEY (New York Telephone Company, New York City): Does Miss Stone think the time element in putting safety posters up would affect the field of the average employee?

MISS STONE: That is highly technical. Baron Collier could give you a far more intelligent answer than I on that. It so happens that I am a bulletin board hound and always read every bulletin that is put up. However, I do not think that it pays to keep up a bulletin until it becomes worn looking. I would much rather leave a poster up for two or three days and take it down and have a bare bulletin board for the balance of the week or month than to leave it up until you have a new poster to put in its place. You may take it down and leave it down for the balance of the week and put the same poster back up again on Monday morning, I don't care, but don't leave it there until it gets to be a monotonous thing. Does that answer your question?

CHAIRMAN OPP: Any further questions or comments?

You will note the introduction of Miss Stone was somewhat unusual. Generally when speakers are introduced you hear from the presiding officer all about them. In this particular case, we have reserved the biographical sketch of the introduction until the conclusion so that you can now weigh very definitely the remarks that have been made.

When Miss Stone graduated from Cornell University, she accepted a position with Joseph and Feis Company, Cleveland, where she was in charge of the employment of women operators.

At the beginning of the war she resigned and became connected with the Quartermaster's Department as an inspector of the working conditions in factories having government contracts.

In 1919, Miss Stone accepted a position in the Employment Department of the Hawthorne Works of the Western Electric Company, at Chicago. She was in charge of various phases of this work until 1924 when she went abroad to study and become more fully acquainted with working conditions in the factories of England, France and Jugo-Slavia. At the present time, Miss Stone is in charge of personnel work for women in the operating branch of the Western Electric

Company, Hawthorne Works; and in preparation for her part in our program she spent considerable time in the punch press departments of that company getting actual experience as an operator.

Miss Stone is a member of the Board of Directors and Chairman of the Industrial Committee, Chicago Y. W. C. A., member of the Industrial Girls Work Committee, Council of Service Agencies, and member of Committee on Women in Industry of the Illinois League of Women Voters.

We certainly are very proud to have had you with us today, Miss Stone. As a last chance, are there any questions that you wish to ask Miss Stone before we pass on?

H. N. FOWLER (Liability Insurance Company): I wonder if Miss Stone can tell us anything about the use of the colored chalk blackboard bulletin service?

MISS STONE: I am sorry, but I can't tell you a thing about it.

CHAIRMAN OPP: The preparation of a program for such a session as this one has largely devolved in the past, at least, upon the Council Headquarters Staff. In order to get more of the opinions of you folk who contribute to the success of the program, it was decided this year to have a set of officers elected at this meeting, their chief purpose and function being the preparation of a program for next year's Congress. I am very happy at this time to present to you Mr. John P. Eib, who as chairman of the Nominating Committee has a slate to present for your approval.

Report of the Nominating Committee

JOHN P. EIB: Mr. Opp, having in mind all of the things that you outlined, the committee has the following nominations to present to this meeting:

Chairman, George Hodge of the International Harvester Company, Chicago, Illinois.

Vice Chairman, Carl J. Rutland, Safety Engineer, Texas Power and Light Company, Dallas, Texas.

Secretary, Elmer L. Hewitt, Manager of the Detroit Industrial Safety Council, Detroit, Michigan.

CHAIRMAN OPP: As chairman of the Nominating Committee, I presume you put that in the form of a motion?

MR. EIB: Yes.

CHAIRMAN OPP: Do I hear a second?

(The motion was seconded and carried.)

CHAIRMAN OPP: We will have the vice-chairman in this case, in the absence of a secretary, cast the ballot for this slate, if you will so move at this time.

MR. EIB: I so move.

(The motion was seconded and carried.)

CHAIRMAN OPP: I am sure that with the selection of a set of officers like this there will be no question about the content and quality of next year's program. At any rate, however, let me remind you that your own suggestions submitted to these officers or to the National Safety Council headquarters will be very much appreciated and more than likely incorporated in the program for next year's meeting of the General Round Table. You can contribute your own ideas during the coming ten months, allowing at least two months for the preparation in final form of the program.

We have a feature today that is outside of the arranged program. There has come to my attention an individual, very remarkable, who has a story to tell in which I am sure you will all be interested. I am going to ask our good friend

Bill Winans to introduce the next speaker at this session. Mr. W. H. Winans of Union Carbide and Carbon Corporation:

W. H. WINANS: Mr. Chairman, Ladies and Gentlemen: Walter Darling, who is here with me, about five years ago was an expert service operator and demonstrator of the Linde Air Products Company. At that time he suffered a very severe accident, as a result of which he was totally blinded. Since then, he has made a better man of himself than he was before. His ambition from now on is to devote his life so far as he can to preventing others from going through the experience he went through. He will tell you in a very few minutes what he thinks about safety. We in the Union Carbide and Carbon Corporation are proud of him as a former fellow employee and want to do everything we can to make it possible for him to accomplish the results he is after.

The Cost of An Accident

WALTER DARLING: All of you are familiar with accidents and accident prevention work. I wonder how many of you have stopped to consider just what it costs to have an accident. To the manufacturer, the increasing number of industrial accidents each year means a higher experience and the expenditure of large sums for safety equipment. It means a great deal of industrial inconvenience such as the training and replacing of men. It means the added expense of maintaining industrial relations and first aid departments. To the industrial insurance companies, it means more claims and more money for medical service, hospital bills and compensation for time lost. To the victim, it means injury, pain, suffering, and the worry of being incapacitated or handicapped, not only in a physical way but as to the continued support of his family.

Although all of these are big and serious items and amount to large sums of money, that pay dividends only in good will among men, still they represent only a minor part so far as the actual costs are concerned. If you will allow me to tell you my experience, it will show you a new version of what the costs of an accident are.

My parents, like most parents, had spent a great deal of time and money raising me, and I suppose I gave them, like most boys, a great deal of trouble, especially when I was only a child. Before the war, I was at an age where I was not of much help to them, and while in the service I could not help them to any extent. Then, after the war, I settled down to the business of getting somewhere in the world and began to save and to help and in a way repay my parents for what they unselfishly had given me. In the next few years, I managed to pay off a small mortgage on the old home, and it looked as though my parents might lay down their work and let me bear the care and the worry they had borne for so many years. I continued to save, and as the load got lighter I became engaged, and then just as things were at their best, the unexpected happened.

A Flying Piece of Steel

I had a most serious accident. In an explosion, I was struck across the face with a piece of steel and the damage was great and far-reaching; more so than I realized at the time. I was taken to the hospital a torn and bleeding mess, living, but still a pitiful piece of humanity. There were X-rays and ice packs. After a few days my family were notified. My father came to that hospital, and to this day, folks, I am thankful that the bandages hid the extent of my

injury. He was unable to see the condition of my face. But, as I felt his hand, I felt tears on mine. When a big man, weighing 180 pounds, sheds tears, he has a mighty good reason for it. Right then and there I said that were it ever in my power I would prevent heartaches such as these from occurring to the loved ones of others. I knew what it meant to my father, because he would have to comfort my mother.

After seven weeks, I was able to leave the hospital and make the trip home. Upon my arrival, I was put under the care of a specialist. There was a chance that I would have the partial sight of one eye, and to this end a series of operations were started, seven in all, lasting over a period of three years. Each time I came from that hospital, I had to be treated at home. This was my dear old mother's work. My eyes had to be bathed and fresh bandages applied and drops administered. I am sure that it was only the caring for my needs that carried my mother along, for after the operation was over and it was decided that nothing more could be done, that I could never see again, my mother died.

As I stood at her grave that cold day in October, I again said that I would do my part to save someone else's mother from what mine had gone through. Fourteen months later when I laid my father at rest beside my mother, for the third time I said I would do my part again to kill this awful condition brought about by accidents.

I could not quite get over the terrible ending that had come to my family after all their work and sacrifices for me. I do not tell you these things, folks, to enlist your sympathy; I don't need it and I don't want it. I must, however, have your help in so worthy a work. There isn't a bit of doubt in my mind but that anyone here could have and would have borne it equally as well. For the victim it is not so bad. A good physician or surgeon can with cocaine stop your pain or relieve it. But, remember, that neither he nor anybody else can give an anesthetic to the heart and the feeling of those who actually do the suffering.

CHAIRMAN OPP: Mr. Darling, you have my word that your story, told in the manner in which it was, not to make a touching story at all but a story, a true story of the price of an accident, certainly has left a deep impress upon us. We thank you for coming here today. We thank you, Bill Winans, for bringing Mr. Darling.

A picture such as that, gentlemen, ought to remind us oftentimes of the responsibility that we, either as executives or safety men, carry upon our shoulders. We have heard a lot about the incidental costs of an accident. This is a new item, I am sure, for Mr. Heinrich to include in his remarkable list.

Now, we proceed to the matter of discussing our most serious problems and how they were solved. Stories of accomplishments, stories of things done are always of interest, and we shall be very happy as we go down this galaxy of experts along safety lines to hear from each and every one the problem that in their own mind was the greatest, and then to hear of the accomplishment that met their work upon those problems.

The first one to speak is Mr. D. Frank Lord, Safety Engineer of the M. J. Whittall Associates of Worcester. He is a member of the Worcester Safety Council, and one of the organizers of the Worcester Chapter of the ASSE-Engineering Section of the National Safety Council. He is the new chairman of the Textile Section of the Council, and yesterday he was elected a member of our National Executive Committee.

Our Most Serious Problems and How They Were Solved

By D. FRANK LORD
Safety Engineer, M. J. Whittall Associates
Worcester, Mass.

Since my subject is one that I cannot well cover in the brief space of time allotted to me, I will confine my remarks to the problem that I found the most difficult to solve, namely the "Foremen."

It will be necessary for me to describe briefly the conditions existing at our mills when I took charge of the safety work. Our mills had been running many years before such a thing as "Employers' Liability" or "Workmen's Compensation" had become popularized. The foreman and the overseers were men who had been brought up in the business and had been at the plant many years. It is quite true that we had done everything the insurance companies asked for when the "Workmen's Compensation Act" was put in force, such as guarding machines, having a safety committee and enough of the first aid organization to cover their requirements. The safety committee met occasionally and there were a few perfunctory inspections, but it was not until 1923 that real activity began.

Selling Safety to the Foreman

Then came the question of selling safety to the foremen. These men had been used to taking care of the worker as best they could. They were a kindly lot and meant well, but did not quite understand. This condition puts me in mind of a story that I heard recently regarding a fellow who went from one of our large eastern cities to a ranch in the west.

He furnished himself with all the necessary equipment including a wonderful saddle, bridle, chaps and a beautiful silver mounted six shooter. Upon his arrival at the ranch he sought out the chief wrangler and said, "Now I am all ready but I want a horse." "What kind of a horse do you want?" said the wrangler. "Oh, I want a good one." "Have you ever ridden a horse?" "Well no, not much." "Well here is one that nobody has ever ridden and that's what you fellows in the city call a 50-50 proposition."

I think you can readily understand the position that I was in, in regard to the foreman. The first thing I did was to create a feeling of confidence in the foremen by showing them that I had considerable enthusiasm and assurance on the subject of safety. I tried to show them what safety really meant in connection with the men, that they might be kept at their work, thereby insuring them of continued wages and rendering to the management a full measure of production.

I called meetings and at the start made suggestions to them and it was not long before sufficient interest had arisen so that they were making suggestions to the committee. A safety committee had been formed consisting of the foremen and overseers. All accidents were investigated and reports together with suggestions as to how to prevent further accidents of like nature were made.

Speaking for just a moment of the safety committee, I am very strongly of the opinion that one of the greatest benefits that can be derived from a Safety Committee is to change its membership and organization at least once a year being careful to retain on the new committee enough members of the old committee to carry on the work satisfactorily.

Letters from the management criticizing the men when they failed, and praising them when they had done good work, resulted in the building up of an interest that

is hard to pull down. Every month I made it a particular point to present at the meeting of the safety committee the results of the previous month. I saw to it that they had a copy of the report. We have arranged with the National Safety Council to have enough copies of the NATIONAL SAFETY NEWS for circulation among all the foremen. These are marked on the cover with the names of the foremen to whom the magazine is to go and any particularly interesting article in the magazine is indicated on the cover with a request that they read it. Each magazine is sent to seven different foremen with the request that each read and pass the magazine along to the next name printed on the cover, but not to retain the magazine over four days. We also were able to create sufficient interest among our foremen so that a large number of them attended safety rallies, which were sponsored by the Worcester Safety Council. The foremen soon got into a frame of mind very strong for safety. I am quite proud to give you a few figures as a result of this intensive work.

A Fine Showing

In 1922 we had 35 lost time accidents, 14 of which were compensated for, a total of 460 lost time days. In 1923 we had 38 lost time accidents, 22 of which were compensated for, a total of 798 lost time days. It was at this time that intensive safety work was started. In 1924 we had 37 lost time accidents, 14 of which were compensated for, a total of 467 lost time days. In 1925 we had 25 lost time accidents, 13 of which were compensated for, a total of 319 lost time days. In 1926 we had 18 lost time accidents, 12 of which were compensated for, a total of 346 lost time days. In 1927 we had 22 lost time accidents, 9 of which were compensated for, a total of 265 lost time days.

These comparisons had best be made with the knowledge that there were employed an average of 1,500 men and women. The compensated accidents are those which kept the injured person away from his work more than seven days, and you will notice the steady decrease from 1922 to 1927 and that the greatest number of lost time days was in 1923, of 798, and this was reduced in 1927 to 265. However, if we are able to continue this year's work as well as has been shown from the first of January, 1928, we will have a much greater reduction than during the previous year.

I feel confident that after the interest of the foremen is aroused, greatly improved conditions will obtain. I thoroughly believe that, first, last and always, the keyman in any plant, for safety, is the foreman. That there have been other serious problems is beyond question of a doubt, but they have all been solved in due course of events; the one that is outstanding, in my mind, is the one which I have tried to describe.

CHAIRMAN OFF: Mr. Lord, we thank you for your part of the contribution to the subject of the problems that have been solved. Unless there is something specific at this point we will omit discussion on each particular paper, going on through the list of the various problems and then having general discussion upon all of them.

The next speaker is Charles H. Black, Division Manager, Stone and Webster, Inc., construction engineers of Boston, Massachusetts. Mr. Black was the chairman of the Poster Committee of the Construction Section during the past year.

Our Most Serious Problem and How It Was Solved

By **CHARLES H. BLACK**

Division Insurance Manager, Stone & Webster, Inc., Boston, Mass.

Perhaps many of you think that I will start in by telling you about some particular operation incidental to our construction jobs that made us pull our hair because of the hazards involved, but to begin looking for a special risk on a construction job would be a problem in itself for I think the construction industry represents the greatest hazard from a safety viewpoint of any industry in the universe.

I am not going to take the time to enumerate construction hazards. Each of you has a pretty good idea of the ever changing hazards involved.

With only five minutes to go and knowing of the desire of the National Safety Council for us to stay on schedule I am going to ask you to visualize in a few seconds the construction operations of a large organization having jobs in about twelve different states and each job under the supervision of a superintendent who rates ace high in his field.

Now here's my story:

It was felt that an organized safety movement was needed, as too many accidents were occurring on the jobs. On looking into the matter it was found that there was a frequency rate of 87 lost time accidents per 1,000,000 man hours. Hard to believe but it was so. Various safety programs were undertaken, monthly letters to the superintendents pointing out benefits of safety work both financial and humanitarian and monthly statements showing competitive standing of the various jobs were sent out. When you stop to consider that in the construction field like that undertaken by Stone & Webster when a job is finished the supervisory force moves to a new location and has to instruct a new crew in the practices of safety, I think you will feel as we do that we did accomplish something in reducing our frequency rate from 85 lost time accidents per 1,000,000 man hours to 65 lost time accidents per 1,000,000 man hours.

The next question was how were we to reduce our lost time accidents still further. The members of our General Safety Committee continually kept after the jobs under their supervision. Those in charge were called to task concerning the serious accidents and safety had come to be a special feature on our jobs. The idea was conceived of analyzing our accident summary to determine the four principal causes of our lost time accidents. The procedure we used was that outlined by the National Safety Council in Safe Practice Pamphlet No. 21. The four principal causes proved to be falling objects, stepping on or striking against objects, falls of persons and handling material and objects.

In October, 1927, a letter, with a supply of special bulletins, was sent to all of our superintendents. I shall read the letter:—

Dear Sir:

Examination of our accident record for the period August 16 to September 15, 1927, will show that our frequency rate is much lower than for the corresponding period last year. Considering the increased exposure this record is very encouraging and indicates that the work of our safety committees is not in vain. There is still room for improvement, however, and we are anxious to have more of the smaller jobs under the caption "Section A," "Jobs that had no lost time accidents."

It should be borne in mind that a high frequency rate on any particular

job results in a higher average for all our operations, and, therefore, the job with a poor record not only stands out as an apparently unsafe job, but it also nullifies, to some extent, the job with a good record, for as pointed out above, it raises the average for all our construction operations.

Classifying Accidents

An examination of the last comparative statement will show that there are four classes under which the majority of the accidents are listed and these are as follows in the order of the number of injuries:

1. Falling objects.
2. Stepping on or striking against objects.
3. Falls of persons.
4. Handling material and objects.

The above will show the operations that are the most hazardous and which produce the greatest number of lost time accidents, and we would ask that you take extra precaution during the month of November to prevent accidents occurring under the first class.

By an examination of the causes of most of the accidents on your own accident record, you may find a way that will help to reduce the number.

We shall select for the month of December accidents of the 2nd class and so continue through the list each succeeding month.

The efforts that are made to reduce accidents of any one class will, of course, be additional to the routine safety work that is part of the construction program and we hope by concentrating on the hazards which cause the greatest number of accidents that much improvement will be shown in our operations as a whole.

We are enclosing a supply of posters which you should place in conspicuous locations around your job.

I trust that we shall have your hearty cooperation in making November and the succeeding months the best that we have had since the safety campaign was started.

Yours very truly,

W. N. Patten, Vice-President,
Division of Construction and Engineering.

Similar letters and bulletins were sent out in November and December, also National Safety Council Safety Calendars were sent to safety committee members and foremen. The classes of accidents that were responsible for lost time accidents were forcibly brought home to the men on our jobs and the jobs were given the idea of how to analyze their own records of causes of lost time accidents, and on the whole excellent results have been obtained. Not only were the lost time accidents classified under the titles falling objects, stepping on or striking against objects, falls of persons and handling material and objects reduced but a reduction was effected in all classes.

We had our jobs in Massachusetts participate in a safety poster contest sponsored by the Massachusetts Safety Council. A poster was placed in the hands of hundreds of workmen and foremen on construction jobs of approximately twenty-four contractors throughout Massachusetts. Cash prizes were offered for the best answers to the question "What's Unsafe in This Picture?" Our own campaign that I previously mentioned was also in process at this time and it was pleasing to Stone & Webster to have four out of the six prizes won by our men. We took the first, second, third and one of the two five dollar prizes given as the sixth

prize. An official list of fifty-three unsafe practices was given to the judges with the poster, but the surprising part of the contest was that the prize winners found considerably more than that number. Our first prize winner was able to enumerate one hundred and thirty-six unsafe situations revealed by the picture.

Previous to our special campaign the yearly average frequency rate was 65 lost time accidents per 1,000,000 man hours. Forty-one lost time accidents per 1,000,000 man hours has been the average frequency rate for the past eight months. I think we have reason to be proud of our record when the magnitude of our work is considered and the fact that we do not have the same workmen on all our jobs as do the average local contractors. This is a mark for the larger construction companies to aim at and if your frequency rate is not so good you should do better. If your work is not construction you do not have our hazards in the other industries and, therefore, this rate is not comparable to the frequency rate you may enjoy.

In closing I want to emphasize the need of classifying your accidents. The method recommended by the National Safety Council will aid you in the solving of your accident problems and will help you to find the evils that are eating into the efficiency and financial coffers of your business. If you would study your accident analysis as you do your financial statement and act accordingly, your accidents will diminish and your savings will increase.

CHAIRMAN OPP: Thank you, Mr. Black, for your contribution.

The next speaker is one who is getting rather nervous that I might introduce him with some of the applesauce that sometimes is associated with introductions. I think last evening's issue of *The Crash* indicates that all my applesauce is delayed en route between Detroit and New York in a box car along with other miscellaneous notes. Unfortunately, we haven't an added flourish to sound for Mr. Armstrong. We just take it for granted that as safety engineer of the Eastman Kodak Company, Rochester, he has a real job. He may indicate upon rising to his feet just what his connections may have been in regard to the story that he is going to tell.

Solving Our Most Serious Problem

By A. L. ARMSTRONG

Safety Engineer, Eastman Kodak Company, Rochester, N. Y.

We started a few years ago a work in our plant which I believe is rather different from that done by any other concern. Our problem was to reduce what had been thought to be a very good accident record—that is, comparing it with statistics which were available. As a means of preventing accidents, especially in the chemical industry, we decided to launch an educational program. In other words, we wanted to find out what was causing the accidents. Some of you may say, "That is easy." If you do, you are not in the chemical industry. We put our proposition squarely and fairly up to the employee, had them in, talked over our problems and from them received a knowledge of hazards which existed in the plant that we had no knowledge whatever of.

The work was started in a small way as an experiment in our chemical plant. We checked over all the accidents that had occurred, and we produced these accidents on a laboratory scale for the men. They were asked how this type of accident happened. The answer was that they did not know. In other words, men were handling acids, alkalis and other corrosive substances and did not have a sufficient knowledge of those materials to handle them properly and safely. That is pretty general throughout the country of a great many materials, contrary to a great many people's belief.

We showed different reactions of acids and caustics. That was one of the first things we did. The next thing we did was to impress upon the employee the necessity of using water on acid burns. To do this, we poured acid over the hand and immediately put it under water. Then, we took a piece of burlap and poured acid over the burlap to show how quickly the burlap could be destroyed. We did that because in our work we handle a lot of burlap. This one demonstration, I believe, saved us a very severe if not fatal accident shortly after we had gone into the work.

Safety Training Saves His Life

One of our employees was transferring acid from one building to another. He put the pressure on the blow tank and started in to inspect the line. A six inch nipple blew out, showering him with a mixed acid. He immediately got under the shower bath. I saw him three hours afterward in a hospital and the only place that the alkali showed any reaction was in the ear where the acid had not been thoroughly washed out. That particular thing has been discussed in the Chemical Section a great many times.

A man came to me this morning and said, "I don't know how you get your men to use water; our men want to use linseed oil." It is easy to give that demonstration and talk to the men about it.

Because of the nature of our work, we use a great deal of static equipment to remove static from materials and inflammable liquids. Many men will not believe that static will ignite gasoline or benzol fumes. In fact, I have seen men throw a lighted cigarette into a pan of gasoline to show how quickly it would be extinguished and how impossible it was to ignite gasoline with a spark.

Take the Toronto accident, which was one of the worst we have ever had. A man didn't want to pay for having his drapes dry cleaned. He went out and bought some gasoline, took the drapes down and put them in the washing machine. The fumes given off finally got to an explosive concentration. The static charge built up in the machine blew up the house. Both he and his wife died at eight o'clock that night. The next morning, I believe it was, they found the two little children in the cellar with their legs burned off up to the hips. It blew the house next to it partly down. When you get that sort of thing among people who have real good intelligence, educated people, when they do that sort of thing you can't expect your \$30 or \$35 employee to go out and handle materials of that kind safely unless you can in some way instill in him the seriousness of not handling it properly.

For demonstrating purposes we use a static machine and set up equipment on a laboratory scale the same as is used in a department, and by moving the equipment out of adjustment show how high potentials can be built up and made to jump through space, also igniting fumes from inflammable solvents. When you have shown a man that, there is no question in his mind but what it is serious and the equipment must be kept properly adjusted.

The argument may come up that workmen cannot be made to understand or appreciate this type of hazard because of their lack of technical training, but this sort of work need not be done along technical lines. In fact, much better results are obtained by keeping away from the technical or going into the reason for static or how it accumulates.

After trying this work out in our chemical plant, we branched out into other manufacturing departments and eventually took in all of our E and M foremen and gang bosses, as well as our truck drivers and riggers. Some of you may say, "Why the truck drivers?" The truck drivers have to handle

all the dangerous materials that come in. One of the first questions I got put to me was, "Suppose we throw a cylinder of ammonia on the paper will it do any harm? We had one of the manufacturers up here several years ago and he told us it was all right." If they throw off ammonia, they will throw off chlorine, and they will throw off other substances.

We had in all our E and M bosses. Another question brought up by a truck driver was, I believe, something like this: "Does the supervision in this plant have to hold all their conferences in the middle of the street and just around blind corners?" In other words, you immediately get from the employee the fact that you can't establish rules which you wish him to live up to unless your supervision is going to live up to the same rules. If this work is done and you instill in the employee the proper attitude, they won't be a bit backward in telling you what they think of conditions throughout the plant. If you are going to have safety in the plant, that is the one thing you have got to do.

Discuss Accidents in Other Industries

We make a very careful study of accidents, fires and explosions which happen outside our plant and tell our employees how these accidents happened, where we have parallel conditions at Kodak Park and what can be done to prevent this same sort of accident in our plant. The average man will not read safe practices pamphlets and he is not interested in accidents which happen outside his own plant. Of course, there are exceptions to this rule but I believe it is pretty general among all workmen. However, they are very glad to discuss this sort of thing with someone else. A great many times they will point out conditions which exist in the plant which might be the cause of a serious accident. In fact, we have received a great many very valuable suggestions from our workmen, some of which have led us to discover hazards which we did not know existed.

Our school will accommodate 30 employees. We have them in during working hours and spend from two to three hours with them, depending upon the size of the class. All new employees go through this school within two or three weeks after employment. After this we have them in once a year, and I might add that we have found that it is advisable to handle not more than thirty employees at a time. In starting this work in a large plant, I would advise that it be tried out in two or three departments which will give the man doing the work an opportunity to install proper equipment for demonstrating purposes and make up his lecture work to fit the different groups. This man should have a thorough knowledge of manufacturing conditions throughout the plant. He should also have a thorough knowledge in regard to safe practices for handling materials which are used in the plant, such as welding equipment, ammonia cylinders, carboys of acid, drums of caustic, tank cars, and materials of this sort. It is also very necessary for him to have the confidence of the employees because without this he will be unable to get them to discuss the different conditions around the plant.

We have a stenographer sit in at the discussions after the demonstrations are given and every question and answer is written down, and a copy of those questions and answers go to the superintendent and also to the plant manager. The employee's name is not taken. I might add here that if you take the employee's name you might as well quit. One of the first things I got when I first started in this work was, "What the hell have you got us over here for—to get us in trouble if we say something?" That is the attitude of the average employee. I don't think our plant is any different than any other. If you don't take the name and they have real confidence in you, they will tell you about these

things and talk them over. If the situation is handled as it should be, you can do a lot of good work and not hurt anyone's feelings.

A Good Accident Prevention Record

We have in our plant about 6,000 employees. A little better than one-third of these are girls. We have 112 different departments. Out of these 112 departments we had 58 which operated during the year 1927 without a lost time accident. In 1928, up to the first of October, we had 72 departments operating without a lost time accident. Our severity rate per thousand hours work for the two years was: 1927, 2.65; and 1928 to date, 1.05. That includes such departments as sulphuric acid, nitric acid, cotton nitrating, silver nitrate, steel fabricating, machine shop and carpenter shop. I might add that in our steel fabricating department we have 110 men who have operated about fourteen months without an accident. I think that is a real record for anyone to shoot at.

Our experience after going into this work and doing it for two, practically three years, is that a great many accidents happen throughout your industry entirely because of the lack of knowledge on the part of the employee. I also believe that if you are going to put over a safety program you have to give the employee a part in that safety program. I don't think it can be a one-man job. I think you have got to get them interested. If you want to get them interested you have to let them talk. When you do that, I think you will find out what is causing your accidents. In other words, I don't believe it is possible unless you have established confidence in the employee to go out and properly investigate an accident and get the results. In other words, they won't tell you unless they are absolutely sure that if they tell you something about the supervision or the way the department is run that you are not going to go to the superintendent and get them in dutch.

CHAIRMAN OPP: Thank you kindly, Mr. Armstrong. The next speaker presenting his problem and the solution is listed as George Martinson of Pickands, Mather and Company, Hibbing, Minn. Is Mr. Martinson in the room?

The next, then, is Arthur D. Berquist, Safety Inspector of the Youngstown Sheet and Tube Company, East Chicago, Indiana. In 1926 at the Detroit Congress, Mr. Berquist played the part of "Careless Cal" in the playlet "The Education of Careless Cal," presented at the General Round Table session. He has been nicknamed "Careless Cal" as he has played the part on several other occasions. We are happy to have "Careless Cal" with us today.

Our Most Serious Problems and How They Were Solved

By ARTHUR D. BERQUIST

Safety Inspector, Youngstown Sheet & Tube Co., East Chicago, Ind.

I haven't any reputation to lose as an orator, although I have taken a couple of lessons in Mr. Hardy's school of Public Speaking, and if I do make a flop, it will not be any reflection on him, because I haven't gotten my diploma yet.

I have heard a number of remarks in various meetings of this Congress that have kind of struck me, and before I give my talk I just want to say a few things in connection with them.

At some of the meetings, some men have brought up petty little things as to why workers will not conform to safety rules or regulations, as laid down by the plant. There was one mentioned here this afternoon, and with all due respect to the men making these remarks, I just want to express myself in this way:

You lay out the work for the people that are working in your plant, you expect them to do their work in a certain way, they are not going to tell you how they are going to do their work; it is up to you to tell them how to do their work safely.

I heard a remark yesterday morning by Mr. Homer L. Ferguson, President of the Newport News Shipbuilding and Dry Dock Company, in which he stated that the simplest problem of management is safety, as it can be enforced without fear of contradiction. I think that is one thing that every one of us ought to realize. We have got to do it. I want to say also, that if we accept the excuses and alibis for not following safety rules and regulations as laid down in our plant, we don't have the courage and conviction of carrying out those rules and regulations, but we sit by and wish that the employee would do it and worry about the possibility of a future accident.

The subject of this discussion is, "Our most serious problems and how they were solved." What is our most serious problem? What are we trying to do? Stop accidents. Who gets hurt? The man. The man then is our problem. What are we going to do with him? It has often been said that about 75 per cent of our accidents are due to carelessness, ignorance or some other form of unsafe practice that eventually leads to disaster.

If that is the case, it is a question with us as to what we are doing to try to stop carelessness, indifference, ignorance or unsafe practices. It has been said that education is the solution to unsafe practices or the dangerous way of doing work. If that is the case, we must map out a system of education that will reach every man and one in which we have some reaction to know that it is being carried out.

That leads me up to the things I want to talk about or the things that we are doing in our plant; three things, taken from our entire work, which I wish to bring to you to show you how we are trying to solve the problem of education. And rather than have the safety department tell them what is going to be done, we are asking the foremen, the superintendents and the operating men what they are doing.

About three or four years ago, we instituted a system in our plant of holding safety meetings of foremen in each department at which time we discussed everything that we knew of that pertained to safety to educate the foremen and expected he would carry it to his men and that we would get safety in that way. We did make a reduction in lost time accidents, but nothing near what we think could have been accomplished or what other plants were doing in the country, with the result that an order came from the superintendent of the plant that every foreman would have to hold a safety meeting of his men at least once a week or by-monthly, according to the size of the department and the record they made. A form is furnished on which this meeting must be reported. The form shows the department, the foreman's name, the date and the number of men present at the meeting and who conducted the meeting. It also shows a place for the report, that is, what unsafe practices were reported or what conditions were reported. This form must be sent to the safety department where a record is kept.

Daily Report Required of Foremen

We have instituted in our plant, and I think we are the originators of it, a system of reporting by the foreman daily which we have entitled "The daily report of unsafe practices corrected." The foreman must send this in every day to the superintendent of his department. It is then forwarded to the safety department to be checked against the foreman's record. In the event the foreman

finds an unsafe practice, he must write out the man's name, check number and the description of the practice and how he remedied it, signing the report and sending it in. If he has no unsafe practice, he writes across the face of the report, "No unsafe practices found," or words to that effect, and also sends it in.

We realized that the foreman, confined to his little shop or department, could not always come in contact with things that would be of interest at a safety meeting or a warning to any of his other men. We have arranged in the safety department to issue a weekly bulletin, run off on a legal sized mimeograph form in which we write up records of near accidents, unsafe practices and cases of discipline.

Those are the three things I wanted to call to your attention. They are measures or features that have helped us considerably in cutting down unsafe practices. There is a psychological effect in the handling of these reports. We feel that a foreman writing out his reports of a safety meeting has the things or items which he writes out on the report indelibly impressed in his memory. The prime purpose of the unsafe practice report was to make that foreman think of safety at least once a day. What effect has it had? I am glad to say that in our plant (we employ 4,500 men) we have had a 35 per cent reduction in the number of lost-time accidents for the nine months of this year as compared with last year, and the year 1927 was the best record we ever had in the history of the plant.

CHAIRMAN OPP: Thank you very much, Mr. Berquist, for your contribution to the program.

The gentlemen will be ready to discuss any part of the matter that has been presented after the next speaker concludes his contribution to this program.

The next speaker is one who has had considerable experience in the public utility industry. You will note how varied this program has been this afternoon, both in personnel of organizations represented, in industries in which they are engaged, and also in material which they have contributed. The next speaker is a man who has recently been awarded a McCarter medal for work done in resuscitation. He is the Manager of the Safety and Claim Department of the Northern Indiana Service Company of Hammond, Indiana. I have pleasure in presenting Mr. Harry M. Keller.

The Problems of Responsibility

By HARRY M. KELLER

**Manager, Safety and Claim Departments, Northern Indiana Service Co.,
Hammond, Ind.**

Much of what I intended to talk to you about has already been discussed.

I feel our biggest problem has been getting the foreman or supervisor to accept his responsibility in our accident prevention program. Therefore, I am just going to touch lightly on that for two or three minutes, and try to get to you our ideas as to how the foreman should be dealt with.

In the beginning of our safety work, the foreman was overlooked. We felt that, like a good many other companies who were inexperienced, this thing could be overcome by the management issuing those orders and those orders were to be lived up to. We soon learned that foreman support is absolutely necessary. We must remember that safety work is not and cannot be the responsibility of any individual in an organization employing a great number of people; the responsibility must rest with the various department heads and foremen.

We had a very hard time convincing our foremen that safety work was a definite part of their job and an operating problem. They could not see why, when there was a man there to devote his entire time to safety, that man should not do all the work. There must be a very close understanding between the foreman and the safety director of any organization. The foreman in any industry has what we call job pride. Every foreman is anxious to make a good showing. One of the things that stand out in this matter of job pride is that of doing the job without accidents.

We devised a plan of issuing each month a bulletin covering the various districts throughout the state in which we operate. We showed on this bulletin the number of accidents in each district, the name of the employee, the name of the man's foreman and the number of days lost. That sheet soon became known as the black list; and believe me, not only the foreman but the employees on down the line were anxious to keep their name off the black list.

Reducing Motor Vehicle Accidents

As I said, a good deal has been said about the foreman, so I am going to pass on and try to just bring up here something that we have adopted that has aroused considerable criticism, and we have had letters from a good many companies about it; we think you will be interested in it. We operate a good many motor vehicles. We are having a great many automobile accidents. We decided that we must do something, adopt some plan to stop those accidents. We adopted a rule that when an employee has three automobile accidents, he cannot drive an automobile for the company again. Some people say, "That is pretty hard-boiled." It does sound so. They will say, "Suppose the man is not to blame, suppose he is going down a through street and some one crashes into him; that is not his fault, why should you hold that against him?"

Here is the way we work it: We have a card record of each and every employee in the company. Every accident report comes through the safety department and shows on that card the date of the accident, the nature of the accident; and then, when a man has three automobile accidents, his reports are pulled and sent to the vice-president of the company. He reviews the details of these accidents. We have not made any exception to the rule that a man shall not drive a car again. As a result of that, during the past year we have laid off four employees, but our automobile accidents have decreased 60 per cent. The automobile accidents are a thing of the past. That record, we believe, will be a great deal better during the coming year.

We also have combined with that the rule that if a man has three lost time accidents his case is passed to the Vice President. He reviews the details of the accidents and some disciplinary action is taken. That also is very effective.

This year I am happy to say we had only one fatal accident in our line department as against seven last year. Our lost-time accidents are the lowest in the history of the company.

While this rule may seem, as I say, hard-boiled, I think you will agree that the results justify the adoption of such a rule.

CHAIRMAN OPP: Thank you, Mr. Keller, for your contribution to the program.

Now, gentlemen, the speakers are all here awaiting your onslaught. I trust you are going to give them some real "posers" of questions to answer. The meeting is in your hands.

MR. CHAPIN (Philadelphia, Pa.): I was very much interested in the remarks regarding the training of foremen. I have just come from a luncheon of the National Carbon Company where I heard a most interesting talk by Mr. Conroy

of the Niagara Falls Carbide Company. He said they had reduced their accidents from 1,100 in 1927 to something over 800 this year, up to date, 600 days of which were penalty days on account of a lost member. You said, Mr. Berquist, that you have your foremen report unsafe practices; how do you know that they know an unsafe practice when they see it?

Mr. Conroy takes the foremen into his office and draws a diagram on the blackboard. He says, "We are going to do a job here; we are going to load a car, we are going to do some operation around the plant, and this foreman here (pointing one out) is going to tell us when we are doing it right." He then starts with the beginning of that operation. He says to the foreman, "I am a new man; I am going to do this work; if I do anything that is wrong you are to tell me I am doing it wrong. Every time I do something that is wrong and you don't tell me about it, I am going to take ten off that hundred." He starts the game. The foreman tells him what is right and what is wrong. Sometimes he gets the percentages down as low as 40 and sometimes he has a minus chalked up. He said at first it didn't make much difference, but gradually, after the first three months, there was a marked improvement in the interest on the part of the foremen and in the accident record in the plant.

I wish Mr. Conroy were here to give it to you more directly.

The interest of workmen can be aroused in another way. I heard of a colliery company where the president walking on the property, got off the train and walked up the track and he was going between two cars that were about fifteen feet apart when somebody on top of the hill hollered, "Get that guy." Two fellows came rushing toward him and said, "You can't go through there; that is against the company rules; don't you know that; you are fined fifty cents." They looked him over. They saw he had on a white collar. That did not make any difference. The president was fined fifty cents for disobeying a rule of safety. The president then knew his men were on the job and had safety on their mind. They were watching the safety rules of that company.

F. A. OXLEY (Union Carbide Company): Referring to the statement of the speaker a few minutes ago saying the foreman should have something written to impress upon his mind the safety of the company once a day, I would like to say that if the foreman has to have something written to impress safety on his mind once a day, he has no place in industry as a foreman and should not be retained in any line of work as a foreman.

CHAIRMAN OPP: That is a very good contribution. Thank you.

B. K. GODFREY (Georgia Power Company, Atlanta, Ga.): I would like to ask Mr. Lord how he figures his record there on the basis of days lost, for instance, lost time going over from one year to the next. How would you charge up a fatal accident or one causing permanent disability?

MR. LORD: The number of lost-time days in any one year is charged to that year. If it laps over from one year to another, the next year gets the penalty. We haven't had any experience yet with fatal accidents. We have to give them 6,000 days. We haven't had any permanent disability cases. I am not going to cross the bridge until I get there.

MR. COLLINS (Claim Department, Youngstown Sheet and Tube Co.): I would like to inquire of Mr. Armstrong what manner of shower he uses to take care of acid burns?

MR. ARMSTRONG: We use the number three spraying nozzle in rooms such as an acid screen room (if you are familiar with that), where an employee is liable to get acid over the head or over the entire body. There is only one exit, and when he steps out, he steps on a platform and this platform operates the shower.

Anything finer than a number three spraying nozzle will not answer the purpose. If we are going to prevent an acid burn, we have to get a lot of water on it.

MR. ROGERS (Southern Chemical Company): I would like to ask Mr. Berquist whether they consider it an honor for a foreman to report many unsafe practices or whether he is criticized if he reports more unsafe practices than they consider should exist? In other words, are the number of unsafe practices considered indicative of a foreman's ability as an executive?

MR. BERQUIST: I can answer that in this way: That we credit a foreman when he reports an unsafe practice, but if he reports the same one too many times it is a discredit and he is told so. If he continually reports unsafe practices, we know that he is looking for them, he is on the alert. We also tell him that he has too many unsafe practices in his department and it is time to have some discipline.

FRANK AYER (Morenci Branch, Phelps Dodge Corp., Morenci, Arizona): Referring to Mr. Berquist's scheme of being pretty hard-boiled with the men, we have at a company which I have operated in Mexico, used a similar scheme, not to be hard-boiled but to get results. We had a very great deal of difficulty getting our men to wear their goggles on their eyes instead of on their hats. For that reason, we put in a system whereby when any man was found disobeying the goggle rule, his foreman turned him over to what we called a Careless Workmen's Committee. This committee was composed of some of our best and most reliable workmen. These workmen gave this man a raking over such as he never got before and he never forgot this talk that the workmen gave him. On top of that, the workmen recommended to the chairman of our company's safety committee that his man get a formal notice warning him that if he disobeyed this rule twice more his connection with the company would be severed. We found in the first year that we had something like 80 of these letters sent out; the second year, only 12 were sent out. When I left the employ of that company about a year ago, it had not been necessary to send a single man his third letter which dismissed him from the company.

The result was that in our goggle campaign instead of having some 250 eye accidents, we reduced them down to zero.

We have worked down through our foremen, as has been mentioned, and are getting to our men as closely as possible. We have reached a point now where the men are shoving us just as hard as they can. We like to be shoved. Our campaign has been quite productive in the last five years. We have reduced our accident rate so that it is one-thirtieth of what it was five years ago, and figuring it out on a million hour basis, which I notice is used here, it figures about five lost-time accidents per million man-hours. I figure that even though that record is pretty good, there is no reason if we put in the same amount of work in the next five years that we did the last five it shouldn't be one-thirtieth of what it is now.

CHAIRMAN OPP: Thank you, Mr. Ayer. Are there any further comments?

If not, the rest of the meeting will be devoted to the presentation of your problems. Tell us what your trouble has been. Ask any question you wish in that connection. We will make some effort to see that you get an answer either here now or from the National Safety Council later on.

CHAIRMAN OPP: Your Vice-Chairman, Mr. Earl F. Blank of Jones & Laughlin Steel Co. will speak.

E. F. BLANK: Before I go, I would like to just raise one question in regard to our problem which has not been touched on at all. I believe that every safety engineer's most serious problem is how to arouse and maintain interest in safety.

Several have spoken in regard to arousing the interest of the foreman. I don't believe that in the plant where the top men, the president or general manager, are sold on safety that that is any problem at all, because the man who runs the job asks his supervisors to get out production and they get out production in the way he wants it gotten out. In regard to safety, it is the same proposition. If he is active and sincere in safety, he tells them that he wants the work gotten out safely. That is all there is to it. There is no problem that I can see at all in selling the supervisor or the line organization. There is a problem that all of us have in arousing and maintaining interest in accident prevention work down the line.

The phase that happens to be my particular hobby now (I used to have the statistical hobby) is the safety competition hobby. In our work we have aroused and are maintaining at the present time more of the safety spirit among our men than I have seen any place in the country. What I mean by that is, that you can go through our plant, any place, and you can ask any workman what safety means and what would happen if he had an accident, what the program is, and he could tell you pretty closely what our entire safety program is. The reason that we have been able to get that across is that we have safety contests between the plants and interdepartmental contests in each of the plants. There is a trophy put up and every month that is awarded to the department that has the best record. The reports are put up monthly on the bulletin board so that each man, each workman can see where his department stands.

We have been able to get these men intensely interested in safety through the competitive idea. I just want to register that with you. It hasn't been mentioned at all this afternoon. Of course, we have a number of different ways of reaching the men. But, it is the interest in the contest that keeps them alive.

We use the same system that Mr. Berquist does at the foreman's meetings. In fact, we stole the idea from him a year or so ago. We have the foreman report when he has a safety meeting, and all of these foremen hold meetings weekly or every two weeks or sometimes just once a month. When the foreman gets up and talks about safety, they know that he knows what he is talking about. It isn't like the safety engineer going out and delivering an oration on safety. The men know that the foreman is the man that can hire and fire them.

At the meetings he lines them up on unsafe practices and gets suggestions on machinery that needs to be guarded. The meetings are held on company time.

The first year we had the contest, our accidents were reduced 39 per cent. Last year, we reduced them 57 per cent. You can see from that that it is getting results.

ADJOURNMENT.

SEVENTEENTH ANNUAL SAFETY CONGRESS
NATIONAL SAFETY COUNCIL

Fire Prevention Session

October 5, 1928

RUDOLPH P. MILLER, Chairman
Consulting Engineer, New York City

The session on Fire Prevention at the Seventeenth Annual Safety Congress was called to order at 9:40 o'clock by the chairman, Rudolph P. Miller, Consulting Engineer, New York City.

CHAIRMAN MILLER: I think the outstanding object of the National Safety Council is the conservation of life. In fire prevention, for many years this work has been going on, thinking more of the conservation of property. In recent years, however, this conservation of life has come to the fore. I believe this is only the second time that the National Safety Council has had a Fire Prevention session. It is to be hoped that this division will continue, and the thoughts that might be brought out in this connection will be repeated each year, or not necessarily repeated, but perhaps emphasized, and new thoughts brought forward.

Commissioner Hamilton, State Industrial Commissioner of New York, in addressing the Construction Section on Monday, called attention to the fact that in New York State, in the year 1927, there were nearly 100,000 casualties for which compensation was claimed. If the proportion holds true for the entire country, that means that there must be about a million casualties in this country each year, in industry. That is not counting the casualties resulting from traffic, and I doubt whether it includes the casualties that result from fire in all cases.

At the Wednesday afternoon meeting, Mr. Heinrich of the Travelers Insurance Company, stated that 98 per cent of all industrial accidents are preventable. Why there should be so many of them is hard to understand. He says that 88 per cent of them are due to the failure to observe rules, the ordinary rules of safety, and 10 per cent are due to the physical condition of the plant in which they occurred.

Mr. Dublin, statistician of the Metropolitan Life Insurance Company, on Monday, referred to 95,000 deaths due to accidents in this country. The figures apparently bear out the figure I just stated a moment ago. About 25 per cent of these, he says, occur in homes.

Of those that occur in homes, about 20 per cent are due to asphyxiation and suffocation, and about 19 per cent to scalds and burns. That means that about 40 per cent of the accidents that occur in homes are due in some way to fire or the result of fire.

The fatalities from fire in the country throughout the year are generally estimated at about 15,000. We have nothing very definite on that point, so that is more or less of an approximation, but it seems to be consistent with the statements that have been made by reliable authority.

In New York City, we have kept for a number of years fairly accurate figures as to the deaths from fire. For the six years, from 1920 to 1925 inclusive, the total deaths from fire were 756. Of those deaths, 55½ per cent occurred in tene-

ment houses, houses in which three or more families live and carry on their households independently.

Another 25 per cent occurred in other residence buildings, that is dwellings and furnished-room houses. Altogether, 80 per cent of the deaths from fire occur in residence buildings. The New York Board of Health figures corroborate these statements and give as the chief causes of those fires, children playing with matches, explosions and ignition of flammable oils—that is, probably starting a fire in the stove with kerosene. The third thing is carelessness with cigars and cigarettes. It is remarkable how large a loss of property is attributable to smoking and matches. The National Board of Fire Underwriters' figures show that about \$30,000,000 annual loss results from the careless use of matches and carelessness in smoking.

To meet these hazards, it seems we might follow one of several courses, or should follow all of these more or less.

In the first place, there is the matter of construction. We can prevent fires in a large measure by building our building properly. The greater use of fireproof construction will contribute very largely to that. But even better than that, and something that can be more generally observed, is good housekeeping.

In this matter of housekeeping, when we look over the National Board's figures, and assuming that housekeeping includes the handling of hot ashes and coals, the use of open fires, taking care of rubbish and litter, and the proper use of stoves, furnaces and boilers—we find that nearly seven per cent of the annual loss by fire in this country is due to that cause.

Another thing we must look after is that we have ample exits in our buildings so that when fire does occur, those who are in the building have the opportunity to get out safely. That means not merely sufficient stairways. More important than the number of stairways, in my judgment, is the proper enclosure of the stairways. If the stairways are kept properly enclosed and kept for that purpose only, not used for the storing of materials and things that are likely to burn, a great contribution will be made to the safety of the occupants.

I have no use whatever for the so-called fire escape as a proper means of exit. It is a makeshift that we may apply occasionally where something better cannot be done on an existing building, and when something must be done; but for new buildings, we should not allow the so-called fire escape to be used.

Another point in meeting this life hazard from fires is the prompt extinguishment of fires. That means, when the fire occurs, notify your fire department at once. Do not wait to see what you can do, but notify the fire department. After that, if you have the facilities at hand—a good soda acid extinguisher or some other extinguisher, even a garden hose attached to your cold water spigot at the kitchen sink will help you—you may save the fire department some trouble.

Of course, that applies more particularly to the home, but in the plant one of the best means that we have yet found for prompt extinguishment of fires is the automatic sprinkler. It has had such a splendid record in the extinguishment of fires that I cannot help but mention it at this time, not as an advertisement of automatic extinguishers, but as an effective means of promptly extinguishing fires.

I think I have said enough in the way of introduction, and I am sure you are waiting to hear from those who are on the program.

I regret very much that Mr. Franklin H. Wentworth, the Secretary of the National Fire Protection Association, who was to have presented the next paper, isn't here. But he has sent us an excellent substitute, in the gentleman who is going to talk to you.

I take pleasure in introducing Mr. Percy Bugbee.

Facts Written in Flame

By PERCY BUGBEE

**Assistant Managing Director, The National Fire Protection Association,
Boston, Mass.**

My subject might lead you to believe that I am to indulge either in some fiery oratory or in a statistical treatise of the problem. To reassure your minds, before I launch upon my talk, I am glad to say that I will not treat my subject in either of these ways, and that I conceive the topic assigned to me and the purpose of my being asked to address this meeting as an opportunity to bring before you some generalizations of this whole fire-waste problem, and to open the session and pave the way for the more distinguished speakers on your program, for their discussions and papers.

It seems to me that probably everybody in this room is thoroughly familiar with the enormous fire waste in the United States. The statistics have been hammered at you through all sorts of publicity mediums for years. It isn't necessary to describe the terrific losses of life and property that we have to face in this country.

It might be better, and it seems to me more to the point, to think of the facts to be written with flame, to be burned into the consciousness of the people of this country, along this line. The fire waste in the United States will never be reduced by passing resolutions. The fire waste of the United States is an individual, municipal and industrial problem. It must be attacked by the individual community and the individual industry before it can be successfully solved.

Fire waste in this country must be treated with common sense; practical methods must be looked squarely in the face. The issue must not be dodged, if we are to expect to reach any very satisfactory trend in the downward curve of our fire losses.

I think the reluctance of the people of this country to interest themselves in this fire waste problem must unconsciously go back to the old days of the fire worshiper, the people who looked upon fire as a dangerous and uncontrollable force, people who were simply treating fire as an act of God, a conception of uncontrollable power which could not be met with and harnessed as our other sources of energy could be.

Of course, the difficulty we have to contend with in all our fire prevention activity is that question of ignorance and indifference to the whole subject, on the part of the general public. It is a curious thing to notice that the people who have never had a fire, who have never known of any of their close friends or business acquaintances being touched by fire, show very little direct interest in the problem.

The man who has had a fire in his own home or in his own business, or whose friends have suffered by fire, is the man who takes a whole-hearted life-long interest in the reduction of fire waste. It is so easy for us to "pass the buck" on this problem to the insurance companies. If you have a fire, you may be glad to see your insurance agent, but you never want him to come around again. You appreciate the destruction, the waste of time and energy and labor and money that are involved in a disastrous fire.

We are trying, through our work in the National Fire Protection Association, to overthrow this long-range conception of the problem on the part of the public and to get the individuals, in their communities and in their cities, to look at the fire-waste problem through a microscope—to analyze it, and to deal with it in a direct, personal, common-sense way.

Fire is a chemical reaction. It is subject to ordinary physical and moral laws. It must be so treated and analyzed if we are to get any results in this kind of work.

Why was last year's fire record \$70,000,000 better than any record for a good many years? We believe that this result is obtained through a combination of circumstances, a combination of the work that a body such as this National Safety Council is doing, to interest the general public in the serious problem. And that encouraging trend, the first we have seen in that work in a great many years, must be in part due to a general awakening to the importance of the subject.

Probably the best way to treat this subject briefly is to cite some personal experiences which we have had in our attack upon the fire-waste problem.

The National Fire Protection Association initiated its field service about five years ago. We decided to go into the cities all over the country and to attack the fire-waste problem at its source, by appealing to city officials, chambers of commerce, local Safety Councils, and any other avenue of local approach we might reach.

We found from the very beginning there is apparently no conception on the part of these cities of this fire-waste problem as a whole. For instance, we might find a city would have an excellent water supply system, but along with that a very poor fire department. We might find that a city would have a good building code, but no ordinances controlling the ordinary common hazards of fire, so the effect of the code might be lost. We would find that a city might only have a few dry-cleaning establishments but have very rigid rules controlling the hazards of that industry, and yet over half the fires might be caused by wooden-shingle roofs, and the city would have no ordinance prohibiting the use of wood shingle roof coverings in the city.

I was looking through our files the other day and picked out a letter which seemed to me typical of the problem we have to meet, and I thought I would read it to you. It is a letter written by one of our field engineers last spring to a city of about 25,000 population, in the middle west. It is directed to the Commissioner of Public Safety. It reads as follows:

"Dear Mr. Commissioner:

"I enjoyed very much the chance to make your acquaintance and talk to you about Smithtown's fire situation, when I was in your city a few weeks ago. I know you are interested in the safety of your city. I think you will be interested in my reaction to your local situation, which is given below.

"The fire situation in Smithtown appears to me to be very serious indeed. In the first place, the fire department is very short-handed, having scarcely enough men to man the apparatus. There are no men for the one aerial ladder which the city owns, and if this is needed at a fire it is necessary to send back for it. This makes the ladder practically worthless, as they are needed in the early stages of the fire in order to save life.

"The fire department is short of equipment. The city has only two engines. One is so old the chief does not like to run it through the streets, the inference being it is not in any too good shape from the safety point of view.

"As I mentioned before, there is only one aerial ladder in the city, and that does not respond to alarms at all. This is aggravated because of the fact that Smithtown, being at a considerable distance from other cities, could not count on any great amount of aid. I understand one pump station could be obtained from Johnstown, ten miles away.

"In addition to that, structural conditions are very bad from a fire standpoint. There are numerous places where bad fires could occur. There are relatively few installations of automatic sprinklers.

"Although structural conditions are bad, there is no supervision of building construction, the building code being practically worthless, because of the lack of any penalty, and no building inspector has ever been appointed to enforce it.

"All that means that Smithtown is (more than most places) liable to have a severe fire, and the city is ill prepared to meet such an emergency. The lack of apparatus means delay in controlling fires. The lack of building supervision permits fire-breeding buildings to stand without any protection.

"An attempt is made by the fire department to do fire-inspection work, one man being sent out every day, when he can be spared from fire duty. At least one man should be put on full-time inspection work and relieved from fire duty.

"I know you are aware of these conditions (for the most part), but there has been no special inclination on the part of the city to spend the money necessary for their improvement. I have asked the Chamber of Commerce to take an interest in these affairs, in the hope they will support what action the city officials take in these matters."

Is it any wonder a city in that condition has a terrific fire-loss record over a period of years? Until that city takes a direct personal interest in looking over its fire hazards and studying these problems, it will continue to have such an unfavorable record.

The same proposition applies to an individual industrial plant. An example of that, about as good as anything I can give you, occurred about six months ago. I was in a city and had an opportunity to go through a large paper plant. The fire chief of the plant prided himself on the money and time and effort that the plant spent in their fire protection and fire prevention work. They had an elaborate system worked out and all the latest appliances in use. Conditions were generally much more satisfactory than in the ordinary plant.

I walked through the plant with him and called his attention to a particular building which seemed to me not up to the standards of that protection. About two months later I got a letter from the local Chamber of Fire Prevention Committee of that city, which read as follows: (It was directed to Mr. Bond, one of our engineers.)

"When you see Mr. Bugbee, tell him I was at the X Paper Company today, and that the chief stated that Bugbee was 100 per cent right, as they had a fire the other day right in that portion of the plant Mr. Bugbee predicted there probably would be.

"However, the city department was able to hold it, and we understand the loss wouldn't run more than \$5,000 or \$6,000."

That is simply another instance of the failure of our people to conceive this fire prevention problem as a whole. They are going at it hit-or-miss. They will see one obvious hazard and pass right by another one, and until the problem is treated with the same scientific exactness and splendid results that they have treated the accident problem in industry, we cannot hope to very much improve our records.

I was in an automobile-painting establishment a little while ago. They were cleaning cars with gasoline and using a lot of paint and other finishes in there; and they had for heat in that plant, an open stove, about six feet from where they were cleaning cars with gasoline, with absolutely no ventilation, no particular segregation of their painting and spraying operations.

I said to the owner, who was smoking a cigar at the time, that it seemed strange to me he hadn't burned the place down.

About a month after I left that city, I had a letter from the fire chief saying the plant was a total loss. They had an explosion there and the fire had burned with such rapidity that they weren't able to save the walls. This is another example

of the failure of ordinary common sense in the treatment of this fire hazard problem.

The interest which the local Safety Councils throughout the country are giving to the fire prevention problem has been extremely gratifying to us in the National Fire Protection Association. I could not conclude my remarks without paying a tribute to these local councils.

To conclude, I think the following statement about sums up the remarks I have given you—that until the general public is willing not to dodge the facts and to apply common sense to the correction of a needless, dangerous, and stupid waste of lives and resources, we will not hope to solve the fire-loss problem.

CHAIRMAN MILLER: We have certainly had some good thoughts in this paper, and the main point that I should draw from it is the fact that we must reach the public at large and the individual in particular. Now I am going to ask if there aren't some thoughts in these many heads here as to how that can be accomplished. How can we arouse the public interest in this subject to that extent, that we will reduce not only this enormous property loss but the life loss as well?

I would like to ask Mr. Lacount to say a word or two. Mr. Lacount was formerly President of the National Fire Prevention Association.

H. O. LACOUNT (Associated Factory Mutual Fire Insurance Company, Boston, Mass.): I think, Mr. Chairman, that the real point to all this is not the generalization of the large statistics that are brought to us at these conventions so much as how to reach the individual—not the public at large, but the individual. He is the man who occasions most of the fires, not because he wants to but because he is calloused and ignorant and thoughtless.

I think the study of causes of fires is a very helpful means to this end, not that the individual shall be told about the causes in another city or another state, but even a study in localities. I think Mr. Bugbee would say that they are doing that in their work, studying causes in the townships and the cities where this field service of the N. F. P. A. is in operation.

I think it makes a great deal of difference to you and me whether the fire has happened or we are convinced that the next fire may happen in our alley. It looks a great deal different than it does on the next street or the next county, and we may be sure that it is only a matter of time when a fire will break out in our vicinity, and we may be the guilty party for that particular fire.

So if this could be brought home—not in general conventions like this, although this is a good starting point, but if it ends here the individual will receive no benefit—if it can be brought back to our localities, our companies, our towns, our communities, I think there is still a great work to be done in impressing the individual with his responsibility as a duty, or as a privilege, to safeguard his own interests. Perhaps self interest comes first, but he can safeguard the interests of those who are closer to him and in the large reduce the tremendous cost of the fire loss and cost of equipment and facilities, through the public development and other means of fire protection, which by the way is not so honorable as fire prevention.

The fire that we prevent, we do not have to extinguish. We cannot prevent them all, and therefore, we have to have these public departments for local protection, which run into great expense.

Even then statistics tell us that we are not only burning up property at a tremendous rate, but that we are endangering life, which of course is more serious in the end, a very serious matter.

So, Mr. Chairman, I certainly am impressed every time this matter comes up with the responsibility we have in bringing it to the attention of the localities and eventually the individual.

MR. VOGUEMAN (Travelers Insurance Co., Hartford, Conn.): I am pleased to announce that beginning next week, Station W O R is going on the air with a very novel fire protection program, and building up that program has been a remarkable thing. Great activities have been going on. It is the work of the Protection Fire Department, and the result has been that every man in the fire department has talked on fire prevention more than the average speaker.

I think it would be a good idea if the news could be broadcast as far as possible by the people here. The program is intended to hit home with the women and children mostly. Any further publicity you can give this thing by word of mouth, I am sure, will be appreciated.

E. E. BACH (Chamber of Commerce, Philadelphia, Pa.): The one great problem to be considered in fire prevention is the matter of creating sentiment against it. In most of our cities we have to consider this one thing: Someone must be responsible for it. We can't let everyone do this thing. There must be some organization in the city that takes a real interest in the thing and will see to it that there is a continuous program of fire prevention the year through.

Philadelphia eleven years ago had a very live fire marshal, Mr. George Elliot, whom you probably all know, who constantly hammered at the matter of fire prevention, day after day and year after year. The result was he finally created a sentiment against fire, until three years ago there was put in the City of Philadelphia an organized fire prevention program, held by the Fire Prevention Committee of the Philadelphia Chamber of Commerce.

This committee has been consistently working along this line. They have taken as a principal part in the program, the matter of the education of the people of Philadelphia, the men, women and children, trying to create an "air mind." That has been the large problem.

They have circularized the citizens through the schools, through the various industries, and they have been spoken to at the luncheon clubs; and there has been an organization created of all the various clubs in the city, the civic organizations and things of that sort, to act concertedly in this matter of fire prevention. The Chamber of Commerce has helped in this particularly.

The result has been that three years ago when we went into this large, nation-wide fire-prevention contest, the National Fire Protection Association, sponsored by the United States Chamber of Commerce of Washington, D. C. The first time we were active in that was three years ago. We simply got to second place in our class of cities, above 200,000. The first group of cities was 200,000 or over. We have 2,000,000 people in Philadelphia. We have 129 square miles to protect, and it didn't seem as though that were just fair. The people in small cities of 200,000 never said a word about it.

The next year we entered with 500,000 and over and were able to get to second place again. Last year we succeeded in getting to first place in the National Fire Prevention Association, with the reduction of \$2,500,000 in our fire loss in two years, in Philadelphia.

It can be done if everybody works concertedly along that line. We have one of the best Fire Prevention Departments in the United States. We have the city organization back of it. We have the various organizations I mentioned back of this whole thing, and we are now having a concerted sentiment against fire in Philadelphia, and we are certain that we can reduce the fire loss because we have done it in the past, and we are continuing and not lying down. We hope to make a new record in the coming year.

MR. ELTON (Chamber of Commerce, Pittsburgh): I think the last two speakers touched on a vital point in fire prevention. If I may, I would like to stress one portion of their remarks.

It is our opinion in Pittsburgh, after a study of the problem for several years, that you can arouse your adult population for a week or ten days to an interest

in fire prevention or any other civic activity, but you cannot continue that successfully over a period of years without a great amount of effort.

You have in your schools a coming generation which is ready to be told of the evils of fire prevention and of the needlessness of it. We find that the schools are the real place in which to plant the idea of fire prevention. Our schools are taking a very active interest in the problem.

Children in school remember things they are taught. We adults have become rather set in our ideas. We believe that the fire insurance companies pay the loss. We can get over to the students in school the idea that they pay the loss and when they come out and take up their places in the business world, they are going to carry on the messages which you are implanting in their minds at the present time.

I think that is a real fertile field for education, and I think it will prove very successful.

CHAIRMAN MILLER: We have had several suggestions. One way is to reach the individual through the schools; another way is through the local Chamber of Commerce; another way is through the radio, which is so very effective in transmitting matters these days.

Has anybody else any other suggestion to offer or any other thought to present on this subject?

A. AMRAN (Hamlin & Company, 17 Cedar Street, New York City): With reference to the remarks of the gentleman from Pittsburgh, whose remarks are no doubt very good, about teaching fire prevention in schools; I would like to raise a question.

Why is it I have never heard of any European country, where the schools are excellent and fire prevention is taught, and yet the fire losses as you all know—I don't have to emphasize that—in Germany or France or other European countries are almost nil compared with the losses in our country?

CHAIRMAN MILLER: Mr. Bugbee might possibly offer a thought on that point, about the comparative losses.

MR. BUGBEE: I think the whole solution of the proposition of the difference in fire loss as between this country and European countries falls into two categories.

In the first place, the general building construction abroad is infinitely superior, as far as quality is concerned, than the construction in this country. They don't have the wood to build with that we have in this country. They have always been obliged to build safer and better than we do here.

The other proposition is simply in their general attitude of mind toward the fire-waste problem. In France and Germany, for instance, we have the Code Napoleon, which says that if a man has a fire, he is responsible not only to the community for bringing out the fire apparatus, but to his neighbor for destroying his property. He is made personally responsible for a fire loss through carelessness or design on his own property.

I can't conceive of that idea being wide-spread in this country at the present time. We are not a nation that is so trained that when an individual suffers from fire he is made responsible. We are sort of careless in that attitude, and while we have in certain individual states and cities a personal liability law, which says that a man is so responsible, we are a long way from reaching the European idea of individual, personal responsibility for fire losses.

MR. ELTON (Chamber of Commerce, Pittsburgh): European nations have been teaching fire prevention for centuries, until the people in those countries have begun to consider it as a part of their nature. They are naturally, as a rule, a frugal people. We are a nation of spendthrifts. We have wasted our resources with a free hand, and until just recently we have not begun to realize that this waste will materially reduce our resources.

So in Europe their problem is not to convince the adult of the value of fire prevention, but simply to carry on the education of the need for conservation of all resources. Our problem here is to completely change the adult idea of the use of natural resources, and it can be done more quickly by instilling the proper thought in the minds of the coming generation than it can by changing over our present generation.

J. A. NORTHWOOD (Bethlehem Steel Co., Johnstown, Pa.): I would like to add one thing to what has already been said. This educational program with the young is very fine. But I feel, as this is a section of the National Safety Council, and as they have another section of Plant Publications, one of our ways to spread the gospel of fire prevention and to further the education of employees or plants who will cooperate is through the plant publications, stressing in the plant publications the value and good of your own fire marshal and department in your plant.

CHAIRMAN MILLER: That is a very good suggestion.

Are there any further thoughts?

EDWARD R. COLE (Acheren Graphite Corporation, Niagara Falls, N. Y.): I am still interested in the garage man Mr. Bugbee told about. He could not educate that individual under that condition. I wonder if he now has been educated up to the point where he believes what you would tell him under the same conditions. I also wonder if he could be reinsured, if he would read bills.

CHAIRMAN MILLER: I dare say he has been educated if he is still alive. Possibly he went up with the plant.

MR. GOLF (Municipal Employee, Oklahoma City, Okla.): Being a fire chief, I am very much interested in the subject. I agree with the gentleman from Pittsburgh that the way to teach fire prevention to the future generation is through the school children.

But that doesn't cure our ailment at the present time in the larger buildings. I would like to find some way of reaching the architect. They are the ones that give me my trouble at the present time especially.

CHAIRMAN MILLER: You are not alone in that. I think that is a problem, to reach the designers so they will build properly. Fires occur even in well-built buildings, but they occur to a less extent, as statistics show, than they do in the poorly-built buildings.

JOHN SHAW (Hercules Powder Company): There is just one other avenue I think of, gentlemen; and that is through the corporation house organ, which is read in the homes of the employees. I needn't say more. You know what I mean. A great many children as well as parents and wives read the house organs of corporations. That is another possibility of education.

CHARLES W. HANKO (Pittsburgh Steel Company, Monessen, Pa.): I have been interested in this subject, being a safety engineer myself. I just wonder sometimes if our fire departments don't lack a little bit in fire prevention.

That is a pretty broad statement to make, but nevertheless it is a fact. If you go to a fire department they pride themselves on the wonderful fire-fighting equipment—wonderful, in some cases—wonderful trucks, ladders and fire engines. But when you get down to the heart of that fire department and ask him about the fire prevention bureau, there is none. They are there to fight fires and nothing else. I believe it is just as much the duty of a fire company to prevent fires as it is to fight them.

I think if our fire departments throughout the great country would adopt, with the chamber of commerce and our civic organizations back of them, the work of fire prevention, the fire question could be solved to a great extent. I think the fire department should take up fire prevention as well as fire fighting.

I happen to live in the city of Baltimore. We conducted fire prevention through the school there, and the fire department got back of it. We took speakers

and a fireman with us. We explained the fire conditions to the boys in the schools. The firemen were there, and we told the children what the firemen's duty was, but we wanted their help. We had questionnaires. They filled out the questionnaires, and it was surprising the amount of interest they took and the results we got.

For quite a while after that you would be stopped on the streets by the children, telling you just what part they have taken to help to prevent fires. I think if the fire departments throughout this country of ours would take that interest and get a bureau and get busy in the line of fire prevention, a great part of the losses on account of fire could be cut down.

MR. ELTON (Chamber of Commerce, Pittsburgh): The fire department in Pittsburgh is the principal agent through which we are educating the children in the public schools. We have firemen appearing in every school in the city. We have fire companies training boy scouts in fire prevention, merit badge work. We are putting on a great fire demonstration to teach the boy scouts how to handle fires. If you are not connecting your fire department and public school system, you are overlooking your biggest bet in teaching real fire prevention work.

MR. PARKIN (New York): I would like to know what percentage of this fire loss and death is in the outlying districts outside of our cities, and what is being done there to educate the people?

CHAIRMAN MILLER: I don't know that the figures are readily available for that. Undoubtedly the fire hazard in the outlying districts does present a series problem.

I have in mind a particular case, a rather small town of about 30,000 inhabitants, in the State of New York, in which the fire loss has been reported high.

The average fire loss throughout the country per capita is given at a little less than \$5 a year. In that town it has gone considerably over in some years and one year it went up as much as \$11 per capita. In looking over their fire records, as I had occasion to do some time ago, I found that the large losses were on the outskirts of the town where the fire department had difficulty in getting there on time, probably did not have a prompt alarm. A comparatively small loss, the destruction of a complete fine residence—the finer residences are generally in the outskirts of the town—sometimes amounting to \$15,000, \$20,000, or \$30,000, immediately raised the per capita loss for that town by perhaps \$1 for the 30,000 inhabitants.

W. E. FELLER (Westchester Lighting Co., Mt. Vernon, New York): I think any concern which spends money in advertising, as the insurance people do, could improve upon their calendars. You see many calendars gotten out by insurance companies, which merely say "Blank Insurance Company." If they had some picture showing children being burned at fires happening in tenements or garages, to bring that forcibly before the people where the calendars are distributed, I think that would be a good thing.

CHAIRMAN MILLER: The thought is that the calendar should be developed into a poster, which has been found so successful in other safety work. It is a good thought.

JOS. T. PRATT (Reading Company, Reading, Pa.): I happen to be a member of the fire association both in Chester County and in Lancaster, and when they have meetings at different points they have a man by the name of Dr. Rank, who gives instructions on preventing fire. He has gone through schools and had questionnaires made out in that way. They are doing a great work in the way of education in fire prevention.

MR. GOLF (Fire Chief, Oklahoma City): I would like to have some idea as to what can be done about the architects.

MR. VOGUEMAN (Travelers' Insurance Company, Hartford, Conn.): It seems to me an architect is a pretty reasonable sort of man. Suppose you get some

figures. Here is a case of some I saw recently. Take an area around New York City, an area within a radius of about 20 miles. The fire loss of 1927 was just about enough to pay what the two states paid for the Hudson Vehicle Tunnel, \$20,000,000.

In your little home circle, figure what public improvements have been made in that neighborhood. Start figuring your fire losses and call the architects in; call them publicly at the same time, and I am sure you will get improvement.

When a building is going up, have one of your firemen get into the building and see what is going on. The Chief of Newark told me that in four or five buildings he had his men go; notwithstanding the city ordinances they were putting stand pipes in there, where in case of fire, according to the size of the pipe they never could connect their hose.

P. C. ABELL (British Columbia Safety League, Vancouver, British Columbia): As you probably know, our greatest resource in British Columbia is our timber asset, and over a number of years we have been carrying on an extensive educational campaign, the major portion of which has been directed to work in the schools.

We know that the message put in the schools is taken home, and I am very glad to be able to tell you that after a period of years in British Columbia, the statistics show that our fire loss in the forest at least is one-third only of what it was even last year.

CHAIRMAN MILLER: Are there any further thoughts on this subject?

I am not an architect, but perhaps I might say just a word in defense of the architect in connection with his planning of buildings. He is not always free. He has an owner to satisfy, and if that owner is not convinced of the necessity of certain things in connection with the planning of that building which make for fire prevention, it is difficult for the architect to ignore that. He cannot ignore the owner's wishes to carry out his own ideas.

I will say also that the American Institute of Architects is taking a very lively interest in this subject of fire prevention, and is trying to get the message over to the architectural profession at large. The work has been slow and rather hard, and I think they had a hard time reaching most of the architects, but it will be done in time undoubtedly.

N. L. PARMELEE (The Celluloid Corp., Newark, N. J.): Could that not be settled by a standardized code, that the cities would be compelled to incorporate in their building codes?

CHAIRMAN MILLER: Efforts are being made in that direction. The National Board of Fire Underwriters has had for years a recommended building code.

Making standard codes is a rather difficult proposition, and the problems in cities are different; the same code cannot always be made to apply. But there are no doubt a great many points on which provisions in the codes can be similar.

Another effort that has been made in recent years and is still continuing was inaugurated by the recent Secretary of Commerce in organizing a Building Code Committee, a committee that for the last eight years or so has been studying this question of possible standard provisions and has issued a number of reports with recommendations as to what might be done. That committee is now at work on a report on fire prevention measures or provisions, and it is very difficult. But I can assure you it will have careful consideration, and I think some valuable thoughts will come from that report.

W. E. FELLER (Westchester Lighting Co., Mt. Vernon, N. Y.): I have mingled considerably with the fire departments in Westchester County, and I am free to state that the whole question resolves itself into just one fact, and that is this: Education.

The gentleman struck the keynote when he said we must educate our school

children. There has never been a time in the history of the work when the appeal to human judgment has been more compelling than at the present time. You can't get away from that. Every man here should resolve himself into a committee of one and go back to his community and preach the gospel of fire prevention, and then we can get results and not until then.

Your fire departments are seriously handicapped in many instances. But we as individuals can and must educate the young, and then you are going to have the desired results in fire prevention.

W. D. GREER (North British Mercantile Insurance Co.): I would like to speak a word or two along that line. It has been my duty for many years to superintend inspection and improvement, if possible, of risks of all sizes, all the way from dwelling houses to enormous industrial plants insured by my employers. The results of such inspections indicate, as we all know, an almost incredible condition of carelessness on the part of many people, sometimes amounting to almost criminal carelessness. You have only to read the daily papers to be convinced of that.

The root of the matter lies, as many gentlemen have pointed out, in our national, deeply-rooted attitude of indifference, carelessness, and if I may use the term, "don't-give-a-dammitness." There is no question about that.

I have talked with many people during many years—I started in the business when I was little more than a boy. I have talked with many, many men. One of my men or myself would investigate a plant, make a careful survey of it, possibly point out some things that might be changed.

The invariable question would be, "What reduction are we going to get in our insurance rate?"

"You are not going to get any reduction in your insurance rate. This is a matter of upkeep. You are not going to get a reduction for it any more than if you washed your face and hands and put on a clean collar. This is a condition imperiling the safety of the risk and the lives of perhaps hundreds of employees."

That is exactly what a man said to me one time, when I kicked because he had a paint, oil and sweeping rag closet under the principal stairway in the plant, the only means of exit for all the people in that plant, many of whom were women.

He wanted to know what reduction he would get in his insurance rate. I said, "You won't get any. There is a chance you may get a good, stiff increase if somebody catches you. That is the only thing I can say."

I think there are many gentlemen present who have had an experience similar to mine, and they can corroborate a good many things I say. The average plant owner is very apt to be influenced by reasons of expediency, the outlay of money.

I saw a plant a while ago, or one of my men did, that has always had a good record for care and cleanliness. He reported it was in a shocking condition. I visited the treasurer. I knew him very well. I said, "What is the matter, John? Your place is getting a terrible racket."

He said, "Our business is not good, and the old man (meaning the president who was quite a man on efficiency and things of that kind) has fired the two sweepers we have and one night watchman. We have no sweepers and only one night watchman, and our men can't start the cleaning. That is the trouble. We have to hire men all the time to keep clean, and the Old Man is economizing and cutting down, so we fired them."

I said, "All right, that is up to him, of course. Some of these days he will have trouble and wish he hadn't fired them."

I thoroughly believe, gentlemen, the only way we can get at this thing is, as several gentlemen have pointed out, to start at the roots. Don't treat the

symptoms; treat the disease. Begin at the roots. Educate the children; begin in the school.

They often get the idea of:—Never mind the other fellow's property; he has insurance; I have insurance; we will collect from the insurance company.

Only this week I had occasion to examine a very large plant which many of you would recognize by name. Several of the buildings were very light frame construction, very combustible. They didn't have value. They seriously endangered the rest of the plant.

I was talking with the secretary of the company and spoke about those buildings. He said, "You needn't worry about those. They are not insured. We wouldn't insure those at all."

I said, "That is fortunate, because you would find very few people that would want to insure them. But don't you understand that those buildings, while not insured, and while they don't represent much value, seriously imperil your other buildings, and if you have a fire, the local fire department can't stop it?"

The rest of the plant was equipped with automatic sprinklers, but these buildings were not. They were unprotected. They were full of old truck and rubbish of all kinds. They should have been torn down and moved away. They felt perfectly contented because they weren't insured and the buildings weren't worth much.

If we have to change the national attitude of carelessness and indifference not only to our own interests but to the interests of others, we have to begin with the children. You have to start at the roots and educate the children, and maybe some of these days we will breed up a generation who will look perhaps past their own interests—although it is their own interest, but you can't make them believe it—and think of their duties to their fellow citizens and their duties to the municipalities in which they live.

In Europe, as Mr. Bugbee has said very pertinently, in most of the big European capitals a man is held responsible and strictly accountable in his duty to his neighbor. In Berlin, if a man has a fire, he is hauled over the coals and expected to demonstrate why he had the fire, how he had it, and bring out the facts as to whether he was responsible for it or not. If he gets off without a fine, he is lucky. He probably will get an old-fashioned, German call-down, and his duty to his neighbors will be strongly brought home. I believe the same condition exists in France.

As Mr. Bugbee has said, in many of those European countries the construction is entirely different from ours. It is mostly stone or brick or concrete. Wood is a valuable commodity. They can't afford to use it to put up buildings. But the people of those European countries have been brought up from their childhood, for many generations back, to respect authority.

Berlin is covered all over with authority—You can't do this; and you can't do that. But all those things lead to a respect for authority, an idea of their responsibility to their neighbors and to their communities, and that is something we have to get into the heads of our people in this country, a respect for authority.

I think you all know what I am talking about and what I mean by that. There is a distressing lack of that respect for authority in the American makeup. It is almost *nil*, and we have to start with the children and educate the children, and some of these days we will find our fire loss has dropped.

MR. DERWILDER: Gentlemen, I have heard a lot this morning about children playing a part in this fire prevention campaign. I happen to be interested in school work in a rural community. I have been wondering whether or not when this proposition has been handed to the superintendent of schools, and he in turn hands it to the children, are we going to depend too much on that as a solution in the reduction of accidents?

The thought came to me, in connection with this garage man—How can educating the children remedy that? Now then, how many years is it going to take to get these children to take care of the conditions now? I am not defending the school authorities but there are a lot of things that have to be taken into consideration.

For instance, the teacher is told that she must keep up with school, and she has to study at night. The boys and girls come home, and if they have a lot of safety to take care of and public health and fire prevention, they are coming home with a bad report, and the parents are going to say, "What is the matter, Johnny?"

I agree with you that it is a channel through which we can accomplish wonders in the safety movement, in fire prevention, and in public health. But I tell you, gentlemen, there are those other things which we must take into consideration; and it still stands out that we have the present fire loss to fight. I can't see how the children, innocent children as it were, are going to remedy that.

E. E. BACH (Chamber of Commerce, Philadelphia, Pa.): Under the school laws of Pennsylvania, fire-prevention teaching is compulsory up to the seventh grade. Get after the teacher.

NORVIN E. GREEN (Louisville Car Wheel & Railway Supply Co., Louisville, Ky.): I want to tell a funny thing that happened in Louisville, before I get to my real theme.

A woman called the fire department and in very broken English asked how much it cost to send the fire department. When assured that it didn't cost anything, she told them her house was on fire. She had an idea it was going to cost her because she had the fire.

In connection with the children and your training, it seems to me that if the insurance companies would send an inspector to our residences to inspect the premises as they do to our plants, we could get an educational program across that would be worth a great deal.

Of course, the first thing that is going to come up, is that a lot of people pay so little in premiums that it doesn't pay the insurance company to send these men around. I believe that the saving in the long run would much more than pay for the inspectors, and I think it is worth their consideration.

MR. GREER (North British Mercantile Insurance Co.): I would like to say that many thousands of dwellings are inspected by the insurance companies every year, in the United States. The question of premium and expense doesn't enter into it at all. There are literally thousands of them inspected every year by the insurance company. I have inspected hundreds myself in the last twenty years, all over the United States.

MR. VOGUEMAN (Travelers' Insurance Co., Hartford, Conn.): Unfortunately there are not enough people who want their dwelling houses inspected. I personally do a lot of inspecting, and in the last two or three weeks I have been asked to turn around and leave the place. They said the company had a lot of nerve to send an inspector to their dwelling house.

JAS. T. BURKE (Chief Inspector of Ontario Government, Toronto, Ontario): This question is a very important one. In fact, it is next to loss of life, and it is something we have been handling and discussing for a number of years. I think the time has arrived when we ought to get down to brass tacks and face the issue.

Architects have made attempts in a liberal way, but of course we all know the architect is a hired man and very oftentimes it becomes our duty to go to work and bolster up. Then sometimes representations are made that the fire chief says that the building is quite safe. But in the judgment of the owners it is not.

Then in regard to insurance companies, they regulate your rate according to their regulations. Of course, that is true.

So under the circumstances, it seems to me we ought to try to work together. A good many of us have practical suggestions. We can't have our own way in

the world. If we get together and give and take, I believe we would get somewhere with this subject.

CHAIRMAN MILLER: A gentleman who is a little modest has sent a thought to me on a card. He thinks possibly some educational work might be done through the newspapers. It would be an excellent way, if we can interest the newspaper.

He also suggests that regular courses be established in colleges. That has been done in some of the colleges. I do not recall for the moment which of them, but there are some.

Now we have had a more extended discussion than we expected on this very interesting and important subject, and we could keep on. But we must have in mind the rest of our program. The next topic on the program is, "Organizing to Fight Plant Fires." This is a subject into which we might naturally drift. It was to be presented by a man who would be well worth hearing. I wonder if he is here—Chief Kenlon.

He apparently is not here. In his behalf, I will say this, for his not being here: I am sure it is because he has just a day or two ago returned from an extended trip through Europe, inspecting fire departments over there, and has undoubtedly found his office loaded up with accumulated work that needs his attention. I think for that reason, he may be excused.

I am going to pass then to the next topic, "Recent Developments in Fire Prevention and Fire Protection." On this subject we are to hear from a man who has had a very wide experience in connection with the National Board of Fire Underwriters, in fire prevention work. I am going to introduce, Mr. Harry E. Newell, Engineer, National Board of Fire Underwriters, New York City.

Recent Developments in Fire Prevention and Fire Protection

By H. E. NEWELL

National Board of Fire Underwriters, New York City

The numerous new processes and materials born in the research laboratory have made possible mass production as we know it in this country. These processes and materials have created many problems for the fire protection engineer to solve. Complicated as many of them are, it has been necessary to bring into play scientific knowledge and skill of the highest order. Indeed, research has in many cases been the means of providing the solution of these problems. Research plays such an important part in present day fire prevention and protection engineering that without it industrial progress would be retarded and numerous luxuries enjoyed by all classes of our people as a direct result of mass production made impossible. The more recent developments in the field of fire prevention and fire protection have in a large measure been due to research.

The use of carbon dioxide for fire extinguishing purposes is spreading rapidly. Special systems employing CO_2 have been designed and installed for the protection of telephone switchboards. Considerable progress is also being made in applying this form as protection to electrical generators and other power house equipment. The extinction of fires in generators by means of carbon dioxide is described in detail in an excellent paper by Charles L. Jones, published in the October, 1924, issue of the *General Electrical Review*, an organ of the General Electric Company. This form of protection is now available for dry cleaning plants, and a system for total flooding, or in other words, filling an entire room has been developed. In connection with finishing operations a notable advance has been made in the protection of dip tanks; the CO_2 lines enter the tank at the bottom and the CO_2 bubbled up through the finishing material in the dip tank.

The protection of isolated oil tank farms where water supplies are not available has long been a serious problem for the fire protection engineer. The speaker believes that CO² forms a large part of the answer to this problem. Numerous tests of wood roof tanks of small size indicate that oil fires in tanks of such construction can be readily extinguished by CO². To date, however, no tests have been made in connection with tanks of the size actually used in the oil fields. Further development in this particular case is held up pending the securing of the facilities necessary for such large scale tests.

I might stress just for a moment the importance of any discovery along extinguishing methods for fires that occur in isolated tank storage. We know that every year the principal losses in the petroleum industry are due to lightning, and in most cases the lightning involves tanks of wooden roof construction.

It has been my thought for some time that CO² could be applied to the wooden-roof tank and the isolated tank, my thought being that at various localities in the tank farm would be stationed trucks in which would be loaded the batteries of CO² cylinders. It would be necessary to maintain at least passable roads. Anybody who has ever been in the oil fields knows that as a general rule, moving about the tank farm is a difficult thing, especially in the spring of the year.

Also applying the thought somewhat further, it would be necessary to have pipe connections, either going to the bottom of the tank or coming out of the top and terminating outside, so when the fire occurred the radiation would not be so great as to prevent approaching close enough to connect the CO² cylinders.

You might say that is more or less in the air. It is, but I am firmly convinced from the studies I have made of the extinguishing problem in the oil industry that CO² is the answer.

Bulletin of the Department of Agriculture

In June of this year the U. S. Department of Agriculture issued Technical Bulletin No. 74, entitled "The Value of Inert Gas as a Preventive of Dust Explosions in Grinding Equipment." This bulletin describes in detail the method of introducing carbon dioxide in the form of flue gas, into grinding and pulverizing systems. For several years at least one large company has to the knowledge of the speaker safeguarded the grinding of sulphur by this method. The work of the Government, however, is especially commendable in that all necessary experiments and tests were made in order to demonstrate the practicability of this effective means of preventing dust explosions.

The use of CO² in the form of washed flue gas as a means of preventing fires and explosions aboard oil tankers marks another interesting and valuable development in the use of this valuable gas. For many years, the prevention of such occurrences has been a problem difficult to solve, and even at present it is being given serious consideration by oil companies, dry dock establishments and the marine committee of the National Fire Prevention Association. The Standard Oil Company of California, however, has introduced this method of prevention. The cargo tanks are filled with CO² each time the tanker is unloaded. In connection with loading and other operations, the *National Petroleum News* states as follows:

"When filling the ship's tanks with oil, a further safety feature of this flue gas system comes into play. When an ordinary tanker is loaded, the vapors that have to be expelled from the tanks to make room for the oil are simply pushed out of the vents or 'ullage-holes' onto the deck of the vessel.

"The presence of this inflammable vapor calls for extreme precautions throughout the loading period.

"The use of a flue-gas system provides a double safeguard against this hazard. In the first place, the mere fact that the tanks of a flue-gas equipped ship are filled with a non-explosive mixture would greatly reduce the hazard, even if the

tank vapors were discharged in the usual way—through the ullage holes onto the deck. But these vapors are still flammable when mixed with enough air and are therefore best discharged at some point safe from possible sources of ignition.

"This further safeguard can also be obtained by making use of the flue-gas piping for venting the tanks. The main distributing line is connected into the base of the ship's hollow mast. When loading starts, instead of opening the ullage holes, as has previously been the practice, the valves to the flue gas lines are opened and the tank vapors are pushed out through these lines. A check valve prevents any chance of the vapors being pushed back through the washer into the stack; and consequently they are forced out through the mast at a point so high above the deck that chances of ignition are practically negligible.

"Thus in all phases of a tanker's normal operations—loading, carrying cargo, unloading and running back in ballast—the flue-gas system tends to make a tanker about the safest kind of a vessel afloat. But some of the worst accidents aboard tankers have occurred not in the course of normal operations, but under some special conditions, as when tanks are being cleaned or repaired. Here again the flue-gas system can be called on for a large measure of protection.

"By operating a blower for the purpose of pulling flue-gas out of the stack through the washer and forcing it through the distributing pipe lines, flue-gas can be circulated through the empty tanks of the vessel until all oil vapors have been displaced by flue-gas; and then the usual 'wind-sails' can be used to displace the flue-gas with fresh air. Thus the entire operation of freeing a tank of vapors so that it can be entered for cleaning or repairs can be carried out without, at any time, permitting explosion vapors to exist inside the tank."

You understand that is not my conclusion. I am simply quoting the National Petroleum News. I do firmly believe that this system does make the tank a very safe vessel.

Operation of a Small Chemical Extinguisher

An interesting development in the field of hand chemical extinguishers is the 1½ gallon extinguisher placed on the market by the Fyr-Fyter Company of Dayton, Ohio. According to an article published in the July, 1928, issue of *Fire* this extinguisher is the result of research by the laboratory of that company, leading to the discovery that sodium potassium carbonate in solution is a successful agent in quelling fires. The extinguisher is operated by inversion. An acid bottle falls on a peg which ruptures a frangible bulb allowing reaction of acid with an anti-freeze extinguishing liquid; the reaction generates a gas expelling the liquid which is a special water solution developed by the manufacturer. This extinguisher is suitable for use on incipient fires in ordinary combustible materials where the quenching and cooling effects of quantities of water or solutions containing large percentages of water, are of first importance. It is also suitable for use in the extinguishment of incipient fires in small quantities of flammable liquids, greases, etc., where a blanketing effect is essential.

There has been some interesting development in dry powder extinguishers during recent years. The extinguishing value of bicarbonate of soda has been recognized for years, but its propensity to cake has made it of little practical use and for that reason the usual form of dry powder extinguisher has been tabooed by all authorities.

Claims have been made by several concerns that they have been able to prepare a non-cooling compound of soda which could be thrown on the fire in a powder form with good extinguishing effects. Numerous demonstrations have been made which prove these claims are correct where the material is thrown on the fire as a cloud of soda dust; on the other hand, if simply dumped on the fire it has little effect. The principal disadvantage is that the user must be within a few feet of

the fire, which limits its usefulness to small fires where this close approach is possible without danger to the user. To offset this condition there have been several machines built which blew the powder into the fire by means of compressed nitrogen gas. Portable and stationary soda containers with one or more cylinders of nitrogen and various lengths of one-inch hose, have been built, but none of these have reached a state of perfection where it could be considered by Underwriters' Laboratories. As compared with water lines or foam discharge these systems still are at the disadvantage that the powder can not be thrown more than a few feet.

The Deluge Sprinkler System

Of pronounced interest in the field of sprinkler protection is the Deluge Sprinkler System—Pre-Action type, developed by the Automatic Sprinkler Corporation of America. This is so named because the admission of water into the sprinkler piping and the ringing of the alarm gong is independent of and precedes the fusing of a sprinkler head. It actually is an empty or dry pipe system, but with the air in the sprinkler pipes at atmospheric pressure. The sprinkler heads are of the ordinary fusible link type, fusing at 165 degrees Fahrenheit. The entire sprinkler system is supplied through an approved deluge valve instead of through a dry-pipe valve.

In connection with the system, small air chambers, termed "Heat Actuated Devices" are spaced at regular intervals on the ceiling, thus subjecting one or more of these air chambers to the effect of temperature use from fires occurring within the protected property. These air chambers are connected together by means of flexible copper tubing, this tubing being directly connected to a sensitive diaphragm of a relay device called a remote control release.

Rising temperature causes an expansion of air in the heat actuated devices, thus developing an increased air pressure which is conveyed directly through the air tubing to the remote control release diaphragm against which the air pressure is exerted, thus moving the diaphragm. A fire therefore creates a pneumatic impulse which is conveyed to the release mechanism in the minimum of time.

A compensating vent is connected to the air tubing line. This vent relieves the slight pressure caused by *slowly rising* temperatures, such as from weather conditions, heating equipment, etc. However, *rapidly rising* temperatures (15 degrees per minute or faster) develop a pressure too great to be relieved by the vent, consequently this pressure is directly exerted on the diaphragm of the remote control release causing it to trip.

The tripping of the remote control release causes the deluge valve to open, thus admitting water into the sprinkler piping and alarm gong line.

The vital principle of this system is the differential in air pressure controlled by the ratio of the size of the opening in the compensating vent to the expansion of air in the heat actuated device when subject to temperature use.

I might say that since this article was written it was drawn to my attention by Mr. Hamilton, Mechanical Engineer of the Automotive Sprinkler Section that a very effective supervisory type has been developed.

With reference to finishing processes, the safeguarding of japanning and enameling baking ovens has always been a more or less difficult problem. In spite of carefully planned and installed safeguards puzzling fires and explosions have occurred as their cause has not been readily apparent. Industry is therefore indebted to the Factory Mutual Laboratories for the invention of a device providing an effective means for the prevention of such occurrences. The following discussion of the subject and description of the device appeared in the September issue of the *Factory Mutual Record*.

"One of the major problems today is the prevention of explosions in enamel baking ovens.

"The most important essential is to control the oven ventilation so that the flammable vapors of the enamel are kept below the lower explosive limit. Removing or guarding sources of ignition such as open flames or electric arcs is important but this alone will not prevent explosions, since an explosive mixture under certain conditions can be set off merely by the surface heat of the gas burner boxes, radiator tubes or electric heating ribbons.

"Control of oven ventilation heretofore has been more or less a hit-or-miss affair, because no one could tell quickly the exact concentration of vapor in the oven. The usual laboratory methods of gas analysis require a half-hour or more for results and in that time conditions in the oven might change entirely.

"To meet the need for a device giving immediate and continuous results, the Factory Mutual Laboratories, after two years of study and research both in the laboratory and under actual operating conditions in industrial plants, have developed the "F. M. Flammable Vapor Indicator" which promises to provide a check for the safe control of oven ventilation.

"The device is essentially a continuous calorimeter, in that it burns the vapor and measures the heat given off. A continuous sample of atmosphere from the oven is drawn by a small fan, first through a heating coil which keeps the sample at oven temperature to prevent condensation, and thence through a flash-back arrester to the detector unit. Here an electric heating coil ignites the vapor in the sample and the increase in temperature is measured by a thermo couple and is indicated on a millivoltmeter. The reading is then referred to a calibration curve which gives the percentage of vapor in terms of the lower explosive limit.

"The indicator records without special calibration for the various hydro-carbon gases, alcohols, and ethers, either alone or in combination, since flammable compounds containing carbon and hydrogen, or carbon, hydrogen, and oxygen, give off approximately the same amount of heat when burned at the lower explosive limit. Special calibrations are needed for hydrogen, carbon monoxide and acetylene.

"The device can be set for an ample factor of safety, and can then by the use of relays be made to ring an alarm, turn on a red light, start the ventilating fans, control the speed of fan motors, operate the dampers, turn off the oven heat, or perform any other function suited to particular conditions. Not only is it suitable for enamel baking ovens, but also for recovery processes where flammable vapors may collect in an enclosed space.

"The Mine Safety Appliances Company of Pittsburgh have developed commercial models which are now on the market."

The Tendency to Adopt Pumping Engines

In the municipal field of protection the present tendency is toward providing pumping engines, even in cities where normal pressures are high and formerly only hose carriers were provided. The extra cost of the pump is not great, and when compared, on the basis of the service possible, there is no question but that pumps are preferable to hose wagons in all cities and towns.

In former years, quickness of action on small fires made the large chemical engine or tank a very desirable feature for hose wagons and ladder trucks. With the general introduction of pumpers it was found that a cheaper and equally efficient service could be obtained by carrying a 40 to 80 gallon tank of water, with a connection to the suction side of the pump, and by use of the pump, discharging a small stream of water through the usual chemical line.

Some fire departments are equipping their apparatus with foam chemical tanks

and using foam on all incipient fires. The form of equipment most generally used is two solution tanks, with a cylinder of nitrogen to give the necessary discharge pressure. The principal objection to this is the high first cost.

Foam generators are coming into very general use in fire departments. Their need is being brought about by the increase in use of liquid fuels. Incidentally, the development of the so-called "Phomene Accumulator," a device making use of foam producing chemicals in powder form and made by the Pyrene Company, is worthy of mention. This forms another effective means for the protection of numerous industrial hazards.

The increase in height of buildings is a problem which fire departments in all cities has to contend with. The water tower and ladder pipe are available for moderate height buildings, but for those over 6 or 8 stories these appliances are of little value and dependence must be placed on equipment provided in the building. Standpipe lines are practically the only means of getting hose streams to the top of high buildings; recognizing this a number of cities have recently adopted ordinances covering standpipes and making provisions for house fire pumps.

Thus the development of fire prevention and protection is coincident with or follows closely expansion and development in all branches of industry. New processes and materials frequently create undue fear and excitement—a fact to be deplored. It should be realized that any process or material, once it has been demonstrated to be an economic necessity, deserves and demands constructive treatment at the hands of those interested in fire prevention and protection. After all, fire prevention and protection must render possible the use of these processes and materials in order to justify its classification as a legitimate branch of engineering. Calm, unbiased analysis, or in other words, true engineering consideration of the technical nature of a process or material will usually indicate that much of the hazard can be removed or made relatively safe by the application of intelligently planned safeguards. Fire prevention and protection engineering can in this way co-operate with the research laboratory and the industries making use of its discoveries and creations thus contributing in a constructive way to the industrial development of our country.

Discussion of Mr. Newell's Paper

CHAIRMAN MILLER: In Mr. Newell's paper reference was made to the development by the Pyrene Company, of foam extinguishers, and I think Mr. Timpson has a film to show you, which will be interesting.

N. L. PARMELEE (The Celluloid Corp., Newark, N. J.): I would like to ask Mr. Newell if he can give me any idea of the importance attached to the cooling effect of CO² as an extinguishing agent?

MR. NEWELL: I don't attach any importance at all to the cooling effect of CO². You will note in the Underwriters' Testing Laboratories' list, CO² extinguisher as a cooling effect is not stressed at all. It is the blanketing effect and not the cooling effect. I don't mean to infer that there is no cooling effect, but the cooling effect is slight, and from fire protection standpoint should not be given any serious consideration.

CHAIRMAN MILLER: Are there any other questions on Mr. Newell's paper?

Is there someone here who is prepared to tell us about this matter of organizing to fight plant fires? It seems to me it is a matter of considerable importance to this body, the National Safety Council, who have come here together to get suggestions and interchange ideas about methods that are adopted in various places.

Perhaps you have something in mind.

E. S. CHAPIN (Independence Bureau, Philadelphia, Pa.): I came here to learn,

not to teach, but I am only too glad to tell you anything I can that will be of interest in fighting the plant fire.

In the average plant, probably the first consideration is water supply that is adequate. Make sure to have a water supply that is preferably of a loop type, giving pressure of 35 pounds or over on your static, and discharging the standard nozzle stream from at least four nozzles without appreciable loss of compression.

You may need a sprinkler system in your plant. By all means, have it if you can. There may be some sections of the plant which cannot be sprinkled and you will want to take care of that by a hand apparatus. The type of hand apparatus used will depend upon the type used in your plant. Maybe you want the extinguisher in one section and soda acid in another, and foam in another, and a sand pail in the other. But find what you want and get it. And don't use soda where you should use foam and vice versa.

The organization of a plant-fire brigade is necessary. It will depend upon the number to be served, how many men you have. They should be trained at regular intervals and irregular intervals, responding to alarm and giving the best they have in them when they are being trained, not just simply walking through it, but going as though they meant it every time they turn out, because one of these times they are going to turn out and mean it, and if they want to take things easy they won't get anywhere quick enough.

The First Minutes of a Fire are Vital

The first two or three minutes mean the most. Have an alarm system that will work. The box alarm is better than the telephone alarm. I happen to have been a witness several times when the telephone alarm didn't work. The man got a note from the power house and blew a whistle, and the man who was to blow the whistle was in some other part of the plant and didn't tell him. We waited with watches for two minutes and called again on the phone, and then they got busy. But the first two minutes were a total loss because the human factor didn't function.

It is very necessary to have your night protection adequate. The story was told here of the old man who cut down on the night watchman. We find that often. When you have a few men on duty at night, you should by all means have adequate night watchmen in force, and have those men who are on duty at night thoroughly organized to fight the fire, because as many of us know, a great many of the plant fires take place at night.

The time when your plant is partially shut down also deserves special attention. It may be necessary, due to operating reasons, to have a five-day week, we will say. Make sure that on your off-day, Saturday or Sunday, when you are shut down, you have an adequate fire force.

Make a daily inspection for good housekeeping, if you can. It is most important to see that the little things don't accumulate and get to be big things.

Have your exits kept clear. If your employees complain—their safety is what we are primarily concerned with today—see they have at least two ways out of every working area, particularly those which contain hazardous processes. And then if you can, provide your building from the standpoint of fire spread with fire walls, properly protected by standard fire doors, so in case of fire in one section, the people can escape to another, where it is reasonably safe.

If you do these things, you are doing two things—You can save life, and you can prevent at least part of your property loss.

The point of cutting out exposures has been brought up here today, and I was glad to hear the point brought out. Sometimes you will find that a man has a plant for making acetylene gas or something like that, and he will use that all

through the place. The first thing you know you will find that a wooden shack lies alongside of the acetylene gas plant. That shack may be one that was put up temporarily, and when they built the acetylene plant they didn't pay any attention to the shack that was there.

Go over your plants and see if you have all the bad spots taken out. Separate the buildings so in case you have a fire in one, it will not spread right into another. Have good walkways and pathways so when you need to work on a certain building which is exposed or on fire, you can get around it or confine it to that area.

I could talk probably for another hour on this subject, but I don't want to take your time. If there are any questions I can answer, I will be glad to do so.

CHAIRMAN MILLER: Does anybody have any question to ask? Mr. Chapin I know is well informed from my experience with him.

Would anybody else like to make any suggestions on this matter of organizing for plant fires?

Compensation Paid to the Fire Department

MR. CHAPIN: Mr. Chairman, I have been asked to enlarge upon one phase. That is the compensation paid to the fire department. That is so largely a matter of plant management that we do not ordinarily go into it. But it is usually well-advised to have membership in the fire department properly compensated so the men will realize that you expect something more of them than you do of the others. They should be paid, of course, for drills, and they should be properly clothed for service.

That is another thing. If you ask a man to turn out for fire drill and he gets soaking wet just on a drill, he has to get his clothes changed, and it is a loss of time to him, and so on. If you really have a fire in bad weather, you want that protective clothing—coats, hats, mittens for winter.

The amount of that compensation would depend upon your general plant organization, but I should surely think there ought to be compensation for that service. And don't forget: You want somebody to head it up who knows how to fight fire.

A. W. FISHER (Bird & Son, Inc., East Walpole, Mass.): We have a fire department in our plant, in fact, in all our plants. We have four or five plants. There are 65 members in the fire department, and we have monthly drills. Those men are paid 75 cents a month for the drill. They drill about an hour.

We have rubber coats and hats for the men and try to protect them as well as we possibly can. In the summer time we have outdoor drills. We pull out fire hose and turn on water. In the winter time we have inside drills. In our fire brigade room, we stretch out 250 feet of fire hose and mix it all up so the men will have quite a job coupling it up. It is all uncoupled. We have men try the couplings and see if they are tight and if they are hitched to the dummy hydrant in the fire brigade room, and we must call for water. We take the time to see how long it took them to do it.

The carbon chloride extinguisher is placed here, and the sodium acid extinguisher is placed here and Foamite fire foam. We have a great faith in Foamite fire foam. We use sand pails and all our buildings are equipped with sprinkler systems and fire doors.

I think we carry on fire protection very well.

CHAIRMAN MILLER: We are about ready to see the picture; before we go ahead with the picture, however, I have been asked to call for the report of the Nominating Committee for the election of officers for this section. As the man who was to present this report has to report at another section presently, we will hear that now.

Is Mr. Miner ready to present the report.

Report of the Nominating Committee

H. L. MINER (Dupont Company): **Mr. Banash**, Chairman of the Nominating Committee, came to me last night at the "Smile Party" and said, "If I am unable to present the report tomorrow, will you please present the report of the Nominating Committee?" He isn't present this morning.

The committee unanimously selected:

Mr. A. R. Small, Vice-President of the Underwriters' Laboratories, as Chairman.

Mr. George Elliott, General Secretary of the Philadelphia Chamber of Commerce, as Vice-Chairman:

Mr. Percy Bugbee, Assistant Managing Director of the National Fire Protection Association, as Secretary.

CHAIRMAN MILLER: You have heard the report of the Nominating Committee. I, of course, must ask if there are any other nominations.

Hearing none, I am going to ask somebody to move the adoption by acclamation of these officers for the meeting of the Fire Prevention Section of 1929.

(The motion was regularly made, seconded and carried.)

(At this point **Mr. L. J. M. Timpson**, Pyrene Manufacturing Company, Newark, showed some moving pictures.)

ADJOURNMENT

SEVENTEENTH ANNUAL SAFETY CONGRESS.
NATIONAL SAFETY COUNCIL

Health Service Division

October 2, 1928

WADE WRIGHT, M. D., Chairman
Assistant Medical Director, Metropolitan Life Insurance Company
New York City

The meeting of the Health Service Division at the Seventeenth Annual Safety Congress was called to order at two-fifteen o'clock by the chairman, Dr. Wade Wright, Assistant Medical Director of the Metropolitan Life Insurance Company, New York City.

CHAIRMAN WRIGHT: This meeting of the Health Service Division is really an occasion for huzzas and hallelujahs and congratulations and other similar parts of speech, because it represents in a sense the celebration of the inaugural of a new activity in the National Safety Council—that is, the establishment of an Industrial Health Division.

There is a growing consciousness in the minds of many individuals in the safety movement that perhaps with the introduction of mechanical safeguards, with the development of various methods for rendering toxic substances less dangerous to those who handle them, with our growing knowledge of problems of public safety, the handling of power; and a host of other problems which have been accentuated in industrial service, after all, a great field has been left uncovered; and that safety did not involve alone actual physical damage from external causes to human beings, but that a reasonably high degree of physical fitness involved the consideration of health as well as safety (using the word in a limited sense) and that in consequence industry might very well consider the enormous toll which disease and physical defects are taking, many of them intangible, not admitting of accurate measurement, but perfectly obviously existent to any intelligent observer.

One place and another for years past you have seen figures set forth that for every day lost to industrial employees through accident, there were from five to ten days lost through sickness. It is almost impossible to reckon the total waste due to the curtailment of the period of usefulness in wrecked and unhappy lives.

The new Industrial Health Division of the National Safety Council, of which Dr. Clarence O. Sappington is the director, is going to endeavor to do, perhaps at first in a small way, what the Safety Council has done in a large way in the field of safety. He will tell you of that later. I don't believe I am speculating when I say that, after all, what industry and industrial organizations are concerned with so far as the physical well being of their employees is concerned, is the maintenance of groups of men with a high degree of physical fitness and a high degree of mental alertness, growing in usefulness, growing in opportunity, growing in experience, and continuing long years in the service of their respective organizations.

Neither do I believe that it is speculation to say that such continued service, under the conditions which I mentioned, cannot possibly exist without the main-

tenance of a very fair degree of health. Long continued service, long continued useful service almost inevitably connotes physical competency.

I doubt if there is anyone in the country who could speak with more authority regarding the possibilities and limitations of the statistical methods which may be applied in the measurement of the value of human life than the first speaker on our program, Dr. Louis I. Dublin, Statistician of the Metropolitan Life Insurance Company, New York City. Without further introduction, because he needs very little, I will present Dr. Dublin.

The Economic Value of Life and Health in Industry

By LOUIS I. DUBLIN, Ph. D.

Statistician, Metropolitan Life Insurance Company, New York City

This may be an occasion for hallelujahs for the chairman and the section, but for me this is an occasion for commiseration, for I have been assigned an impossible subject. It would take years to collect information which is absolutely basic to any evaluation, of the economic value of life in industry and it would then take years to analyze it, and we have had but a few weeks. The only thing, therefore, that was left for me to do was to skirmish around a little bit and survey the subject, think out something of the methodology that would be needed to make some progress toward the goal that your chairman had in mind.

I suppose Dr. Wright asked me to discuss this subject because I have been for a good many years now, engaged in studying the economic value of a man in general. You see, connected as I am with an insurance company, that is a very live subject. We try to evaluate a man to his family and have him insure himself for that value as far as his budget will permit. A man, in a sense, belongs to his family. His value resides in his family. His wife and his children are dependents on his earnings. Value here means something, for when a man passes out and leaves no visible means of support, his family is destitute; and there is the source of so many of our troubles and tragedies.

So the insurance company steps in and says to a man, "You are worth so much to your family. You had better provide for them that amount of insurance which will leave them, if not altogether in the same economic condition at least with an adequate measure of support." So with that thought in the background, we set to work to find out what his value to his family is.

Our first effort was in this direction: to find what it costs to raise a human being to the point where he begins to be a valuable citizen. I conceived of a situation something like this: A clock which is wound up and then is set going, releases the energy which has been put into the mechanism. A human being is wound up, fed, clothed, housed, and educated, filled with the tradition of a civilized people, is put in an organized society where he can work, and then he works himself out. But I realized at once that the physical analogy was not a perfect one; that the man produced more than what was put into him, otherwise the world wouldn't move forward.

Our next effort was to consider the subject somewhat differently. We said, the value of the man at any moment of time to his dependents is that amount of money which is the present worth of his net future earnings, assuming a mortality consistent with his class. So to simplify our problem a little further, and realizing that the economic value of the man was a function of his earnings, we considered a series of classes. The first group were those whose income was \$2,500 as a maximum, and at the beginning period of earnings, say age 18, we found the present worth, using three and a half per cent discount, of a man's net future earnings

to be \$29,000. We found, using this method, that a man of thirty in that income class would be worth to his family \$31,000 approximately. At forty he would be worth \$26,000. That means that such amounts of money should be in the bank to draw interest and provide that family, if this man were removed, with the same net income that he would give that family if he lived out his normal existence.

In the same manner we worked out a series of tables giving a man's worth in the \$5,000 and the \$10,000 class. As we increase the income, of course, the values likewise increase.

To make a long story short, we discovered that men have real value; that no one really conceived of the immense assets which are involved in human beings. In the insurance business we had conceived of the problem, had done it in a very modest way, and if these organizations would go out and preach the gospel of men's values they would treble and quadruple their business as they put that idea across. Men do not realize their values to their families, and if they did they would provide more adequately through insurance and other means for the protection of their families when they are gone.

So much for that aspect of the subject.

We also felt that the productive man had value to the community, for what is the community but an aggregate of families?

What is the value of a man to the community? It is obviously not the same thing as it is to his family, and we had no way of evaluating that amount. But, as a rough procedure, we said that if men are worth approximately \$15,000 apiece, that is, the present worth of their future earnings, taking productive adult men, as a class, then, what is the sum total of those values? We also assumed that for active women in the amount was one-half of that for men at the same ages. We found to our astonishment that the sum total of these came to a rough fifteen hundred billions of dollars, which is five times the value of all other goods—real goods, manufactured goods, machinery, agricultural products and everything else that has value. In other words, the productive value of man is equal to five times that of other valuable things.

The Individual's Value to Industry

When the question is put, what is the man's value to industry, what shall we say? Man is obviously of value to industry, for industry would be impossible without him. But what shall the procedure be by which we can evaluate a man to his industry? In the case of a man and his family we have a direct connection. There is an inseparable bond with the family. Obviously, a man is worth so much to his family as is indicated by his earnings. The earnings belong to them. But how about industry? What corresponds to the wife and the children? Obviously, the individual employer. What is the value of the worker to his individual employer? You are at once struck with the fact that that relationship which existed between a man and his family does not here exist. A man is a free agent. He may take himself out of this particular employment and go somewhere else, and he does. Yet there is value, nevertheless, and that is recognized because, as I said, without that man business could not go on, nor would there be profits.

Now, as a man in a measure is responsible for the profits of his concern, there must be some way of determining what that value is.

My suggestion is this: In order to obtain a figure which would have any value, it would be necessary to find what the productivity of the individual is to his industry. We don't know that. There are no figures indicating what a man's productive power to an industry is, what profits industry gets out of a man in his particular field per annum, and until we have such figures it would be impossible

to proceed. But taking the productive world as a whole, we can perhaps make an approach.

If you examine the figures of national wealth, you will find that we have been increasing the national wealth, at the rate of about \$100 per annum per capita. That has been true for the past two decades. If we realize that one-third of the population is in the productive ages, (in our total of one hundred and twenty millions there are some forty million workers) and that would mean that the average productive individual is producing some three hundred dollars additional wealth per annum; It might be possible to integrate those figures and obtain a fractional value for the productive individual at the present time. That hasn't been done. It would be an interesting thing to develop this thought and see where it leads us.

There are other side issues which throw some light on this question of the value of a man to industry. We know that it costs a good deal of money to make a man effective in industry. It takes the employer's time and attention in the industry to train a man up to make him worth something to his industry. When that man breaks down or leaves the industry he has to be replaced. The replacement value of the man can also be readily determined; in some industries it has been determined.

For example, in my own field of work in the insurance business, where there is a good deal of labor turnover, it has been found that it costs all of \$500 to replace a man in the field. That is, if one of our agents should for one reason or another leave our employ, it costs at least \$500 to find a man and train him to do the job equally well. My own suspicion is that the amount named is very conservative, and that the true figure is much higher. In other industries it may be higher or lower. You can see very well that this would depend upon the kind of industry. Where the process is simplified and where it takes little time to teach a man to run the machine, the replacement value is less; where you are concerned with specialists and it takes years to train them, the replacement value is large; and in business where they are concerned with high-grade executives or high-grade managers, they realize that value and do exactly what the wife or family does: protect themselves against that loss by taking out business insurance which accrues to the organization in the event of the removal of that man.

I am putting on the table a lot of considerations, a lot of lights on this subject. I have no solution. It would be an impossible thing for any one man to solve this problem, to give you a figure. It is not like turning a crank and getting an answer. That is not the situation at the present time. What is called for is the accumulated wisdom and skill of a large group of men, sitting around the table months and years, to think out the elements that go into this picture and develop a methodology which ultimately will give the value of a man to industry.

Now, may I say a word in the way of conclusion? I am mighty glad that this question of the valuation of a man has come up because heretofore industry has not given much thought to the value of the human element. We have been talking a good deal about the value of the goods produced and the value of the capital that has gone into the industry, but until now there has been very little said about the human values concerned. It is a very encouraging sign that industry has waked up to the fact that it is dealing with human beings who are the largest factor in the whole field of industry. Just as a man is worth five times all other goods, I believe that conception will give a multiple which will represent the value of man in industry.

That leads me to say this: Whatever be the value that can be ascribed or tied to a man in this or that or the other industry, that ought not to be a measure of the responsibility for that man. It is conceived that industry must remain solvent; that industry cannot be sentimental in its relationships, but must recognize its obligations to the individuals who make up the workers in its field.

This conviction is growing apace. Industry is conceiving of its workers as combined with it in a partnership for the service of the community. It is a combination of capital, of supervision, and man serving the needs of the community, and therefore a paramount issue is the protection of that man.

No consideration can put that out of the picture. So, quite apart from the value, in dollars and cents, of man to the industry, the first obligation of industry is to see that the man stays fit just as long as he stays in that industry, and I believe this sentiment is growing and developing in the hearts and minds of those who are responsible for industry. It is certainly very strongly developing in those who are working in industry. They demand protection, they demand safeguards, because they recognize their own value.

Possibly at future meetings some one will be able to present to you the figures that Dr. Wright had in mind. I, of course, can't do that, but it is to my mind a stimulating discussion and I hope that there will be comment from the floor as to the general plan that I have suggested, as to a method of proceeding which will ultimately give us the answer to this question.

CHAIRMAN WRIGHT: Is there any comment from the floor at this time? Does anyone feel the bursting urge to speak? I would be very glad if we might have some discussion now, or, if you wish, we will defer it until the end of the series of papers. Apparently no one is moved.

It doesn't make much difference what you want to know about, when you want to get to real facts, whether it be about living conditions in the Gobi desert in Mongolia, or the potentialities of a Forty-fifth Street speakeasy, you always want to talk to a man who has been there, a man who knows by actual personal experience of the things of which he speaks. I feel quite certain that there is no one in the country who can discuss as intelligently and with as much real personal knowledge the part which a sound, well balanced medical program may play in the maintenance of a physically competent working force than Mr. Howell Cheney, of Cheney Brothers. Mr. Cheney!

Continuity of Service

By **HOWELL CHENEY**

Industrial Relations Division, Cheney Brothers, South Manchester, Conn.

I find myself under somewhat of a double embarrassment today because I had been invited to speak on the Continuity of Employment and had most strenuously urged that I hadn't any solution to offer that would bring about that one hundred per cent of continuity of employment that we were looking for; but nevertheless I would attempt to try to sketch out some paths of approach toward that problem. So I started this morning with the thought in my mind that you were interested in paths of approach, determining the continuity of employment, and I am rather fearful that Dr. Wright has a different theory in mind.

In preparing myself this morning I happened to open the morning paper and I found a report of a conversation, or an address, by Dr. Dublin. "Aha!" I said, "there I am. It is all sketched out for me." So I took my notes accordingly, and the first speaker introduced was Dr. Dublin. Now, what is a man to do when he finds that his material belongs to the real author and is not devoted to the subject to which he had applied himself in preparation?

However, I am going to stick to the subject that was given me.

What do you mean by continuity of employment? Well, I have been impressed that the idea most predominately in mind in thinking of the continuity of employment is the ability to keep a man on a particular job, and employment managers

and industrial leaders have been led rather far afield from their true values which Dr. Dublin has attempted to sketch by centering their attention on their success in trying to keep a man on a job. The true values in continuity of employment relate to your ability to continuously get the utmost productivity out of a man of which he is capable. Dr. Dublin suggested those to your mind.

I would say, with us, that today a man is producing from \$1,600 to \$1,700 worth of goods annually, where before the war he was only producing \$800 to \$900 worth of goods; and that increase isn't entirely in the increased purchasing value of the dollar, but represents a real material increase in production of about 1.8 times the pre-war production. That is, one man can do today what 1.8 or 1.9 men did before the war; and consequently his increased productivity has a very great value which every manufacturer is conscious of, which he doesn't need to have pointed out to him, and which he really isn't evaluating in so many thousands of dollars per man.

This thought, however, is entirely and consciously on the minds of the managers of all industrial establishments, that whether that productivity per man be in thousands of dollars or in tens of thousands of dollars, it varies all the way from zero to double the average. So that, if the productivity per man in the silk industry be an average of \$1,700 per year, that productivity varies from zero up to \$3,000 per year, and your interest in the man and your expectation of a profit vary in like proportion.

So we are all coming, and I think far more consciously coming, to get away from the point of the reduction of turnover which tells us what our turnover has been in the ratio of exits to entrances or exits to an average working force, to something that is rather more intangible but has far more to do with the profits in our pocketbook. What have we done to maintain a man at his maximum working productivity, not for this year and not for that year, but for the working years of his life?

So continuity of employment means the maintenance over a long period of time of a maximum productivity. There is the definition, there is the problem. Now, what are the paths of approach to that problem (because I only have paths of approach to it, and I wouldn't for a moment be so rash as to suggest that they are cures)?

In the first place, the productivity of a man is directly determined by your success in placement. Has he been placed in proportion to his aptitudes and capacities as you may reasonably ascertain them?

Now, you have research laboratories which determine all the physical characteristics of your raw silk, of all the chemicals with which you dye that silk. You go into exhaustive analysis of your soap and of all the other chemicals that are combined with soap to produce your dyeing liquors. It has, however, remained for a later generation to conceive that the human element which was more than half of the total cost of production was capable of somewhat similar and scientific analysis of its aptitudes and capacities; and there your medical department comes in, not necessarily as an exclusion force, but as a scientific bureau for the analysis of the man power and the woman power that you are going to make your major item of cost. And in proportion as that medical department, coupled with an intelligent bureau of employment, analyzes not the general trends but the individual as he presents himself at your employment window, have you made a start, even a beginning, at maintaining the continuity at its highest point of productivity, of your labor force. You cannot commence to do that without thorough appraisal, with all of the resources that modern science brings to your aid, of the physical capacities of the individual whom you are considering at the time being.

The technique, the methodology of the doing of that have developed a peak. There has developed with it—and I perhaps see it far more effectively than you do

for I live in a one-industry town—an educational force acting upon the whole community. Before, their physical condition meant little. It was immaterial, apparently, to us whether they possessed certain physical capacities, certain probabilities of endurance and continuity in employment. Now the thought is very definitely brought home to every employee that his physical condition is of the first importance, and he comes to appreciate, and the community comes to appreciate, that good health isn't an accident; it is an asset, and if we put it into dollars and cents it is a purchasable asset which may be theirs by scientific study, endurance and patience. In other words, the community has become sold to the idea that physical well being is directly related to its productivity in life, and that physical well being is something that they may seek, not by accident but by a scientific method.

We have reduced to a routine the urine, the blood tests, and X-rays. That, again, has reacted upon the local medical profession which, in a country town, weren't equipped to give those services with the expert laboratory service that went with it, and medical practice today means a decidedly different thing in a country town than it meant ten years ago, because not the practitioner but the practiced-upon has had demonstrated to him that it is a matter of scientific determination and not entirely of guess work.

So much for placement. I want to indicate a further approach to that later.

Continuity of employment next depends upon your keeping the path of promotion open. It is sad and it is true that many industries today don't present very much of an ascending scale of promotion. I find that many industrial employers with whom I talk haven't become conscious of a promotion problem. They have thought of jobs as a job to which an employee was assigned. They lost sight of him after that assignment. The only contact they had was a certain indefinite turnover report that indicated that they had lost a man. But the question as to whether that ascending scale of productivity was going with them or against them apparently hadn't seriously entered their consciousness.

Now, it goes without saying that a man's productivity is not only in proportion to his physical vigor, which your medical department may have correctly assessed when they took him in; but it is in proportion to his interest in that plant and his accumulated knowledge as to the possibilities and resources that that plant offers for his own application of labor. Unless you have a fairly ascending scale of promotion you are going to lose your virile, strong, productive, alert minds and finally the workers. They are going to get away from you. They do in our own plant and they do everywhere, and this is an example of it.

I had in one department a man of the old type, an autocrat, brought up in an English factory on a German training. He believed that because things had been so they were so and they never could cease to be so, and that a man who once was a carder was a carder and there wasn't any use discussing that point, he was going to remain a carder. If you sent him a type of man who insisted on being something else besides a carder, why, he lost his interest in him. The thing went on for several years, and it was becoming more and more apparent that that department was going backward in the productivity of its labor and in its general rate of progress and morale.

He came to me finally and said, "Look here, Mr. Cheney. My men are no good. They don't have any interest. They haven't any pep. They don't feel the way I find the employees in all of the other departments feel. Now, what is the matter?"

Why, the matter was nothing but the simple principle that there was no outlook ahead in that department. There was no energy to be capitalized upon in proportion to its increase of productivity. He valued men simply for what they could do today, and his department inevitably became the place for dull, stupid, nerveless men who were satisfied without any future outlook, until finally the superintendent himself became conscious of that fact.

So to keep the men up to their maximum productivity you have to keep the path of promotion open. You have to let the men know that there is a path of promotion. Chart it for them. Show them the different steps. Let them make their applications for promotion. You have disappointments, you have your troubles. You stir up a feeling in your factory that there is a legitimate promotion for every individual, and you come back to the old stern hard truth that no man can earn a promotion unless he has made good on his past position. So it isn't altogether an easy path. It does increase that trouble a little, particularly in the individual department. But while the turnover in our individual departments may have been increasing, the turnover in Cheney Brothers as a whole since the war period has gone down from 50 per cent to 22 per cent, which is a pretty sure indication that the average man is satisfied and the average man is finding his way out in life.

But again, you are not going to keep the path of promotion open, you are not going to capitalize upon the increased ability that the experience in your plant accumulates to the individual, unless you can keep them in their best possible physical condition; and there again comes in the ideal of the medical department. Every employee may come in as long as he is able to remain at work and our legitimate interest in his physical well being is in keeping him at work as long as we possibly can.

I wish it were possible and I wish I could say that our employees were sold on the practice of periodical physical examinations. They are not. It is only the higher type of salaried man whose income has reached very material proportions who becomes convinced of the value of a periodical medical examination. Nevertheless, when we are giving 25,000 to 38,000 medical treatments a year, we come pretty nearly to seeing at least a half and probably two-thirds of our employees once a year and of getting some check-up upon their physical condition; and also of eternally hammering home to them that good health is a physical asset, is an attainable asset, and has a direct relationship to their plans of personal hygiene.

So the medical department has very definitely as its aim, not something sentimental, not something only relating to the abnormal cases. I wish I could get that out of your mind. The abnormal case is pretty nearly every case. The abnormal case is represented simply by the individual's reaction toward his personal problem; and looked upon that way, the abnormal problem becomes the universal problem. Your medical department becomes, not the agency for taking care of a few exceptional cases but an agency inspired to believe it has no less a problem than maintaining the physical effectiveness of your whole working force.

Now, the next line of approach to that problem reaches what you have come to consider more technically as the continuity of employment. What are you going to do with that employee when he reaches the declining period, when old age begins to have the slowing up effect upon him? There come in some of your most difficult problems in affecting the continuity of employment. There isn't any single cure for it. Periodical examinations certainly help, certainly prevent the degenerative diseases, and an intelligent, thorough, and never-failing follow-up of community health conditions helps to control contagious and communicable diseases which so effect later degeneracy.

We are fortunate to live in a country community which is more or less of a unit. We are fortunate to have the cooperation of that community in the improving of the public health conditions, not only those that relate to sanitation but those that relate to personal hygiene. As an illustration of that, the public health department and the Yale Department of Health came to us with a desire that they might make a study of the incidence of respiratory disease. We approached that problem with a good deal of hesitancy. We said that to bring in a public health nurse from Washington and to turn her loose in our factory would create

all sorts of disturbances and the employees would say, "Oh, that is another one of those silly ideas and here is some faddish woman who has come to ask us whether we sleep with our windows open and have the proper diet and whether we bathe, and to ask all sorts of questions that have no relation to her business or the company's business."

We were very doubtful and took a year to think it over, but we finally came to it. We took a woman in, not as a public health nurse but we introduced her as one of our own nurses, because they were used to our own nurses and were used to having them call at their houses. Over a year's period she quietly studied every case of respiratory disease, and through that cooperation the public health service think they have found—they perhaps have yet to convince us—but they think they have found that respiratory disease is rather directly related to the temperature of the rooms in which the employees work. The incidence of respiratory diseases was very much higher in rooms that ran over 68 than it was in rooms of 66 to 68.

We presented that report to our employees. There was a good deal of kicking, a good deal of insistence that rooms were too cold, and it wasn't an easy matter altogether to put it over. But it is now accepted as just one of the everyday mill problems with a convincing demonstration that if you keep a room at a reasonable temperature the incidence of respiratory disease is very much lower than it is if you keep the temperatures from 72 to 76. The problem of keeping the room at the proper temperature is eternally there with you, but the public has seen that it doesn't have a fanciful sentimental relationship to their occupation but that it means dollars and cents in their pockets, and the employer has a selfish and high-minded consideration in attacking that problem for their benefit.

So there again your medical department has got to be eternally on the job. If it could promote the periodical physical examination, if it could check up on employees, it undoubtedly would be able to reduce the incidence of degenerative diseases that commence toward the end of working life, at about fifty, sixty, or seventy years of age.

We used to think that the pension problem was a solution of the difficulty and that pensions answered the problem of the continuity of employment because it acted as a bait all the way on from the early working life up to the close of a man's working period, and that the prospect of a pension held him there.

I think I can say quite confidently that up to forty-five years of age a pension has no pulling force on continuity of employment, and that after forty-five the curve of interest may increase quite rapidly. But the pension award does not increase the individual's productivity. It gets rid of a sore, it finds a method of disposal; but is it a reasonable and proper method?

You retire a man at the age of sixty-five to seventy, at from one-third to one half of his average income, and he may have accumulated enough with that assistance to carry himself with some restrictions to the time of his death. But you have terminated his interest in life. You haven't capitalized on the accumulation of knowledge and experience and loyalty and devotion that a longer period of happy employment ought to have made yours.

We have been experimenting with another expedient which we call the partial pension system. The partial pension system attempts to make that difficult problem of adjustment somewhat easier when you have to change the job of the old man, because it reduces his income and instead of giving him a full pension you give him a partial pension which reimburses him for perhaps one-half or one-third of his loss of earning capacity. That is a very direct economic gain to the company and a very direct economic gain to the man. Every pension you award means an award of from \$7,000 to \$8,000. A partial pension only means half of that, and if the man can be kept continuously at some employment which represents the

maximum of his productivity, he is far happier, you have retained the productivity of that man in the field of its greatest possible application, and you have prevented an economic loss both to the company and to the man.

I think sometimes we get a wrong perspective on the pension problem, and during the last summer it seemed to come home to me more and more that men looked upon pensions as a decent burial, and the reward of pensions was very often coupled with tears and sobs and heart-rending scenes that brought it home to you that it represented to the man the end of his working life. Is that the legitimate or the necessary or the reasonable end of a working life to that man who still has productive energy?

Specialized processes, bonuses, premiums, piece rates, all put the older man at a disadvantage. He can't stand the speed. But there again your medical department who has been his confidential adviser can present the problem to him, can keep his faith in his legitimate energy, can make him feel that he has productive capacities that may be prolonged perhaps indefinitely, and by a slight assistance, which means far less in cost than a pension, you have been able in a few cases to make an adjustment that is decidedly in a man's interests.

I don't mean that partial pensions are going to be the solution of the difficulty. I don't mean that pensions are by any means a solution of the difficulty because they have got rid of a sore spot in a factory. I don't mean that periodical examinations are going to entirely and by themselves maintain a man at his highest productive capacity. I don't mean that the constant and solicitous care and the freedom with which a man visits the medical department are going to always keep a rational program of personal hygiene before it. I don't mean that the most skilled Placement Bureau with all the knowledge of psychology and personal aptitudes and mental tests that they employ are all going to bring a man to his job with his maximum capacities. I only mean that these are paths of approach, the tools, if you will, with which you may work, and they are successful tools only to the extent that you keep them constantly sharp and alive and fed up with new intentions, new spiritual meanings, new endeavors of higher accomplishments.

They do, however, all have this common path of approach: They must be used so that they bring a higher measure of economic return to the industry. Mind you, I would never for a moment affirm that I would be able to figure in dollars and in cents the exact return that a medical department to Cheney Brothers, any more than I could figure how much a pension system contributed to our morale or lack of morale.

I only mean this: Unless you can reasonably argue them out from the point of view that they do maintain an increased productivity, that they are not charitable expedients, you haven't a sound basis of approach to that problem. You may think if you put it on a charitable basis that you have a truer method of approach to the individual. You haven't. You have a false basis of approach to the individual. Unless you can ultimately make the individual see that any policy has a relation to the wages which he is going to earn you haven't a sound method of approach to that problem.

So every fact bearing on continuity of employment must be related to the economic return it makes to the industry and the individual. Every path of approach, you will find, rests upon sound educational principles. That education may be of a public nature, it may be of an individual nature; but it proceeds from an educational problem, and it has to be presented as an educational problem or it doesn't get over.

Finally, it means organizing all of the resources that you find existing in your own work and making the most of them. Don't feel that you are necessarily going to the nearest university. You will find Professor Winslow ready to help you, but you have resources existing in your own organization that are entirely

neglected. Organize those resources. Make the employees see their relationship. Make it a part of their intimate and daily life, and bring science to your daily routine of life, and you will have an effective organization of the things that already exist in your plant.

So the continuity of employment maintained at its highest productive point depends upon the economic return to the industry and to the individual, and your ability as an educator in leading the employee to appraise it at its true value depends on the scientific resource that exists today in your own control.

CHAIRMAN WRIGHT: Dr. Slater, our third speaker is not present and I have not heard from him. I am very sorry that we will have to omit his presentation of "The Organization and Conduct of a Plant Medical Department," at this time, but his paper will appear as a part of the published transactions of this session.

I think this would be a fit time for the general discussion of Dr. Dublin's and Mr. Cheney's papers. Is there any comment? Are there any questions which any of you would care to ask Mr. Cheney? Dr. Dublin has fled, as he was scheduled for another meeting.

Where is Dr. Thompson? He is vice-chairman of this section and I would be very glad if he would comment upon this general topic.

DR. L. R. THOMPSON (Surgeon in Charge, U. S. Public Health Service, Washington, D. C.): Dr. Wright, I really haven't anything to discuss, but I would like to compliment the people on the program that has been given. It brings to industry the specific problem of health. I think if we keep that always before us, and that the safety engineer has an individual problem, we have made a great step in connecting safety methods with health.

CHAIRMAN WRIGHT: Dr. Geier?

DR. OTTO GEIER (Cincinnati Milling Machine Co., Cincinnati): I can only add my word of commendation. No one can properly appraise such papers as Dr. Dublin's and Mr. Cheney's. I know the problems of industry would become relatively small if all employers had the point of view that Mr. Cheney has so splendidly presented here today. The thing that seemed to me most significant about his discussion, while he didn't call it that, when he spoke chiefly of the physical well being of the individuals under his employment, was to think at the end he was mostly striking at the mental health of his individuals. I think that keeping alive the interest of his workmen, keeping alive their interest in each other and hope in their success in the future as bound up with the company, is perhaps the most striking note in his paper. I think it is one factor that has been overlooked too much in industry even where the medical department has been quite efficient.

I, personally, am very grateful to Mr. Cheney for this paper.

CHAIRMAN WRIGHT: Dr. Watson?

DR. C. H. WATSON (Medical Director, American Telephone and Telegraph Co., New York City): I can only reiterate what Dr. Geier has just said. I have heard Mr. Howell Cheney a number of times and never in better form than today.

One of the most striking things which he mentioned, of course, was the employee past middle age going on the downward side of the hill, having his life plans interrupted by being offered a pension. It has seemed to me that there is nothing more sad than an employee forced to accept that for a lifetime endeavor. While Mr. Cheney doesn't offer the entire solution to the problem, it seems to me the partial pension is in part the suggestion, at least a very favorable gesture upon some line of procedure which will help the employer's effort in helping the man on the downward side of the hill who needs to have the situation solved for him.

May I, also, thank Mr. Cheney for his very delightful and interesting paper.

CHAIRMAN WRIGHT: Are there any questions or comments? Dr. Winslow, would you care to comment?

DR. C.-E. A. WINSLOW (Yale University): I have nothing to add, Mr. Chairman, except to say how deeply gratified I am at the way in which this new health division has been launched. I think the major problem before the health division probably is to increase the realization on the part of the council of the fact that medical service in industry is something more than what our chairman at luncheon described as "finger wrapping." This really very beautiful and finished and stirring address of Mr. Cheney's to which we have listened gives us simply an ideal form of a text or a program to show just what the health service in the factory may really mean.

The Organization and Conduct of a Plant Medical Department

By DR. B. J. SLATER
Eastman Kodak Company, Rochester, N. Y.

The Annual Congress of the National Safety Council is an inspiring sight to a physician. An assembly of such a distinguished group of men and women all interested in the prevention of accidents and disease cannot possibly do any harm and may be productive of great good. Physicians' work generally begins where safety men's work stops. The more efficiently *you* work the less work there is for *us* to do. In spite of this our sympathies are with you and all of your efforts. Those of us who are constantly visiting the great hospitals are appalled at the reckless loss of life which is visiting every community. To each and to all of you we wish every encouragement in the prevention of some of the terrible things which we see in our hospitals.

In the summer of 1924 there was gathered in the West Indies a notable collection of scientific men. They came from India, London, South America, Rochester, Minnesota, Boston, New York and various other representative medical centers as guests of a great industrial organization, namely, the United Fruit Company. Their program was the discussion of the prevention of disease in the areas that are affected industrially by the United Fruit Company. Here we have industrial medicine at its best. We understand that the budget for the hospitals and medical care of this company is about one million dollars a year.

On this occasion there were represented the world's greatest medical authorities in their representative fields. Such high standards are inspiring and show us what may be accomplished by industry when the proper facilities and interest are involved. In addition to an outlay of about one million dollars to the company hospitals and medical department, two or three hundred thousand dollars are spent on sanitation, to make the working conditions of the employee better and to stamp out certain diseases which are endemic to the territory from which the products of the United Fruit Company come.

Most of us engaged in industrial medicine are not part of such an ambitious program, and yet to all of us are given many wonderful opportunities to practice medicine under somewhat ideal conditions. There is no other specialty of medicine which offers such wonderful opportunities for follow-up as industrial medicine. As long as the employee stays in the organization, his physical condition may be followed, of course, always with his permission. Herein the opportunities are, of course, larger than to those engaged in private practice because, it is not so easy nor convenient to have patients come to the office. Inasmuch as there are usually no fees charged for such services, no one may criticize the attitude of the industrial physician for his interest in his patients. One of the first problems should be then the installation of an adequate follow-up system.

In the organization and conduct of a Plant Medical Department three things are most necessary. They are probably as necessary in any other organization as they are in a Plant Medical Department. First of all is the personnel. In the organization of a Medical Department the work of the department is always limited by the intelligence which is guiding it. If I were organizing a department from the very beginning, my selection would be a young man from a Grade A medical school who had shown qualities of leadership in his class and broad general intelligence. He would be advised what the general policy of the company was and asked to organize his department accordingly.

For the last four or five years the advent of the younger man in medical circles has been very noticeable. For instance, St. Louis University with a great medical endowment, has chosen as head of its medical department a man not over thirty-five years of age. Similarly, the University of Rochester with a great medical endowment, equaling that of St. Louis, has chosen as its professor of medicine a recent graduate not over thirty-six years of age.

In the realm of research, younger men are gradually coming to the front. Dr. Berghau, the discoverer of the erysipelas serum, is a relatively young man. Dean George H. Whipple, the physician who by his research work has made possible the giant strides in pernicious anemia, is a relatively young man. Dr. Banting of Toronto, the discoverer of Insulin is also a very young man. My choice of the younger man at the head of the department would be made for the same reason that these universities have made their choice, namely, that it would bring youth, energy, physical stamina and intelligence to a problem. With such qualities results frequently are obtained.

Previous practice has been to select some man who had more or less of a reputation in private practice. By and large the problems of private practice are not those of industrial medicine. Training required in each field is often quite different and habits once formed are, of course, difficult to break. In my opinion every industry large enough should have one physician who devotes his entire time to the company. The whole time physician devotes his whole interest, life and ambition to the work at hand exactly in the same manner that anyone devoted to any other line of work does. The part time physician has a divided interest and while he often brings to the department a much needed point of view, the irregularity of his hours and the separation of his interest, make it desirable that there should be someone constantly on the job to see that the interests of the department are constantly looked after.

As regards the conduct of the personnel of the department, it should be run on the basis of a kindly sympathy for those who need its services. It should be eternally on the job and as pointed out in the beginning should have an adequate follow-up system in operation. The physician or nurse who is constantly on the job even though he or she may not be the most brilliant of his or her profession, is of greater usefulness to an industry than someone more brilliant in his or her particular line who lacks the interest to be constantly and forever on the job. A medical department should be free from arguments of every kind and description. Whenever there is an argument in our department, the burden of proof is to prove that the patient is not right. Our motto should be sympathy, kindness and understanding and we should to the very limit of our ability not indulge in anything not catering to these principles.

As an illustration of what vigilance may accomplish, I might cite the fact that we have not amputated a finger because of infection, in all of our plants in ten years. This record has been accomplished only through the maintenance of an adequate follow-up system. Whenever an employee is injured there is a card bearing his name hung on the wall in the medical department. It is the duty of the nurse to call up his department the following day to find out if the employee is working and if so to see that the employee is sent to the medical department.

This follow-up will save many fingers during the year and, perhaps, some lives. If the employee is not working, it then becomes the duty of the physician in charge to find out why he is not working by a visit to his home. The results in a lessened incidence of infections speak for themselves. Our methods are no better than anyone else's. Our ability, however, to closely follow the cases which are under our care is, perhaps worthy of some attention. After all the difference between a person who is a specialist and one who is not, is only a matter of attention to detail.

In the matter of syphilis in one branch of our medical service, we have run down over three hundred cases. Twenty-five years ago we doubt if any industry had recorded that number of cases of syphilis. It is, however, coming to be a common thing to make the search for this disease a routine procedure. The results are very striking. By constantly being on the job to discover disease one is surprised at the number of cases which will be uncovered. This does not mean that our incidence of this malady is larger than that of other companies. As a matter of fact we are inclined to think it is probably less. It does mean, however, that cases in our employment are under medical supervision and medical care. We have seen to it that all of these persons have received adequate treatment at a very reasonable charge. Since the inauguration of this intensive study no injuries have been complicated by syphilis. In other words, periods of disability have not been prolonged because of a blood disorder. This represents an advance and illustrates the good results which follows such a procedure.

A medical department should be organized with sufficient equipment to make a thorough study of any case requiring treatment. It should have a small laboratory where blood counts can be done; an X-ray laboratory where X-rays of teeth and chests may be readily available. In this connection we feel that a proper X-ray equipment is one of the greatest aids which a plant medical department may have. The services of this department should be constantly available at very short notice in order that a proper diagnosis may be made. The question of the immediate availability of the X-ray is a very important point. It does not take very long to make a chest roentgen-ogram. It takes a comparatively long time to make a good examination of the chest by means of the stethoscope. If the X-ray is difficult to get and there is an unnecessary delay in getting it, the tendency may be to postpone the X-ray which should be taken.

As a general rule it should be the policy of the medical department to examine all people who have been absent for a period of over three weeks. In our company we examine by X-ray people who have been absent because of asthma, pneumonia, pleurisy, bronchitis, certain types of abscesses, nervous breakdown and chronic indigestion. We have routine chest X-rays made of their lungs when they return to work. The results of these X-rays are frequently very illuminating. When employees applying for work give a history of having had any of these diseases, the chest X-ray is taken at once. We have the same routine for those who are 20 per cent underweight.

At a previous meeting of the National Safety Congress one of the speakers asked what a medical department might do to lessen the complications of apparently minor injuries. The answer lies in my opinion in the results we have had in our X-ray work. If people with tuberculosis are permitted to work, the slightest injury may produce very serious complications. It should be the function of the medical department to catch these cases as quickly as possible to prevent the possibility of an injury. If the medical department by its preliminary physical examination is able to detect a large percentage of diabetes, syphilis, tuberculosis and heart disease, then some of the major causes of complications relative to accidents will have been eliminated, if such employees are properly placed in industry. The medical department should be so equipped in its personnel and its physical layout to do exactly this.

You may take it as a certainty that no one connected with an industrial organization asks sick people to work. It has been our experience that those who are not making good at their job, who are hard people to handle and who offer difficult problems from the industrial relations point of view, are frequently either mentally or physically sick. This is a rule which usually is infallible. We have proved time and time again that many employees who are thought to be ill-tempered were in reality sick and evidence of irritability which came from sickness, disappeared when health was restored. On many occasions, knowledge of this character will help to settle many difficult industrial problems.

Finally it is taken for granted that the industry should be able through its medical department to diagnose such diseases as may be thought to originate within the company itself. A physician is familiar with plant processes or should be and his department should be able to answer for the company how far its processes have contributed to a disease in an employee. The employee has a right to know and so has the industry. Familiarity with plant processes should place the physician in industry in a better position to make such diagnoses than the general practitioner who cannot possibly be familiar with such industrial processes.

A newer phase of industrial medical practice is gaining ground. This is the medical examination of food handlers. It is our policy to examine all food handlers to see if they are carriers of diphtheria, syphilis, tuberculosis or typhoid fever. Under no conditions may any employee suffering from any of these diseases touch or handle food. It may interest you to know that in an examination of two hundred and fifty food handlers we found two who were typhoid carriers. These employees had had typhoid many years ago and were still eliminating the germs of typhoid. It does not require much imagination to see how easily such an employee might spread an epidemic of typhoid among other employees. Companies should so far as they are able insist that those employees who handle food should be free from disease which may be disseminated by contact.

This question may be asked: "How far may we carry our medical work in industry?" To my mind there is no satisfactory answer to this question. A broad, humanitarian policy on the part of industry is necessary. The compensation laws have brought industrial medicine here and undoubtedly it is going to stay. The needs of some industries are quite different from other industries as some may have particular hazards not common to others.

Medical departments in addition to the aid which they may give individuals in the plant, by physical examination, by periodic check-ups, by health surveys, by routine examination of various departments for hazards, have other duties to perform. They should in the highest sense possible promote cooperation with other departments, particularly the safety department. All accidents coming to the knowledge of the department, whether large or small, and which bear any relation to safety methods, should be reported to the safety department. Sometimes small accidents point the way to larger accidents just as minor symptoms frequently point to major symptoms which are to follow in disease.

As a question of medical ethics the medical department should carefully avoid anything which is not purely of medical interest. My own feeling is that too many duties which are non-medical should not be thrust upon a medical department. It is not to my mind good practice to hire men of good medical training to do other than medical work unless such individuals deliberately choose to separate themselves from medical interests. While a medical department should not interest itself too much except for cooperation with other departments it should be supreme in its own line and in the management and treatment of patients as well as be the final authority as to what kind of treatment they should receive.

If a physician is successful in industry he will necessarily have a great many friends. The help which he gives to many people cannot but bring him the closest

types of friendship. Many times people may because of this friendship try to get the physician to interest himself in problems which are not purely medical. To the limit of his ability the physician should be on his guard against this kind of thing no matter what the purpose or what the character might be. While in individual cases he may succeed, in the long run such conduct will bring discredit upon him and his department. In a broad general way the best interests are served by each giving meticulous attention to his own work not forgetting to carry out such cooperation as is required between various departments.

CHAIRMAN WRIGHT: As I remarked at the opening of our session, a new bud is enfolding. There is a little bird twittering in the nest, a new ship sliding down the ways. I think it would be very interesting to hear from the new skipper of the ship, Dr. Sappington, who is the director of the new health division. Dr. Sappington!

DR. C. O. SAPPINGTON (Director, Industrial Health Division, National Safety Council): For a number of years, as you probably know, the council has had a Health Service Section. The establishment of an Industrial Division is the crystallization of all of the thought that has proceeded through this Health Service Section from time to time.

I want to go over, in just a very sketchy way, some of the things which we might be able to do in this new division. Of course these are all very tentative and they are open to criticism and suggestion.

One of the first things we thought we might do was to devise and perhaps put out a series of plans for plants of different sizes. This would include equipment, layout in general, personnel, duties, costs, and so forth.

There has been a great deal of speculation and a great deal of theory about the results of medical service in industry. We thought also we might collect some material on that subject, and see just what those results have been.

Again, it was suggested that we might also do work in cooperation with the various health hazard committees—which are formed from time to time.

We should probably have a finger in the formation of the programs of the Health Service Division each year, and also, in the field of education, write articles, pamphlets, and give talks; probably not the least of value, we should carry on correspondence which would endeavor to answer queries of various types coming from plants engaged in diverse manufacturing processes throughout the country.

This, in the main, I think, represents our present idea on the matter. This is a large undertaking. We expect to give a great deal, but we are going to need a great deal of help.

-ADJOURNMENT

SEVENTEENTH ANNUAL SAFETY CONGRESS
NATIONAL SAFETY COUNCIL

Public Speaking Class

October 2 to 5, 1928

C. D. HARDY, Lecturer
Professor, School of Speech, Northwestern University, Evanston, Ill.

The first session of the Public Speaking Class at the Seventeenth Annual Safety Congress was called to order at eight-thirty o'clock by the chairman, Ernest W. Corn, Field Representative of the National Safety Council.

CHAIRMAN CORN: A year ago last summer, in our Institute for Managers at Whitehall, Michigan, we secured the services of Professor C. D. Hardy of Northwestern University to deliver a short series of lectures on the practical problems of public speaking. He was so popular with the Council managers that it was suggested he attend the convention at Chicago last year. Many of you heard him there. To you, the Professor needs no introduction.

I shall not encroach on his time except to say, that I know of no field of leadership, by the very nature of which some ability in public speaking is more needed, than in that of accident prevention. We are the only great national organization that still is able to maintain a mass meeting program, in the first place; and in the second place, there are committees and groups to talk to practically all of the time, especially in industrial accident prevention.

Professor Hardy is not going to give you a four-year course in public speaking in four brief lectures. He will endeavor to crowd together for you some outstanding hooks upon which you can hang your hat, at least, and will outline some of the fundamentals of forceful presentation. I am pleased to introduce Professor C. D. Hardy, of the School of Speech, Northwestern University.

LECTURE NO. I.

The Speaker and His Problem

That was a very pleasant introduction. As I listened to the Chairman in his observations on how I came into contact with this safety movement first, and his suggestions of some of the impressions that seem to have gone out of that early contact, I became a little nervous. I have been afraid, as he talked, that he was going to raise your expectations altogether too high. It would take something of a man to live up to some of the suggestions involved in that speech of introduction.

How seriously I took that I can perhaps illustrate by a little anecdote. I once heard of two negroes who lived in the blackest belt of Louisiana. These two negroes were known as Sambo and Dinah Washington. Dinah was fifty-five years old, Sambo was sixty. They were unusual negroes. They were very thrifty. In order to be thrifty they found it necessary to economize. They couldn't eat any

meat foods because these were too expensive. Sambo was something of a fisherman. He was in an area where he could fish. He fished a great deal. They had fish for breakfast and fish for dinner and fish for supper, in lieu of any meat foods. As Sambo and Dinah approached the years fifty-five and sixty, they accumulated a little property. They had no children. Sambo became anxious as to what they were going to do with the property. One day he said to Dinah, "What are we going to do with the property we have accumulated? We have no children. We have no near relatives. What are we going to do with the property?" He thought a bit and then said, "Now, Dinah, I wish you would go over to Dr. Johnson and ask him if you is too old to have any children."

The next day Dinah went over to see Dr. Johnson. When he came into the room he said, "What can I do for you?" She told him the reason for her visit. Finally the doctor said, "Dinah, how old are you?"

"I'se fifty-five years old."

"Well, Dinah, have you ever had any children?"

"No, I ain't never had no children yet."

"I am sorry to disappoint you, but I am quite sure that, if you should have a child now, it would be a miracle."

Dinah was crestfallen. She went home. When she got to the gate, she saw Sambo running toward her. He said, "Dinah, what did Dr. Johnson say?"

Dinah looked at him and said, "Sambo, you old fish eating nigger, I don't want nothing to do with you no more. Dr. Johnson said, if I ever had a child now, it would be a mackerel."

Now, friends, I don't want you to have any too high expectations as to what you are going to get during these four lectures, if you are courageous enough to hear me from morning to morning. I shall do the best I can to say something that will not be interesting but perhaps helpful to some of you at least.

I suppose the greatest character that came out of the recent World War was Marshall Foch of France. The record shows that he was not always a military man, that is, a military man on the battlefield. The record shows that he was an instructor in the military schools of France, and you will expect he was an extraordinary instructor, not the usual theoretical, standardized type. He adopted some new methods in the military schools of France. He used what we, in this country in our legal profession, call the case method. It was his plan, as he instructed his men, to outline a battlefield. He would first lay out the position of the opposition; their guns, batteries, trenches, and, in so far as he knew them, the machine gun nests. Then, he would discuss the terrain over which they were to go; its nature, its rocks, its trees, the ravines, whatever obstacles there might be in that stretch of territory in his imaginary picture. He would locate his own lines, his own batteries. After he had painted this complete picture, he would say, "Now, gentlemen, we have to advance against the enemy's lines yonder. In order to do that, young men, what have we to do here?"

Now, today, tomorrow, this week in this particular course of lectures that I am going to try to give, what have we to do here? Well, as nearly as I can put it in one sentence, we have this to do: We are to see if there are not some suggestions that can be made as to the fundamental elements or fundamental principles of effective speech from the platform that will be of some assistance to practical men who are confronted with the task of presenting a set of facts or a policy to a group of people, with the end in mind of getting that group of people to respond and to do something.

In order to do that, I am going to group my four discussions in about the following manner: This morning I am going to discuss some of the fundamental problems that the speaker in beginning his discussion must face. Tomorrow morning I am going to attempt to discuss the statement of the point of view that the speaker is to make, some things about it, and to make some observations on the

selection of materials with which to develop the particular or the specific point. On the third morning I am going to say some things about the final or the spoken style that the man is to use in expressing his ideas. The last morning I am going to say some things about the speaker on the platform, his actions, his presence and his oral presentation.

In attempting such discussions, I am going to be serious about it, although I hope not too serious. What I mean is that I think the thing we are going to attempt to do is important, and particularly important in this day and age in which we live.

We are no longer a simple civilization, we are a very complex civilization. The complexity of today, great as it is over the complexity of yesterday, is nothing as to what the complexity will be a generation from now.

Let me suggest this thought to you: We are developing in our use of machinery, developing in our scientific methods of promoting our civilization much more rapidly than we are developing our ways and means of understanding one another, and through that understanding getting an adjustment to these new and complex elements in our civilization. What I hope to do is to make some suggestions (and they will be suggestions only, understand) that will enable us so to express ourselves that we can get a better understanding of each other's problems and the problems of our complex civilization and thereby be able to make adjustments easier.

In this talk this morning, "The speaker and his problem," the first suggestion I want to draw to your mind is this: That the speech is not an end in and of itself. When I say that I must say it with a reservation, because there are certain types of public speech which may be considered ends in and of themselves. There are occasions when speakers take the platform for the purpose simply of delighting and pleasing an audience. Their purpose is to discuss material with the idea of leaving a pleasant reaction or a pleasant emotional experience with the audience. That type of speaker has very much the same point of view as has the poet, when he writes a beautiful piece of poetry, or very much the same point of view as the essayist when he writes an essay for the sole purpose of delighting the reader in the elegant use of prose, in the elegant outlining and illumination of a theme.

I am not particularly interested this morning, and I don't think you are, in that particular type of speech. You are much more interested in the practical side of it, the business man's side of it, who uses his speech as a means to accomplish an end. He thinks of his speech as a tool. I don't care how eloquent he may be, how much a master of facts he may be, how well he can put those facts into understandable and choice language (and all of those things are desirable), his object is to get men to understand facts, to get men to adopt a policy, or to stimulate them to continue in a line of conduct more vigorously than they are now working.

The sales manager, for example, has that latter object very materially in mind, when he stands before a group of his salesmen and attempts to outline for them, to them, the program of activity for the next year, and to inspire them to get into their activity with more energy than they had before.

Speech, then, that we are interested in, in this series of discussions, is not an end in and of itself but a means to an end.

The second suggestion I want to point out as a problem, and a very real problem, that confronts the speaker when he takes the platform is, how can he get attention? That first moment of attention is important. Psychologists point out that one of the elements that make us remember ideas is the intensity with which the idea first strikes the attention. Impressions are deep in proportion as the presentation is striking. How shall we get that attention?

There are no pat rules that I can suggest to you. The one suggestion I do want to make is that the speaker, when he begins, has the problem of saying

something striking, something attention-getting. It may be the presentation of a striking fact, it may be the presentation of an interesting incident. Consider your safety movement, for example. When you are confronted with a group of your people working in industry, sometimes you can fasten their attention, rivet it for the moment, by drawing attention to some striking incident of the operation of safety, or the failure in the operation of safety, devices that has occurred within the knowledge of the people listening to you.

How to get attention. The most I can do this morning is to put an emphasis upon the importance of it. Many a speech has been spoiled for at least the first half of it because the speaker began so badly. The first impression that he made upon his hearers was one of fear, one of timidity, one of hesitation, one of plain dumbness, rather than one of alertness and mastery of the subject material.

Let me give one or two illustrations. These are classic illustrations. In 1886, Henry W. Grady, then an editor in Atlanta, Georgia, and an orator, came to New York City to make a speech before the New England Society of New York City. He was the first southern speaker that had been asked to appear before that Society since the Civil War. It was a crucial moment. He knew it was a crucial moment. He knew that, if he succeeded, he would do a great deal for the South. He knew that if he failed, he would hurt the South irreparably. This is the way he began: "Mr. Chairman and Gentlemen of the New England Society: There was a South of secession and slavery. That South is dead. There is a South of union and freedom. That South is living, growing, breathing every hour."

"These words uttered from the immortal Benjamin Hill in 1880: True then, truer now, I shall make my text tonight."

It would have been a dumb audience indeed that wouldn't have had their attention riveted on Henry W. Grady, when he began with the use of such a striking statement of fact, such a striking quotation. This idea is emphasized in our minds, when you remember the occasion, the man, and the relations of the man to the occasion.

One of the unfortunate things that one faces, when he is discussing these principles, lies in the fact that you have to use your illustrative material totally detached from the speaker himself. If you had Grady here and had him speaking such words you would see the force of the principle much better than the force is apparent to you, when I relate the incident.

Attention-getting! Let me give you another example. In 1895, Booker T. Washington, the colored orator, and the former President of Tuskegee Institute, spoke at the Atlanta Exposition. The Negroes were asked to participate in that Exposition. The question arose as to whether or not a Negro representative should be allowed to speak and, if so, who should be the speaker? The Southern whites were considerably disturbed about the matter and hesitant. One group thought it ought to be done. Finally the decision was reached that it should be done and that Booker T. Washington should be the man selected. On that occasion he delivered a speech which made him famous. In the beginning of that speech he used these words: "A ship was lost at sea. It saw a companion ship coming. It ran up the distress signal, 'Water, water, or we perish.' The approaching ship sent back the signal, 'Cast down your buckets where you are.' Not understanding, the first ship sent up the signal again, 'Water, water, or we perish.' Immediately came the reply, 'Cast down your buckets where you are.' A third time went up that distress signal. A fourth time came back the same reply. Finally the ship sent down its buckets where it was and drew up fresh water out of the mouth of the Amazon River."

Then Booker T. Washington made this application: "To the members of my own race who are looking for the betterment of their welfare, I say: Cast down your buckets where you are, cast them down among the people who know you,

the people who understand you, the people who believe in you, the people who love you." Then, he went on to say, "If I were permitted to say to the whites of the South exactly what I think about their employment problems, I should say to them: Cast down your buckets where you are when you are in search of labor; do not go abroad, cast them down where you are."

I want you to notice two things about that attention-getting incident. The first is that it is an interesting incident. There is a bit of the dramatic in it; it holds you. The second thing is that it leads right into the thought that he has in mind, which is the proper relationship between the whites and the blacks of the South. I do not know of any citation that I could point out of an effort on the part of the speaker to get sympathetic attention that is better than this one.

In your safety business there are incidents that you can use that are striking, or there are striking facts, which may be the summary of the work that you have done, or striking facts showing a lack of activity somewhere along the line, that in and of themselves will be attention-getting.

A third problem confronting the speaker is the matter of sustaining attention. Getting attention is one thing, but sustaining interest, holding interest, is another. I believe it is fundamental to effective talking before a group of people that you can't get them to adopt a policy very well, you can't move them to act, unless you can sustain their interest.

There are a number of things under this general subject of sustained interest that I want to say and to make plain, if I can in the next twenty-five minutes. There are some things a speaker ought not to do. First a speaker ought not to speak as though he had the final word on the subject, to speak in the dogmatic manner. May I suggest that one of the tendencies in speech that I have seen among mature business men, who have accomplished things in the field of industry and in the field of business, is to speak dogmatically; rather than to give the impression of reasoning the subject out together with his hearers. Such a speaker has given the impression of saying the final word that can be said and not calling for any intellectual reactions on the part of those to whom he at the moment is talking. My suggestion is that that method of approach will not get sustained interest, because the impression at once goes out that the speaker does not care anything about what anyone else thinks; he cares only for what he says.

There are two types of men, as I view it, who can speak dogmatically and get away with it. The first man is the type that is a dictator, a Mussolini, who can say, "George, this is so; do it." He can do that sort of thing. The other type of man who can speak dogmatically and be successful in it is the man who knows more about the subject than anybody else in the community or anybody else in the country, and who knows that the people to whom he is talking know that he knows more about the subject than anybody else. He is in a position perhaps to speak with finality. If you know yourself to be in the position of a dictator, if you know yourself to be in the position where you know more about a subject than anybody else and you know that everybody knows that you know more, then you can talk as though you spoke the final word. Unless, however, you are aware of being in such a position, my suggestion is that you cast the speech in a form that calls perhaps for some intellectual reaction on the part of those to whom you are talking.

The second suggestion as to what needs to be avoided, if sustained interest is to be carried on, is the method of the demagogue. What do I mean by a demagogue, anyway? I mean that type of man who bases his appeal purely on emotional responses; or that type of man who bases his appeal purely upon prejudiced points of view; or that type of man who makes facts say something entirely different from what the logic of those facts would say; or that type of man who makes facts say fifty per cent or a hundred per cent more than those

facts will logically or reasonably say. Now, don't misunderstand me. I am a great believer in facts, and I am a great believer in making facts say all they will say, but I warn against the tendency to stretch facts, to make them say more than they will say.

If I may be so bold this morning, I should like to make a suggestion that I think will apply in your own field. Let us assume that you are an executive talking to a group of men in industry and that you are presenting to that group of men a set of facts. If you make those facts say fifty per cent more than the facts justly interpreted will say, don't kid yourself for a moment into thinking that those chaps in front of you don't know that you are stretching the truth. They are pretty apt to know the situation better than you do. Make the facts say all they will say, but don't be a demagogue and attempt to make facts show more than they logically can show.

We are in the midst of a Presidential campaign now. (I am not going to discuss politics at all.) We are in the midst of a Presidential campaign and I hear a lot of things in and over the radio, and I hear now and then a speech. And as is true with all Presidential campaigns, all political campaigns, there is demagoguery evident. I am painfully aware, and must admit it, that there are certain occasions, and for a limited amount of time, when the man who adopts the methods of the demagogue apparently is successful. But you men in industry, where you are going to be for one year, two years, three years, four years, cannot afford to use demagoguery, for sooner or later somebody is going to find you out, and somebody is going to discount practically everything you say because of the methods with which you express yourself.

The third observation that I want to make as to what, it seems to me, sustained interest will not allow is the type of speech that gives the impression of being simply an exhibition, a show-off. We are in our modern days, either because of our materialism or our science or our information or our good sense, growing more and more away from the bombastic, grandiloquent, show-off style of speech. We can't get away from it too fast to suit me. It is empty, folks, and sooner or later the good people of the country are going to find out. What ludicrous things it does sometimes for speakers! Here is an incident. A Congressman from Indiana was delivering a speech on Abraham Lincoln. He was an eloquent speaker in some respects. He warmed to his subject and came to a climax with this sentence: "Abraham Lincoln! Abraham Lincoln! that mystic mingling of star and cloud." He got applause. After the speech was over, one of his friends said, "Say, Congressman, what did you mean by that sentence anyway?"

The Congressman said, "I don't know exactly what it means, but it always gets applause."

If you want results that are permanent, avoid such a style. Another Congressman in Washington (this was in the House of Representatives) was making a speech on the tariff. He was a bit indignant. He got to his feet and said, "Mr. Chairman, I smell a rat. I see it floating in the air. I will nip it in the bud."

I once heard a college student (he was a senior, too) give an oration on democracy. He said: "As college students who believe in democracy, let us go out from these halls determined to be energetic, determined to be courageous, determined to be individuals, determined to have initiative like 'one who wraps the drapery of his couch about him and lies down to pleasant dreams.'"

Those illustrations, of course, are extreme, but after all I don't think they are any more extreme than the realities that we meet every once in a while. Let us avoid that sort of thing, if we expect to have sustained interest on the part of those to whom we are speaking.

Let us turn the subject around a little. Sustained interest on the part of hearers depends, first of all, upon the speaker having something to say, upon the speaker having some information, upon the speaker knowing the facts about which he

is talking. This failure to know the facts about which one is talking is a strange thing. The full significance of it I have never been able to understand. For somehow or other, the moment a man opens his mouth and begins to speak uttering words only, and is not sure of his subject, the lack of facts is detectable in the very quality of the voice that he uses and the inflection with which he expresses himself. Emptiness is unconsciously detected on the part of those who listen. Somehow or other there is a lack of sureness, there is a lack of confidence, with the result that those who listen are but little moved by the man who is uttering only words. An empty barrel makes a lot of noise while a barrelful of apples makes but little. Most American people prefer the barrelful of apples to the one that is only partially filled and makes a lot of noise. That principle applies in this field of thought just as definitely as it applies anywhere else.

Sustained interest then depends, first of all, upon having something to say. Effective speech is not a matter of glibness of tongue, of command of language; it is not an inspiration from the Gods; it is the result of grind and dig and perspiration. Make no mistake about that. I could stand here for half an hour and illustrate that point and enforce it historically in terms of your Webster, in terms of your Churchill, in terms of your Wendell Phillips, in terms of your Grady, in terms of your Woodrow Wilson, and all the rest of the men who did a great deal of speaking.

Once more, sustained interest depends pretty largely upon how well the speaker can communicate with his audience. It is fatal to the effective speaker to lecture at an audience. Communicate with the audience, converse with the audience. Do I mean to say that effective speech is just conversation? Yes, that is about what I mean to say. That is quite different from the type of speech that used to characterize this country fifty years ago.

The main difference between conversation between individuals and conversation between an individual and an audience lies in the fact that in the latter case you have what we call elevated conversation, enlarged conversation. The more intimate a speaker can be and at the same time be large enough in his expression to be heard by a group of people, the better.

Let me give you a striking historical incident of the effectiveness of this point I am talking about. Those of you who remember your American history will remember Wendell Phillips. There are a good many things that could be said about Wendell Phillips in his power of public speech. But, this thing ought to be said. He taught us a new standard, the standard of conversation. How effectively he used it, I can illustrate from an incident in his life. Prior to the Civil War, as you know, he was an agitator, and as you know, the people in the slave States didn't like him and it was very difficult for him to speak near the border cities. One time he was called to one of the border cities. No one was found who would introduce him; they were all afraid to present him. He had been told he wouldn't be allowed to speak. The audience was present. They had waited ten minutes for the speaker. Finally, a gentleman came out from the rear of the platform, came forward and began to talk. The audience thought that it was the Chairman of the evening introducing the speaker. The gentleman had been talking ten minutes before it dawned on that audience that it wasn't the Chairman of the occasion, it was the lecturer of the occasion. So intimate had he been, so conversational was he that he had that direct contact which led him right into his subject and got not only their attention but their sustained interest throughout the whole of the speech.

Any of you who have heard William Jennings Bryan must understand the thing I am talking about. If he had an audience of 150 people his conversation was just that large. If he had an audience of 2000 people his conversation was just that large. If he had an audience of 5000 people he enlarged his conversation to reach that 5000. But, all of the time he was just talking.

Sustained interest in the next place depends upon getting what I call the individual approach to the audience. Three college boys explained the principle. College boy, one, came out of chapel one morning and he said to college boy, two, "I would like to know why Prexy directs his speech at me." College boy two said, "He always directs his speech at me." College boy three said, "You guys are all off, Prexy always speaks to me." What had happened? The Prexy was a good speaker and he had that ability to get the individual approach. When he asked a question, it was so directly put, so simply put that every individual in the crowd thought it was his question. If he made a declaration, it was so directly put, put in such a commonsense, businesslike fashion, that any one in the crowd looked upon it as a declaration directly at him.

There is another phase to this. Why is it that so many men are timid about an audience? I think I know one reason for it. Because they think of the people in an audience as one great composite individual, and that composite individual is so much bigger than they are, that it frightens them. The business man, for example, who, in his office, has all kinds of courage, can jack a man up, call a man down, can say yes or no without any fear at all, if called before 150 or 200 people, is afraid. Why? My opinion is that he is afraid because, unconsciously, he thinks of that body of people as one great individual. He must get the other point of view, ladies and gentlemen, which is the point of view, namely, that he is talking to individual minds; that is, one mind trying to reach another individual mind. You folks here this morning would scare me to death, if I had to think of you as 500 people rolled into one. I am not so terribly frightened at you, when I think of you as 500 different individuals and that my approach to you is that of one individual mind to another individual mind.

Sustained interest on the part of hearers depends pretty largely on the capacity of the speaker to get that individual contact with the people in his audience.

Of course, sustained interest depends upon the capacity of the speaker to be heard. If you are going to allow yourself to speak at all, ladies and gentlemen, be sure you are heard in an audience room of ordinary size. I shall not ask any person to attempt to develop a voice that is large enough to be heard in some of these halls that we have to speak in that will seat 10,000 or 12,000 people and are built like a barn. That is asking too much. But, in the ordinary hall with reasonable acoustic properties, anybody who allows himself to talk at all, ought to appear there with the purpose in mind of being heard. If you can't do that or won't do that, don't take the platform. You really have no excuse for being on the platform unless you intend to get enough force behind that voice to make it heard.

That takes us to the whole matter of the use of voice. I haven't any time this morning and I haven't much inclination to go into a technical discussion of voice production. I will give you just a few suggestions on it. The voice that carries is the voice that is properly produced, properly focused, properly projected. Our whole vocalizing apparatus is the same as our breathing apparatus, the difference being in this: When we breathe, the muscular movements of the diaphragm, the movement of the abdominal muscles and the costal and intercostal muscles, are steady, even movements, while, when we speak they are short movements. The diaphragm muscle, when you inhale, goes down; when you exhale it rises. The throat should be relaxed and the muscular power should start behind the tone, driving it out. (The speaker illustrated this point.) Anybody can obtain some power in voice production, but most people don't practice it any. I am afraid most people don't care. If you are going to speak, do care, because it is important.

Closely related to voice power, if you are going to help sustained interest (I want you to get this thought), is the emphasis that should be placed on speaking so as to be understood. All of this involves articulation. The greatest

weakness of American speakers is indistinctness of enunciation. Wherein lies the difficulty in enunciation that makes people indistinct? It lies in the failure to bring out sharply the consonantal elements in words, particularly final consonants and final combinations of consonants.

Let me illustrate. Take two words, T-R-A-C-T and T-R-A-C-K, tract and track. You have in the one word "ck" a final combination of consonants. In the other word you have "ct." If I were to give those two words to this audience and ask you as individuals to pronounce them while I listen, I venture that in not one-third of the responses of the people in the room would I be able to say whether the word was tract or track, because you would not get that final "t" in the word tract.

Let me illustrate again. Take the word B-O-L-D. You have an "ld" combination. Let me give out that word and ask you to pronounce it. I would get back B-O-W-L; I would not get back B-O-L-D, because you do not stress that final consonant.

Of course, I recognize that you folks in business are not interested in this technical subject, as I am, for I have to teach this subject to college youngsters. But, you are interested in it from the point of view of your job. When you speak, you speak to convey ideas, and the quickest and easiest way to give out ideas and to get ideas grasped is for you to economize the attention and the effort of those who are listening. One of the means of doing that is to speak distinctly; and one of the ways of being distinct in your utterances is to pay some attention to the final consonants.

One other phase of this distinctness arises in long words where whole syllables are eliminated. Take the word M-U-L-T-I-P-L-I-C-A-T-I-O-N. If I asked a dozen college students, to pronounce that word, this is the way I would get it, in half of the cases, M-U-L-T-P-L-I-C-A-T-I-O-N, instead of M-U-L-T-I-P-L-I-C-A-T-I-O-N. That word itself isn't important, but as an illustration of a difficulty that we have in our enunciation, it is important.

Anybody with a normal articulating apparatus, that is, anybody that does not need to go to a doctor or a surgeon, can learn to speak distinctly, if he will have patience and if he will give time to the technical side of the matter.

I have one more idea that I want to suggest. If you are to get sustained interest on the part of an audience listening to you, you must put your thought, in terms of the other man's experience, not in terms of your own experience and your own information. Put your thought in terms of the other man's experience and the other man's information.

You and I, like everybody else, judge of things in terms of our own information and observation. I defy you to form an opinion of anything that you can't relate to, refer to, and judge of, in terms of your own experience.

I ought to elaborate on this subject a little, but my time is up. If you people have the leisure and the patience to come back tomorrow morning, I am going to talk about the selection of a proper subject and some things in the choice of thought materials.

ADJOURNMENT

October 3, 1928**LECTURE NO. II.****The Speaker and His Material**

In our talk yesterday, I made some attempt to suggest some of the preliminary problems that a speaker, I care not who he was or is or when he speaks, would be faced with. I think, perhaps, in order that we may keep these talks tied together and see how one grows out of the other, it might be well for me this morning just to sketch what I attempted to point out yesterday.

I attempted to point out, first of all, that the speaker for practical purposes, such as the purposes that businessmen have in mind, when they use speech, thinks of speech not as an end in and of itself but as a means to an end. In other words, the speaker uses speech as a tool with which he attempts to accomplish results.

I attempted to point out, secondly, that one of the first problems that meets the speaker is the problem of getting attention. I tried to outline by a suggestive method one or two ideas on putting the introductory matter in a striking fashion in order to get that attention.

In the third place, I attempted to point out in that talk the problem of sustained interest, how to get sustained interest, how to keep interest. And in pointing that out I drew attention to some things not to do, some methods not to use, such as dogmatism, demagoguery, and the general method of the individual who is trying to make an exhibition of himself.

I further tried to point out that sustained interest rested, first of all, in having something to say. I did not point out as I would have pointed out, if I had had time, the importance of analyzing and thinking in the material that one attempts to use. I tried to point out the importance of communicating with a group of hearers rather than lecturing at them. I tried to point out the importance of speaking so as to be heard, of speaking so as to be understood, of throwing the thought in a persuasive form.

Lastly, I attempted to point out the importance of the speaker clothing his own thought in the experience and the understanding of those to whom he is at the moment delivering his address. That in a sketchy fashion constitutes the substance of what was said yesterday.

The lecture today is simply one step forward. In brief, I am going to attempt to discuss the speaker and his material from two points of view; first, the selection of the proposition and the finding of the particular argumentative or explanatory points which, after once found and developed, make the speaker's talk effective; and, secondly, I am going to try to present in this lecture some observations on the fundamental matters that need to be borne in mind in the selection of detailed materials by means of which one attempts to illustrate or enforce the point of view that is for the moment under consideration.

I am not going to say to you men this morning anything that is particularly new. As a matter of fact, I will be perfectly frank with you and say that I am talking about old stuff. How old it is I believe I can perhaps illustrate by relating a little anecdote that I heard a very distinguished man relate about a youngster who, when about five or six years of age, lost his mother. He was a playful, cheerful, optimistic youngster. Upon the death of his mother, his grief knew no bounds and it was months before he returned to his normal self. About the time he began to take on his normal, playful, optimistic habits, his father thought that a sufficient length of time had passed for him to take unto himself a new wife. He did so. He married her away from home. Little Willie had never seen this lady that was to be his new mother. His father brought this new Mamma home, took her into the front room and left her there. He went out into the backyard, where he found

Willie playing in the dirt. His father took him up to the kitchen sink and washed his face as well as fathers under those circumstances usually do—you ladies know how artistic a job fathers can do when they attempt to wash the baby's face. Then, he took the youngster by the hand and brought him into the parlor and said, "Now, Willie, I want you to meet your new Mamma."

Little Willie stuffed his chubby hands into his pockets, looked his new Mamma over very carefully, and then said, "Dad, they soaked you. She ain't new; she's as old as the hills."

This material with which I shall deal this morning is old; it is as old as human reasoning is old. I am sustained, however, in going ahead with this because I know that one of the fundamental educative principles that we pedagogues have to bear in mind is that the educative process goes forward on the basis of frequent recollection and real reflection on fundamental elements. In the Illinois State Bill of Rights, that part of the Constitution known as the State Bill of Rights, there is written this sentence: "A frequent recurrence to and reflection upon some of the fundamental principles of liberty are the surest guarantees against the encroachments of tyranny."

Adopting about the same form of phraseology and applying it to our purposes, we can come to this: "A frequent recurrence to and reflection upon some of the fundamental elements of good speech making are the surest guarantees against that result which is nothing but wandering about aimlessly and pointlessly in speech making."

If there be anything worth while for you in what I shall say, it will not be because it is new, but perhaps because of the individual way in which I put it or the individual way in which I throw these fundamental elements.

Most subjects that we have to speak upon are too broad; we have to limit them. In my academic career we say to our students, "You must limit your subject to that breadth of view that you can discuss with some degree of accuracy and adequacy within the space of time that is given to you."

One of the greatest difficulties, and I think the greatest weakness of most of us when we attempt to make a speech, is that we cover too much ground or attempt to cover too much ground and we spread ourselves out so thin that you can scarcely see us anywhere.

The important point is to study the occasion, to study the nature of the audience that is present with you on the occasion, find out what the relationship of that occasion is to that audience, what your relationship to that occasion is, and your relationship to that audience, and then limit your discussion to that particular phase of the whole broad subject that you can cover, with some degree of intensive discussion, in the amount of time that is given to you to make the talk. If you are to have five minutes, then it will have to be a very limited point of view. If you are to have ten minutes, it may be a little larger point of view. If you have an hour, it is still larger.

Every subject must be limited in its extent, as I shall try to illustrate in a moment. That is what I mean by limiting the subject to the compass of the time that may be allowed you.

After you have limited the subject and found a way to phrase it in an understandable form, then comes the question of dividing that subject into its principal parts or its principal explanatory or argumentative issues, which if you develop adequately, clearly, make the subject as a whole impressive.

That, in general terms, is what I have in mind. Let me see if I can illustrate it. I recall when I was a boy, I couldn't have been more than fourteen years of age, Bishop Fowler, then one of the great orators in the Methodist Church of this country, came to a town in Western Iowa. I was then living with my father on a stock

farm, and father and I rode sixteen miles with a team and a spring wagon to this little town to hear Bishop Fowler make his address. Even today I remember that address, and I remember it because Bishop Fowler so successfully limited his subject and so successfully stated his particular points of view. He said when he began: "Ladies and Gentlemen: My subject tonight is Abraham Lincoln. That is a big subject. That is too big a subject for me to cover. What I am going to try to do in that subject is to limit it to this: Why Abraham Lincoln has the position that he has in history, and why Abraham Lincoln will have a larger place in his story in this country than any other historical character we have up to date produced."

Then he said, after he limited his theme, "I am going to say three things under that theme. First, Abraham Lincoln as a great character. Second, Abraham Lincoln as a master in State papers. Third, Abraham Lincoln as a leader of men."

In my mind's eye I can yet visualize Bishop Fowler limiting his subject and stating his points of view. He rigidly held to his outlined plan. It was interesting to note, and I still remember it, how as he got into the discussion of Abraham Lincoln State papers he would say, "Great, I say, in his State papers." Then, he would take up a State paper, analyze it, discuss it, and then come back to his theme, "Great, I say, in his State papers." Then he would take up another State paper, analyze it, discuss it and come back to his point by saying, "Great, I say, in his State papers."

He followed this plan, I suppose, in discussing that phase of his theme, for at least thirty minutes in his hour and a half of discourse. Then, he turned from the subject of State Papers and began to discuss Lincoln's mastery of men, but followed the same plan.

What I am trying to point out, men, is nothing more or less than this: The importance of getting a clean-cut idea that you want to express and then dividing that clean-cut idea into its two or three or possibly four parts, and then discussing each one clearly, distinctly and distinctively before you pass on to another.

I hear a lot of speeches. I have an insatiable appetite for speeches, the good and the bad, and I am constantly astonished at how many times even good speakers miss this fundamentally important element of clean-cutness of outline.

There are one or two things I want to say further about this phase of the subject. The first is that an audience will remember what you say by points and not by detailed information. Let me repeat that. Your hearers can and will remember your argumentative points or explanatory or illustrative points, call them what you will, if you will make them clean-cut and distinct. They will not remember the details by means of which you present those points. Statisticians, and I suppose I am talking to some statisticians this morning, from the point of view of public speaking, make some mistakes here. They present their statistical information as though they expected the members of an audience to carry such information in mind. They are not likely to do so. The statistician needs to present his statistical material around and in support of a point which his hearers can grasp. They will carry that point with them, if it is made impressive to them by means of the statistical material.

I need to say the foregoing with a reservation, because there are now and then some statistical facts that need to be remembered as such. I am speaking in general terms now that apply to all speeches, and if there are exceptions, we will have to bear them in mind and take them for granted. But, in general, what I have been saying is true.

The second reason why this matter is so important is this: An audience hears you but once, hears you while you speak rapidly. If they understand you easily, and at once, they will follow you. If it becomes necessary for them to stop and to reflect on what you have said to see whether they understand it or not, usually

that moment that audience is lost. You have gone on, you have brought in new material.

Note the difference between your situation as a speaker and the author who presents written matter to his readers. The man who presents written matter to his readers can be sure that, if the reader does not get the idea upon the first reading of the paragraph, he can go back and read it again, can reflect on it to find its meaning. But you as a speaker, if you are not understood at once, are not going to be understood at all. It then becomes increasingly important for you to outline your material so clearly that it can be immediately grasped.

I remember, when I was a college student at Northwestern University, there was a preacher in Evanston by the name of John Hugh Boyd, who, on the whole, was the greatest minister I ever heard. He followed the plan of the outline that I have been making here. In fact, he was the first man that gave me a great lesson on that. He would stand before his audience in the morning, usually 1,000 or 1,500 people, and say, "Now, my text this morning is so-and-so. From that text I propose to draw this inference," and he then stated the subject as he limited it. "On that subject, friends, I propose to say two things or three things," and he usually named them all before he began a discussion of any one and he never said more than the two or three that he named and you could always carry away those points with you.

This whole matter applies in your case just as definitely as it applies in Bishop Fowler's case or in John Hugh Boyd's case.

Suppose we are discussing, for example, the safety movement. Immediately the question ought to come into your mind, "What shall I say on this safety movement? Shall I discuss it from the point of view of saving human lives? Shall I discuss it from the point of view of safety devices? Shall I discuss it from the point of view of a new note in business in its relationship to human welfare? Shall I discuss it from the point of organization to promote safety? Shall I discuss it from the point of safety as a dominant idea in the development of modern civilization?" All of those ideas are under the general thought of the safety movement, and the individual who is confronted with the task of discussing safety, it seems to me, needs to limit himself somewhere along this line. I have simply arbitrarily, for illustrative purposes, suggested several views on safety.

Now, suppose we say we will discuss this morning saving human lives as a movement in safety. How shall I get my points of view? Here are three. We want a safety movement to save human lives because of its relationship to the welfare of the women and children in industry; because in the second place, it shows that business is taking a new point of view, not purely materialistic but humanistic, and because saving human lives, in the third place, is the greatest modern movement in the welfare of civilization.

You probably wouldn't consider those ideas at all. You know more about this subject in one minute than I would in a week. I simply make those suggestions as a method of analysis.

We have our proposition, we have it limited, we have our points of view that we are going to discuss.

Let me now make a few observations in the second part of this morning's talk; namely, some principles that need to be borne in mind in the selection of the material. The first observation I want to make is this: Let the speaker at the outset examine the content of his own mind. What does he know about the subject? How much detailed information does he have in his mind about the particular point of view that he wants to develop? Any man who has had anything to do with education and the educative process knows that usually, when anyone is assigned a subject to discuss or to investigate, the first step that individual has at least a temptation to do is to rush off to find out what the authorities have said upon the subject, to go to the library and find out what others have said upon the subject,

to take up Nation's Business or take up an industrial magazine that is making a report or to consult the files of the National Safety Council; go somewhere, anywhere, except to your own head to get your start.

I suggest the proper process is to reverse that, examine first the content of your own mind on the subject. Why do I say that? I say it principally because the only commanding, the only lively speech that you will give utterance to comes out of yourself, not out of a library book and not out of the files of the National Safety Council.

Let me illustrate that with a historical illustration, if you please. It is the principle I am interested in making dominant this morning. Daniel Webster in about 1830 made his famous reply to Hayne in the United States Senate. Hayne had made his speech on one day and Daniel Webster replied to it on the next day. In his reply he talked for four hours. It is an amazing argument from the point of view of its thought, from the point of view of its evidence, and certainly from the point of view of its rhetoric. It caught the nation's eye; it stirred the nation's soul, particularly in the North. His friends were amazed. They said to Webster, "How did you do it? How could you do it with so little preparation?"

Webster's reply is historical, "Little preparation—I have spent my whole life preparing for that speech and all that I did was to take out of my mind what was there and had been there for years."

Study that principle in connection with a man like Webster and you find that his great work on the platform was the expression of the theme of his life. He had lived it and breathed it and was stirred by it.

I emphasize this, folks, because I am as sure as I stand here that none of you will ever make a vital speech until you make a speech that grows out of the inside of you, out of what you know, out of what you feel about the subject. And so, when you begin to select material with which to develop points, let the first step be an examination of the content of your own mind.

The second step that I want to emphasize is the selection of material that is interesting in and of itself, in so far as that is possible. When you approach your task of selecting material from that point of view, you are taking advantage of one of the basic psychological principles that is in all of us. There was a time when many of our teachers were saying to students, "It does not make any difference whether you are interested in a subject or not, you can learn it, you can get concentration upon it."

In that view there is some truth, but modern psychology has been teaching us that, if you want to get concentration upon a subject, get first of all interest in the subject. If you want to get people to concentrate upon a subject, first of all arouse their interest in the subject. As an educator, and of course I occupy a very modest place in the educational world, I am thoroughly convinced that the way to get a modern student interested in a subject is to get a modern subject and to get him to master it by first getting him interested in it. That applies to the public speaker just as definitely as it applies to me in my classroom at Northwestern University.

I think that the advertisers and the journalists have something to teach us on this subject. Are you students of modern advertising? Are you students of the feature stories in some of the leading journals of today? What does the feature story writer do? When he examines his events, whatever they may be, he is especially interested in selecting from those events just those human interest facts, human interest stories that, in and of themselves, will catch attention. The advertiser does the same thing; in a little different way, to be sure, but nevertheless he follows the same principle. He is after those facts, in connection with his subject material, that, if presented will be interesting.

I have of recent date been reading all of the feature stories of James O'Donnell Bennett in the world's greatest newspaper in Chicago about Alfred E. Smith. It

is an interesting study to me in the development of material that will catch attention. He selects interesting data, in and of itself, relative to this man. Isn't there something there that is worth while for you and for me to note as speakers?

My third suggestion is that in the selection of material try to find that material that is not too remote, either in space or thought or time, from the subject that you are at the moment discussing. Let me illustrate that (I can teach better by illustration than any other way). Just recently, some of my colleagues and myself were discussing some social conditions. My colleague was saying this: That if we are to have a harmonious social welfare in the immediate future, we need to get back to the same type of society that you had in England when the Guilds were active. Well, that interested me very much and I encouraged him to go on. He discussed the value of the Guilds in England, their organization and so forth. He said, "That is what we need here." It left me cold. Why? Because the condition about which he talked was so remote that it seemed to me to have no connection whatsoever with modern times.

Let me illustrate again. In 1920, or just before 1920, we had a great deal of discussion in this country as to whether or not the League of Nations should be adopted. There were a good many arguments for and a good many arguments against. There was one argument that did not impress me very much. That was that we should not adopt the League of Nations because George Washington, in his farewell address, warned the country against foreign entanglements. I may say here frankly, lest I be misunderstood, that I was not particularly enthusiastic about our joining the League of Nations, but my objection to joining the League of Nations, I assure you, was not based upon what George Washington thought about foreign entanglements. The point I want to make with you here is that we have here an argument, a bit of evidence which was used to keep us from joining the League of Nations that was so remote from the actual circumstances, and the importance of the facts in 1920 or just before 1920, that it seemed to me to have no worth while bearing on the matter at all.

Let me illustrate again. A few years ago, I should say a half dozen years ago, one of our distinguished Western Senators made a good many speeches in this country about the advisability of cooperation among farmers. He made a trip to Europe. He studied cooperative marketing among the farmers in Denmark. He came home and in several speeches, one of which I heard, he drew attention to the organization in Denmark, how it was functioning and how it was financed, how it was advertised and so on, and then wound up by saying, "There is no reason why the farmers here in the Middle West, the wheat growers of our fourteen States, should not organize a cooperative association or cooperative associations just like they have in Denmark."

What ever may be said about cooperative marketing or cooperative organizations among agriculturists to solve the farm problem in this country, it does not strike me that the argument brought from Denmark, as to what they do in Denmark, is particularly vital in its bearing on what ought to be done in this country.

All I am trying to do is to point out that you have, in this case, a man with a subject of today supporting his argument with evidence entirely too remote from the situation about which he was speaking.

Let me carry that same idea just a little bit farther and say that in the selection of evidence or illustrative material, let it be in so far as possible from the most recent events discoverable. Suppose you were to discuss the safety movement on the basis of the figures and the experiences of twelve or fifteen years ago. It becomes at once apparent to you that you would not be able to get much of a hearing. Why? For the reason that the facts in connection with safety in this country have been revolutionized, have been changed very materially within ten years.

I hold in my hand here this morning this manual for speakers. I picked it up yesterday afternoon. I have been examining it a little. I think for tomorrow

morning I will select, for illustrative purposes, a few figures out of this. Here, it seems to me, if you are talking safety, you have the most up-to-date and the most reliable, though I suppose not altogether reliable, information obtainable upon this subject. It is recent. My point is that in the selection of evidence let it be as recent as it is possible for you to get it.

In the next place, select that material which falls within the experience of your hearers. I said something about this idea in general interest yesterday but from a different point of view, namely, sustaining self-interest. I want to say something about it today from the point of view of the selection of material that comes within the understanding and the experience of your audience.

I heard a man make a political speech just the other day. In the body of that speech he discussed the value of protective tariff, and it was interesting to me to note that he discussed protective tariff from the point of view of protection of infant industries, the line of argument that was offered on protective tariff fifty years ago.

What does the modern man know about infant industries and the protection of infant industries? You don't and can't call the United States Steel, General Motors, our coal organizations, our railroad organizations, infant industries. There was a day when they were all infants. That was not an argument that came within the purview, the experience, the information, the intellectual and emotional reactions, of those to whom the speaker was talking. There may be all kinds of arguments for protective tariff. I happen to be not particularly opposed to protective tariff. I am not interested in discussing it. What I am interested in showing is that, if you are going to discuss protective tariff or any other subject, get your material right out of the thought of those to whom you are talking.

We have a splendid illustration of that in our political history in this country. Do you remember the time Bryan nominated himself for the presidency for the first time in 1896? He did it by a speech, a speech that took him about twenty minutes, in the Coliseum of Chicago, to deliver. There was nothing new in that speech. Bryan himself said there was nothing new in it. There was just one paragraph that he hadn't used dozens of times. What did Bryan do on that day? What Bryan did on that day was to gather together the thought, the sentiment, the ambition, of a majority of those who were in front of him and put it into a language which they understood. Put that idea the other way. What Bryan did that day was nothing more or less than to state his idea in terms of the experience and the understanding and the ambition of those to whom he was talking.

Select material which appeals the most dominantly to the most active motives of those to whom you are at the moment talking. What do I mean by that? I mean about this: That we all act on motives. We think we are reasoning beings. As a matter of fact, not many of us, in many of our reactions in human life, act on the basis of reason, we act on the basis of other motives. I have tried to get the psychologists who study this thing all of the time to give me an answer as to what percentage of our reactions to whatever comes to our mind is based upon reason or logic and what percentage is based upon other motives, sentiments and whatnot. I can't get a definite answer. I have, however, this general answer, that about ninety per cent of our responses in human life to advertisements, to speeches, to salesmen, are based upon motives other than reasoning. What are some of those motives? There is selfishness, there is self-interest, there is ambition, there is desire for power, desire for reputation, there are our tastes, our ambition to be associated with our fellows, our gregarious instincts, our patriotism, our love of the beautiful, and there are others that might be named. All of those are motives that dominate our thinking and dominate our feeling.

The point I want to make is that in the selection of evidence that you are going to use at a particular time, select that evidence which makes an appeal to the motives of those to whom you are talking, whatever those motives may be.

May I make just one or two other suggestions here? Select material that comes from classes of facts, the least complex. Why? The A-B-C form must dominate the public speech. I have already stated why. You have an aggregation of people of average intelligence, and average intelligence is not expert on every conceivable subject, not by any manner of means. If that be true, then you have got to get your material in as simple a form as possible. To get your material in as simple a form as possible, it must come from classes of facts that are simple in and of themselves, wherever it is possible.

I understand that there are exceptions to that, that there are times when you must be complex, in the very nature of your discussion, but not to the general public, not to the general average hearers.

I have just two or three minutes left. I want to illustrate that. Two or three years ago an engineer came to me. He was trained in the technological schools of Germany. He was one of the most highly trained men I have come in contact with. He was a master of information in his particular field. I said to him, "What are you coming to me for?"

He said, "I find there is something the matter with me. I know my subject but I can't convince anybody else that I know my subject. I can't convince my Board of Directors that the scheme I have in mind is a good one. I want your help so that I can put that information in the proper form."

I said, "I don't know anything about your material, but if I can be of any help I will."

He was going to construct an ice plant in St. Paul. I said to him, "You come to me a week from today and make the speech that you propose to make to the Board of Directors about this ice plant." He did. I gave him a blackboard. He first drew a picture of this ice plant. I then said, "Now, go ahead and make the speech that you intend to make to your Board of Directors." He did, and he used all the technological terms that he had learned in Germany. It was a very, very fine discussion from a technological point of view. When he got through I said, "Is that the kind of a speech you would use when you would present this material to your Board of Directors?"

He said, "Yes, that is."

I said, "You know your subject, there is no question about that, but if you know any more complex facts than you have used, I don't know where you can find them. (Laughter) If you know any more technical language than you have used, I don't know where you can find it. Remember this: You are talking to a Board of Directors that are financial men, they are men not versed in the technical side of the subject; they have hired you to look after the technical phase of it. What you have got to do is to show that this thing when installed will make money, will bring in dividends."

Light dawned on the fellow. He never thought of it from that point of view. Why? He was a technical man, the whole background of his experience had been technical (I am not criticizing him at all); and when he got his illustrative material, he selected all of it from that background of experience and put it into his language just to ordinary folks.

I happen to know his Board of Directors. I know how much technical information they have, which is pretty nearly zero with the rim knocked off. (Laughter) They just didn't have any technical information. Yet they were able men in their own field. When he got his explanation into their field and into their motives he began to get somewhere with his subject.

I must stop at that point. Just a word about what I am going to do tomorrow. Tomorrow I am going to try to apply these general principles, and these general tests that I have been discussing, to the final statement; that is, the use of evidence and the statement of evidence.

ADJOURNMENT

October 4, 1928

LECTURE NO. III.**The Speaker and His Statement**

In the discussion yesterday, I went one step beyond the discussion of the first day. I think perhaps it might be well this morning to begin very much as I began yesterday morning and call attention to what I attempted to do yesterday as a way of leading into what I shall attempt to do today.

Yesterday I drew attention to what seemed to me to be two important propositions. The first was limiting one's subject to a compass which could conveniently be discussed in the amount of time that the ordinary speaker is given to discuss the subject. Second, as a part of that first half of the lecture, I drew attention to the importance of dividing the subject into its main issues or its subsidiary points and getting each one of those main issues clearly stated. I attempted, at least, to make the point that the successful speaker needed to do that because audiences could remember by points or divisions of a subject, when they could not remember and would not remember by details. Some details will be remembered; most of them will not. Now and then a striking presentation will be remembered, but for the most part nothing but the main lines of argument will be held or can be held in mind by the hearer.

Yesterday I attempted to point out certain fundamental principles that I thought ought to underlie one's selection of materials with which to develop, to explain, to enforce or to argue the points that he, during his discourse, attempts to develop. I said that I thought it was important, first of all, for the speaker to examine carefully the content of his own mind; to do his own thinking. I was interested in that primarily because, in my judgment, if you are going to get vital speaking, you will have to have vital thinking, and vital thinking comes out of one's own head and not from a printed page.

I said, secondly, in the selection of material that it was important for the speaker to get material that was interesting just in so far as it was possible. I said, in the third place, to get material that was not remote, if that was possible. I pointed out, in the fourth place, that it was important for the speaker to select his facts from as close a date to the particular occasion as possible. I pointed out, in the fifth place, that, in the selection of material, it should be selected so as to make an appeal to the experience of those to whom he was at the moment talking. Then, I said in the last place, that it was very important, in my judgment, that the speaker bear in mind the motives of those to whom he was talking.

In this discussion today, I want to say something about final statement, that is, the final form in which a speaker shall put his material; the dress, so to speak. Up to this point we have been discussing fundamental principles of outline, of organization. Now, I want to discuss some of the basic elements or basic suggestions that apply to final statement.

The first suggestion is, that final statement is but little, if indeed any, less important than the organization of material and the selection of evidence. A final statement, ladies and gentlemen, may spoil or it may make a speech. It is in the final statement that after all the individual makes himself clear or fails to make himself clear. If you will examine the history of what has been done by great speakers on this point, you will discover, I am sure, that a very large part of the power of a man like Webster, like Abraham Lincoln, like William Jennings Bryan, like Woodrow Wilson, was in their capacity to make a statement.

William Jennings Bryan says somewhere (I think it was in his speech on Abraham Lincoln) that truth is self-evident and that what you need is just a

bare statement of the truth. He drew attention to the fact that the great strength of Abraham Lincoln lay in his ability to state a truth, and to state it in such language that the ordinary individual could understand him.

Words: Is there anything to be said about words? I think there is from the point of view of the public speaker. Let his words be simple words. If he is an American, certainly let his words be Anglo-Saxon words, if he can find Anglo-Saxon words with which to express himself. I wish I might take time this morning to select certain paragraphs from the very best speeches that Abraham Lincoln delivered and then count with you the number of little, single-syllable, Anglo-Saxon words that the man employed in the most eloquent passages that he used. Consider his Gettysburg speech, which I suppose is recognized as one of the most eloquent, if indeed not the most eloquent short speech that has ever been delivered in America, and you will find that most of the words are in your vocabulary. I doubt if there is a word used in his speech that is not in your vocabulary. Did you ever make a Gettysburg speech or anything like a Gettysburg speech? Greatness of speech, then, does not depend upon unusual words, colorful words, and involved terms.

Sentences: Get simple, understandable sentences; short sentences, if you will, but not necessarily so, but a sentence that the average man or the ordinary individual can follow. I am spending a good deal of time emphasizing this. The fundamental element that lies here, I think, is illustrated in the difference between the mind of a philosopher and your mind and my mind. Your mind and my mind works in specific terms, commonplace terms. We do not think a thought out into its ramifications, into its implications. The philosopher does. He is trained to do so. But in your case and in my case, our thinking is such that it is very important that the speaker do the work for us in his final statement.

So much for final statement in general. There are four or five means to enable one to make this final statement that I want to draw specific attention to this morning. One can make his final statement by the use of one of them; he may make his final statement by the use of two of them in combination, or possibly three of them in combination, or he may make his final statement by the use of all of them in combination.

Let me run through them with you. First, restatement of the proposition as a means of developing the idea; second, the use of details, specific details in the development of the final statement; third, the use of illustrations; fourth, the use of authority or the citation of references to authority; fifth, if we get time before we get through, I want to discuss the possible use of humor as a means of final statement.

We will go back to the first; restatement as a means of development of the idea. We begin with an assertion; we affirm something to be true or we deny something to be true. At times that affirmation or that denial is sufficient. Usually for spoken discourse it is not sufficient. We must amplify, we must enlarge upon the assertion. How shall we do it? Well, one means of doing it is restatement; stating the same thing over and over and over all of the time, using different language, but emphasizing the same fundamental idea. Examine the best that you will find in speeches and you will discover that a very large proportion of those speeches are made up of this type of development.

I have this morning before me, a speech by W. C. Redfield, who used to be Secretary of the Department of Commerce at Washington. This is a speech which he made on the general subject of "Some elements that are basic in success in business." He doesn't call his speech by that subject, but that is its subject matter, if you attempt to give it a theme. I want you to note, first of all, that he specifically states the subject that he is going to develop; second, he divides that subject into three parts. He says: "Get facts; see far; think through." That is exactly what I said yesterday was important in the development of a subject, to

get at the special issues or the special points which, if developed, would make the subject impressive.

Of course, I am not going all through this speech. The first point then is to get facts. The first element in the success of business, according to Mr. Redfield, is to get facts. I want you to note how he uses restatement to emphasize the idea of "get facts." I will read one paragraph. Note that he virtually says the same idea in a number of different ways.

He says: "First, then, get facts. If we apply this principle as a measure to the business world, we shall soon see that men who live up to this principle are relatively few and lonely and that those of us who deal to a greater or less extent with fancies or with fallacies which we hope or believe are facts, are not. Few of us will go so far in practice as the man who said to me, 'If I don't know why I know what I think I know, then I want to know.' Most of us are content with assumptions, and few follow the scriptural maxim to prove all things and to hold fast to that which is good. Yet, facts, as has been well said, are stubborn things, and you may make up your mind now that during your business lives, if you do not get the facts, the facts will get you. It is not always easy to get the facts. On the contrary, it is commonly hard to get them, and because it is hard, we are apt to accept assertions as to the facts from those who think we ought to know instead of exerting ourselves to learn them directly. A business man feels, for example, that his competitor uses unworthy practices and is tempted himself to follow the bad example, lest in competition he be outdone. He does not know that his competitor does these things; he is told it and believes it, because he cannot otherwise explain some of his competitor's accomplishments. It is commonly a mistake. If he sought patiently for the facts, he would often find them, and they would save him from an error of judgment respecting another and from business mistakes upon his own part. Again I say to you, first of all get the facts."

Perhaps that passage isn't particularly interesting as read to you, but if Mr. Redfield were here on the platform and said to you, "First of all, men, if you are to be a success in business get the facts," and he should go through the quotation with lively interest, by the time he got through, his final statement would have emphasized in your minds the value first of all of getting the facts; and he would have done nothing but restate the same idea in a half dozen different ways.

This development of the ability to master restatement is not easy. It demands a lot of imagination. It demands that you see the idea that you have in mind from all of its points of view. You are never tiresome in restatement so long as you keep your idea revolving, so long as you keep your hearers seeing that idea from just a little different angle at every restatement.

I pass on now to details. What do I mean by details? I mean the statement of your general proposition as it works out in human life in one specific instance. What we need in speech to be more clear, to be more impressive, in my judgment, is details and more details and more details, provided—one reservation—you constantly keep the idea moving forward; provided that every time you introduce a new detail your idea moves forward one step farther.

I want to illustrate that. I am going to spend most of my time illustrating. You will probably get tired of me for it. Yesterday I drew your attention to William Jennings Bryan's famous cross of gold speech. I said that in that speech there was just one new paragraph, one that he had not used before. I want to use that paragraph this morning to illustrate going into details, or taking the general statement from the general and expressing that general statement in details. I am not going to be able this morning to give you the exact language of Mr. Bryan in this paragraph. I am speaking purely from memory. I haven't

seen the printed page of the speech for a half dozen years, and I don't have the speech with me.

In this paragraph the general idea is this, speaking of the opposition: "You have made your definition of a business man altogether too narrow. We do not agree with you in that definition and we propose to present our principle upon another definition." That is the general statement. Now, watch how he follows that into detail. He says: "The farmer who goes forth in the spring and plants his harvest, who goes forth in the morning and toils all day, works all summer, harvests his crop, is just as much a business man as the man who goes to the Board of Trade and bets upon the price of wheat; the merchant at the cross-roads store is just as much a business man as the merchant prince in the metropolitan center; the banker in the village, in the rural district, is just as much a business man as the group of magnates who control the money at Wall Street. The miner who goes down into the earth hundreds of feet or climbs to the mountain top thousands of feet, digs into the ground and takes from it the treasures of the earth and gives them to the human race, is just as much a business man as the man who gets in a back room and corners the money market of the world. I say to you that it is for this larger group, this larger division of business men that we are here to speak."

Note the general statement, note how he goes into details; then, after he has gone into details and shown how his idea works in specific instances, he comes back to his original proposition. That is what he meant by saying, "You have made your definition of a business man altogether too narrow."

This takes me to the third step, the use of illustrations. There is, of course, considerable relationship between the use of illustration and the use of detail. Men, if you don't think anything important, in all of these four talks that I shall deliver, I do not believe you can escape the importance of this one, this point, if you expect to deliver talks to general audiences. If you don't remember anything else that I say I beg of you to remember this and to apply it.

What do I mean by an illustration? By an illustration I mean the way a general idea, when it is applied to human experience, works. Why is it so important? Why does it get hold of an audience as it does? It goes back to the principle I mentioned in the opening of my remarks, that we, as a people, have the ability to see a general idea when it is at work, when it is applied, when we don't have the ability to think it out into its implications, unless that is done for us in a specific illustration.

I want to examine carefully the use of illustration. I want to illustrate the thought in two or three different ways. First, I am going to take an illustration from Russell H. Conwell's great lecture, "Acres of Diamonds." Russell H. Conwell, as I suppose some of you remember, was the President of the Temple University in the City of Brotherly Love to the south. He delivered this lecture 6500 times. Do you know how often that is? That means one lecture every day for more than eighteen years. Why do I mention that? I mention it to show that this lecture had vitality. Wherein was its vitality? In my humble judgment, its vitality with great masses of people rested in the skill with which he used concrete illustrative material.

Let me show you, from just one section of that speech (I have used this paragraph in the presence of a few of you before, but it is well to repeat it) how Conwell expressed himself. The general theme of this lecture is this: Your success lies in grasping the opportunity that lies next to you and not going somewhere else. Again and again throughout this two hour discourse he uses illustrations to enforce that idea. Here is one of them:

"Professor Agassiz, the great geologist of Harvard University, that magnificent scholar, told us at the Summer School of Mineralogy, that there once lived in Pennsylvania a man who owned a farm, and he did with his farm just what I

should do if I owned a farm in Pennsylvania, he sold it. But before he sold it, he decided to secure employment selling coal oil. He wrote to his cousin in Canada that he would like to go into that business. His cousin wrote back to him, 'I cannot engage you because you don't understand the coal oil business or anything about its production or anything about its marketing.'

"Then said the man, 'I will understand the coal oil business,' and with commendable zeal he set himself at the study of the whole theory of the coal oil subject. He began away back in the second day of God's creation. He found that there was once another sun that shone on this world and that then there were immense forests of vegetation. He found that the other sun was put out and that this world, after a time, fell into the wake of the present sun. It was then locked in blocks of ice. Then, there rose mighty icebergs that human imagination cannot grasp and as those mountains of ice did ride those stormy seas they beat down this original vegetation. They planed down the hills and toppled over the mountains and everywhere buried this original vegetation, which has since been turned by chemical action to the primitive beds of coal and in connection with which we find our finest supply of oil. So, he had found where oil originated. He studied it until he knew what it looked like, what it smelled like, and how to refine it, how to sell it, and where to sell it.

"Now," said he, in a letter to his cousin, 'I know all about the coal oil business from the second day of God's creation to the present time.' His cousin replied to him, 'Come on.' So, he sold his farm in Pennsylvania for \$833,—even money, no cents.

"After he had gone from the farm, the farmer who had purchased his place went out to arrange for watering his cattle, and he found that the previous owner had already arranged for that matter. There was a stream running down the hillside back of the barn. Across that stream from bank to bank the previous owner had put a plank edgewise, for the purpose of throwing over to one side of the brook a dreadful looking scum through which the cattle would not put their noses, though they were perfectly willing to drink on the lower side of the plank.

"Thus, that man who had gone to Canada and who had studied all about the oil business had been himself damming back for twenty-three years a flow of coal oil which the State Geologist, in 1877, said was worth to the State \$100,000,000. The City of Titusville, Pennsylvania stands bodily on that farm now. And yet, though he knew all about the theory of the coal oil business, he sold that farm for \$833, and again I say to you, no cents."

There are two or three things in connection with that illustration I want to emphasize. Let me take you back to the point from which we started. This is rather a large class, but nevertheless this is an academic class. This is a school-room this morning. I want to take you back to the point from which we started. I said I wanted to point out the value of the use of illustration. I want you to note how he states his theme, which is, that the greatest, finest chances any man will ever have for success will be found in grasping the opportunities that lie next door to him. Then, with that general principle in mind, he goes forward to use this illustration, which is taken from life.

The first thing that I want you to note is that the illustration is interesting; it is an interesting incident in human life; it has human values in it. You listen to it as a delightful story of human experience. If it didn't have any thought-developing or thought-arguing or thought-explaining value, it has interest in and of itself.

The second thing I want to point out to you about that illustration is that it is simple, it is conversational, it is just common sense.

The third thing about that illustration to which I want to draw your attention is that it moves his thought forward; it amplifies, it enforces. The last thing I want to draw to your attention about that illustration is that it is enertaining.

It has just a touch of delightful humor in it; gentle, to be sure, nothing biting, nothing stinging, nothing sarcastic about it. It isn't ridicule; there is just a touch of humorous observation. The finest humor in the world, certainly of American humor, is of that kind.

The man who expects to make speeches needs to learn to be a master of illustrative material. Let me go a little bit farther. Suppose we want to illustrate our ideas by the use of statistical material, and that is a good way for a business man to develop an idea, if he is skillful in his use of statistical material. Let us take a proposition, and I will take some facts that I happen to have in my head with which to illustrate it. Let us take this proposition: The marketing of food commodities in the United States is a complex, interdependent and interlocked business. The people living in one section of the country—we will use a little restatement here—are very materially dependent upon the people living in another section of the country. Let us state that idea again. The people living in one section of the country are very much dependent for their food commodities upon the people living in another section of the country who are responsible, let us say, for transportation, or interested, let us say, in manufacturing.

Note how the idea works in actual application. I am indebted to Superintendent Johnson of the Pennsylvania Railroad for some figures which I think illustrate my point. He says that in a given year there were loaded and shipped in this country 60,921 carloads of fresh vegetables and fruits that had their origin west of the Mississippi River. The average per car haul between the source of the production and the source of ultimate consumption was 2503 miles. He goes on to say that there were 5222 carloads of these commodities, these food commodities, that had their origin south of the Mason-Dixon line and the average per car haul between the source of production and ultimate consumption was 1030. There were 20,060 carloads of these fresh vegetables and fruits that had their origin north of the Mason-Dixon line, and east of the Mississippi River, and the average per car haul, between the source of production and ultimate consumption, was 433 miles. That shows over 85,000 carloads of fresh vegetables and fruits shipped in this country in one year with an average per car haul of 1520 miles.

All I am trying to do here is to show how one can use statistical facts as illustrative material to bring out one point which is that our marketing of foods in this country is complex. You may say in general terms as eloquently as you are capable that our marketing system of food commodities is complex and I don't believe you can make it as vivid, that you can make it as impressive as you can make it impressive and vivid by the use of some such statistical material as I have pointed out.

We are engaged in the safety business in this convention. I want to point out by way of illustration the use of just one figure that I find here in this book. Suppose we are interested in safety as a means of preserving human life, and we want to show how serious a problem it is in the United States. I may turn to this speaker's manual which I hold in my hand and I discover the statement made here that the total accident fatalities in the United States in 1927 was 95,500 people. That is a detail, that is statistics. How much does 95,500 mean to the average hearer? It may mean a good deal. It will mean a good deal more if you, as a speaker, somehow or other can take that figure, hold it up to view, analyze it, compare it with something else and make its bigness apparent.

There might be many ways in which to do that. I want to suggest one way. Beginning in 1917 and running to November 11, 1918, we were in the World War. We left a lot of soldiers buried over in France. Yet I call your attention, friends, to the fact that we kill in industry and in social life in this country, each year, nearly twice as many American people as were killed and buried in France as a result of the World War. We are horrified at the loss in war; yet we just move easily along in our industrial life and scarcely reflect upon the significance of the

industrial and social loss. All I am trying to do now is to show how, by the use of illustrative material, you can enforce an idea.

I said that perhaps it was possible now and then to use humor to amplify and to enforce one's idea. I don't happen to be a humorist. I wish I were, that is, sometimes I wish I were a humorist. Humor is an excellent thing in speech making, provided you know how to use it and don't overuse it. Humor is a dangerous thing for the speaker. Let me make this suggestion to you humorists. If you ever expect to be taken seriously don't get a reputation for being a funny man. It will ruin you as an effective speaker if you desire to be taken seriously. Tom Carwin, who used to be one of the great orators and statesmen from Ohio, always thought, I think went to his death thinking, that the only reason he was not nominated for the Presidency of the United States on one occasion was because he had the reputation of being a funny man.

An overdose of humor defeats itself but a judicious use of humor can be very, very effective in this matter of final statement. Let me just illustrate with a story that I think is a bit old. I know I have used it before. I heard one man, at least, besides myself use it. Let us take our general proposition now. Suppose we are trying to illustrate the significance of the United States as a geographical and a business and a social unit, its extent, its magnificent accomplishments and magnificent distances; and anybody who travels around over this country, if he uses any imagination at all, must be tremendously impressed with the extensiveness of the United States. That is our general idea. Let us see if we can use humor to illustrate the significance of it. An Irish traveler who considered himself very much a traveled man, who had been all over Ireland, planned to come over to this country and to take in the United States. He landed in New York. After considerable confusion, he found himself in one of the rear Pullmans in the Grand Central Station, and with his ticket for Chicago, San Francisco, Los Angeles, El Paso, Tulsa, New Orleans, Birmingham, Washington, Philadelphia and back to New York.

As you know, if you have gone out from the Grand Central Station, it takes a long time for the conductor to come back to collect your ticket, especially if you happen to be in one of the rear cars. By the time the conductor got back to collect the ticket, the Irishman was considerably disturbed, and as he pulled out his yard and a half of green paper he said to the conductor, "Now conductor, you won't let me go by, will you?" (Laughter) Just remember, he is on his way to San Francisco. The conductor promised he wouldn't let him go by. The train went north through Harmon, Yonkers, Poughkeepsie and Hudson, and after two hours and a half stopped in Albany. Here the Irishman got up, picked up his bags and started to get off and was considerably surprised when it was announced that he hadn't reached San Francisco yet.

The train went on through Syracuse, Rochester, Cleveland, Toledo and into Chicago. Here, you know, in the nature of things, he must change trains. He was very indignant when the red cap insisted upon his getting on another train. He did so. He was on his way west, out across Illinois and Iowa and Nebraska and through Wyoming. After three days and nights of rather tedious travel, the train rolled into San Francisco. By this time the Irishman was completely subdued. He sat back in his Pullman seat in a sort of a semi-comatose state. When the train stopped, he made no move to get off at all, until the porter came in and said, "This is San Francisco; this is as far as you go."

The Irishman got up, picked up his bags, stepped down on the platform and stood there looking over the Golden Gate of California. Then he said, "So, this is San Francisco, is it? And they say it is wonderful that Columbus discovered America. It is not wonderful; how in hell could he have missed it."

Well, that is a good yarn even though you have heard it before. I get a kick out of it every time I hear it. What I am trying to suggest is that one may use

humor to illustrate, to enforce, to amplify his idea, and wherever it is possible to use humor in that way, it is an excellent thing to do.

Abraham Lincoln was one of the greatest masters in the use of humor. He was known as a story teller. Examine his history, as I have gone to some pains to do, and you will find that nearly always, when Abraham Lincoln used humor and at times when he was criticized for doing it, he had a thought, an argument to make by his application of it.

May I suggest, just in closing on this particular point, that the speaker be careful about the use of ridicule just because it is funny. If you expect to be taken seriously, use ridicule guardedly is my suggestion. I don't mean to insist that there are not some values in certain types of ridicule. I mean to suggest this, ladies and gentlemen, that when men get to be masters of ridicule, and some of them are, they want to ridicule everything. When ridicule has a sting in it, you don't win, you repulse. Avoid it, is my suggestion.

When you use humor, let the element of human kindness and human sympathy get into that humor. One need not be less humorous because he is kindly or sympathetic. Such humor is likely to be in the long run more effective.

There is one other form of support that I won't have time this morning to discuss, but just suggest, namely, the use of authority. In a complex age such as we have, it is very important now and then for us to depend upon authority. When we do so, let me suggest the importance of testing that authority. Is it mere hearsay, is it prejudiced, has the man you quote been in a position to know, does he understand what he is talking about, is there too much dependence put upon one authority, is the authority supported by other evidence?

Lastly, is the authority cited by you, as a part of your final statement, likely to be accepted by those to whom you are talking? Such are some of the general tests that need to be applied to this last form of support, the citation of authority.

Tomorrow morning, I expect to get the speaker on the platform and to say something about his performance there. If you still have endurance, I shall be glad to see you again tomorrow morning.

ADJOURNMENT

October 5, 1928**LECTURE NO. IV.****The Speaker on the Platform**

In our talk yesterday, we spent some time trying to develop the important elements that needed to be observed in making the final statement. In that discussion, I made an effort, at least, to emphasize the importance of final statement, saying that even a good argument backed up by thorough-going, thoroughly analyzed evidence might be very materially marred because of the ineffective way that the final statement was put together. I tried to illustrate that thought by drawing attention to how masterfully such men as Webster and as Lincoln had illustrated the importance of final statement.

As a means to get final statement, I pointed out five different steps. I drew attention to restatement as the first step, which means nothing more or less than this, holding the single point of view up to attention long enough for those who are listening to be impressed by the importance of it. Sometimes a mere statement of the point of view is sufficient. At other times, it is not sufficient.

I made some distinction between putting a point just for the purpose of clearness and putting a point for the purpose of impressiveness. An idea may be expressed so that it is clear but yet not be particularly impressive. The main step in getting impressiveness is to hold the idea before the hearer long enough for him to examine it from many points of view. It takes restatement to do that.

The second step I emphasized was the matter of putting your statement in details.

The third step, I emphasized yesterday and I suppose so long as I live will emphasize, was the importance of the concrete illustration, which is nothing more or less than an enlarged detail. There was one thing I neglected to say about an illustration that perhaps I ought to say, lest I be misunderstood somewhat. An illustration in and of itself is not argument. It may help an argument. It may clarify an argument. But, since it is but one detailed bit of evidence, extended and applied in life, one cannot rely upon it as the sole body of evidence that he uses. But, for the purposes of clearness, for purposes of persuasiveness, for purposes of getting attention and sustaining attention, I do not believe, as I tried to point out yesterday, that there is any step, in this whole matter of speech, that is quite so important as the correct, the adequate use of the illustration.

Then, I tried to point out that humor might be used as a means of getting final statement. I offered one or two bits of caution on this matter of entertainment. The last form of support to which I alluded was the matter of use of authority.

There was one phase of that that I did not get time to emphasize yesterday that perhaps I ought to emphasize a little bit more today. I think we have too much tendency, as speakers, to rely too soon, and perhaps too frequently, upon authority. As a matter of fact should we not become so thoroughly familiar with the material with which we deal that we are authorities ourselves upon it? Should we not get such a grasp of the evidence, upon which our conclusions are based, that we ourselves become authorities and don't have to rely so frequently upon the statements of others? But, as I pointed out yesterday, in this complex age that is not always possible. We must rely in some cases upon the judgment and the conclusions and the investigations of others.

In this talk today, I call the speaker to the platform. That is rather a large subject. I remember that Opie Reid, the author, appeared one summer on the program of a Lyceum and Chautauqua Association. He always began his address by saying, "Ladies and gentlemen: My subject for this lecture is 'First one thing and

then another.' I select that subject because I can say anything I want to say on it and never get off the text."

That is pretty nearly what I can do with this subject that I have in mind this morning, the speaker on the platform. I am afraid this talk will be a bit scattered, not particularly well organized, because there are a number of hasty suggestions I want to make, and they will be suggestions only.

When the speaker steps upon the platform before an audience, what is the sense that is first appealed to? The first impression that an audience gets from a speaker is, how he looks. Does he look the part? Can he be made to look the part? I do not mean that the man who is handsome or large. A balloon is large, but the inside of it is light of weight. I have seen speakers that were not so very far from that characterization. I do not refer to anything of that sort. Does the speaker, when he takes his position before a group of people, give the suggestion of command of the situation, or does he give the suggestion of being afraid? Does he, as it were, pull away? Let me make this suggestion to you: Either you will command the situation or the situation will command you.

I don't know of any more painful experience through which a man can pass than to step before an audience and feel that that situation and that audience commands him instead of him commanding the situation. The speaker under such circumstances simply dies by inches. You need, first of all then, before a group of people, to give a sense of command in the way you step before them. You are eager; you, for example, are not afraid to look that crowd straight in the eye. Have you, when you step before a group of people, the command of your thinking and emotional machinery so that you can look a man in front of you right in the eye and keep on thinking? It is an unusual relationship, it isn't quite normal, but it is a relationship in which the man must learn to take the aggressive, the commanding attitude.

I am so fond of using William Jennings Bryan as an illustration that you will think I am one of his enthusiastic supporters. I never agreed with William Jennings Bryan on anything. (Laughter) I never agreed with him politically, and I may say religiously. I wouldn't say I entirely disagreed with him on matters of religion, but certainly on matters of politics I do disagree with him, and sometimes I have been mistaken, too. I never disagreed with the proposition that William Jennings Bryan was a master on the platform. I do not believe in my generation we have had his equal. When he stepped upon the platform, you knew by the way he looked at you, by the way that personality of his radiated energy that he had a command of himself and a command of the situation. Can you get it?

You are not William Jennings Bryan's nor am I, but we can develop some power by thought, by practice, by getting a mastery of material and thinking through ways and means of controlling one's self.

Secondly, as that audience looks at you, when you step before it, does it get the impression of a friendly individual or an unfriendly individual? One good speaker that I know is a thorough-going, natural born, aristocrat. When he begins his speech he is distant to his audience and his audience feels it. It is only after the man gets emotionally warmed up that you begin to feel anything like communication between the hearer and the speaker. Among the incidental things, there is nothing I think that is any more important than to give the audience the impression that you like them. If you know yourself not to like them, if you know that you do not have patience with the mistakes of folks, patience with human foibles and idiosyncrasies, I doubt very much if you ought to try to approach them through the medium of public speech. If on the other hand you do like folks, there isn't much of any reason why you can't give the people the impression of liking them.

Let me give you a striking illustration of this principle as it worked out on a great occasion. I quoted yesterday from the Commoner's speech in 1896. Just preceding Mr. Bryan on the platform was a Senator who was no mean speaker; a

man of a good deal of power. I do not remember which side of the resolution he was debating at the time. It does not make any difference. I remember this, and this is the record, that the Senator had not been speaking more than a minute or two, when somebody in the audience who was opposed to his proposition, shouted at him. Immediately the Senator clinched his fist and for the next thirty minutes just shouted and smashed at that audience and they jeered back. He was not heard by more than 100 people in that crowd of 15,000 people.

When William Jennings Bryan took the platform, what happened? The first thing that William Jennings Bryan did was to smile. His smile was persuasive. The first thing that he did was to radiate good nature. He liked folks. He showed that he liked folks and before he had gone a half dozen sentences that radiating, friendly, personality was out over that hall. He got his hearing. And one element in it, not the only element, there were many of them, was the fact that instead of slashing that audience with a bitter tongue, he appealed to them with a friendly approach. The speaker as he faces an audience gives that impression at once or he fails to give that impression at once.

Now, the third suggestion, which is a very general one, is on the matter of sincerity. The very position you take before a crowd, the very way you look at them has a good deal to do with whether or not you suggest sincerity for the occasion. I know that there are those who attempt and sometimes simulate sincerity, but I am one of those who believe you can't do it very long. If you don't know a subject, and if you do not have conviction within you about the subject, very soon that limitation gets out into the personality; it becomes a part of the inflection and the quality of the voice that you use and, without your knowing how gets to the crowd and gives it just the impression you do not want given.

The second impression that comes to an audience is through the sense of hearing. They hear what you say, and that goes to the whole matter of voice. In the first lecture I said something about the voice, the production of the voice, the projection of the voice, and so forth. I am not going to repeat what I then said.

There is one phase of the matter of voice to which I do want to make allusion, because the question has been raised with me, how to avoid the speaker's sore throat, how to avoid strain so that the man isn't completely tired out? I have just one suggestion on that. Usually the speaker's sore throat does not arise from a wrongly produced voice, a wrongly placed or focused tone. It usually arises out of an overuse of the voice with the result that there is muscular strain. Let me see if I can amplify that just a little. Your whole vocal mechanism is delicate. It is delicately adjusted and, when you subject it to the same strain at the same rate for too long a time, it is going to get tired and, of course, it is going to wear out.

I had a splendid illustration come under my observation some time ago of a young preacher who talked three times on Sunday. He always got hoarse about midway in the second sermon. He came to me for some help. When he talked to me, he had an excellent conversational voice that seemed to be properly produced. He didn't have anything physiologically the matter with him, and I told him so. Then, I suggested that he get some passage like Lincoln's Gettysburg address, commit it to memory and come to present it to me as nearly as he could the way he preached. This he did. It was interesting to me that he began just as vigorously as he could and as rapidly as he could, with that simple conversational bit of English, never varying the loudness or the rate. He hadn't spoken a minute when I had discovered his difficulty. It was not a matter of voice production, nor placement at all, it was a matter of overuse of his voice on the same dead level. We don't allow that in music. If a musician would attempt to do that, you would either egg him or run out of the hall. But, we allow it again and again and again with our speaking. We lack variety.

That leads me into the four or five main suggestions I want to make in connection with the oral effectiveness with which we can express thought.

Why do we have speeches anyhow? We have speeches because we believe that through the medium of speech we can make thought effective, in a way that we couldn't make thought effective without the medium of vocalization. If we didn't believe this we wouldn't have our preaching, we wouldn't have our after-dinner speakers, we wouldn't have our oral discussion of any kind. The basic elements of this effectiveness, from an oral standpoint, lies in emphasis, ways and means of emphasizing thought by the use of the voice and the personality. What is emphasis anyhow? No technical definition will here be given. I have one suggestion. Emphasis is contrast. You make an idea emphatic because you make it stand out above or beyond or aside from that general level of expression that we call the normal.

You folks in earnest conversation are emphasizing all the time and are unaware of the fact that you are using contrast in oral discussion to bring out emphasis. There are five means of getting this emphasis and this contrast that I want to present to you. I will name them. The use of slide, the use of change of pitch, the use of change of force, the use of change of rate, and the use of change of time. Let us look at them very briefly, each one of them. What do I mean by the use of slide as a means of emphasis? The slide of the voice, 3-4-5-6, notes on the musical scale on the keynote word of an idea to make that idea impressive. You grip the idea by a vocalized slide upon the important word in the midst of other words that clothe or express the idea. Every time my finger falls I drive the word home. Let us take a sentence. "The world will little know nor long remember what we say here, but it can never forget what they did here." That is a line from Abraham Lincoln's Gettysburg address. Let us emphasize it a little bit. The world will little know nor long remember what (The speaker here illustrated the use of the slide by his own emphasis.) we say here, but it can never forget what they did here. The "saying" is made to stand out against the "doing" by the use of the slide of the voice.

I have illustrated the use of slide, where you have contrasting ideas, but you use slide in every sentence whether you know it or not. What I am suggesting to you or wanting to suggest to you is this: That if you will study what you do in earnest conversation and then will enlarge the emphasis on the keynote word in the use of that same sentence before an audience, letting the slide be twice or three times as long as in conversation, you will have produced the emphasis that meets the demands of the public speech. Anybody who will give attention to this matter can develop some ability in the use of slide.

The next step is variety in pitch. Here we American speakers have not developed, I think, as much facility as we should. We speak almost entirely upon the same dead level of pitch. Let us draw three lines here, imaginary lines. I have a blackboard and I am drawing three lines. Here (indicating) is our normal level, and this is high pitch and this is low pitch. For the most part, we speak right on this level (indicating). Remember that emphasis is contrast. We can emphasize an idea by shooting it up to the higher level, and that idea will be emphatic just in proportion as the line is long between this normal level (indicating) and this higher level (indicating). We can, by dropping the idea to the lower level, get a contrast. We do not have much facility in doing that because we haven't paid much attention to it. There isn't any reason why we shouldn't get more facility than we have.

There is just one phase of this thought that I want to draw special attention to. I said emphasis was contrast. Why don't we, when we speak, go quickly from high pitch to low pitch? Note the sharp contrast? I submit to you, you don't do that sort of thing very much. Have you ever given it much thought?

I suppose a number of you listening to me heard Rabbi Wise the other night. I did not hear him, but I have heard the man. I know something about the methods unconsciously used by him. One of the striking elements of emphasis he uses to make his thought emphatic is this wide range in the use of the various

pitches of the voice. Rabbi Wise has a voice of marvelous range. It is not uncommon for him at all to be up here (indicating) and to have the next word drop down here (indicating); and every time he does, he gets attention, every time he does he arouses a little intellectual curiosity as to what he is talking about. We can develop some of this power.

The third suggestion, because I see I must hurry on, is as to variety in force. Once more I want to say that we, as American speakers, have just one direction in which we use force as a means of emphasis, and that is more force and more force and more force. My minister friend in front of me here will remember the day, I am sure, when the typical Methodist Bishop was thought of value as a preacher, just about in proportion as he could shout himself up to Heaven. What I want to suggest is that force is emphasis in proportion as there is variety in its use.

Let us think of it in lines now. Here (indicating) is our normal level. If you increase in volume up to that point (indicating) there is emphasis. If you stay there too long, it ceases to be emphatic because there is no variety, there is no contrast. Too much force, for too long a time, lacks emphasis just as much as a dead level conversation for too long a time lacks emphasis; and loud force is unpleasant, if you have to listen to it for any great length of time.

Is there any reason why the speaker in his address, provided the thought allows it, should not use a great deal of force at one moment and then the lighter degree of force the next, thus getting sharp contrast? To get facility at this point is worthy the effort of any man who wants speech power.

I now come to the fourth suggestion, which is change in rate. Once more I say that we speakers express ourselves almost entirely at the same rate. If we have any change of pace, it is from the slow to the fast and then to the more fast. Why not change that pace and give your audience a rest? May I pause here to emphasize the psychological, almost the biological phase of this? You folks, as you sit out there in front of me are imitative creatures emotionally, whether you are conscious of it or not. If as I speak, I speak at a continuous strain, without any change of rate or of force or of time, very soon you drop into my tenseness and I wear you out. You imitate, but you are not conscious of it. That is the way we are made up. We are delicately adjusted nervously. The speaker who does not remember that the people with whom he is dealing are thus made up, is not using the strongest devices that he has.

The fifth and last suggestion is the change of time, the use of pause as a means of emphasis. Few American speakers, excepting those who are intensely dramatic, or perhaps are dramatically trained, use pause very effectively. Let me illustrate that by one sentence. I will take a sentence by Charles Dickens in which he is characterizing or describing a little girl. He speaks about her poverty and about how hard it is for her to get a breath of fresh air, and then he says: "Nobody came to see her, nobody asked about her, nobody (indicating pause) cared about her." Do you see how you can hold attention on that word "cared" and bring out the full meaning of it? You don't do that very often, friends, in speaking. The change of slide, change of pitch, change of force, change of rate and the use of pause, all of these elements can be used more effectively than we have used them.

I said in my first lecture that the outstanding fault of the American speaker was his indistinctness. In my judgment, the outstanding second fault that I would emphasize in connection with the weaknesses of American speakers is their lack of variety, and you as businessmen, who are called upon to speak, never give any attention particularly to the subject. Don't misunderstand me, I am not criticizing you or blaming you for this, I am simply stating what I believe to be a fact as a result of my experience with a great many businessmen and of my attempts to help them.

Here is an interesting situation. If any of you were to attempt to sing, and probably some of you do sing, how long would you take in training yourself to be singers? If any of you were attempting at any time in your lives to attempt to be artists, painters of pictures, how long would you give to the subject of training to be painters or sculptors? You know well enough that no musician would give a public performance of any kind without spending a large part of a lifetime in mastering the technique of his art. Yet, we have, in this country, a notion that if you have something to say all you need to do is to get up and say it and the result is the best possible. The art of expressing ideas orally effectively, persuasively, pleasantly, is just as complex an art, as the art of oral expression of music. The musician, however, has this advantage over you, the path over which he is to go is written out, he goes up, he comes down, he changes rapidly, he moves, or he pauses according to his written page. What do you do? As speakers you make your own music as you go along. We are continually doing that sort of thing without any preparation at all. I want to emphasize the use of these elements I am talking about this morning as a difficult thing and it takes time to use them well.

So much for the use of the voice. There are two or three other suggestions I want to make. What about action, physical action, gesture and whatnot? I usually avoid talking about gesture and physical action. But just as sure as I do, before I get out of that door somebody will come to me and ask me about it. Shall there be any physical action? I am not particular whether there is physical action or not. I have no pet rules or pet hobbies at all on the matter. Some of the best speakers I know scarcely have any action whatever and some of them act a great deal. A great deal depends upon the individual. I would not, if I could, make model speakers out of you. I would not standardize you, if I could. There are two or three suggestions, practical ones, that I do want to make. If you are going to act at all, don't let that action get in the way of your effectiveness. I have no doubt at all but you have seen speakers begin on the platform with their notes here, they will get down over a note, look at it, and then with their hands behind them, they will walk over here and talk at you and then before they finish that portion of the subject will be back over here where they will get another note and start over here and then walk back over here. (Speaker indicating.)

There are two things to be said at this point. The first is that the speaker who does that is constantly suggesting to his audience emotional unrest on his own part. That unrest, without his being conscious of it, is getting from him to that audience. An important item to be borne in mind in this matter of movement is this: That nearly everyone in an audience likes to have the speaker in line of vision. Every time the speaker moves from this position to that position, the heads out there in front of him have got to change to keep him in line of vision, because as the speaker moves, a head comes between somebody's eyes and him. But, as he gets over here and talks to his audience and gets them all nicely settled, he at once takes it unto himself to walk somewhere else (laughter) with the result that there must be a complete adjustment with a very large number of people out in the audience.

I had a very striking illustration of that come to my attention with a friend of mine who was quite active, almost athletic upon the platform. He said to me, "I don't seem to be able to get people to rivet their attention upon me. I work for everything that is in me and I can't hold their attention for any length of time. You are in this business, tell me what is the matter." I couldn't tell him what was the matter. I said to him, "You tell me when you are going to deliver the next speech and I will go and listen to you." I watched him with his parade. I had the answer to the question. He was an interesting speaker. He had interesting material. I had to get him to stand still.

I don't know how many of you are going to speak to large audiences, that is, audiences of 5,000 people. (Laughter.) That seems to be funny. You may get a chance to do that sort of thing before you know it. Let me make this suggestion to you so far as action is concerned. If you have a large audience, don't talk to the man over on this side and then talk to the man over on the other side. Every time you do that, you cut off a much larger percentage of your audience than it is necessary to cut off. If you talk straight in front of you, you are going to get the direction of your voice and the direction of your thought to the largest number of people possible in that audience. It is true that these people on the side will not get the same direct address that these people in front will, but they will get much more effectiveness when you are talking here than these people over here will get when you are talking over there (indicating). I saw this matter illustrated with an audience of 5,000 people most capitally in Rochester, New York, many years ago where one speaker stood still and held his audience riveted. The other speaker did this sort of thing (indicating) and a large part of the time when he was talking over here, nobody over here got anything. A little thing, I repeat, but worth attention.

I don't suggest that you attempt to eliminate all of the individual characteristics that you have, not by any manner of means. I think Clarence Darrow of Chicago would spoil his effectiveness before a crowd a great deal, if he would take the hunch out of his shoulders. I don't know whether any of you have heard him or not. He has a peculiar hunch in his shoulders. That is a mannerism of his. I wouldn't suggest that he take it out, because when you see that, you know something is coming and you listen for it. It really is an asset. If you know that your mannerisms are assets, keep them. However, this general rule ought to be applied: whenever a mannerism gets in the way of your thought and fastens the attention of an audience upon it, it ought to be eliminated.

For example, I have a very good friend, a teacher, who, when he lectures to his class has just three things he does. First, his notes; second, the corner of the room; third, the window. He just cuts that triangle for a solid fifty minutes. He never looks at a student. What happens? I will tell you what the students tell me happens. They take out their watches and time him, see how long it takes him to make the rounds. A little extreme, surely, but I have seen things almost as bad as that. I know a man who speaks a great deal who does this constantly (indicating). His collar is plenty large enough and for the most part, I think, it is comfortable because when he isn't on the platform he doesn't have any trouble at all. When he is on the platform he does this sort of thing (illustrating) quite continuously until he begins to attract attention and the folks wonder when he is going to do it next. An individual characteristic that becomes a mannerism of that kind ought to receive a little attention.

I have just one more thing. If you are going to gesture, let the gesture correspond to and be a natural outgrowth of the type of thought that you are using. Let me give you one or two extreme illustrations of that. One of my old college professors used to be very fond of telling us in chapel how he loved us as students. He would say, "I love you." But, every time he said so, he would say it this way: "My dear students, I do love you," and then he would shake his fist. I suppose he wanted to emphasize the depth and height and breadth and thickness of his affection. We college boys used to sit down in front, and we caught nothing of the intensity of the dear man's emotions; we watched his pugilism.

I have heard men talk about the immortality of the human soul and just pound the pulpit until it hurt. That is a strange misfit. If we are going to have action, let us get it to fit the occasion and in proportion to the thought and the emotion and the coloring of the expression. The important part of a physical action, if used at all, is the finish. A gesture like this (illustrating) is terrible. A man

begins to talk enthusiastically about a subject and his hand will begin to rise, and you see it quiver with emotion, and just about as he gets the important part he finishes up this way (illustrating). The strength of the action is in the finish.

My time is exactly up, and there are one or two other things I wanted to say but can't.

Speech is my hobby, but one phase of it is also my hobby, stop when they ask me to stop.

Friends, you don't know what a joy your presence here and your attention and your long suffering, patience and endurance has been to me this week. I want you to know that I appreciate it. I am going to take my train in a few minutes. Before I do, I want to wish you good luck and a safe, safe year for the next one. Thank you.

R. B. MORLEY (Secretary-Manager, Industrial Accident Prevention Association, Toronto, Canada): Gentlemen, I think, if we left this room without a formal motion of thanks to Professor Hardy, that we would be doing a thing that no safety man would do, and that is an ungracious thing. I want to move, if I may, and I would like one of the ladies to second the motion, that a hearty vote of thanks be extended by his good friends to Professor Hardy for what he has done for us in these four days.

(The motion was seconded.)

(The audience arose and applauded.)

ADJOURNMENT .

SEVENTEENTH ANNUAL SAFETY CONGRESS
NATIONAL SAFETY COUNCIL

A. S. S. E.—Engineering Section

New Section Officers 1928-29

Chairman—J. I. BANASH, Consulting Engineer, Chicago, Ill.

Vice-Chairman—E. F. BLANK, Jones and Laughlin Steel Corporation, Pittsburgh, Pa.

Vice-Chairman—C. B. AUER, Westinghouse Electric and Manufacturing Company, East Pittsburgh, Pa.

Secretary—W. DEAN KEEFER, National Safety Council, Chicago, Ill.

Assistant Secretary—GENE S. WOOD, 29 W. 39th Street, New York City.

Executive Committee: THE OFFICERS AND—

R. M. ALTMAN, Marathon Paper Mills Company, Rothschild, Wis. (*Paper and Pulp Section*).

A. L. ARMSTRONG, Eastman Kodak Company, Rochester, N. Y. (*Chemical Section*).

CAPTAIN G. BARTLETT, Cosmopolitan Shipping Company, Hoboken, N. J. (*Marine Section*).

E. W. BECK, United States Rubber Company, New York City.

J. C. BERND, Sinclair Refining Company, East Chicago, Ind. (*Petroleum Section*).

G. W. COOK, The Travelers Insurance Co., Hartford, Conn. (*Textile Section*).

F. A. DAVIDSON, Chesebrough, Whitman Company, Inc., Long Island City, N. Y. (*Construction Section*).

A. F. DUNNEBACKE, General Motors Corporation, Detroit, Mich. (*Automotive Section*).

H. W. FORSTER, Brown, Crosby and Company, Philadelphia, Pa.

J. B. GIBSON, Western Electric Company, Chicago, Ill.

H. B. HARMER, The Philadelphia Electric Company, Philadelphia, Pa. (*Public Utilities Section*).

S. H. HARRISON, Vulcanite Portland Cement Company, Phillipsburg, N. J. (*Cement Section*).

ERNEST HARTFORD, American Society of Mechanical Engineers, New York City.

C. L. HUNGERFORD, Firestone Tire and Rubber Company, Akron, Ohio. (*Rubber Section*).

F. L. HURLBUTT, Patent Scaffolding Company, Chicago, Ill.

S. R. JENSEN, Armour and Company, Chicago, Ill. (*Packers and Tanners Section*).

ALEXANDER LACKEY, Consolidated Expanded Metals Company, Boston, Mass. (*Boston Chapter*).

M. G. LLOYD, U. S. Bureau of Standards, Washington, D. C.

R. MCA. KEOWN, Industrial Commission of Wisconsin, Madison, Wis.

- F. F. McLAUGHLIN, Rock Cut Stone Association, Washington, D. C. (*Quarry Section*).
 EDWARD MALTZ, The Cleveland Railway Company, Cleveland, Ohio. (*Electric Railway Section*).
 T. O. MEISNER, American Can Company, Maywood, Ill. (*Power Press Section*).
 H. W. MOWERY, American Abrasive Metals Company, New York City.
 G. A. ORTH, American Car and Foundry Company, New York City. (*Woodworking and Lumber Manufacturing Section*).
 R. E. PROUTY, Aetna Life Insurance Company, New York City. (*Food Section*).
 A. D. RISTEEN, The Travelers Insurance Company, Hartford, Conn.
 G. E. SANFORD, General Electric Company, Schenectady, N. Y.
 H. S. SMITH, Union Carbide and Carbon Corporation, New York City.
 W. R. SMITH, P. S. Production Company, Newark, N. J. (*Northern New Jersey Chapter*).
 R. C. STRATTON, The Travelers Insurance Company, Hartford, Conn.
 R. F. THALNER, Buick Motor Company, Flint, Mich.
 J. M. WOLTZ, The Youngstown Sheet and Tube Company, Youngstown, Ohio. (*Metals Section*).

Retiring Officers

1927-28

Chairman, R. McA. KEOWN, Industrial Commission of Wisconsin, Madison, Wis.; *Vice-Chairman*, J. I. BANASH, Consulting Engineer, Chicago, Ill.; *Vice-Chairman*, W. GRAHAM COLE, Metropolitan Life Insurance Company, New York City; *Secretary*, W. DEAN KEEFER, National Safety Council, Chicago, Ill.; *Assistant Secretary*, GENE S. WOOD, 29 W. 39th Street, New York City. *Executive Committee*: THE OFFICERS AND R. M. ALTMAN, Marathon Paper Mills Company, Rothschild, Wis. (Paper and Pulp Section); A. L. ARMSTRONG, Eastman Kodak Company, Rochester N. Y. (Chemical Section); C. B. AUER, Westinghouse Electric & Manufacturing Company, East Pittsburgh, Pa.; E. W. BECK, United States Rubber Company, New York City; J. M. CARMODY, Coal Age, New York City (Mining Section); R. E. COLVILLE, United States Gypsum Company, Chicago, Ill. (Quarry Section); G. W. COOK, The Travelers Insurance Company, Hartford, Conn. (Textile Section); F. A. DAVIDSON, Chesebro, Whitman Company, Inc., Long Island City, N. Y. (Construction Section); E. ROSS FARRA, Grand Rapids Safety Council, Grand Rapids, Mich.; J. B. GIBSON, Western Electric Company, Chicago, Ill.; W. F. HANNA, United Railways and Electric Company, Baltimore, Md. (Electric Railway Section); ERNEST HARTFORD, American Society of Mechanical Engineers, New York City; H. W. HEINRICH, The Travelers Insurance Company, Hartford, Conn. (Hartford Chapter); THOMAS B. HOWE, Aetna Life Insurance Company, Cleveland, Ohio (Taxicab and Fleet-Owners Section); F. L. HURLBRUT, Patent Scaffolding Company, Chicago, Ill.; S. R. JENSEN, Armour and Company, Chicago, Ill. (Packers and Tanners Section); M. G. LLOYD, U. S. Bureau of Standards, Washington, D. C.; T. O. MEISNER, American Can Company, Maywood, Ill. (Power Press Section); H. W. MOWERY, American Abrasive Metals Company, New York City; G. A. ORTH, American Car Foundry Company, New York City (Woodworking and Lumber Manufacturers' Section); R. E. PROUTY, Aetna Life Insurance Company, New York City (Marine Section); A. D. RISTEEN, The Travelers Insurance Company, Hartford, Conn.; W. L. ROLLER, The Hocking Valley Railway Company, Columbus, Ohio (Steam Railroad Section); R. C. STRATTON, The Travelers Insurance Company, Philadelphia, Pa.; C. W. SMITH, Standard Oil Company (Ind.), Chicago, Ill. (Petroleum Section); G. E. SANFORD, General

Electric Company, Schenectady, N. Y.; THOMAS S. STROBHAR, Wagner-Taylor Company, Philadelphia, Pa. (Food Section); R. F. THALNER, Buick Motor Company, Flint, Mich. (Automotive Section); A. J. VAN BRUNT, Public Service Corporation of New Jersey, Newark, N. J. (Newark Chapter); T. A. WALSH, American Optical Company, New York City (Metropolitan Chapter); THOMAS J. WHELAN, The Travelers Insurance Company, Boston, Mass. (Boston Chapter); S. E. WHITING, Liberty Mutual Insurance Company, Boston, Mass.; W. H. WINANS, Union Carbide Company, New York City (Metals Section).

October 2, 1928

R. McA. KEOWN, Chairman

Engineer, Industrial Commission of Wisconsin, Madison, Wis.

The first session of the American Society of Safety Engineers—Engineering Section of the National Safety Council—was called to order at 2:15 o'clock by the chairman, R. McA. Keown, engineer, Industrial Commission of Wisconsin, Madison, Wisconsin.

CHAIRMAN KEOWN: Gentlemen, the meeting this afternoon is in the nature of a public hearing on topics which have been the subject of considerable study by two committees of the A. S. S. E.—Engineering Section. The first is on the annealing of chains. I will turn the meeting over to Mr. R. F. Thalner, the chairman of that committee, who will conduct this part of the meeting.

(Mr. R. F. Thalner, Safety Director, Buick Motor Company, Flint, Michigan, took the chair.)

CHAIRMAN THALNER: You undoubtedly know that this research has been under way for a year and a half. Just previous to this meeting I was asked: Why is it taking us so long to make this research and get the information that we are after? The answer to that question is this: We have all been discussing the annealing of chains question for the past twenty or twenty-five years. The practice has been in vogue to anneal chains by heating them to various temperatures all the way from 1,200 to 1,700 degrees. Probably no two formulas are similar. This research requires a good deal of work and thought.

We must be sure of our footing. We must know the research has been conducted properly and that the results are correct. Your committee is endeavoring to complete the subject as rapidly as possible. Professor Harold A. Thomas of Carnegie Institute of Technology and his assistants are working diligently on it. In addition to the many other problems he has, such as his regular work, a recent appointment to the War Department, and a special survey for the City of Pittsburgh, he has completed the report you have today.

Progress Report of Research Committee on the Effects of Annealing on Chains

By R. F. THALNER, Chairman

Safety Director, Buick Motor Company, Flint, Mich.

The history and scope of the committee were given in the progress report presented before this Section last year. That progress report also contained the plan of procedure which had been approved by the committee.

Causes of chain failure were discussed at the meeting mentioned above. Professor Harold A. Thomas led the discussion of the progress report and described the work that had been done at Carnegie Institute of Technology in connection with the design of an impact testing machine.

Immediately following the discussion of the progress report submitted last year, Professor Thomas submitted a report of progress and a revised program of tests. That report was submitted to all members of the committee and approved by them. The report is found in *Appendix A*.

During the past year, Professor Thomas has made numerous preliminary tests on the fundamental properties of the grade of steel ordinarily used in the manufacture of chains. These properties are considered to have an important bearing on certain questions arising in connection with chain failure and annealing. Fatigue tests were made on straight bar chain stock with a rotating beam machine. Impact tests were also made to determine the effect of impact upon various specimens. In addition certain tests were made to study the effects of annealing and reannealing. The report on preliminary tests as submitted by Professor Thomas is found in *Appendix B*.

According to the report submitted by Professor Thomas, it is necessary to withhold a final statement of conclusions until the completion of all aspects of the research. Certain inferences, however, are pointed out which appear to stand out clearly as a result of these preliminary tests. These inferences are understood to be strictly of a tentative nature and subject to recall if later work proves this necessary. They are as follows:

1. Summary of General Tentative Conclusions.

(A) Our tests do not afford any evidence that the "surface impacting" received in service is a contributing cause to the failure of chains. On the contrary our tests on soft steel chain stock invariably show that surface impacting strengthens and toughens the metal, so that its tensile strength is somewhat increased and its fatigue resistance is greatly increased.

(B) Our tests do not show any evidence that the effects of fatigue in soft steel are cured or relieved in any way by annealing. In other words the total number of repetitions of loading which can be carried by a specimen of chain before failure cannot be increased by stopping to anneal the specimen at intervals.

(C) Annealing is capable of reducing the fatigue resistance of chain stock, if extreme care is not taken to exclude all air from the surface of the metal during the annealing process.

(D) There is no surface indication that a sample of chain is at the point of incipient failure due to fatigue from repeated heavy loading.

(E) It is not possible by any pulling test or proof test to discover the fact that a chain is at the point of incipient failure due to fatigue from repeated heavy loading. Even though the fatigue cracks may have penetrated to a considerable depth in the metal at the point of impending failure, a chain may still show its full original strength in a tension test, and finally pull apart in a different place from that at which the fatigue break would have occurred.

2. Practical Application of Tentative Conclusions.

(A) We have not been able to discover any fact regarding the properties of soft steel chain stock which supports the theory that periodic annealing is beneficial in any way to chain used for lifting *cold* loads only, or that such periodic annealing will afford the slightest protection against sudden failure of chain subject to repeated overloading with *cold* loads.

(B) The only possible method for insuring safety against the sudden fatigue failure of chains after long service in handling *cold* loads is a rigid prohibition against using the chain to lift loads greater than safe working loads, such as those recommended by the National Safety Council. These working loads are far less than the chain can carry without breaking in a single lift, but cannot be exceeded without stressing the metal in certain parts of the link beyond its endurance limit, and causing its eventual failure.

3. Hot Loads.

Although the effects of *hot* loads have not as yet been taken up in connection with these preliminary tests, it seems desirable to mention the fact that periodic annealing of chain used for carrying *hot* loads is unquestionably necessary as a safety measure for eliminating or minimizing the weakening due to "Stead's brittleness." This is a brittleness which develops in soft steel or wrought iron which has been subjected to high temperature for a considerable period of time.

No change has been made in the personnel of the committee during the past year except that Mr. A. C. Badger, Assistant Metallurgical Engineer of the Youngstown Sheet and Tube Company, Youngstown, Ohio, has kindly consented to act as a member. The remainder of the personnel of the committee is as follows:

Chairman, R. F. Thalner, Safety Director, Buick Motor Company, Flint, Michigan, representing Automotive Section, National Safety Council.

Secretary, Stewart J. Owen, Jr., Safety Engineer, representing National Safety Council.

E. F. Blank, Safety Director, Jones & Laughlin Steel Corporation, Pittsburgh, Pa., representing Metals Section, National Safety Council.

L. E. Frazier, Metallurgical Engineer, representing American Chain Company, Inc., Bridgeport, Conn.

R. H. White, Engineer of Construction, American Locomotive Company, Schenectady, New York, representing American Society of Mechanical Engineers.

W. J. Merten, Westinghouse Electric & Mfg. Co., East Pittsburgh, Pa., representing American Society for Steel Treating.

F. M. Waring, Engineer of Tests, The Pennsylvania Railroad, Operating Department, Altoona, Pa., representing American Society for Testing Materials.

Carnegie Institute of Technology, represented by: Professor James Aston, head of Department of Mining and Metallurgy; Professor F. M. McCullough, head of Department of Civil Engineering; Professor H. A. Thomas, Associate Professor of Civil Engineering; Professor L. R. Van Wert, Assistant Professor of Mining and Metallurgy; Professor J. M. Daniels, Instructor, Civil Engineering Department.

Frank A. Bond, Vice-President, U. S. Chain & Forging Company, Pittsburgh, Pa., representing Chain Manufacturers' Institute.

A. R. Markel, Resident Manager, representing The Columbus McKinnon Chain Company, Columbus, Ohio.

M. H. Christopherson, State Insurance Fund, New York State Department of Labor, 432 Fourth Ave., New York City, representing International Association of Industrial Accident Boards and Commissions.

George C. Ramsdell, Engineer, The Travelers Insurance Company, Chamber of Commerce Bldg., Pittsburgh, Pa., representing National Bureau of Casualty and Surety Underwriters.

Horace H. Thayer, Naval Architect & Marine Engineer, Witherspoon Bldg., Philadelphia, Pa., representing Society of Naval Architects & Marine Engineers.

David Arnott, Chief Surveyor, American Bureau of Shipping, New York City.

Sydney V. James, Engineer, Casualty & Automotive Departments, representing Underwriters Laboratories, Chicago, Illinois.

Frank A. Bond, Vice-President, representing U. S. Chain & Forging Company, Pittsburgh, Pa.

Lieut. Com. H. N. Wallin, Construction Corps, U. S. N., Bureau of Construction and Repair, representing the Navy Department, Washington, D. C.

APPENDIX A

By J. M. DANIELS and H. A. THOMAS
Carnegie Institute of Technology

(1) *Division of the Research into Periods:* In response to a suggestion made at the recent meeting of the National Safety Congress at Chicago, the following brief summary has been prepared, covering the work already accomplished by the Research Committee on the Annealing of Chains, together with a revised outline for the program of tests to be carried out in the immediate future. For this summary the research may be considered as being divided into the following three periods:

I. *The Period of Reconnaissance.* This has now been completed.

II. *The Period of General Investigation of the Effects of Annealing on the Strength of Chain.* This is intended to bring out the fundamental relations between the failure of chains and their annealing. A primary object of the work of this period will be to discover which tests are of most value and significance in studying this relation.

III. *The Period of Specific Investigation to Determine the Best Temperatures and Conditions for Annealing.* The detailed outlining of the work of this period is to be postponed until after the full or partial completion of the work of Period II.

(2) *Summary of Work Accomplished During the Period of Reconnaissance.*

(A) By officers and other members of the committee.

a. Organization and outlining of the work in general.

b. Correspondence with firms, individuals, and organizations in this country and abroad who have had experience bearing on the effect of annealing on the strength of chains. Much valuable information has been received through this correspondence.

c. Securing numerous samples of chain which has failed in service in manufacturing plants in different parts of the country, together with descriptions of the causes and conditions of failure.

d. Preparation of a printed report of progress by Chairman Thalner. The presentation of this report before the Engineering Section of the American Society of Safety Engineers, at Chicago, Sept. 29, 1927, secured an extensive discussion from members of the society. A number of valuable and constructive suggestions were received from this discussion.

(B) By members of the Committee of Carnegie Institute of Technology:

a. Preliminary tests to study the behavior of chain under ordinary tensile loading.

b. Search for and careful study of available published information having to do with the strength of chains.

c. Visits to plants manufacturing and using chains, including close inspection of various details of the process of manufacture, conversation with superintendents and workmen on the causes of failure in chains and the

utility of annealing, and inspection of numerous broken or damaged chains and links in the scrap piles of the repair shops.

d. Preliminary tests to study the properties of soft steel bars on which a hard surface skin has been produced by numerous blows with a light hammer. (1) Effect on tensile strength, (2) Effect on resistance to repeated bending.

e. Preliminary tests to determine how much the tensile strength of soft steel bars is reduced by repeated bending.

f. Preparing of preliminary plans of two special machines for use in these tests.

(a) A machine for subjecting chain to repeated loading.

(b) A machine for impact tests on chain links.

(3) *Summary of the Causes Tending to Produce a Crystalline Fracture in Chain Links.* As a result of the work now accomplished, it has become evident that out of the numerous causes for the failure of chains, there are only certain ones that produce an effect which could be remedied by annealing. The latter are apparently all of a type tending to produce a crystalline fracture in the metal of the links. Failure with this type of fracture is accompanied by little or no elongation of the metal, and under certain conditions may occur without warning and at comparatively small loads. The following list summarizes the causes which have been brought to our attention as being capable of producing a crystalline fracture in a wrought iron or steel chain link, aside from original defects in the metal.

a. Fatigue of the metal due to repeated loading.

b. Failure caused by a load applied suddenly.

c. Crystalline structure produced in the metal of certain parts of the link during the welding operation by high temperature and insufficient working.

d. Crystalline structure caused by prolonged exposure of the metal to dull red heat (Stead's brittleness).

e. Cracks starting in a brittle surface skin produced by numerous blows and impacts received in service.

f. Cracks starting in a brittle or weakened surface skin produced by rusting or other corrosion.

g. Severe bending and abuse of links in certain parts of the chain, involving a much greater deformation of the metal than is ordinarily considered in fatigue tests.

h. Effect of extreme cold weather in decreasing the ductility of the metal and lowering its resistance to the actions listed above as tending to produce crystalline fractures.

Note: In addition to the above items, mention may be made of the belief which is current among workmen and others that iron or steel of good original quality can deteriorate or "crystallize" in ordinary service without being subjected to heating, corrosion, or to severe or repeated loadings. Although few men of technical training share in this belief, it would seem desirable to include in our program a fair experimental demonstration of the existence or non-existence of such an action in connection with failures of chain.

Outline of Work for Period II. General Investigation of the Effect of Annealing on Chains. On the basis of the work now completed it seems desirable to alter some of the items of our original program, as published in Mr. Thalner's report, and to include other items which have come to our attention since this program was prepared. The revised program is as follows:

(A) *Preparation of Test Specimens.* From each sample of chain as received, the following types of test specimens are to be prepared, each specimen con-

sisting of a number of links. (Detailed explanation of the different items is given on a subsequent sheet.)

Type (1) Chain as received.

- " (2) Subjected to surface impacting.
- " (3) Subjected to repeated loading.
- " (4) Subjected to both surface impact and repeated loading.
- " (5) Subjected to prolonged exposure to dull redheat.
- " (6) Subjected to surface corrosion.
- " (7) Links subjected to severe abuse in bending.
- " (1a) Type No. 1 annealed.
- " (2a) " " 2 "
- " (3a) " " 3 "
- " (4a) " " 4 "
- " (5a) " " 5 "
- " (6a) " " 6 "
- " (7a) " " 7 "

(B) *Standard Tests.* On each of the above types of test specimens the following standard tests are to be carried out.

- (a) Tension tests to destruction.
- (b) Impact tests to destruction.
- (c) Repeated load tests to destruction (except types 3, 4, 3a and 4a).

(C) *Auxiliary Tests.* These are to include:

- (a) Analysis of chain metal as received.
- (b) Metallographic studies of internal structure and composition of metal, (as required).

(c) Use of straight specimens of chain stock, plain and welded, to investigate the fundamental effects of fatigue, impact, surface hardening, etc., on the metal before and after annealing.

(d) Study of the effects of extreme cold in increasing the brittleness of chain.

Comment on the Above Outline. It is not thought that all the combinations of specimens and tests outlined above will give equally valuable and significant results, or even that all will give positive results. These combinations are included to make the work complete and to furnish experimental data to answer as many inquiries or criticisms as possible. As soon as the work has progressed to an extent sufficient to show that certain combinations are not necessary, these may be omitted from the subsequent tests.

Explanation of Items Under Preparation of Test Specimens.

Type 2. *Surface Impacting.* This is to be produced in a foundry rattler using a standard charge of metal balls. A standard number of revolutions will be determined by trial, to give a degree of surface impacting similar to that attained in six months of ordinary service.

Type 3. *Repeated Loading.* A standard loading and its number of repetitions will be chosen to represent approximately six months of ordinary service.

Type 5. *Prolonged Exposure to Dull Red Heat.* Standard temperature and duration of heat to be adopted after preliminary tests to bring out "Stead's brittleness" effect.

Type 6. *Surface Corrosion.* Surface to be corroded with sal ammoniac to correspond with condition of chains lying six months on the ground.

Type 7. *Severe Abuse in Bending.* Links to be gripped at one end in a vise and bent back and forth through a given angle for a given number of times, to be determined by preliminary experiments.

Annealing. A standard temperature and method of annealing is to be adopted for all tests of Period II.

APPENDIX B

By H. A. THOMAS

Carnegie Institute of Technology

1. *Purpose of Tests.* The purpose of these tests was to investigate certain fundamental properties of the grade of steel ordinarily used in the manufacture of chains. These properties are considered to have an important bearing on certain questions arising in connection with chain failures and annealing. In particular it was desired to determine:

(A) How the endurance of this steel under repeated loads is affected by the occurrence of "surface impacting" such as chains receive during service, and

(B) Whether the effects of fatigue in this steel are relieved or obliterated by annealing.

2. *Advantages of Tests on Straight Bars.* The fundamental fatigue properties of a metal can be studied more satisfactory by tests on the material in the form of straight bars than in the form of chain. In standard fatigue tests on straight bars, the various factors affecting endurance can be readily separated and studied individually. In fatigue tests on chain the irregularities in the welding, heating and hammering of individual links necessarily produce a considerable "scatter" in the numerical results of tests. In testing chains, this "scatter" has a tendency to obscure the effects of individual factors, so that a much greater number of tests must be averaged to secure positive conclusions than when the tests are made on straight bars.

3. *Description of Specimens.* The test specimens were made of soft steel chain stock, which was supplied through the courtesy of the United States Chain and Forging Company. The specimens were from the stock ordinarily used in making $\frac{3}{8}$ inch hand-welded chain, this being a continuous coiled bar, approximately round and about $\frac{13}{32}$ of an inch in diameter. These specimens were cut to a length of $13\frac{3}{4}$ inches, this being the length required by the fatigue-testing machines at Carnegie Institute of Technology. The material of these specimens is a dead-soft steel having a tensile strength of about 48,000 pounds per square inch. Before testing, the specimens were straightened with a copper hammer. In general, the specimens were tested with the surface of the metal in its original condition or as modified by annealing or hammering. In a few of the tests the surface skin was removed by filing and polishing, as noted in the record.

4. *Description of Rotating-Beam Machine for Fatigue Tests.* In a repeated stress machine of the rotating-beam type, the specimen to be tested consists of a horizontal bar of circular cross section. At its ends this bar is encircled by two ball bearings which support it and permit it to rotate freely as a shaft, and near its middle it is encircled by two more ball bearings by which it supports a heavy weight. This weight can be adjusted to produce any desired tensile stress in the bottom fiber of the bar considered as a beam. When the bar is rotated, the stress in any given external longitudinal fiber varies from this tension to an equal and opposite compression as the fiber moves from its lowest to its highest point. The bar is rotated by an electric motor, which is stopped by a circuit breaker when the specimen breaks. A revolution counter registers the number of revolutions required to produce failure.

Machines of this type are simple, inexpensive, and positive. In adapting these machines for tests on chain stock, which could not be made perfectly straight beforehand, it was necessary to construct a device which permitted the load to be applied to the specimen gradually, thereby straightening the bar and centering its rotation automatically.

5. *Severity and Scope of Tests.* Ordinarily, fatigue tests are made to determine the "endurance limit" of a metal (that is: the greatest stress at which it would be safe from failure under many millions of repetitions of the load). In these tests on chain stock, however, the object was not to determine the endurance limit, but rather to subject the metal to a stress sufficiently severe to cause it to fail under a number of repetitions of load which might be obtained by an ordinary lifting chain in constant service. With this in mind, preliminary tests were made to select a load which would cause the original or un-annealed bars to fail after about 200,000 repetitions. In service this number would correspond to a lift once a minute, ten hours per day for 330 days. After being once selected this same load was used in all the subsequent tests. With the machines running at 1,500 revolutions per minute, the time required to run off 200,000 revolutions would be two and one-third hours. As it required about one hour's work to center the specimen in one of the machines, the time required for making a single test would ordinarily be from three to five hours.

A number of ordinary tensile tests and cold bending tests were also made on some of these specimens of chain stock.

6. *Nature of Fatigue Failure.* In an ordinary tension test on a ductile metal, such as chain stock, failure of the specimen is accompanied by extensive elongation and deformation of the metal in the neighborhood of the fracture. In a fatigue test no such deformation occurs but the metal breaks off suddenly and without previous deformation or warning. This type of failure is particularly dangerous in the case of chain. It is well known that fatigue failures are caused by the spreading of a minute crack, which usually starts at the surface of the specimen. In some of the tests of this series the existence of these cracks in the incipient stage could be made clearly visible by making a tensile test on one of the pieces of a specimen which had failed in the fatigue tests. The stretch due to the tension would open up the minute fatigue cracks and make them visible to the naked eye.

The condition of the surface of a fatigue specimen has much to do with the starting of cracks, and therefore has an important effect on the endurance of the specimen under repeated loads. In these tests it was considered that the results could be most practical if the specimens were left with their original surface, and were not filed or polished. As fatigue resistance is affected by the chance location of tiny surface flaws, there is more "scatter" or variation in the results of such tests than in those of ordinary tensile tests.

7. *Tests to Study the Effect of Surface Impacting.* The first tests of this series were made for the purpose of investigating the effect of "surface impacting" on the endurance of chain stock under repeated loads. Some time ago the National Safety Council received a letter from a well-known British scientist, expressing the emphatic opinion that sudden failures of chain were caused by cracks starting in a hard and brittle skin produced on chain links by the effects of a multitude of surface impacts received during service. For the purpose of planning our future tests on chain, it appeared highly important to determine at the start whether this theory of failure was a correct one. In order to duplicate in the laboratory the effects of surface impacting received in service, the surface of each of several specimens was subjected to several thousand blows with a small hammer. These blows were sufficiently heavy to slightly indent the surface, but not heavy enough to affect the interior of the specimen or reduce its diameter. Certain preliminary tensile and cold bending tests on these "surface impacted" specimens brought out the fact that the impacted surface should not be described as "hard and brittle," but rather that it should be described as "strong and tough." In the tensile tests, failure invariably occurred outside the impacted portion of the specimens, thus indicating that the tensile strength of the metal had been raised by the cold working

of its surface. In cold-bending tests in which the metal received extremely great deformation, the surface impacted specimens showed no more tendency toward cracking than was shown by the original bars.

The comparative results of rotating-beam fatigue tests on original bars and on surface-impacted bars are given in tests No. 3 to No. 10 on the "Log of Experiment" sheet. From inspection of these results it is clearly evident that the surface impacting has in no case decreased the endurance of the material, and in some cases has increased the endurance enormously. The explanation of this phenomenon probably lies in the fact that the cold working of the outer skin has given it higher strength and elastic limit than are possessed by the original metal.

The results of these tests, therefore, seem to point strongly to the conclusion that there is no truth or merit in the theory that sudden failures of chain are caused by the effects of surface impacting.

8. *Tests to Study the Effects of Annealing and Re-Annealing.* The second object of these tests was to study the question as to whether the effects of fatigue on chain stock could be obliterated by annealing.

Tests No. 11 to 28, inclusive, indicate the results obtained in this connection. The treatment referred to as "annealing" consisted in normalizing the specimens for 30 minutes at a temperature of 1,500 deg. F. in an electrically heated muffle, followed by air cooling.

Tests 11 to 16, inclusive, when studied in connection with tests 3 to 6, inclusive, indicate that a single annealing does not necessarily improve the fatigue resistance of chain stock, but on the contrary, that it may lower this resistance. The cause for this action is probably found in the formation of an oxidized surface on the metal by air penetrating within the muffle used in annealing. This oxidized surface, though hard to the file, is relatively brittle and probably tends to start and localize the cracks which cause fatigue failure.

Tests 17 to 22 when studied in connection with tests 23 to 28 clearly indicate that the effects of fatigue in chain stock are not in the slightest degree relieved or obliterated by annealing. This same fact has been noted by other observers in tests on various other grades of steel. (See Moore and Kommers; "Fatigue of Metals," pages 56 and 220.) The explanation of this phenomenon evidently lies in the fact that annealing temperatures are far too low to produce any welding together of the walls of the tiny incipient cracks whose spreading will eventually cause the failure in fatigue.

Tests 29 to 32 when studied in connection with tests 11 to 16 and 23 to 28 bring out the fact that no considerable increase in the fatigue resistance of chain stock is produced by removing the scale from the surface of the metal. This point has an important bearing on the fatigue resistance of chains under service conditions, where surface scale is removed by wear.

9. *Tensile Tests on Fatigue Specimens.* In the case of specimens 3 to 13, inclusive, tensile tests were made on one of the two fragments of the specimen obtained after failure in the fatigue tests. In explanation of these tests it may be noted that the clear span of the original specimens between the end bearings was 12 inches, and that the ends of the specimen projected $\frac{7}{8}$ of an inch beyond these bearings. The two bearings applying the load were spaced 3 inches apart, each being $1\frac{1}{2}$ inches from the middle of the bar. As the fatigue break seldom occurred at the exact center of the specimen the longer of the two fragments would furnish an opportunity for making two tensile tests, pulling the specimen apart at the two following points: (A) at the point where the loading bearing had been applied, and (B) at the point where the supporting bearing had been applied. At the first of these points the material had been subjected to an intensity of stress and number of repetitions exactly the same as at the place where the fatigue

failure had occurred. At the second point the material had been subjected to no stress and was in its original condition.

The results of these tensile tests bring out the remarkable fact that the tensile strength at the first of these points is invariably as high or higher than that at the second point. This was true even when the incipient fatigue cracks at the first point had become sufficiently deep to be plainly visible after the specimen had been stretched in tension. The explanation of this phenomenon must lie in the fact that the repeated stressing of the specimen has the effect of cold-working the metal until it is stronger than in its original condition.

Two conclusions of much importance can be deduced from these tensile tests:

(A) That absolutely no warning can be expected in case of fatigue failure of chains. Up to the very instant of failure there will be no change in the appearance or dimensions of any parts of the links, nor any diminution of strength which could be detected by a proof test in tension, or by any other known test.

(B) In planning research tests on chain it is futile to adopt any program which depends on pulling tests to determine how much a chain has been weakened by service conditions or repeated loading.

10. *Summary of General Tentative Conclusions.*

(A) Our tests do not afford any evidence that the "surface impacting" received in service is a contributing cause to the failure of chains. On the contrary our tests on soft steel chain stock invariably show that surface impacting strengthens and toughens the metal, so that its tensile strength is somewhat increased and its fatigue resistance is greatly increased.

(B) Our tests do not show any evidence that the effects of fatigue in soft steel are cured or relieved in any way by annealing. In other words the total number of repetitions of loading which can be carried by a specimen of chain before failure cannot be increased by stopping to anneal the specimen at intervals.

(C) Annealing is capable of reducing the fatigue resistance of chain stock, if extreme care is not taken to exclude all air from the surface of the metal during the annealing process.

(D) There is no surface indication that a sample of chain is at the point of incipient failure due to fatigue from repeated heavy loading.

(E) It is not possible by any pulling test or proof test to discover the fact that a chain is at the point of incipient failure due to fatigue from repeated heavy loading. Even though the fatigue cracks may have penetrated to a considerable depth in the metal at the point of impending failure, a chain may still show its full original strength in a tension test, and finally pull apart in a different place from that at which the fatigue break would have occurred.

11. *Practical Application of Tentative Conclusions.* While it is necessary to withhold a final statement of conclusions until the completion of all aspects of this research, it seems desirable for the benefit of those who are waiting for practical results, to point out certain inferences which appear to stand out clearly as a result of these preliminary tests. These inferences are understood to be strictly of a tentative nature, and subject to recall if later work proves this necessary.

(A) We have not been able to discover any fact regarding the properties of soft steel chain stock which supports the theory that periodic annealing is beneficial in any way to chain used for lifting *cold* loads only, or that such periodic annealing will afford the slightest protection against sudden failure of chain subject to repeated overloading with *cold* loads.

(B) The only possible method for insuring safety against the sudden fatigue failure of chains after long service in handling *cold* loads is a rigid prohibition against using the chain to lift loads greater than safe working loads, such as

Results of Fatigue Tests on Specimens of Chain Stock

DIAGRAM SHOWING SET-UP OF APPARATUS USED FOR
 ROTATING-BEAM FATIGUE TESTS ON CHAIN STOCK.

Mean diam. of specimen = $13/32" = 0.4063"$.

Bending moment in middle 3" section = $\frac{78.6}{2} (4.5) = 176.8" \pm$.

Max. fiber stress = $\frac{10.18 (176.8)}{.4063^3} = 26,800 \pm 2/0"$.

Explanation of terms used in table and diagram on preceding page:

"Annealed": Subjected for 30 minutes to temperature of 1500° F. in a closed muffle, followed by cooling in air.

"Surface impacted": Surface of middle of specimen subjected to several thousand blows with a small machinists' hammer, each blow being hard enough to produce a perceptible indentation.

"Cycles": Each cycle represents one complete revolution of the specimen.

"Scale filed off": Surface filed and polished in lathe with fine emery cloth.

Note: Some of the specimens varied by a few thousandths from the nominal diameter of 0.4063". The corrections for these variations are not included in the table on sheet 1, as these corrections do not appreciably affect the final averages in the last column of this table.

PRINCIPLES AND DATA RELATING TO CHAIN TESTS

Relation between Pull and Stress:

For chain links of ordinary shape the theory of elasticity gives the following relation between the pull on the link and the tensile stress in the metal at the critical point A.

$$S = \frac{2.5P}{d^2} \quad (\text{Univ. of Ill. Bull. 18})$$

where, S = tensile stress in metal at A, lbs./sq. in., P = pull on link, lbs., and d = diam. of bar, inches.

This formula applies only to cases where the metal is initially unstressed and the deformations are within the elastic range of the material. If initial stresses exist or plastic deformations occur, the same formula $S_r = \frac{2.5P_{max}}{d^2}$ is used to compute the "modulus of rupture" S_r or a fictitious fiber stress occurring at A at the time of failure under the load P_{max} .

In repeated-load tests on chain links, plastic deformations during the early loadings produce initial compression in the metal at A, so that the modulus of rupture is higher than the actual fiber stress at A.

Loadings

for
3/16" Chain

Loading	Load P, Lbs.	Mod. of Rupt. S_r , lbs./sq. in.
Load corresponding to ordinary working stress for soft steel	901	16000
Safe load recommended by Unwin.	1576	28000
Load Used in Series 1	4880	86700
Load Used in Series 2 and 3	3500	62200

Results of Repeated-Load Tests on Soft-Steel Chain and Chain Stock.

Number of Repetitions of Loading.

those recommended by the National Safety Council. These working loads are far less than the chain can carry without breaking in a single lift, but cannot be exceeded without stressing the metal in certain parts of the link beyond its endurance limit, and causing its eventual failure.

12. *Note on Hot Loads.* Although the effects of *hot* loads have not as yet been taken up in connection with these preliminary tests, it seems desirable to mention the fact that periodic annealing of chain used for carrying *hot* loads is unquestionably necessary as a safety measure for eliminating or minimizing the weakening due to "Stead's brittleness." This is a brittleness which develops in soft steel or wrought iron which has been subjected to high temperature for a considerable period of time.

CHAIRMAN THALNER: We have until three-thirty for the discussion of this particular subject. Prof. Harold A. Thomas of the Carnegie Institute of Technology will lead the discussion on this subject.

Discussion of the Committee Report

By PROFESSOR HAROLD A. THOMAS
Carnegie Institute of Technology

I desire to emphasize the fact that these conclusions are of a tentative nature. We are eager to receive comments and discussions, either favorable or unfavorable, any facts which will throw light on these conclusions which are startling to ourselves and probably the same to you.

The first diagram of Appendix C shows a diagrammatic sketch of the machine which has been designed and built for making repeated load tests on chains. This machine was designed by myself after several attempts to design a machine of reciprocating type. The machine is built on the principle of having no reciprocating parts, having rotating parts only.

It has been very successful and has enabled us to test the four specimens at the same time and to get alterations of load at about a thousand per minute.

In a machine of reciprocating type, built by the Yale & Towne Company, in which they lifted a weight and let it down again, it required three years to obtain a test on a single sample of chain, whereas with this machine running at high speed we can obtain a test within a few hours.

I might explain the principle of the machine, although I think it is quite clear in the sketch. The four samples of chain to be tested are bolted on the four sides of a rotating lever. The lever carries a weight at its end and when the chain is in the topmost position the chain carries the entire load at the end of the lever with a multiplication of 24. When the chain is below, it hangs slack and carries no load, and when it is in a side position, it also carries no load.

Table I of Appendix C shows some repeated load tests on chain. The sample of each test consists of nine links of $\frac{3}{8}$ -inch, hand-welded, soft-steel chain. The figures in the table give the number of repetitions required to produce failure.

We designed this machine for $\frac{3}{8}$ -inch chain, with the idea that if there were any errors in the design of the principle, it would not be so expensive as if we designed it for 1-inch chain. We hope some time in the future to have a machine for testing larger chains.

The machine used was donated to the National Safety Council by the Jones-Laughlin Company of Pittsburgh, through the efforts of Mr. Blank, safety director of that company and a member of this committee.

Table I shows the results of the repeated load tests which were obtained during the past months. In Series 1, our tests were made with quite a heavy overload on the chain. The total load was 4,880 pounds. That was possibly 200 pounds at the end of the lever, and the multiplication was 24, giving the total load. The average number of repetitions for loading which that machine carried under the heavy overload was 138,000.

It is interesting, especially, to see the great variation in the results of the individual tests. Specimen 13 carried 221,600 repetitions of this loading, whereas Specimen 9 carried only 25,000, a variation of nearly nine to one.

This extreme variation and the results of the test seem to be characteristic of the chain, and make it somewhat difficult to interpret the results on the basis of averages only.

From the standpoint of safety, we are interested more in the low value than in the average value. Those low values can only be cited by making a great number of tests.

I was not able to discover any surface indications of the reasons why Specimens 6, 7 and 9 gave such low values.

Series 2 and Series 3 were made with somewhat lighter load. Nevertheless they were heavier loads than the ordinary working loads per chain. The specimens of Series 2 were the original links as received, and those of Series 3 were the same links after a single annealing. Series 2 on the unannealed links showed an average number of repetitions of 410,920, and Series 3 on the annealed links shows 184,260.

It is very evident that in these $\frac{3}{8}$ -inch chains the effect of single annealing is to lower the fatigue resistance. I think the explanation is that the working of the chain and the hammering it receives works the material and stiffens it so it has a greater fatigue resistance.

You will notice in Series 2 there is also a wide variation between the maximum and minimum number of cycles, the first perhaps corresponding to a month and a half of service and the second corresponding to a year and a half of service under extreme conditions.

Notice in Series 3 the effect of a single annealing makes the results somewhat more uniform but still does not eliminate all low tests. Specimen 58 carried 81,320 repetitions, whereas Specimen 48 carried 240,560 repetitions, a variation of about three to one.

Table II of Appendix C gives the results of tensile tests on chain. The samples used for each test consisted of four lengths of $\frac{3}{8}$ -inch hand-welded, soft-steel chain. Specimens listed in the first three groups consisted of unbroken portions of the samples obtained from chain which had passed through the repeated load test listed in Table I.

Group 1 is unannealed chain after passing through repeated load test, and it shows the average tensile strength of slightly over 10,000 pounds. Group 4 on the original chain shows practically the same tensile strength.

This brings out the remarkable fact that all this fatiguing of the chain doesn't affect the tensile strength. There may be some tiny, incipient cracks that are invisible to the naked eye and may cause failure. Still, if you attempt to bring those out by tensile stress you cannot do it, because the material at the base of those cracks has been cold-worked by the repetition of loading and is stronger than the rest of the chain, and the chain will break at a different place.

Group 2 shows practically the same thing that is shown by Group 1. Groups 3 and 5 show the effect of single annealing on this $\frac{3}{8}$ -inch chain, Group 3 being on the fatigued specimens and Group 5 being on the unfatigued specimen.

You will note that annealing this material plainly reduces not only the fatigue

strength but the ordinary static strength. Notice how much more uniform the tensile strengths are in the ordinary static tests than in the fatigue tests.

The Principles and Data relating to Chain Tests include certain data with an attempt to reconcile the theory and practice regarding the specimens of chains. The diagram shows the distribution of stresses attained in accordance with the mathematical theory. The greatest strain in the chain link is at point "A." Tensile stress is matched at that point.

Right at the peak of the chain, on the inside, there is a compression stress, which is greater than the maximum tensile stress, but that compression stress does not appear in the chain failure. All your failures come at point "A," where the tensile stress is high.

The table shows various possible loadings for $\frac{3}{8}$ -inch chain. For example: It is desired to load the chain so as to get only a stress of 16,000 pounds per square inch, at point "A." The corresponding load for that chain would be 901 pounds.

A safe load recommended by Unwin, an eminent British engineer, which stresses the material to a load of 28,000 pounds per square inch, at "A" corresponds to a load of 1,576 pounds per square inch at "P."

The load used in Series 1, 4,880, would produce a theoretical stress of 86,700 pounds per square inch. That is higher than the ultimate strength of this material, nearly twice as high, and is evident that it is a fictitious stress rather than a true stress.

The reason for that is in the fatigue test on chains the early part of the loading develops initial stresses in the material, so that at point "A" there is a certain initial compression of the material which relieves this maximum tension so the material never actually reaches 86,700 pounds per square inch, but fluctuates between a value of 30,000 pounds and 40,000 pounds.

In the diagram we have plotted some of the results of repeated load tests on some of the steel chain and on chain stock. There is a line corresponding to the typical curve for some of the steel obtained in a large number of tests in the University of Illinois. Our tests on chain stock fall slightly below that curve. I think the explanation for that is our chain stock has a rough surface, whereas the University of Illinois tests were on stock with smooth surface.

The tests on $\frac{3}{8}$ -inch chain are plotted at the top of the diagram. It is evident the theoretical stresses in that chain are higher than the stresses in ordinary bars of stock.

These values are averages and not low values. If only average values were considered it would evidently be possible to use very high working stresses for chain and loads such as recommended by Unwin, or even greater loads would be perfectly feasible.

When you consider the low individual tests, it seems unreasonable or impossible to make use of these high-working stresses, and it would seem very desirable to hold the working loads per chain to very low values.

I want to emphasize particularly the idea which has continued to impress me during all these tests; that is, the only protection to the user of the chain is the avoidance of overloading the chain. It seems to me impossible to secure the effects of overload. If a chain is habitually and regularly stressed several times, its safe-working load, it will develop flaws which simply cannot be cured by annealing and will eventually cause failure.

The above result will not be acceptable to a great many of the men who have pinned their faith on annealing, because the human being believes the things he would like to believe in a great many cases. A foreman would certainly like to believe he can abuse the chain as much as he wants to and cure such effects by annealing.

My tests convince me more and more that is impossible, and that the National Safety Council's activities through this Section should be in the form of propaganda against overloading chains, and then the question of annealing is a minor question.

Within the past few days the members of the Committee have received a paper by Mr. Merten of the Westinghouse Electric and Manufacturing Company at Pittsburgh, giving a very excellent study on the photomicrographic results obtained in annealing of chains. In that paper it is recommended higher temperatures be used for annealing than have ordinarily been used. The paper is excellently prepared and the work is apparently accurate and scientific, and yet, in my opinion, it does not exactly hit the point.

The author brings out the point that high annealing temperature is required to obliterate the fine structure caused by cold working on chains, and that you cannot obliterate that fine structure without these high temperatures.

My tests seem to show it is unnecessary to obliterate that fine structure. Fine structure is a benefit rather than a disadvantage. The thing which would cause the chain to fail eventually is not the fine structures, but the little, fine, incipient cracks, which you could not find in any individual section, cut and examined with a microscope.

CHAIRMAN THALNER: You have heard some startling revelations. You may have some questions to ask. Prof. Thomas is ready to answer any questions you care to ask.

Bear in mind that the committee is open to any suggestions, and this report, while being of a tentative nature, is a progress report, and as far as we have gone, is the best which can be obtained in the research laboratories of Carnegie Institute.

The completion of this research has not been a matter of six months or a year. We are now on our second year. The subject is an important one. The information we now have at hand seems to indicate we may have been on the wrong track. We should be sure the results we are to give to the public and to our industries are absolutely correct.

For that reason, the research will be continued. It may possibly be finished during the course of this year, so that a complete report can be had, at least at our next annual conference.

But kindly be patient because the committee is doing everything in their power to complete it. We are just as anxious to get the information for you as you are to get it from us.

Numerous inquiries have been received regarding the progress of the research, and undoubtedly there are men in your plants who are anxious to know just what is taking place and what results are being obtained. Kindly pacify them with a copy of this report and tell them that as soon as possible the research will be completed.

We would like to have some suggestions relative to what maximum size of chain you men think necessary to test, whether it should be a $\frac{3}{4}$ -inch chain, a 1-inch chain, a $1\frac{1}{4}$ -inch chain, or $1\frac{1}{2}$ -inch chain. You are the men who are using the chains, and we would like to have the benefit of your experience in conducting the remainder of the research.

May I ask you, Mr. Slaymaker?

S. H. SLAYMAKER (Fairbanks-Morse Co., Beloit, Wis.): We don't use anything larger than $1\frac{1}{8}$ -inch chains.

CHAIRMAN THALNER: Does anybody think we should use chain stock larger than $1\frac{1}{8}$ -inch? Probably $\frac{3}{4}$ -inch is an average.

A. D. BERQUIST (Youngstown Sheet and Tube Co., East Chicago, Illinois): In

these fatiguing tests, was the structure of the chain past the elastic limit before you got the ultimate tensile strength?

PROF. THOMAS: In that chain the elastic limit was extremely low, so the tests were all past the elastic limit; however, not outside the elastic range of the material. The first load we put on the chain stretched it slightly. After that it would run for an hour or so on the machine without any sagging down of weight. I can't answer that question correctly.

MR. BERQUIST: Evidently from the report, the lifting of a load with the load swinging and striking against piles of material will not damage the chain seriously. Also, pulling chains from underneath loads does not have any ill effect on the chains.

PROF. THOMAS: Our tests showed anything that cold-works the surface of the chain benefits it rather than harms it, understanding, of course, the cross section is not affected.

L. W. HOPKINS (American Chain Co., Bridgeport, Conn.): One thing that should be considered in the test is that chains are made of three different and distinct materials—steel, iron, wrought iron. There is a distinction, and I think it should be considered.

I believe the committee's report should make the distinction clear that all the tests have been run so far on steel alone and no reference is made to tests on iron.

There is another thing. Mr. H. J. Gough of the National Physical Laboratory in England saw fit to put before this committee a reference to tests that he had under progress at one time. The National Physical Laboratory has published a 170-page report, covering work over a period of four years, on the failure of wrought iron chains.

There is plenty of evidence in that report, which anyone can obtain, to show that overloading is not causing the failure in chains. I recommend that anyone who wishes to get a fair and impartial story of both sides of the picture should obtain the report and read it over thoroughly. It refers only to the wrought iron chain and is very thorough. The research covers a period of four years.

So far as the surface impact is concerned, I believe an impact test will detect there is something to surface impact. A fatigue test will not. Mr. Gough brings out very clearly in his report that a fatigue test has nothing to do with it.

PROF. THOMAS: We have not completed the impact machine which has been designed. I was much impressed by Mr. Gough's statement, and I made all the tests I could think of to try to discover this brittling effect caused by surface impacts. I have not been able to find any kind of laboratory test that would show such effect.

I have impacted the chain surface by thousands of various blows with a light hammer. Some blows were light, some were heavy. The number of blows also varied. I then tested the tensions. I also put the chain in a vise and slowly bent the chain back and forth. I put it across supports and pounded it rapidly. I have never been able to determine any lowering of the strength or brittleness or cracking caused by that surface skin.

I am open to conviction and anxious to discover any such effect as suggested in Mr. Gough's report, but I have not found it in the tests I have made.

As to the point of not viewing any material other than steel, we have no intention of confining the tests to steel, but that is the material we have worked with so far and have spent all of our time in trying to bring out the facts that need to be discovered. Before making our conclusions at all final, we wish to test the other materials and other sizes of chain and chain stocks.

J. A. NORTHWOOD (Bethlehem Steel Company, Johnstown, Pa.): I was surprised to hear Prof. Thomas make the statement that dragging the chain out from under a load would not injure the links. A report from the American Chain Company on

some trouble we were having gave that as the cause of our trouble. Your statement is just the opposite of the American Chain Company.

PROF. THOMAS: I was referring to the strength of the material rather than to the deformations. I think if the metal were deformed in that process so the shape or cross section were changed, then it would certainly be harmful. But from any tests that I have been able to make there is no reason why the pounding of the metal or the rolling of it or bending it back and forth would lower its strength.

W. N. CLINTON (Staff Engineer, Metropolitan Life Insurance Co., New York City): Prof. Thomas, if the modulus of rupture is higher than the actual fibre stress "A," have you been able to determine yet whether or not that differential is constant and proportionate with the various diameters of chain, or have you got into diameters greater than $\frac{3}{8}$?

PROF. THOMAS: This machine we have now only takes the $\frac{3}{8}$ -inch chain, and we have not been able to follow up that point.

MR. CLINTON: I wonder whether it is your opinion the stress would be the same if it were plotted out on the curve.

PROF. THOMAS: I think we would get the same values in the modulated rupture in larger chains as in the larger bar with straight stock.

E. F. BLANK (Jones & Laughlin Co., Pittsburgh): In view of what Prof. Thomas has said in regard to the cold-working effect on the chain, I would like to ask this question: If the cold working makes the chain stronger, wouldn't it be better to cold-roll the same chain stocks for making chains? Would that raise the strength of the chain?

PROF. THOMAS: I think if it were possible to get a good weld and then subsequently do something to increase the strength of the material, we would have a better chain. I think the principal reason for using the dead cold material is we are getting better welds. If it were possible to use cold-rolled material and then hammer the weld in after the welding, it would give a better chain.

MR. BLANK: I don't mean to use higher carbon steel. Take the same steel we are experimenting with at the present time and cold-roll it.

PROF. THOMAS: If you use cold-rolled steel at the unwelded end of the link, the link would be stronger even at the welded end. After you heated it, the cold-rolled would be gone, of course. If it were possible to subsequently hammer that welded end and it would do the same thing as cold-rolled would do, I think we would have higher property in every way.

C. L. YORK (General Electric Co., Schenectady, New York): Have you tried electric welding?

PROF. THOMAS: The tests so far include the hand-welded chain. I realize the $\frac{3}{8}$ -inch size, hand-welded chain is not established at the present time. We chose that as a representative of the larger sizes, and we are very anxious to get the tests on that welding chain, but have not been able to do it so far.

CHAIRMAN THALNER: Are there any further questions? We have obtained much from this discussion and the questions asked. I hope you will all take these reports with you, thoroughly digest them and give them consideration.

Bear in mind that in any discussion of this report which you may have with anyone else, the report is purely of a tentative nature. Tests have been performed only on $\frac{3}{8}$ -inch steel chain. Consequently they do not cover the range we all wish for. The final tests will take in the various materials and different sizes.

The other point to remember in discussing this report, is the fact that it applies only to cold loads. Hot loads will also be taken up in the research.

MR. NORTHWOOD: In order to get it into the record, I would like to know where we can get the report the American Chain Company man referred to.

MR. HOPKINS (American Chain Co., Bridgeport, Conn.): The title of the report

is, "The Causes of Failures of Wrought Iron Chains." The report is from the Department of Scientific and Industrial Research, 16 Old Queen Street, Westminster, S. W., London, England.

CHAIRMAN THALNER: If there are no further questions, we will bring the discussion of this report to a close. I thank you and hope next year we will have a complete report on the question of annealing of chains.

(The meeting recessed.)

(Chairman Keown resumed the chair.)

CHAIRMAN KEOWN: Gentlemen, the next committee which will report this afternoon is a research committee on Low Voltage Electrical Hazards. They have no printed progress report for you, but Mr. S. E. Whiting, of Boston, is chairman of this committee, and I wish to turn this part of the meeting over to him to conduct as he wishes.

(Mr. Whiting took the chair.)

Report of the Low-Voltage Electrical Committee

By S. E. WHITING
Chairman

Gentlemen, I only wish we could report to you as thoroughly and constructively as your committee on the Annealing of Chains has just reported. Our problem is quite different from theirs. Those of you who have been following our Committee know we began four or five years ago as a very small committee and then about two years ago, with the approval of the main Executive Committee of the National Safety Council, we brought into our organization the representatives of all the different national associations that are interested in this problem. Many of those representatives are here today and I hope that you will have the privilege of hearing from them.

If you were at our meeting in Detroit, you will recall at that time we discussed the technical details of how to prevent these fatalities by proper electrical construction. There is no argument about that part of the program. The electrical industry knows very well how to prevent low-voltage fatalities by proper use of electrical apparatus and devices. Our problem is, how to get this message over to the actual user, and it is not to go into technical details of insulation design or installation rules.

First of all we must decide whether there is any appreciable low-voltage electrical hazard. We have been stumbling along for some time, trying to get statistics. We attempted first, through this A. S. S. E.-Engineering Section, to get you gentlemen to report those statistics, and we got a meagre six or eight fatality reports. We did not think that was the whole story. We were glad you did not have any such death cases in your own plants, but we wanted to get all there were in industry, in the homes and elsewhere.

We did not know how to get this record until, last fall, we learned of one source of such information that is confessedly a very unreliable source, not reporting with any scientific accuracy at all, but yet a record of apparent death cases from apparent exposure to low voltage. We got, in the three months period of last fall from newspaper reports apparently country-wide, made available to our committee, 45 death cases that had occurred on low-voltage equipment. By low-voltage equipment, we mean anything from, say 700 volts down. In some cases we knew from the report or could easily guess what the voltage was. We found some of

those death cases were on 110-volt lighting circuits. We found some were occurring in the homes and some in industry.

Thereupon Safety Council Headquarters approved the attempt to get further statistics from newspaper sources, and that is what we have been attempting to do in this past year. Unfortunately Headquarters did not get complete service of that sort for some time, so we did not begin to get everything that happened until about the middle of last June. Then the cases began to come to us in bunches,—and they are still coming in. All I have had opportunity to do is to analyze three months of such newspaper reports, taking them for what they are worth.

You may recall also that we reported, in this section, at the Detroit Safety Congress, some 80 electric-shock fatalities on low-voltage equipment, but the period and the territory over which that exposure had taken place were entirely indefinite. It was merely the accumulation of past years that we happened to get hold of from insurance companies, mostly. The experience already mentioned (three months in the fall of 1927) was that we were getting a rate of 15 death cases from low voltage per month, country-wide.

I have put on the following chart, a first analysis of the newspaper reports during this summer. Of course, the newspaper reports send in all electrical cases, high-voltage as well as low-voltage. I made the attempt to separate the high from the low. There are no cases here included where the person killed was connected with an electrical power company. Any report saying that a "lineman" of such-and-such a place was doing so-and-so, was thrown out, as also were accidents to power station or substation operators. It is not our function to analyze high-voltage exposure. That is handled by another of our Safety Council sections, the Public Utility Section.

Recent Low-Voltage Fatalities

(Approximate data only)

Principally from newspaper reports throughout United States during three summer months of 1928.

Comprises all utilization circuits below 750 volts including trolley and third-rail circuits of railways, mines and industrial plants.

Excludes all cases on any voltages, occurring among electric power company employees.

General Classification

Type of Utilization Equipment	No. of Deaths
Fixed Machines, Switches & Wiring in Industry.....	59
Extension Lamps & Cords in Industry and Homes.....	43
Portable Tools in Industry and Homes.....	33
Home Electric Equipment (other than Lamps & Tools).....	28
Electric Railways	17
Miscellany	7
Total	187

Average Frequency During Summer Months

Total Cases from June 15, 1928 to Sept. 15, 1928.....	143
Average Rate During This Period.....	10 Deaths per Week

I do not know that all of these cases actually occurred on low voltage nor even that any of them did. All I do know is that they were reported to have occurred in the handling of utilization equipment which would not be operating normally at high voltage. I want to call your attention to one point in this connection. We have been somewhat criticized for saying a man was killed by an extension lamp on low voltage. How do we know it was low voltage? Why was it not possibly a high-voltage charge momentarily on that extension lamp?

When my own company has had the liability for an electrocution in a plant nearby and the equipment was left alone intentionally until I went out there and had a chance to test it, I could not even then, knowing the entire details, say whether it was high-voltage or low-voltage shock. There might have been a momentary high voltage at the time the man was killed, and the low voltage that I measured, as 110 or 220 or 550, may not have been the actual voltage at the time of the accident. The point is, we do not care, from the standpoint of prevention, whether it was low voltage or not. We want to prevent these electric-shock fatalities altogether, and this hazard from improper handling of utilization equipment would be all the more serious if it were true that high-voltage leaks were the real cause of them.

There are reasons that were discussed in a former meeting of our Committee (see Detroit Safety Congress Transactions) why these cases probably are genuine low-voltage fatalities, so we need not take the time to go into that at this meeting.

That is the record—187 cases sent to us this year so far. Fifty-nine were on "Fixed Machines, Switches and Wiring in Industry." That means anything in the factory that is fixed in place. Next in number come "Extension Lamps and Cords," 43 cases partly in the factories and partly in the homes. The group "Portable Tools," wherever used, was 33. The fourth item is 28 cases of "Home Electrical Equipment" not including extension lamps and portable tools. The "Street Railway" deaths of 17 cases are included as examples of genuine low-voltage deaths from trolley circuits. Finally, there are seven from miscellaneous causes.

Some of these latter cases were quite amusing, if a death case can be amusing at all—for example, where a man got tired of life and electrocuted himself. He knew enough about the hazard at least to get into a bath tub first because he wanted to be sure of the job. He would take perhaps a copper plate and tie it on one side of him, and sit on another plate, and turn on some water and, of course, connect the plates up to a lamp circuit, and then pull the chain. His body was found that way. Some cases were apparently where men thought they could give themselves electrical treatment. One man wove electric wires into his bath robe.

That is our present situation. We do not know whether this is the average rate or not. We know merely that we were getting fairly complete newspaper reports during that three months period. I think it is entirely fair to say that since this three months period included an abnormally wet season, the record is higher than we should expect on the average, because wetness is one of the prominent elements of low-voltage fatalities. Some of the accidents are where the man was out in the rain at the time or came indoors with his clothes wet, or perhaps had gone into a basement to start a pump where the cellar was flooded. Such cases would not be normal in dry weather.

There were some other electric fatalities not here included that are of interest to all Safety Council members as public fatalities. Indeed, they are of interest to you all personally in looking out for your own family. I refer to Fallen Wire and Radio Antenna fatalities. The tabulation excludes these because they are both usually in the class of high-voltage accidents. If we wished to include these latter cases, we should have to add about a third more and run the total number

up above 250 in this three months country-wide exposure to non-technical persons, still omitting the specialists like electric power company employees who are handling the problem in a trained manner. Thus, excluding all wiremen, linemen and operators, we have had this summer a frequency rate of one thousand electric-shock fatalities per annum throughout the United States. That gives us some rough quantitative measure of the severity of this hazard to the layman. In comparison with the automobile hazard, it is not particularly bad,—only about 4% as bad, but it does equal or exceed the record of other hazards we make a special effort to counteract, such as certain mechanical hazards, chemical hazards, etc.

Now what is the electrical exposure compared to other industrial hazards? The exposure is absolutely tremendous if you consider all the electrical equipment in homes as well as in factories, and the rate of fatalities in respect to exposure is therefore quite low.

However, being safety men, we should like to cut down even that figure if we could, and we get back to the question: What are we going to do about it? We have decided that the electrical industry knows exactly how to prevent these cases. They have a National Electrical Code that has been in existence for a generation, but is kept right up to date. Practically all these cases occur in violation of that Code. Why is the Code being violated? Because you and I in our homes, when we want any electrical connections made, do not hire an electrical contractor to come around and charge us \$5 or \$10 to connect an extension lamp in a safe manner. We go around to some store and buy the sockets and the lamp cord, etc., and wire them up ourselves. That tendency I think is increasing with the use of radios and even radios are no longer confined to the trifling battery voltages but are run right off our lighting circuits.

Some of the reported cases are quite tragic,—for example, the bath tub cases. We must learn to use more care in such situations. A person will take some electrical hair curler, vibrator or heater into the bath room, get into a tub of water and then use that device. Or else, if the lighting wiring is below standard, there may be a brass socket drop cord over the bath tub,—an absolute violation of the wiring rules. The drama comes in when that person is killed. Take one striking case in Chicago last summer. A man of middle age, living with his mother in Chicago, was an invalid. (That will give the skeptic a chance to say he died from a weak heart, but never mind that.) He went to take a bath and had an electric heater from which apparently he received a shock. It is surmised his mother, hunting for him, went in there later and trying to save him, got a shock too and was killed. Nobody had occasion to visit that family until ten days later, when they found the bodies.

Gentlemen, you should keep in mind that there is a possibility—only a remote one fortunately—of catastrophies in connection with electric-shock hazards. By a catastrophe an insurance man means five or more killed by the same accident. In fact there was during the summer period one such case, although it was high voltage. Five persons were killed by a fallen wire down in Arizona. One person got wound up in the wire and another naturally went to his help, and he was killed. A third went and the third was killed; and then a fourth and fifth were killed. This impulse to rescue those in danger is instinctive, of course, but we all need to learn more effective methods than were shown in this Arizona case.

Take industrial exposure if you prefer, where most always you have electric portables of some kind. Consider the ordinary coal yard where power-driven loaders are often used. There is one in a New England city that had such a situation. They were using a 550-volt portable loader in the yard and it had rained during the morning. The loader wiring was not up to the latest standard, but I need not go into the details of that. Three men were pushing that machine closer to the pile of coal and all three of them were killed.

That is not a very nice thing to happen to a poor innocent coal dealer who does not know anything about electrical hazards. I can not blame him for such an accident. I do not know that I blame the electrical contractor who put in the wiring so that, by chance, three men were killed. Many electrical contractors still believe you can not get fatal shocks on low voltage. They are still from Missouri on this danger and so too are many city inspectors. Nobody, of course, would have allowed that triple fatality to occur if they had fully appreciated the possibilities of the situation. That accident was the result of pure ignorance and this ignorance needs to be dispelled. Gentlemen, if any of you have this condition in your own plant, you ought to apply the practical remedy that is already available to you.

I know you will enjoy hearing from some of our Committee members who represent prominent outside organizations. The National Electric Light Association has been very much interested in this problem from the beginning. Practically all electric power companies are members of that Association. Mr. E. W. Gorry of United Electric Light & Power Co., New York, is our regular member, but he was taken ill with a cold last night and can not be here. Mr. Hammer is taking his place.

Report for the N. E. L. A.

H. B. HAMMER (Philadelphia Electric Co., Philadelphia): Mr. Chairman, Mr. Gorry has asked me to make a brief report as to what his committee in the N. E. L. A. is attempting to do toward passing out information relative to educating the public and others upon the low-voltage hazard. Mr. Gorry is Chairman of a Subcommittee of our Accident Prevention Committee, that is dealing specifically with this question. He tells me that a circular or pamphlet has been prepared which contains the fundamental precautions concerning low-voltage hazards. This will be brought up for consideration and probably approved at a meeting to be held in Philadelphia next week. That pamphlet is for distribution to the public, and according to Mr. Gorry's plans, it will be distributed in large quantities. The material has already been prepared, and is now awaiting approval by the Committee which is sponsoring this work.

In addition to this, a similar pamphlet is being prepared for distribution to employees of N. E. L. A. members and to electrical contractors, which will differ somewhat of course from that prepared for distribution to the public. The preparation of this second pamphlet has not been carried as far as the first one, but it is on the way towards completion and it is expected to be available in the near future.

In addition to this, arrangements have been made, in a series of pamphlets put out by the Women's Committee of the National Electric Light Association and known as "More Power to the Home" series, to incorporate our new pamphlets, which bring out the precautions which are pertinent to that particular subject. The precautions will also be incorporated in all existing pamphlets as they are revised and republished. These pamphlets have been given a wide distribution among company women employees and their specific purpose for use in meetings of various sorts is as a sort of hand book on general constructional material, relating to various appliances in the home. I believe, Mr. Whiting, that is practically all Mr. Gorry has to report in the way of specific educational work that is under way.

CHAIRMAN WHITING: There are two other representatives of the National Electric Light Association here. We all know how extensive that organization is. The new chairman of their main Accident Prevention Committee, Mr. C. R. Beardsley of Brooklyn Edison Co., will say a few words.

MR. BEARDSLEY: Mr. Whiting and Friends: It goes almost without saying that our interest in the National Electric Light Association and your interest in the National Safety Council is absolutely the same. There can be no conflict of our intentions or aims in the matter of accident prevention, and in the specific matter of low-voltage hazards, I see no difference in those aims and intentions. Sometimes we do differ slightly in the method of presentation. That is a matter that can be adjusted, and we propose to go about the adjustment of it.

Two Phases to the Subject

Last year the subcommittee Mr. Hammer mentioned was appointed to attack this subject. As we see it, there are two phases. One of the education of the public and that is a long drawn-out process which has been attacked in the manner which he has described. The other side of it to my mind is a good deal more difficult. It is the prevention of the sale of defective devices. I just came across a letter on my desk yesterday, from one of our members. Possibly some of you have seen the publication. It is a description of a lot of wiring devices which are substandard. You can buy an electric toaster for 15 cents. You can imagine what it is.

Possibly that is an extreme comparison, but the same element runs through very many of these devices. It is a problem which is very difficult to attack in any way and yet many people are uninformed and are buying those devices. When we view that prospect and what it may lead to, I think there is reason for our concern. I am very glad that all these various groups are getting after it and are interested.

Now as to the matter of presentation, I think that you will agree, I hope you will, that the more people we can get back of this prevention work, the stronger we shall all be, and we are not going to get other people in our industry back of us until we approach them with a presentation of which they will approve and which they can put out over their endorsement. That is the only point in which we will have to sit in together and come to a little compromise. We are very anxious to combine our efforts. We are very anxious to cooperate in any way possible. We do have to consider some other viewpoints. I do not need to go into the detail of those viewpoints at this time, but I think you will recognize that if the other man is approached in such a way that he will endorse our methods without reservation, his strength is going to be thoroughly added to any efforts we make.

CHAIRMAN WHITING: Mr. Maxwell, being an electrical engineer, you can tell us something about the engineering side of it.

ALEXANDER MAXWELL (National Electric Light Association, New York): There is, I believe, one aspect of the subject which the other speakers have not developed, in which you know my interest very well, and that is the statistical aspect. Our organization has been trying very hard to organize some statistical source that will give us technical information. That, we feel, is indispensable in dealing with the engineering side of the low-voltage hazard.

Mr. Whiting has told you already that there is no recognized source for such statistics. Indeed the chart that he has posted here is the best thing I have seen on the subject anywhere at any time and although we are all indebted to Mr. Whiting for that, I think he would be the first to acknowledge that it is not good enough. We need a lot more information. We need more detail as to the situation and conditions surrounding the individual cases. We need a tabulation according to voltage and various other things. I wish that it could be managed.

I want to say that there seems to be very little prospect for its being managed on any basis of general organization, but even if we could get what exists, it

would help. Here, for example, are some 187 cases. Mr. Whiting on another occasion reported 80 cases. I have heard from time to time of others interested in the subject who have so many cases, perhaps a hundred, perhaps only a couple of score. If all of those could be brought into some central point and examined in great detail and the duplications eliminated, it might not be wholly successful but on the other hand there might be some yield. An effort could be made to secure those essential technical elements that are generally lacking in press notices.

I think we could thus make quite a little progress on it, and I don't mind saying, on behalf of our own office, that if all of those who possess these individual cases would give them to us we would be quite willing to undertake the labor of elaborating them as far as that can be done. In the light of earlier experience, I certainly would not want to promise too much, but we would be very glad to do what we can in that connection. I wish your Committee might be the agency to collect the material.

CHAIRMAN WHITING: There is a gentleman who is connected with the New York Edison Company, who has had the privilege of representing, on our Committee, both the American Society of Mechanical Engineers and the American Institute of Electrical Engineers. Furthermore he presented a paper in the General Session Monday on "Safety Through the Utilization of Electrical Power." I would like to have Colonel Jackson tell us his viewpoint on how we can do some educational work on this problem.

COL. J. P. JACKSON (New York Edison Company): Mr. Chairman, I think it was a year ago that we had a meeting of our Committee in Chicago, and this educational question came up first as a vital problem to be taken up and pushed. At that time I represented Mr. Gorry for the N. E. L. A. as well as my own representation. In the course of the discussion I suggested to the Committee that there was one body in the United States which was well qualified to carry on the electrical hazard educational work, in fact better qualified than any other, and that was the National Electric Light Association, and I believed that Association should be asked to take the lead in that kind of education.

Mr. Whiting and his Committee talked it over, and it was finally agreed that that was the wise move to make. Through that action, the matter was brought to the Committee of which Mr. Beardsley is Chairman, the N. E. L. A. Accident Prevention Committee, and last year at Louisville the matter came up, and the special subcommittee concerning which Mr. Hammer spoke this afternoon, was appointed to go into this matter.

Adhere to the Chicago Plan

In other words, your Committee, at the stated meeting, did all the work that the National Safety Council should do on this subject. I believe, personally, we should adhere strictly to that plan that was started in Chicago. In the first place, the National Electric Light Association has within its membership the great bulk of the electric light and power companies of the United States which have, according to the paper Mr. John M. Lieb gave on Monday, that I had the honor of reading, already reached through the homes 63 per cent of our whole people, through installations of electricity. As to our shops, the electric light and power companies supply 75 per cent of all the power used in the industries of this country. The home lighting, shop lighting, and use of electric power are increasing rapidly, so within a few years practically all power of a character that does not require heat will be from central stations.

That means that the electric light and power companies as a group can reach through their customers practically all our home people and industrial workers. Furthermore the electric light and power companies, through their individual

experience, probably know better than any other industry how to reach the customers and the kind of information and education they ought to have. So I maintain that the policy we adopted in Chicago of following the National Electric Light Association and helping them and cooperating with them through our own publications should be continued.

CHAIRMAN WHITING: I regret one of our members was unable to get here, Mr. W. J. Canada, representing the National Electrical Manufacturers Association, to discuss what Mr. Beardsley mentioned, this 10 and 15 cent stuff you can buy at many stores. The N. E. M. A. is doing what it can to make utilization equipment safe. I have been rather astonished to see in the past some of the reputable electrical device manufacturers in this country making, for example, holders for extension lamps (and not cheap ones either) where they did not recognize fully the possibility of electric shock. They did not attempt to avoid exposed metal parts that could easily become charged when the device gets wet, as any electric lamp holder is bound to get sooner or later. Mr. Canada has already taken up this problem.

You will be interested to have a brief resume of what can be done from the wiring standpoint on some of these electrical hazards, particularly on portables. I will call on our member who represents the Bureau of Standards, Dr. Lloyd. He is also chairman of the National Electrical Safety Code, a most valuable standard for the safe installation and operation of all kinds of electrical equipment, both high-voltage and low-voltage.

DR. M. G. LLOYD (Bureau of Standards, Washington, D. C.): Mr. Chairman and Gentlemen: I think perhaps an assembly of men such as we have here, who are connected to some extent with industrial plants and with utilities, is a good place to give some publicity, and through them to a still larger circle, in regard to the recognized methods for preventing some of these low-voltage accidents.

In this assembly of cases here you will notice more than one-third are concerned either with extension cords or portable tools. The 1928 edition of the National Electrical Code has recognized that hazard by having incorporated within it a new rule covering the grounding of portable devices in an industrial establishment. Probably not many of you have seen this new code yet—the 1928 edition that has just come out during the last month.

A New Code Rule

There is a new rule, No. 908, page 134, under the title, "Method of Grounding Portable Equipment in Industrial Establishments." The rule reads as follows: "In industrial establishments portable devices having exposed metal parts used in industrial operations shall be equipped with a cord containing an additional insulated conductor to be used for grounding purposes only and easily distinguished from the circuit conductors, or with metal armor." And then it refers to recognized types of armor and goes on to make corresponding provisions for polarized plugs and receptacles to be used with such a portable cord.

You will notice there are two methods of grounding in the case of a portable device. One is by having the cord made up with a separate conductor for the grounding purpose, which is connected at one end to the casing of the portable device and connected at the other end (that is, at the receptacle, through a prong of a special plug) to either the steel conduit, if it is a conduit installation, or the armor of the flexible cable, which of course conducts the ground up to the receptacle. That is a new rule in the Code and it is something that has not been generally done. Individual plants have taken steps to carry out that idea before. For example, Mr. Goodspeed told me that they do it in the General Electric plants. In the city of Detroit it has been required for some years that the entire city be

equipped that way, not for 110-volt devices but for 220 and 440-volt devices. The city of Grand Rapids, Michigan, I know has been requiring it.

Hereafter it is going to be a general rule, applying not only to the higher voltages but also to 110-volt portable devices in industrial plants. It will probably take some time to get this new rule into working condition. Many contractors and jobbers around the country perhaps have not been carrying this kind of equipment, but undoubtedly they soon will be if this rule is put into effect in different municipalities and of course by the inspectors of the fire underwriters. Most of these groups generally enforce the provisions of this National Electrical Code.

Just a word about these methods; the one of using additional wires in the cords and the other of using a portable cord which has a flexible armor around it. Of the two, it seems to me the flexible armor is the best practice, because it does two things. It not only carries the ground connection from the wall receptacle to the device itself but provides mechanical protection for the connecting flexible cord itself, which the other method does not do. Looking again at that table, we see 43 cases of death due to extension lamps and cords, and I would guess that a large number of them are due to defective cords which have worn bare, exposing a conductor so that contact can be made with it. I have known of several cases of that kind in my personal experience, and have no doubt most of the 43 are of that type. If you use a cord with an armor around it, it seems to me it is going to cut out that class of accident represented by the 43 as well as the class represented by the 33.

According to this compilation, the 43 group is the more important, and it may be more important to protect that cord from wear which will expose the conductors than it is to ground the case or frame of the portable device itself.

I hope you will all take this thought back home with you and spread the idea of this new rule in the wiring Code and the advisability of carrying it out in order to avoid the casualties that we have been having right along.

CHAIRMAN WHITING: Mr. Barnes represents the Association of Electragists, International. They are the electrical contractors who are as close to the users of electrical devices as any technical group. He will be glad to give the viewpoint of the electrical contractor on this subject.

One Hundred and Ten Volts Can Kill

H. W. BARNES (New York City): When Mr. Whiting was speaking formerly, he mentioned the common belief that 110-volt circuits are "low-voltage and won't kill." It has been my personal experience, and I presume it has been the experience of a good many others, that even 110 volts will kill. I would like to see anyone contest the point by sitting in a tub of water with 110 volts in either hand.

The cases that come up are not very much under the control of the contracting industry because the contractors rather follow the regulations that are made than initiate them. It is, however, the desire and one of the purposes of our group of electrical contractors, who call themselves the Association of Electragists, International, to see to it that their members follow out the rules and provisions of the National Electric Code, and particularly of local ordinances and other standards of installation, taking into account the hazards to life and property which go beyond even the requirements of the National Electric Code.

As the gentlemen representing N. E. L. A. said, we have to take a good many viewpoints into consideration in the electrical industry. The man manufacturing an article which costs the public more money immediately runs into a sales resistance for that article. Consequently he may be interested in another form of article that does not cost so much. Our purpose is to study first, what are

the necessities of life hazard and property hazard protection, and then get out the best article from an engineering standpoint and from a practical point of view for the public to use, but to absolutely squash all materials and appliances which fall short of that standard. The Association of Electragists is always glad to commit itself to such a program.

CHAIRMAN WHITING: I suppose, if the electrical fire inspectors or the city wiring inspectors were entirely onto their job, we laymen would not have to go into this problem ourselves because there would not be any more of these bath tub fatalities. I would like to hear why that is not done, from the representative on our Committee, of the Association of Electrical Inspectors, Mr. Cahaskie, who is also Chief Inspector of the Electrical Bureau of New York Board of Fire Underwriters.

Problem of the Inspection Bureaus

C. S. CAHASKIE: Mr. Chairman and Gentlemen: You have given me a very hard job to explain why all these accidents have not been prevented by the inspection bureaus. I would like to tell you that every accident that is brought to our attention is investigated carefully and notes taken to see whether the electrical equipment complies with the local rules and with the National Electrical Code. If we find it does not comply with the Code, we immediately call it to the attention of the owner of that equipment, and they failing to correct it, the building is "put on a slip," which means that the fire insurance rates are increased up to 50 cents per hundred. A 50-cent rate is almost a prohibitive rate, so that means, if they carry fire insurance at all, they must make corrections immediately.

We cannot force them. We have no police duty nor police authority. The only weapon we have is that of the fire insurance rate. We have found that the people are willing to cooperate with us in most cases. Lighting companies are very much interested in this. They have helped us a lot. They are probably closer to these people than we are and can present the hazard to them forcibly.

In this city we have a rather large committee, representing all branches of electrical industry, of which Mr. J. C. Forsythe, Supervising Engineer of the Electrical Department, New York Board of Fire Underwriters, is Chairman. We have brought sub-standard conditions which exist here before all the large department stores, manufacturers, chain stores, and the smaller contractors. We are gradually reaching out to get every one of them. I am very glad to say that the large department stores and the chain stores that we have reached have all been glad to cooperate with us in this movement to eliminate sub-standard electrical material which I believe is the cause of a great many of these accidents, principally of the 43 mentioned here in this table.

I find that the cords and devices for lamps have been the cause of a good many accidents. The lamp wires put out are pretty cheap. They are made to sell at a price to compete with other stores who are running sales. The devices are not properly made. The conductors are of the poorest. The insulation on the conductors is of the poorest class. All of these people, including the 5 and 10 cent stores and other chain stores have agreed to eliminate this material gradually; that is, when they order new material to put in their orders at Underwriters Laboratories standards and all material and devices will have to be furnished on that basis. We should gradually get rid of all that sub-standard material. With those who do not work with us, we shall have to be a little more severe and use the rate.

CHAIRMAN WHITING: I am going to call on two of your Engineering Section members to close this discussion. Mr. Opp, will you say a few words?

GEORGE OPP (Detroit Edison Company, Detroit, Mich.): I am very happy to see this world-wide interest in this subject. It shows that everybody is thinking about

it. And just as soon as we get our thoughts put together there is bound to be a solution before long. I want to praise each and every one of the speakers for presenting his viewpoint, and I trust that the committee, in getting together for the coming year, will consolidate those viewpoints and accomplish something within the next twelve months. You are on the road, and God speed.

CHAIRMAN WHITING: The last speaker I have a particular grudge against, because he is the man who gave this committee to me. But I will heap coals of fire on his head by calling his attention to two cases that were noted when we made this analysis of newspaper reports. The man who spends all his time at a Safety Congress, playing golf, wants to be pretty careful that he does not get killed by lightning. In all seriousness, a golf player should not, when a thunder storm comes up, run to shelter under a tree. That is the worst thing he could do. He had better stay out in the rain and get his togs all wet than to get under a tree. There were two cases in this three months' period where a golf player ran under a tree in a lightning storm, and that was just where the lightning struck, and he was killed.

Mr. Banash may close the discussion, and tell us anything he wants to.

Human Life Above Monetary Value

J. I. BANASH (Consulting Engineer, Chicago, Ill.): Mr. Chairman and Gentlemen: After those complimentary remarks, I want to announce that I have not played golf yet during this convention. I guess Steve is right; I did wish this job on him. I was the original Chairman of this Committee, but Steve is a fellow who likes to work, so we gave it to him.

Looking at this thing by and large, from our own viewpoint, that is the American Society of Safety Engineers, if the low-voltage hazard has been so insignificant as has been statistically proven, and here shown, why are we taking so much time and trouble about it? One of the answers is probably this: Human life in the volume shown here for that short period is perhaps more valuable than can be measured in money. Another thing is that any such occurrences, which receive the publicity they do, without detailed explanation which the newspapers cannot give, is a detriment to the industry, and a continuation of unsafe practices will gradually accumulate a larger accident record.

I am very glad to hear of the cooperation which is being received from the chain stores in New York. But I wonder if it is going to be possible for those people to remain in any electrical business if they agree with Mr. Cahaskie to handle nothing but the preferred material. Perhaps when it comes to that point there will be a division of opinion, which I hope will not occur.

I have not much to add in the way of contribution to this discussion except one thought. Our friends of the N. E. L. A., who have spoken, have shown considerable progress. This Committee of ours has no definite intention of bringing out specific codes, but it runs in my mind that if the cooperation between the various bodies interested could be extended just a little further, as by giving Mr. Whiting, as Chairman, an opportunity to read and perhaps comment on the proposals which are to be up for adoption by N. E. L. A. at Philadelphia next week, it might perhaps with no change, perhaps with some changes which are not significant, be possible to get our Executive Committee to agree to lend the added weight, if any, of our endorsement to such publications.

MR. BEARDSLEY: I am very glad to commit the Accident Prevention Committee to the proposition of having Mr. Whiting review what we have before us in Philadelphia, after it has received the consideration of our own executives.

(Chairman Keown resumed the chair.)

CHAIRMAN KEOWE: I am sure I express the sentiments of the Section in thanking Mr. Whiting and the members of the Low-Voltage Electrical Committee for the work they have done, and also the speakers of the afternoon, who have contributed to its success.

ADJOURNMENT

October 3, 1928

R. McA. KEOWN, Chairman
Engineer, Industrial Commission of Wisconsin, Madison, Wis.

The second session was called to order at one twenty-five o'clock by the chairman, R. McA. Keown.

Report of the Steering Committee on Research, Standards and Codes

The work of your Steering Committee on Research, Standards and Codes during the past year has been similar to the work of other years. This has included:

1. Giving advice to the Executive Committee of the National Safety Council upon subjects proposed for codes or research.
2. Appointing Research Committees.
3. A general check-up of research, standards and code work which is in progress by members or representatives of the A. S. S. E.-Engineering Section.

At the present time there are six Research Committees:

1. The Effects of Annealing on Chains, R. F. Thalner, chairman.
2. Elimination of Harmful Noise, Dr. H. Clyde Snook, chairman.
3. Low Voltage Electrical Hazards, S. E. Whiting, chairman.
4. Static Electricity, Thomas W. Butler, chairman.
5. Wire Rope Attachments and Connections, Charles C. Sunderland, chairman.
6. Sandblasting Hazards, Dr. Leonard Greenburg, chairman.

Progress reports will be presented at this Congress for discussion on The Effects of Annealing on Chains, Elimination of Harmful Noise, and Wire Rope Attachments and Connections. Work of the Static Electricity Committee has been delayed pending the completion of negotiations which are under way with certain engineering colleges for making desired static electricity tests. It is expected these tests will be started this fall.

Because of the lack of condensed and authoritative data relating to accident and health hazards confronting employees in many industries, seventeen committees have been organized to study the hazards in seventeen industries and to prepare reports of practical recommendations to decrease or eliminate those hazards. It is intended these reports will be used as bases for Safe Practices pamphlets which will be guides for all persons in the industries involved. The seventeen committees are as follows:

1. Bakery Operation Hazards, Walter S. Paine, chairman.
2. Candy Manufacturing, Glenn W. Cook, chairman.
3. Clay Products, H. H. Hamm, chairman.
4. Dairy Products, F. W. Braun, chairman.
5. Dry Cleaning and Dyeing Establishments, Dr. Morton G. Lloyd, chairman.
6. Enameling and Japanning, R. C. Stratton, chairman.
7. Excavating and Pile Driving, M. E. Arkills, chairman.
8. Food Preserving and Canning, H. J. Potter, chairman.
9. Hotel Accidents, W. Graham Cole, chairman.

10. Lacquers and Miscellaneous Pyroxylin Products, John S. Shaw, chairman.
11. Leather Tanneries, Oliver F. W. Cromwell, chairman.
12. Mercantile Establishments, David S. Beyer, chairman.
13. Paper Box Making, W. A. Weir, chairman.
14. Printing and Bookbinding, John J. Lamb, chairman.
15. Rayon Manufacturing, G. E. Minshull, chairman.
16. Structural and Sheet Metal Fabrication, D. L. Royer, chairman.
17. Tunnel and Caisson Work, R. McA. Keown, chairman.

Other committees on additional subjects should be organized as conditions warrant. All members having statistics or other data which will be of value to any of the above named committees are urged to submit such information to Stewart J. Owen, Jr., Safety Engineer, National Safety Council headquarters, Chicago, Illinois.

The A. S. S. E.-Engineering Section is sponsor or joint sponsor under AESC procedure for fifteen safety codes six of which have been approved and published:

1. Forging and Hot Metal Stamping.
2. Ladders.
3. Point of Operation Hazards of Rubber Mills and Calenders.
4. Power Presses and Foot and Hand Presses.
5. Pulp and Paper Mills.
6. Colors for Traffic Signals.

The following nine safety codes are not as yet completed nor published:

1. Compressor Air Machinery—The formulation of this code is well under way.
2. Floor and Wall Openings—A draft of this code is under consideration by the Committee.
3. Gas Mask Canisters Color Code—The work of this code is well under way.
4. Rubber Machinery—Considerable work has been done on this code. One part dealing with the point of operation hazards of rubber mills and calender has been approved and published.
5. Scheme for the Identification of Piping Systems—The work on this code is practically complete.
6. Standardization of Methods of Recording and Compiling Accident Statistics—The sectional Committee has recently been organized for this code.
7. Textiles—The third draft of this code has been sent out to the committee members for their consideration.
8. Walkway Surfaces—The work of this code is well under way.
9. Window Washing—The first draft of this code has been submitted to members of the sectional committee.

The American Engineering Standards Committee has committees on seventy-three safety codes. The 29 approved and published codes are underscored. Where A. S. S. E.-Engineering Section representatives have been appointed the names of such men are given after the title of each code. Copies of safety codes which have been approved and published may be obtained from the National Safety Council.

Our Society is also ably represented by H. Weaver Mowery on the National Building Codes that are being formulated by a special committee organized by Secretary Hoover, and by Walter G. King on the committee on light and safety of the Illuminating Engineering Society.

Mention has been made in previous reports that the work of a code committee is difficult and exacting. Many of the meetings are held in widely scattered places and, therefore, much of the work must be done by correspondence. All of our representatives on the various codes have given freely of their time and advice in order that the section may be properly represented. All members should cooperate with these representatives through submission of information, recommendations

for adoption of the codes, etc. It is only by close cooperation between the members of the section and our safety code representatives that the desired results will be obtained.

Report of Membership Committee

One year ago we had ~~100 members and 402 associate members~~, making a total membership of ~~502~~.

During the past year, your Membership Committee has secured 25 new members and 33 new associate members, a gross gain of 58.

Unfortunately, however, there have been 45 resignations during the year, of which 25 were members and 20 associate members.

During this same period, 21 of our associate members have been raised to full membership.

Thus, we now have a total membership of 1,005, of which 648 are members and 393 associate members. This is a net gain of 7.

S. V. JAMES, Chairman
W. E. WELCH
F. L. HURLBUTT

Report of Steering Committee on Regional Safety Conferences

Through the wholehearted support and cooperation of the local safety councils, industrial sections, Council members, and outside organizations, your committee has the pleasure of reporting that twenty-two successful regional safety conferences were organized and held during the past year under the sole or joint sponsorship of the ASSE-Engineering Section, National Safety Council. This is three more than the total reported for the previous year, and it is most gratifying to note that the total attendance has exceeded the records of all previous years. Furthermore, it is thought that a better geographical distribution was obtained.

In addition to the twenty-two conferences that were held under our recognized auspices, your committee assisted in formulating the plans for twenty-one other safety conferences for which we received no formal recognition. These conferences included such meetings as the New York State Safety Conference, the All Ohio Safety Congress, twelve conferences conducted by the Portland Cement Association, several organized by the National Petroleum Association, and others.

Thanks to the cooperating bodies, ten of our twenty-two conferences were miniature safety congresses and were held in Boston, Mass.; Lansing, Mich.; Kansas City, Mo.; Newark, N. J.; Chicago, Ill.; Oshkosh, Wis.; Janesville, Wis.; Wausau, Wis.; Philadelphia, Pa.; and Los Angeles, Calif. Here, various sectional meetings were held simultaneously, and those who attended emphasized the fact that their individual problems were much more intimately discussed.

The remaining twelve conferences of the year were held in Duluth, Minn.; Erie, Pa.; Pittsburgh, Pa.; Portland, Oregon; Birmingham, Ala.; St. Louis, Mo.; Allentown, Pa.; Providence, R. I.; New Orleans, La.; Seattle, Wash.; Spokane, Wash.; and Tacoma, Wash.

So great has been the interest shown in regional safety conferences that in several instances the demand for tickets for the evening dinner meetings exceeded the available accommodations. Many companies send their entire supervisory forces, particularly to the evening meetings.

The free exchange of ideas and experience has brought about the success of these conferences, and those attending stress the fact that their superintendents, foremen, and others get the spirit of the safety movement more forcefully than in any other way.

Encouragement has thus been given to your committee to proceed with tentative plans for other conferences to be held during the coming year, and on behalf of our new committee on conferences, I bespeak your full assistance and support. If any of our members want regional safety conferences in their communities, just make your wishes known to your committee and an immediate response and offer of complete cooperation will be forthcoming.

Report of the Committee on Chapter Organization and Activities

During the last year the Northern New Jersey chapter has been recognized as a full chapter of the A.S.S.E.-Engineering Section. Its membership is largely made up of engineers in the Newark district who found it impossible to attend meetings of the Metropolitan chapter which formerly covered this territory. The new chapter is strongly organized, and the members are taking an active interest in safety and engineering developments.

At Worcester, Mass., another chapter has been organized and will ask the Executive Committee at its next meeting for recognition as a full chapter of the A.S.S.E.-Engineering Section. This new chapter has a membership of 36 men who are enthusiastically interested in this line of work. We expect the organization to grow rapidly and become one of our most successful chapters.

Attempts were continued to interest the California Society of Safety Engineers and the Southern California Society of Safety Engineers in affiliation with the A.S.S.E. After giving the question careful consideration these societies declined membership in the A.S.S.E. largely because of our membership rules which provide that a member of the A.S.S.E. must also be a member of the National Safety Council. We hope, however, to eventually succeed in interesting these men in affiliation.

Unsuccessful efforts have been made to revive interest in the Hartford Chapter. Local politics however, have done much to dampen the ardor of the more active members. Interest is now centering around the establishment of a chapter of the National Safety Council in Hartford and when this is a reality we should be able to reorganize the chapter of the A.S.S.E.

We have also corresponded with the Pennsylvania Society of Safety Engineers, the Ohio Society of Safety Engineers and the engineering Societies affiliated, with the local Chapters of the National Safety Council in Detroit, Kansas City, Cleveland, Atlanta and St. Louis.

This committee has listed a number of arguments for affiliation with the A.S.S.E. which have been sent to several independent engineering societies in an effort to interest them in the A.S.S.E. A definite program is planned to follow up these letters at regular intervals to further emphasize the advantages of affiliation.

In connection with the organization of new chapters the committee compared the Constitutions and By-Laws that were submitted for approval by chapters of the A.S.S.E. Investigation showed that there was considerable variation in the laws and rules governing our different chapters. The committee deemed it advisable to prepare a standard form of Constitution to be adopted by all chapters. This investigation also covered the Constitution and By-Laws of the A.S.S.E.—Engineering Section (parent organization) and in these the committee has suggested several minor changes that will be presented for approval and adoption.

The objections of the California Societies suggested the desirability of creating a new grade of membership in the A.S.S.E. It is the belief of this committee that there is a large number of qualified men who are not members. These men are interested in the work of the A.S.S.E. and would be glad to take an active interest if the qualifications for membership were so changed that they could be afforded the full privileges of the organization without the financial objection of keeping up an individual membership in the National Safety Council. We believe that this is one of the foremost obstacles to our efforts to interest independent engineering societies in affiliation with the A.S.S.E. While such a change in the membership rules would be contrary to past and present custom, we feel sure that in the long run it would be helpful in securing new members not only for the A.S.S.E. but also for the National Safety Council. In conformity with these views we have presented the question to the Executive Committee for consideration.

This committee has also prepared and distributed among chapters of the A.S.S.E. and several engineering societies a list of speakers and the subjects on which each one is qualified to talk. We hope that this list will be helpful in arranging interesting programs.

Plans are now under way to establish a systematic exchange between our chapters, of programs for meetings, minutes of meetings and other information that may be helpful in securing full attendance at meetings and a wider membership for each chapter.

We wish to express our appreciation for the splendid cooperation and help extended to us by all of the chapter leaders. Special mention should be made of the support which we received from Mr. Keefer. Any success that we have had and any progress that we have made should not be credited to the Committee inasmuch as a great deal of the real work was done by Mr. Keefer.

Respectfully submitted,

H. W. Heinrich, chairman

Report of Committee on Accident Prevention in Engineering Colleges

During the past year, your Committee on Accident Prevention in Engineering Colleges prepared the first four of a series of illustrated safety lectures for use in engineering colleges.

Accident Prevention—A Factor in Engineering.
Preventing Accidents on Woodworking Machines.
Safety in Foundries.
Preventing Personal Injuries in Machine Shops.

Copies of these lectures were sent to deans of one hundred and thirteen engineering colleges with letters explaining and urging their use. Unfortunately, many colleges received these letters too late in the closing semester to use them before the start of the summer vacation. Nevertheless, five colleges did use them and reported that they were favorably received by the students. Thirty-eight others acknowledged their receipt, indicated their interest, and expressed their willingness to use them after the start of the new fall term.

This has encouraged your committee to believe that other lectures should be added to this series as rapidly as practicable. Accordingly, six new lectures are now in the making.

To further promote the use of these lectures, your committee has appointed a member of the ASSE-Engineering Section in each college town to serve as a liaison officer between our Society and the local engineering college. These men are helping in no small way to secure greater recognition for the safety movement in the minds of our future engineers and industrial executives.

CHAIRMAN KEOWN: Each of you has at hand a copy of the reports of the various committees of the section. I wish to briefly touch upon some of the high spots in those various reports. Heretofore it has been the practice to have each of the committees report individually. This year we are trying out the scheme of bringing them all together.

The first report in your pamphlet is that of the Steering Committee on Research, Standards and Codes. This has been a rather busy committee. Mr. George Sanford, vice-president in charge of engineering of the council, has been chairman of this committee.

There are, as the paper shows, six principal research problems under way. Yesterday afternoon we had progress reports on two of them, namely, the Effects of Annealing on Chains, and the Low Voltage Electrical Hazards. Tomorrow afternoon there will be an open meeting of the Committee on the Elimination of Harmful Noise. This report states that the Committee on Wire Rope Attachments and Connections will have a report, but the committee will not report because at the time the program was made up for the Congress their report was not in complete form. They have had a committee meeting during this Congress but are not ready to make their report. The Sandblasting Hazards Committee is being formulated at the present time. I think that will be a very important subject, and we ought to get a lot of good information out of it.

Arrangements are being made now with the Bureau of Standards with a view of having them do the test work for the Static Electricity Committee.

This year it was the thought of your officers that if we could get more of the membership actually doing the work we would have a more successful section.

With that thought in mind and also knowing that we had very little material on a number of subjects, a list was prepared of topics upon which we desired information.

Seventeen different subjects were suggested, and a questionnaire was sent out to the membership of the section asking them to designate as first and second choice those which they would like to work upon. We got a very fine response.

As a result, seventeen different committees have been formed. Your program shows the time and place of meeting of each one of those seventeen committees. I hope if there are any of you who are members of those committees you will make it a point to be at the meeting. There is no report to make, I presume, by most of them, because they are just getting started. I believe the work will be of great value when it is completed. One of the most important things the membership can do, is to assist those committees in collecting material which can be used as the basis of safe practice pamphlets for the various industries involved.

There is also listed here the codes in which the A. S. S. E. Engineering Section is interested. Those codes in which the council is asked to be sponsor are handled by the A. S. S. E.—Engineering Section. All of the various safety codes being formulated under the American Engineering Standards Committee are listed here together with the names of our representatives. This ought to be valuable for reference.

The Membership Committee report is given, and you will notice we have made a slight increase in membership. There are quite a number of new members, but there were also some resignations, so that at the time this report was made up we had one thousand and five members, of which six hundred and eighteen are full members and three hundred and ninety-three associate members. The report doesn't show a very large growth, but I don't think it is necessarily the size of the section that counts. However, if any of you know of men who are eligible and ought to be in this section, we desire you to send in their names to the Membership Committee so that they may be acted upon.

The committee on Regional Safety Conferences has been active during the year. There have been held in the past year twenty-two different original meetings, of which this section has been sponsor, cooperating sponsor at least, for about ten of them. I have personally attended several, and they have been very successful. They are in effect really miniature congresses, with different sections running simultaneously and a general session or two. It is desired the work which has been largely under the direction of Mr. George Burns of the National Council Staff, will continue.

The committee on Chapter Organization and Activities has a report. The statement is made that the Worcester Chapter would apply for its charter. That has

already been taken care of by the Executive Committee of your section since the report was prepared, so that we now have a chapter at Worcester.

The committee on Accident Prevention in Engineering Colleges has made some progress. During the year pamphlets have been printed on four topics. There has been some demand for them, not as much perhaps as there would have been had the list of subjects been larger. We feel, however, that this work should be carried on, more subjects developed, and that we give publicity to the fact that such material is available. Three of these lectures are illustrated, and slides have been prepared for sending out with these lectures.

The committee has appointed liaison members of this section in connection with one hundred and nine colleges throughout the country. Those men should be a valuable help to us in getting this work across. It has always been difficult to get this material to the young engineering student.

I wish to take this opportunity of thanking the various committee members, and especially the members of the headquarters staff, Mr. Keefer and Mr. Owen, who have done such good work during the year in looking after the details, keeping after these committees, and getting the work done. I hope this kind of cooperation will be continued, as I know it will, for the new officers who are coming in.

The next item of business is the proposed amendments to the constitution. Copies of the amendments were sent with a letter ballot to all members of the section. However, the response to the letter ballot was not great. I submit the amendments for your consideration. I think Mr. Heinrich, chairman of the committee, had best speak and tell you what is proposed.

H. W. HEINRICH (Asst. Supt. Engineering and Inspection Division, the Travelers, Hartford, Conn.): I believe Mr. Keefer's letter dated August 30, 1928, sums up in rather conclusive form the way the amendments may be considered. Was it your thought I am to discuss the amendments themselves?

CHAIRMAN KEOWN: Perhaps many of the members here are not familiar with them, or haven't their copies. I wish you would explain the changes proposed.

MR. HEINRICH: It is believed necessary to change the existing statement in the rules referring to the object of the A. S. S. E. Engineering Section. It is thought to be an advantage to change the wording, and the change is a simple one fundamentally.

The rule now reads, "The object of this society is to promote the arts and the sciences connected with engineering in its relation to safety for life and property."

In the suggested change we believe it would be better, instead of referring to the relation between engineering and safety for life and property, to relate engineering to accident prevention and to the protection of property. The change is in no way so fundamental as to upset the line of thought under which the original rule was proposed.

The second change relates to the term "corporate members." It is the thought of the members of the committee on Chapter Organization and Activities that the term corporate is a little bit ambiguous. It is vague, not so clearly understood, and the suggestion is made that full privilege members be substituted therefor.

The third suggestion is that a new section be added to the constitution which will make it possible for the Executive Committee to fill vacancies among the officers or in the Executive Committee by vote of the remaining members of that committee.

It seemed to the committee on Chapter Organization to be a sensible thing to do, in order to avoid delays and the embarrassment that would naturally result if vacancies which occurred during the term of any one of the officers and members of the Executive Committee were allowed to continue unfilled until the term had expired.

The fourth suggestion is that the by-laws be amended by a three-fourths vote of the entire Executive Committee in session or by letter ballot. There is no

particular change there.

If there has been opposition—and I sense perhaps there is some opposition to a change of this kind—I believe it is more the kind of opposition that is based upon a misunderstanding rather than upon any real merit. For example, the rules, as they now read in connection with that point, are very similar to the proposed rules. A very slight change is requested. The present reading is as follows: "A proposed amendment to the by-laws may be presented at any meeting of the Executive Committee and if passed by a three-fourths vote of those present may be finally adopted by a three-fourths vote of the entire committee by letter ballot. Any such amendment after adoption shall be published in the official publication."

The proposed change reads the same; except that a proposed amendment may be presented at any meeting of the Executive Committee and if passed by a three-fourths vote of those present may be finally adopted by a three-fourths vote of the entire committee in session or by a letter ballot. In other words, there is just simply a choice, an alternative. You may adopt by letter ballot or by the entire committee meeting in session, but only after the amendments have first been presented to the committee meeting in session.

The fifth change, I believe, will not be taken up at this meeting.

In all of these proposed amendments there is very little change, and no changes whatsoever, as I see it, that affect the fundamentals of the organized activities of the A. S. S. E. They are merely changes that lead to a better and a clearer understanding of what the real intention is.

It is the recommendation of the committee that these amendments be adopted, and I so move.

(The motion was seconded.)

CHAIRMAN KEOWN: Is there any discussion?

A. J. VAN BRUNT (Director Safety Education, Public Service of New Jersey, Newark, N. J.): I would like to discuss this for a few moments. It is true that we have received through the mail memoranda showing us what these proposed changes are in detail as read by Mr. Heinrich. Mr. Heinrich has not told us how much, if any, opposition was developed in reply to the memoranda received on the subject.

Considerable opposition in my mind has been developed against the adoption of these amendments. If I may speak in a general way, I would say that I consider the phraseology of them entirely too ambiguous.

For instance, the last subject that Mr. Heinrich spoke on—Number 4—he told us there was an alternative. He didn't tell us who should decide the alternative. In a general way it seems to me that the entire matter had better be laid on the table for more intense consideration by those who have been members of the A. S. S. E. for many years, long before the amalgamation of the A. S. S. E. with the National Safety Council. Incidentally, I do not wish to see the A. S. S. E. as a separate organization entirely wiped out.

I come from the State of New Jersey. After the A. S. S. E. activities had assumed a certain magnitude in New York City, we expended considerable time, mental effort and no little amount of money in organizing the Newark section. Progress is apparent. Our meetings have been held regularly. I believe the Metropolitan Section will admit that we have afforded them some assistance.

My objections to these amendments are: first, they are not clear; second, these amendments would ultimately merge the A. S. S. E. into this section. Therefore I move that the entire matter be laid on the table for future consideration.

H. W. MOWERY (American Abrasive Metals Co., New York): In seconding that motion I would like to call attention to another matter. In the résumé sent out to the members there was no mention made of what appeared to me in the list

of the proposed amendments, as another very material change, I think, ought to be called to the attention of the membership. That change is this: It is proposed through these amendments which were not called specifically to the attention of the individuals, to require anyone who wished to have membership in the A. S. S. E. to first have his organization or company take membership in the council and then delegate him to represent them. Then he would have permission to become a member of the Engineering Section if he had the necessary qualifications. There is no door left open for a man like Herbert Hoover to make application for membership in the A. S. S. E. direct without first coming in through the council.

The idea, as I understand it, and always have understood it, is that the other door is to be open, and a man can make application for membership in the A. S. S. E. and then become a member of the council automatically by reason of his membership in this society. I believe that wants to be looked into a little more carefully.

I see no objection to the provision permitting the Executive Committee to fill vacancies, but it seems to me there is a decided objection to amending the by-laws so that three-fourths of the Executive Committee in session may determine upon a policy, or what not. I believe the letter ballot is a protection we all should insist upon retaining. If the entire Executive Committee is present you can have a vote without resorting to the mails. The present provision does not require a letter ballot, and if at any time you have the entire Executive Committee present you can take your ballot there at that time without going into this amendment.

There is also the question of grades of members. We have at the present time two grades of members—members and associate members. There is some distinction between the two. It is slight, but they are both full privileged members, and I don't quite like the idea of being called a full privileged member. I would much prefer to be an associate member or an active member.

CHAIRMAN KEOWN: The chair is of the opinion that this motion to lay upon the table is not debatable, so therefore we will proceed.

W. E. WELCH (Senior Engineer, Engineering and Inspection Division, The Travelers, New York): I would like to know if the present by-laws and constitution as now in effect have worked any hardship to the A. S. S. E.—Engineering Section or the National Safety Council.

CHAIRMAN KEOWN: Mr. Heinrich is more familiar with that. His committee has been dealing with chapter organizations and the promulgation of constitutions for those chapters. Will Mr. Heinrich explain that?

MR. HEINRICH: It is apparent the proposed amendments are of great interest to the members, as they should be. It is also apparent to me there has not been a suitable opportunity for a full understanding and for full discussion of these things which seem so important. Therefore I am wholly in sympathy with the thought they should not be adopted until the majority of the members understand them and have been given an opportunity to consider the various points involved and to discuss them in detail, notwithstanding they were introduced by the committee of which I am chairman.

However, in regard to the particular point that has just been raised, I wish to read one paragraph from the published report of the committee on Chapter Organization, which is:

"It is the belief of this committee that there is a large number of qualified men who are not members. These men are interested in the work of the A. S. S. E. and would be glad to take an active interest if the qualifications for membership were so changed that they could be afforded an individual membership in the National Safety Council."

I am most certainly in sympathy, as an individual and as a member of the A. S. S. E. and also as a member of the Chapter Organization Committee, in getting into our organization men who are not necessarily members of the National Safety Council, a qualification which now stands. The committee on Chapter Organiza-

tion is not adding anything new in that particular way. We are simply repeating the old qualification when we list as a qualification for membership in the A. S. S. E. that a man must be a member or that his company must be a member of the National Safety Council. There are lots of men, lots of good engineers, like Herbert Hoover and hundreds of others, who probably could be induced to seek membership in this organization and would do us a world of good. But there is an objection, which is that of membership in the National Safety Council.

Of course we are members here of the National Safety Council. We want to see that organization grow. We ought to give due consideration to the disadvantage that exists in allowing men to get into a branch of the National Safety Council without being National Safety Council members. But there the proposition stands. It is of wide interest. It is of value. I personally have reported as being in favor—and so has the committee which I represent—of allowing men to enter the A. S. S. E. without necessarily being members of the National Safety Council or of having their companies members of the National Safety Council. That is an objection. I believe it retards to some extent the growth of this particular branch and well deserves consideration.

MR. MOWERY: A point of information, please. Am I correctly informed it is the understanding of the committee that a man taking membership in the A. S. S. E. and paying ten dollars for membership must, in addition, pay a membership fee to the National Safety Council?

CHAIRMAN KEOWN: That is not my understanding.

MR. MOWERY: That is not my understanding either. You pay ten dollars for membership in the A. S. S. E. which also pays membership fees in the National Safety Council.

MR. HEINRICH: You automatically become a member of the National Safety Council by payment of A. S. S. E. membership fees.

CHAIRMAN KEOWN: Or if you are already an employee of an organization which is a member that is not necessary.

MR. MOWERY: But the proposed amendment closes that door, and you must first become a member of the National Safety Council before becoming a member of the A. S. S. E.

CHAIRMAN KEOWN: That is not my understanding.

MR. HEINRICH: That was not the thought of the committee.

CHAIRMAN KEOWN: We have but five minutes until we must adjourn. You have heard the motion made and seconded to lay the entire matter upon the table. All those in favor of the motion signify by saying "aye"; opposed "no." The "ayes" have it. That means if brought up again, it will come up at the next annual meeting, not before.

The next order of business is the report of the Nominating Committee. Mr. Fonda is chairman of that committee.

Report of the Nominating Committee

MR. FONDA: The report of your Nominating Committee for officers for the coming year and also for three directors to be elected for a period of three years to succeed three outgoing directors, is as follows:

Chairman—Mr. J. I. Banash, Consulting Engineer, Chicago.

Vice-Chairman—Mr. Earl F. Blank, Jones and Laughlin Steel Co., Pittsburgh.

Vice-Chairman—Mr. C. B. Auel, Westinghouse Electric and Manufacturing Co., East Pittsburgh.

Secretary—Mr. W. D. Keefer, National Safety Council.

For directors to succeed three directors whose terms expire, these directors to serve three years:

Mr. R. F. Thalner, Buick Motor Company, Flint, Michigan.

Mr. H. W. Mowery, American Abrasive Metals Co., New York.

Mr. H. S. Smith, Prestolite Company, New York.

Proposing the nomination of Mr. C. B. Auel who is at the present time a director with still a year to serve means we must elect another director to finish out Mr. Auel's unexpired term. We propose Mr. H. W. Foster, of Brown, Crosby Co., Philadelphia.

MR. VAN BRUNT: A point of information, please. We have an assistant secretary located in New York City, a very desirable office to be filled. I heard no mention of that assistant secretary's name on the part of the Nominating Committee. I refer to Mrs. Gene S. Wood without whose assistance I doubt very much whether we would function as well as we have in the past.

MR. FONDA: That is correct. Mr. Van Brunt's remarks are to the point, and Mrs. Woods' name is included on the original report as assistant secretary.

CHAIRMAN KEOWN: You have heard the report of the Nominating Committee. What is your pleasure?

MR. WELCH: I move its adoption.

(The motion was seconded and carried.)

CHAIRMAN KEOWN: I would like to have the newly elected officers and directors rise so that you may all know who they are.

ADJOURNMENT

October 4, 1928

DR. H. CLYDE SNOOK, Chairman
Consulting Engineer, New York City

The third session of the American Society of Safety Engineers—Engineering Section—was called to order at two o'clock by the chairman, Dr. H. Clyde Snook, Consulting Engineer, New York City.

CHAIRMAN SNOOK: The Secretary will please call the roll.

(Roll Call by the Secretary.)

CHAIRMAN SNOOK: I will read the Progress Report of the Committee.

Progress Report of the Research Committee on the Elimination of Harmful Noise

By H. CLYDE SNOOK
Chairman, Consulting Engineer, New York City

The personnel of the Committee on the Elimination of Harmful Noise is as follows:

- H. Clyde Snook, Chairman, 175 Fifth Avenue, New York City.
- Stewart J. Owen, Jr., Secretary, National Safety Council, 108 East Ohio Street, Chicago, Ill.
- W. M. Bertram, Morse Chain Company, 50 Church St., Room 1871, New York City.
- F. C. Dockeray, Department of Psychology, Ohio Wesleyan University, Delaware, Ohio.
- H. Fletcher, Bell Telephone Laboratories, 463 West Street, New York City.
- E. E. Free, 175 Fifth Avenue, New York City.
- E. W. Gorry, United Electric Light and Power Company, 130 East 15th Street, New York City.
- Donald A. Laird, Department of Psychology, Colgate University, Hamilton, New York.
- John J. B. Morgan, Department of Psychology, Northwestern University, Evanston, Ill.
- H. W. Mowery, American Abrasive Metals Company, 50 Church Street, New York City.
- Mrs. Imogene B. Oakley, Chairman, Committee on Unnecessary Noise, Civic Club of Philadelphia, 1300 Spruce Street, Philadelphia, Penn.
- A. T. Poffenberger, Department of Psychology, Columbia University, New York City.
- M. C. Rosenblatt, Acoustical Engineer, 1700 Walnut Street, Philadelphia, Penn.
- S. Rosenzweig, Korfund Company, 11 Waverly Place, New York City.
- G. O. Small, General Electric Company, Lynn, Mass.
- C. Van Horn, Travelers Insurance Company, 30 East 42nd Street, New York City.
- F. R. Watson, Department of Physics, University of Illinois, Urbana, Ill.
- H. B. Williams, Department of Physiology, Columbia University, New York City.
- H. S. Williams, Equipment Division, City Department Street Railways, Detroit, Michigan. (Representing A. E. R. A.)

The National Safety Council has been a natural target for a long time in a bombardment of requests for the regulation of noise. Noise is generally disliked and regarded as a probable cause of harmful effects upon the human body. Previous reports of this committee have pointed out some of the known contingencies of noise such as accidents resulting from a lack of warning to impending danger, impaired physical health, increased nervousness, inefficiency, deafness, depression upon the sick, etc.

Certain progressive industrial organizations have recognized the economic value of noise reduction. Substantial economies have been realized. The results have not been generally published but this committee will endeavor to secure and to publish in a report, the decisions already reached.

This year's record shows an increased number of public press announcements of the estimated economic cost of noise. The weekly loss in the United States was recently computed to be \$5,000,000. The continuous effort which is being made to estimate this economic cost of noise, emphasizes the lack of sufficient data upon which such estimates can be made with even a fair degree of accuracy.

The committee's report of last year showed the existing fundamental data as insufficient to justify the drawing of any line between the noises to be tolerated and the noises which should be reduced. With this objective the committee has undertaken a research program to ascertain some of the fundamental effects of noise upon the human organism. Certain research workers who are competent and who desire to assist us in this investigation have consented to become members of our committee.

At a committee meeting held in New York, April 8, 1928, this program was analyzed in detail.

As now planned, the committee desires to ascertain whether physiological reactions may be found which will serve as indices of the effect of noise upon the human organism. For this purpose, Dr. John J. B. Morgan of Northwestern University, is continuing his work with the electro-cardiograph as a detecting instrument. Last year, the committee reported upon preliminary work of this kind which indicated noise does produce a change in the rate of the heartbeat.

Professor F. C. Dockeray of Ohio Wesleyan University, is beginning work to ascertain the effect of noise upon certain factors having to do with the mind. His work will include studies of fatigue, attention, physical and mental activity, emotions, etc.

Dr. Morgan and Professor Dockeray are now equipped to carry out their investigations for this year. Sufficient apparatus for this work has been loaned to us through the generosity of the American Telephone and Telegraph Company and its associate, the Bell Telephone Laboratories, to supplement that made available by Northwestern and Ohio Wesleyan Universities.

The committee's program includes a study of metabolism as affected by noise. Metabolism is the sum of the chemical changes continually going on in the living cells of the body whereby energy is provided for the vital processes and new material is assimilated to repair waste. Variations of metabolism may be a useful physiological index of human reaction to noise and of the effect of noise upon physiological activity. Professor A. T. Poffenberger of Columbia University, has agreed to undertake this work. The General Electric Company has offered to loan certain apparatus for it. Unfortunately, the committee has not as yet succeeded in obtaining the funds needed to provide the necessary special apparatus. This study is of unquestionable fundamental importance and it is hoped the very modest amount necessary for this work may be obtained soon.

I desire to call your attention to the fact we have a new member of the committee with us today, Dr. Harvey Fletcher of the Bell Telephone Company Laboratory, who is interested in the study of noise from the standpoint of hearing.

Later I will ask him to tell you something about the phase of the work in which he is interested.

I will read to you two letters we have received. The first letter is from Professor John J. B. Morgan, of Northwestern University, Evanston, Ill. I asked Professor Morgan if it would be possible for him to be with us today and this is his letter.

My Dear Mr. Snook:

It will not be possible for me to attend the meeting of the committee on October 4th, much as I would like to do so.

I have no criticisms for your report. I think it is encouraging and shall try during the year to fulfill my part of it. I have three graduate students beginning work on different phases of the problem and I feel quite confident that before the end of the year we shall have something definite to report.

Cordially yours,

(Signed) JOHN J. B. MORGAN.

CHAIRMAN SNOOK: You will recall that Professor Morgan, while he was at Columbia University, did a lot of research, a most important piece of research work in the beginning, when interest in this subject, how noise affects the human being, was first inaugurated. His work was published I believe in 1916. Am I right, Professor Poffenberger?

PROFESSOR POFFENBERGER: Yes.

CHAIRMAN SNOOK: It was brought to my attention and as you can see by Professor Morgan's letter, his interest is as great as ever, because he has undertaken to continue this work, especially with the electric cardiograph. As a matter of interest it may be well to state the electric cardiograph is a sensitive instrument which has galvanized strings or coarse fibers. This instrument is used by connecting opposite ends of silver coarse fibers, or gold-plated coarse fibers, to certain parts of the body and observing the magnification of the instrument. The heart responds to very minute electric currents.

When the fibers move from one side to the other as a result of changes in the magnetic field, these changes register the differences in electrical potential of the crude fibers of the heart. This instrument can be applied to the feet, arms, or other parts of the body. Professor Morgan took up this work last year and discovered that the heartbeat is increased or retarded under the influence of noise. He has kept a record of his experiments and he expects to do more work. That is all he promises, but many of us who know Professor Morgan well would be willing to promise more for Professor Morgan than he is willing to promise for himself.

I have a letter here from another member of the Committee, Professor F. R. Watson, of the University of Illinois, Urbana, Ill.

Dear Dr. Snook:

This is a note concerning the activities of the Committee on the Elimination of Harmful Noises. It is not likely that I can attend the conference on October 4th in New York City, and I doubt if I have any constructive suggestions to offer beyond an approval of the program as you have outlined it in your letters.

Concerning financial support for the work of Professor Poffenberger, I may be able to secure some funds, but wish you would send me immediately some idea of how much is wanted.

With best wishes, sincerely,

(Signed) F. R. WATSON.

CHAIRMAN SNOOK: There are several more of the members of the committee who will be with us today but they have not arrived as yet.

Professor Dockeray is here. He has come all the way from Ohio to take part in this meeting.

PROFESSOR DOCKERAY (Department of Psychology, Ohio Wesleyan University, Delaware, Ohio): I have not much to report, no more than Dr. Morgan has. As Dr. Snook has told you, through the kindness of the Bell Telephone Company we have received some apparatus for our experiments and this will make it possible to carry on this work.

We have set up the apparatus furnished by the Bell Telephone Company and it is similar to the apparatus which we used a few years ago in the study of attention and distraction. We dropped the word "distraction" because we get an increase or decrease in the amount or quality of the work, and then we dropped the word "attention" because I don't know now exactly what attention means, perhaps the study of the effect of noise on general activity would be better.

With the old experiment we tried to measure—it is rather complicated—but we tried to cover the reaction in a coordinated way. I have five students who are working with me this fall. They are very enthusiastic at the present time, but how long I can keep them going is a question. We have just started and I wish the meeting had been two weeks from now. I believe in that case we might have had something definite to offer. All I can say at present is I have divided my subject into two groups. I find the students who have the best records in the University generally show an improvement when confronted with noise that is a distraction. With the poor students, the kind that do not readily adjust themselves to the college situation, the opposite seems to be true.

The question then is raised about the better student, and I believe that is the question Professor Poffenberger is going to study and the one that Dr. Morgan made his early experiments with; the better student, the better man, puts more work into the situation when there is something to be combated. I hope to make a study of that and I believe it would be well to consider the work done along that line by Dr. Starr, of the University of Pennsylvania. This question has also been taken up by Dr. Free. I have not started on it as yet but believe by Christmas, perhaps, we may have something a little more definite to offer, the responses to the different degrees of sound, loud and mild noises, as well as high and low pitched noises.

CHAIRMAN SNOOK: I desire to ask Professor Poffenberger to explain something about metabolism and any other thing he may care to bring up regarding the work.

PROFESSOR A. T. POFFENBERGER (Dept. of Psychology, Columbia University, New York City): Mr. Chairman and gentlemen: I am in rather an embarrassing position, the position of one who is soliciting funds. It is not as bad as that because we are going along with the work without them as far as we are able. The University has helped us out very nicely in giving us some money and some equipment we needed.

The equipment is the expensive part because we can make the noise all right, that will not cost us so much but the equipment necessary to measure metabolism will be expensive. I am more interested in that I believe than in the effect of noise. We have a general laboratory problem with a great variety of conditions in this subject of metabolism. One is, the effect of noise. Any support from this organization would be directed, of course, to that noise problem.

When I started out—I am not going to tell you much about metabolism because it is a long story—we took up the question, "What Does Noise Cost the Individual?" We took this up just as you would any problem, as you would take up the question of why an engine did not give the proper results. It might be because of a poor grade of oil or several things might enter into it, a poor lubri-

cant, etc. The same thing applies to noise, whether noise causes a reduction of power in the individual.

There are various ways of trying to find this out. Dr. Morgan has tried to ascertain the effect on the heart and someone else is going to give the physiological effect; now what we want to measure is the effect on the energy consumed by the worker. Just as we can tell the amount of electric energy necessary to drive a certain machine, we want to know how much energy it takes to drive the human being in doing the work under noisy and quiet conditions.

We were forced to do this it seems to me because the other measures we have used for measuring the effect of noise have had something wrong with them. As Professor Dockeray said a few moments ago the human being has a most remarkable capacity for meeting these changes, these changed conditions, and he can keep his output uniform in all sorts of distractions.

You may say that these noises make no difference because a person can work just the same, that these obstacles have no effect, but Dr. Morgan began this work because he became suspicious—and so did I—that something else was involved. There were certain indications that shows us the quantity and quality of the work remained the same but it cost the individual more to produce that same quantity and quality of work.

Now what we want to do is to measure the energy used in a specific way and I am afraid that is too involved to discuss at this time. We don't know whether the noise causes any trouble or not. That is what I want to find out. If the noise does cost something to the individual, when the noise is first introduced, we don't know whether it is not possible to adapt ourselves to it so that it does not cause any trouble later on.

The question in my own mind is, are such noises harmful, and how harmful are they? Can we adapt ourselves to them so they will no longer be harmful? That, I believe, is the question. Some such serious question as that. We would have to make these measurements and see whether the organism does adapt itself so that the operation which originally cost quite a bit of energy now can be performed with relatively little cost to the individual.

The workman in training expends much energy. After three or six months' training, the same noise, the same conditions and the same output require less expenditure of energy. It may be that after living under certain noise conditions the energy expenditures would be reduced and would not exhaust the individual more than working under quiet conditions. I don't know anything about it, it is a question I raise.

I do not care to say any more than Dr. Morgan and Dr. Dockeray have said. I am going to go to work on the question. I told Dr. Snook when I undertook the job I would not guarantee anything inside of five years but if anything did turn up it would be welcome, but I make no guarantee.

We have been working since April getting the equipment ready, such as we had, and our technique developed. In about six weeks or so we ought to be able to get some information.

CHAIRMAN SNOOK: Thank you Professor Poffenberger. I believe it is very good, indeed, to have these men come to us and tell us something about what they think on the subject. We all realize that some fundamental questions are involved in this program—in this problem of noise.

We stated very definitely in one of the reports of this Committee that this work would require a long time and would probably at times be most discouraging. Professor Poffenberger has given us a glimpse of how he feels and what he is doing and he, like the rest of us, realizes the difficulty of this problem.

A little more financial support is certainly to be desired because small sums of money will be needed from time to time over a period of years in order that

worthwhile results may be obtained. There is a matter that involves the function and the purpose of this Committee, particularly as relates to what others may consider the function of the Committee and its work. That, of course, involves the Committee's name. The name of the Committee at the present time is "The Committee on the Elimination of Harmful Noise." The Committee was originally known as the Committee on the Elimination of Excess Noise. Then the question arose, what constitutes excess noise, for what purpose, for what object must the excess noise be eliminated. It was believed the function of the committee would be best described by a slight change in the name.

The function of the National Safety Council is to conserve the safety of the people of the Nation. If noise has an influence that is not beneficial to the people, it must exert some harmful influence on them and so we strove to discover how the Committee might direct its energies toward determining what noise would be harmful to the people.

The study involves conditions affecting the welfare of the people, not only in respect to accident, but also to other causes that involve the safety of the people.

In order not to restrict the scope and work of this Committee it was agreed at the time that the name should be changed.

There is a question among the membership of this Committee whether or not the Committee is bringing to the National Safety Council membership sufficient emphasis upon the function of this Committee in regard to accidents. I desire Mr. Owen to talk to you for a few moments on that subject.

SECRETARY OWEN: The National Safety Council, as you know, is interested in accident prevention, not only in the industrial world but in public places and in the home. Perhaps some accidents have been due to noise. It may be well to change the name of the committee, to make it more expressive. The name suggested is "Noise a Factor in Accident Causation."

One man said this afternoon he is interested in the noise caused by street cars and he wondered if that noise causes accidents. In such cases the public is interested. You may have noises in industry and around the home. If they are the cause of accidents the National Safety Council is also interested and will seek to reduce them.

If the noise in the drop forge plant decreases efficiency of the men or causes accidents, the manufacturer wishes to know what can be done about it.

It seems to us if we change the name of the committee to the one mentioned it will be more descriptive of the work this committee is endeavoring to do.

CHAIRMAN SNOOK: I believe many of us realize the changing of the name of the committee would not alter the necessity for unearthing the fundamental factor with regard to noise. We want to know where to draw the line; noises that are to be tolerated and noises that should be eliminated, in order that a definition may be made regarding noise as a factor, or causation of accidents. Is there anyone present who would like to discuss this subject? Mr. Van Horn, have you anything to say?

C. VAN HORN (Travelers Insurance Co., New York City): I may say as a member of this committee and also because of my connection with the Travelers Insurance Company, that the first thing asked the insurance company was whether we had done any research work with regard to noise being productive of accidents.

As a matter of fact we have not. The average insurance investigator does not go into the question of noise as an accident cause, nor as having any influence on accidents, so having no data along that line, whatever I might say would have no influence on the Council taking any action along those lines.

There is one thing I may say and that is we know accidents are sometimes caused by a mental condition. There are certain types of accidents in industrial

plants that have a direct bearing on the mental condition and reasoning along that line of logic, maybe there are certain types of accidents due to the noise affecting the mental condition.

CHAIRMAN SNOOK: Does anyone else wish to speak on this subject? Have you a better or more appropriate name to suggest for the committee? Have you a name that will bring to the National Safety Council a better idea of what the committee is doing, and what the committee ought to do?

There is another member of the committee present at this time and I desire to hear from him. Dr. Fletcher of the Bell Telephone Laboratories, is our youngest member in point of time of service; he is our newest member. He has made a special study of hearing, he is an expert on the function of hearing, he knows more about how we hear and how we don't hear, than anybody else in the world. He has accepted membership and is going to help us solve our problems. I desire to take this opportunity of introducing Dr. Fletcher. I wish he would tell us something about that peculiar form of deafness, temporary deafness that comes as the result of noise being present. I wish he would talk on any other phase of the work that he desires. Dr. Fletcher.

DR. HARVEY FLETCHER (Bell Telephone Company, New York): I confess I have been very much puzzled this afternoon about what this committee is trying to do.

It is true, you do actually find that many men hear better in a noise. Well, what then? Somebody hears poorer in a noise; what then? What action can you then take? It does not seem to me that either one of these questions will help us. Take, for instance, the heart; I do imagine noise has some effect one way or the other, but I wonder when we get through will we get anything? What answer will the National Safety Council get and if they do get some answer from these experiments will they go out and eliminate noise, or will they not?

I was hit by an automobile last week and I still cannot think very clearly. At the time there was a lot of noise and I don't know whether that had anything to do with it or not.

Now coming down to the question the chairman asked me to speak on, the question of hearing. The chairman particularly mentioned the noise that causes temporary deafness. Take, for example, this room. I am talking very much louder than it is necessary because of the awful noise. It is an effort for anyone to speak in this room and it would not take an elaborated investigation to say the noise should be eliminated. We could get along much better if it were quieter. I don't believe there is anyone in the room who would not agree on that without any investigation. If there were some way of getting rid of that noise we would all be much happier and certainly it would be much less effort to speak. One of the things we have to measure is the deafness, the temporary deafness produced, for example in this room.

We are all about thirty units down; by that I mean, if we are all affected so that our hearing goes down thirty to forty units, we would be able to hear just the same, because of the noise outside. Now if deafness causes accidents, noise causes accidents, that is the only conclusion you can come to, because when you are immersed in noise you are deaf to a certain extent.

I don't know of any activity in the National Safety Council that would say that deafness is the cause of accidents. I know at one time I was of the opinion all chauffeurs ought to have an examination for their hearing in order to prevent accidents, but I'm not so sure of it now.

I am identified with the American Federation of the Hard of Hearing and I have received assistance on the subject, and it is their opinion—and I believe it is correct—that the people who are hard of hearing are more alert mentally and are free from distractions, like noises. They use their eyes more than most

people who have their hearing and as a consequence they have fewer accidents than those who are not deaf.

What I am saying is adding more or less confusion to what has already been said. It was a confused issue before I started, but I don't see clearly where we are going, I confess. Nevertheless, I agree that it is a good piece of research work, a very valuable piece of research work and I believe it valuable because such men as we have here today are interested in it. It is interesting; whether it will have any practical result or not, that is another question. That is all I wish to say at this time.

CHAIRMAN SNOOK: Dr. Fletcher is right; we don't know whether this research will lead to the information that will permit us to do what the committee has been asked to do; namely, to find out how much noise ought to be eliminated and reduced.

The National Safety Council has received a number of inquiries, asking how noise may be reduced or eliminated. The committee was organized to try to plan out what could be done about reducing noise. Unless this committee gets some fundamental information regarding noise and its effect on the human being, the committee never will have the information that will enable it to know where to draw the line.

I don't blame Dr. Fletcher, or any other man or woman, for being a bit confused because the connection between what this committee is now trying to do and what the committee has been asked to do is difficult to see, because the committee is striving to find how noise affects us, that is all, and until we find some answer to that question this committee has no work to do.

If it attempts to reduce noise at the present time without knowing how far to reduce it, then this committee will be in trouble, so we have attempted to get a few of the men of the country who are capable of answering this question, to ascertain how noise affects the human being. That is why we seem at this time to be so far away. As stated in our report of two years ago, I believe it was, it is a long and difficult thing and will require years of work on the part of men who, as Dr. Fletcher admits, are interested in the problem of finding out how noise affects us. They must give time and labor to this work in order that we may find out what is at the present time an unknown factor, these things that are now unknown but which will enable us to see ahead and get ahead, as to how much noise should be reduced.

That is what we are driving at and we want to know whether or not we should continue to drive at that or should we stop it, or should we drive at something else?

This work is interesting as Dr. Fletcher has said, it will enable us to find out the effect of noise on the human body and that is exactly what we have set out to accomplish.

DR. FLETCHER: Would the standard of noise that could be tolerated and still have conversation go on be of any help? That is rather well known. That is something in which we have been interested in the telephone company. We know we will have noise whether people are going to be happier or not. All of these things have to be taken into account.

CHAIRMAN SNOOK: I am sure the line of thought suggested by Dr. Fletcher would be very interesting to the membership of this Committee and to the National Safety Council.

DR. W. J. FRANCIS (Medical Examiner, Department of Commerce, New York City): With regard to people hearing I may say there is the condition where the ear is clogged with wax; about one man out of every six has this condition, the ear is plugged with wax and even when it is possible to take it out the ear-drum has become inflamed so that the ear is then not fundamentally normal.

Certain conditions of the nose and throat may also cause this condition, altering the circulation to the ear. It may sound like an exaggerated statement to say that one man out of every six has plugs of wax in his ears but I have had an opportunity to examine a large number of men in all walks of life who thought they were healthy and who have that plug of wax.

When that wax was taken out they would have in many cases an inflamed or congested ear-drum. I also found that men who are exposed to a great deal of noise fail to protect the ear-drum by wearing cotton or some other protection, so that the hearing is definitely reduced.

CHAIRMAN SNOOK: I hope anyone else who desires to speak on this subject would do so at this time.

L. L. PARK (American Locomotive Co., Schenectady, N. Y.): I desire to ask if the committee can tell us the best type of individual to work under certain noisy conditions. Take, for instance, the boiler trade. It is difficult to reduce the noise but if we knew the type of individual who could best stand that condition in the boiler shop, it would be a great help. If the committee can give us some help, some information as to the correct type of man to employ in the boiler shop, it would be of great help in the industry.

Another phase that might enter into this is that the young man, as a rule, is not affected, but he is bound to grow old in the industry and later on he is more readily affected than when he was young and learning his trade. If it is possible to discover the type of individual who is not readily affected by noise, it would be a great help to us in placing the men in the work.

Perhaps you have also found that men who have become partially deaf, as most boiler makers do, hear better in the noise than people with normal hearing power do. That evidently means the hearing mechanism becomes adapted to the condition by long exposure.

That is one of the problems upon which we have very little information, and it seems to me that if the Committee did find, as the work progressed, some information as to the type of worker who is least affected by noise, it would be of interest.

CHAIRMAN SNOOK: I believe some investigations have been made regarding this very point. I do not have the report of the investigations at hand but I believe the committee can give you some information.

Is there anyone else here who wishes to speak on this subject? Have any of you any information regarding the type of individual best adapted to noise conditions, as the boiler shop, where they work in extreme conditions and apparently have an increased hearing in such conditions. That is something Dr. Fletcher might tell you about.

DR. FLETCHER: That is one of the questions that has been debated by a number of individuals, both pro and con. I believe it is largely a point of view.

If there is a noise that is constantly hammering on the nerves of the ears it will make you hard of hearing, we are told. If that is true then most of the people in New York City would be deaf because of the noise. When you are on the subway you are immersed in noise and the same is true of the streets. This matter was brought up at a meeting and some men advocated a survey and it was believed New York City would have a much lower average hearing, but that has never been demonstrated. I believe it has been demonstrated there is such a thing as boiler makers' deafness, a larger number in the boiler shop become deaf than in other departments, you have found that to be true?

MR. PARK: Yes.

DR. FLETCHER: Apparently the exposure to the severe noise finally causes deafness. We all know very loud noises, such as the firing of a cannon, will produce deafness. During the war we had a number of cases where men had their hearing damaged in this manner, but whether noises such as come from the street are

a help or a hindrance is a question and someone will have to prove whether it increases or decreases the hearing.

There is a little device that perhaps may be used by men working in boiler shops. It is used by aeroplane men because it has always been impossible for them to carry on a conversation. It is a little mechanism which fits snugly in the ear. Aeroplane men have found it is the best possible thing to use in aeroplanes. Perhaps something of that kind could be constructed for workers in boiler shops and other places where there is an excessive amount of noise; it might preserve men's hearing and still allow them to converse with others.

CHAIRMAN SNOOK: Dr. Fletcher just how does it work?

DR. FLETCHER: It is a little mechanism that fits into the ear. You connect it to a telephone if you want to talk; at other times it cuts out the noise.

CHAIRMAN SNOOK: Mr. Rosenblatt is a member of our committee. May we hear from him on this subject.

M. C. ROSENBLATT (Acoustical Engineer, Phila.): I have not much to say. I cannot elaborate upon what has been said. We don't seem to get anywhere; look at the people here in New York, they congregate where there are noises. You can't say they like noises because of the fact that they don't get away from them. It is not necessary for them to be here. They could probably be on a farm or in a less congested center but they seem to like to gather in these congested places. It seems to me that while noise is harmful in a certain physical degree it is compensated for by other activities human beings like, things that bring them into this very noise.

In other words while it is doing harm it is almost compensated for by some other facts. It seems to me that it would be difficult to find a solution.

CHAIRMAN SNOOK: Is there anyone else who would like to speak at this time?

W. D. BURROW (Globe Indemnity Co., Atlanta, Ga.): I am just a layman trying to obtain some information. I am hunting for knowledge that will help me in preventing accidents.

To my mind there can be very little question about the fact that noises do have a harmful effect on the human organism. I am slightly deaf myself in my right ear due to the fact that some years ago I was exposed to a continuous noise on the right side, so I can hear now better with the left ear than with the right.

The gentleman from the American Locomotive Works spoke about the condition in the boiler shop and if there has been anything done to relieve this condition I would like to hear about it, I would like that information.

It seems to me that the telephone company has a proposition that does not present itself to the average person. I refer to the operators. At one time I was connected with the telephone company. I believe you will find the average telephone man can hear better with the left ear than he can with his right, due to the fact that he uses that one more, so that the extraneous noises would occur in the right ear and not the left. A person usually uses the receiver at the left ear.

I believe there has been some effort made by the typewriter people toward the elimination of noise and the reason given is that the noise produces fatigue. The action of the typewriter does that in itself in as much as the sensitive nerves at the ends of the fingers are constantly pounding on the keys.

Now it would take a much better man than I am to disassociate or differentiate one from the other but I want to find out if noise is harmful and if it is how can it be prevented, and if you cannot prevent it as in the case of the boiler maker, is there any protection, any protective device we can use to help us keep away the evil effects of noise?

CHAIRMAN SNOOK: Another member of our Committee has arrived, Mr. Mowery. Mr. Mowery, the Committee has discussed the report and considered in some details the research program that has been outlined and undertaken by some of the members of the Committee.

The matter of a change of name for the Committee has brought out discussion. You may discuss it or any other subject that you wish.

H. M. MOWERY (American Abrasive Metal Co., New York City): I wish to apologize for not being here on time but I give as my excuse that this is a very strenuous week.

In regard to the proposed change of the name of the Committee, I believe it would be desirable to change the name so that members of the National Safety Council who are particularly interested in the industrial phase of accident prevention will see there is a tie-up between the program confronting them and the program confronting us, that there is some consideration to be given to noises and accident causation.

It might be well to review, if you have not already done so, the reason for the existence of this committee. About seven years ago the National Safety Council headquarters received a great many inquiries and as a result of these inquiries a committee was appointed. That committee comprised a number of the leading members of the National Safety Council engaged in different branches of industry. After two years work practically nothing was done, and another committee was organized. I believe this committee was brought into being through a follow-up of the work of the other committee. Finding that nothing had been done the new chairman suggested a new committee be appointed. A committee was appointed to go over the field to find out what had been done along the lines of eliminating excess noise. Because the National Safety Council was interested in accident prevention, it was suggested the name of the Committee be changed from Excess Noise to Harmful Noise. It was changed and the committee was then known as the Committee on the Elimination of Harmful Noise.

After continuing to work for several years we came to the conclusion there was absolutely nothing available to prove conclusively that noise was harmful to the human system, so the present research work was outlined. You have heard about that from Dr. Snook. This work was proposed and something has been done along these lines of research.

The assistance of the Executive Committee of the National Safety Council has been withheld from this research work for several reasons, the chief being they had no funds available for the purpose, but they have generously allowed the committee to go out and secure funds independently. I was told the other day that the Executive Committee of the National Safety Council might be a little more lenient if they could be sold the idea that there is a definite tie-up between the work of our committee and the cause of accidents. If we cannot do that, then the work of this committee will be transmitted to the Health Service Division as being a matter concerning the human body more than the cause of industrial accidents.

There is the situation as I understand it. I believe at the present time we are interested primarily in noise as an accident causation. I believe the fundamental research program which was proposed should be carried out because we must determine whether human energy is lessened or increased by noise and if we can find out then I believe it will be a short step to the conclusion that it is an actual accident causation.

CHAIRMAN SNOOK: Thank you, Mr. Mowery. These gentlemen on the committee are interested, I believe, in ascertaining the effect of noise on the human body and it is upon that basis we have been working and we have been enabled to interest them in this matter. We want the facts that are in their minds, the unbiased facts and we have gone into this in that way.

Many of us believe that noise will be found to be the causation of accidents.

Is there anyone who would like to make a motion with respect to this matter of a change of name for the Committee?

T. S. WORTHINGTON (T. S. Worthington and Co., Ltd., Montreal): I have listened to Professor Poffenberger and the other gentleman over there. I believe the name of the Committee is somewhat misleading. I believe Noise and its Relationship to Accidents might be better, that might be more attractive. I am convinced that the gentleman on my left and the gentleman from the American Locomotive Works agree a man's efficiency is lessened in industry if his hearing is impaired.

I don't know much about the boiler industry. I know more about mining. There is no question that people who are working in the bowels of the earth sometimes have their hearing impaired and that also impairs their efficiency. I move that the name of the committee be "Noises and Their Relationship to Accidents."

CHAIRMAN SNOOK: We have a motion that the name of the committee be changed to Noises and Their Relationship to Accidents. Is there a second to that motion?

C. VAN HORN (Travelers Insurance Co., New York City): I believe the gentleman from the American Locomotive Works might have gone a little further and told us whether they have the more accidents in the boiler shop than in any other department.

MR. PARK (American Locomotive Works): Mr. Chairman, we have not established the relation of noise to accidents in the boiler shop but the boiler shop always stands well up in the list of lost-time accidents. As far as accidents are concerned other departments go for four or five months without an accident but the boiler shop seldom goes more than a month without a lost-time accident.

There are other causes that enter into it perhaps, the heaviness of the work, the work itself is more hazardous and yet when you compare it with other departments handling heavy pieces, the frame shop where the heavy frames are handled, the boiler shop does seem to appear more frequently in the list of lost-time accidents than any other department we have. We, of course, would be interested to know something about the effect of noise upon the individual so we can determine more clearly whether part of that effect is produced by noise or whether it is due to the type of man who is willing to work in the boiler shop, whether they are more prone to accidents than the men in the other shops, whether the work is perhaps of a kind requiring less physical and more mental ability.

MR. MOWERY: We have not yet fully determined whether there is any relationship, that is the thing that has to be solved.

CHAIRMAN SNOOK: That is a five or ten years job.

MR. MOWERY: I believe it would be better to have it known as the Committee on Noise as an Accident Causation. What do you think of it, Mr. Owen?

SECRETARY OWEN: I believe that would be better.

R. V. PARSONS (Johns-Manville Co., of New York): For 18 years I have been in the business of eliminating noise, I believe if you can find the answer as to whether noise is a factor in accident causation you can get the remedy immediately. The minute you touch a man's pocketbook you always have a remedy.

Something was said a few minutes ago about the noise in the subway. The subway could be made just as noiseless for the man who is riding in it as the elevated cars but it would cost money. The boiler shop could be made very, very quiet and so could other industries but it would cost money. It could be done but it might cut down production. Riveting and welding could all be done quietly but it would cost money and take more time and my thought is that the name should be put in the form of a question. I believe in that way you will interest the people and get an answer and if you get an answer you will get a remedy. I believe it should be "Whether Noise Is a Factor in Accident Causation."

CHAIRMAN SNOOK: We have a motion before the house.

MR. WORTHINGTON (Montreal): I withdraw my motion.

CHAIRMAN SNOOK: Mr. Worthington has withdrawn his motion. Now what do you think of the name just proposed? I believe the Committee might have a

happier name than that, something that would indicate to the National Safety Council the direct relationship that we hope to discover sometime. Mr. Mowery won't you tell us again the name you suggested?

MR. MOWERY: Committee on Noise as an Accident Causation.

CHAIRMAN SNOOK: Is there a second to that, that this be known as the "Committee on Noise as an Accident Causation?"

MR. VAN HORN: I second that motion.

CHAIRMAN SNOOK: What about you, Mr. Owen?

SECRETARY OWEN: If the name indicates the purpose for which we are working, it is sufficient.

DR. FLETCHER: I like the other one, the relation between noise and accident, I believe it is simpler.

CHAIRMAN SNOOK: I believe the one Mr. Mowery has suggested is better adapted to selling the idea to people who do not understand the broadness of the problem.

MR. WORTHINGTON: Why not put it this way, "Is Noise a Factor in Accident Causation?"

MR. VAN HORN: I believe there is an objection to a committee with a name that asks a question. As I understand it the committee was formed for the purpose of compiling data to submit to the National Safety Council, whereby they could consider whether this particular thing was important enough to take up, to take some definite action on. If we put the name of the committee in the form of a question the National Safety Council can rightfully come back and say "That is what we appointed you for."

MR. MOWERY: I believe it is chiefly a matter of simplifying matters, whether or not noise is an accident causation, that is what the Committee is trying to determine.

DR. FLETCHER: It is simply a question of noise and not which noise, not whether it is gun-fire or some other noise.

CHAIRMAN SNOOK: Mr. Mowery, may I ask if this broader name would appeal to you as satisfactory? The Committee on Noise and Its Relation to Accidents?

MR. MOWERY: Yes, as far as I am concerned.

(The motion was seconded and unanimously adopted.)

CHAIRMAN SNOOK: Is there any further business to come before the Committee?

DR. FLETCHER: I wish to say we have made some investigations about people hearing better or worse and we found there was no difference between telephone users and non-telephone users in that respect, they hear the same in both ears apparently. The telephone does not seem to affect the hearing. It is simply a case of getting used to putting the telephone to the left ear. You are awkward if you use it the other way, but as far as cutting down the hearing there does not seem to be any difference.

MR. BURROWS (Globe Indemnity Co.): I am only using my own case, I have no comparative figures. After I had worked in the telephone company for a couple of years I was examined for a life insurance policy and they found that the one ear was better than the other.

DR. FLETCHER: We have an instrument for measuring hearing and we have measured three or four hundred people who were telephone users and who always used the phone in one ear and taking the average there is no evidence at all that one ear is better than the other.

ADJOURNMENT

SEVENTEENTH ANNUAL SAFETY CONGRESS
NATIONAL SAFETY COUNCIL

Automotive Section

New Section Officers

- Chairman*—E. H. COTCHER, The Murray Corporation of America, Detroit, Mich.
Vice-Chairman—H. L. SAIN, Delco-Light Company, Dayton, Ohio.
Secretary—H. L. FRACHER, Detroit Steel Products Company, Detroit, Mich.
Chairman Poster and Slide Committee—M. J. MCCARTHY, Fisher Body Corporation, Detroit, Mich.
Chairman Membership Committee—K. A. CALLAM, Kelsey-Hayes Wheel Corporation, Detroit, Mich.
Chairman Publicity Committee—C. W. BISHOP, Lycoming Manufacturing Company, Williamsport, Pa.
Chairman Engineering Committee—A. F. DUNNEBACKE, General Motors Corporation, Detroit, Mich.
Chairman Statistics Committee—PAUL J. BRAND, Pullman Car and Manufacturing Corporation, Pullman, Chicago, Ill.
News-Letter Editor—C. M. DOTTERER, Graham-Paige Motors Corporation, Detroit, Mich.
Executive Committee: THE OFFICERS AND—
A. M. WILLIAMS, Chrysler Corporation, Detroit, Mich.
J. S. BURNS, Reo Motor Car Company, Lansing, Mich.
L. E. AVERILL, Packard Motor Car Company, Detroit, Mich.

Retiring Officers

Chairman, A. M. WILLIAMS, Chrysler Corporation, Detroit, Mich.; *Vice-Chairman*, E. H. COTCHER, The Murray Corporation of America, Detroit, Mich.; *Secretary*, H. L. SAIN, Delco-Light Company, Dayton, Ohio; *Poster and Slide Committee Chairman*, H. L. BUNTING, Olds Motor Works, Lansing, Mich.; *Membership Committee Chairman*, L. J. PARRISH, A. O. Smith Corporation, Milwaukee, Wis.; *Publicity Committee Chairman*, H. L. FRACHER, Detroit Steel Products Company, Detroit, Mich.; *Program Committee Chairman*, O. J. OLSEN, Fisher Body Corporation, Detroit, Mich.; *Engineering Representative*, R. F. THALNER, Buick Motor Company, Flint, Mich.; *Statistics Committee Chairman*, W. S. SMITH, Ford Motor Company, Detroit, Mich.; *News Letter Editor*, E. R. COMPLIN, General Motors Company, Ltd., Oshawa, Ont., Canada. *Executive Committee: THE OFFICERS AND* H. J. MELLUM, The Nash Motors Company, Kenosha, Wis.; CHARLES J. KOLB, The Pierce-Arrow Motor Car Company, Buffalo, N. Y.; A. F. DUNNEBACKE, General Motors Corporation, Detroit, Mich.; G. A. KUECHENMEISTER, Dominion Forge and Stamping Company, Walkerville, Ont., Canada; F. J. CORBETT, Chandler Motor Car Company, Cleveland, Ohio.

October 2, 1928

H. L. SAIN, Chairman
Safety Engineer, Frigidaire Corporation, Dayton, O.

The first session of the Automotive Section at the Seventeenth Annual Safety Congress, was called to order at nine-thirty o'clock by the chairman, Mr. H. L. Sain, Safety Engineer, Frigidaire Corporation, Dayton, Ohio.

CHAIRMAN SAIN: I might say that our old Company name was Delco Light but the first of January, this year, we got a divorce from Delco Light—Frigidaire did. We all are under the same "Daddy," under the same organization, General Motors, but the first of the year we were divorced completely from the Delco Light organization and are now the Frigidaire Corporation of Dayton.

We are proud not only of the record we have in regard to safety but in many other ways. If you will come to Dayton to visit us, not for one day but for two or more, we will try to show you our plan of handling the Safety, Personnel and Employment, and Medical Divisions. They are all so closely related to the human side that I don't see any chance at all to separate the three.

I don't know of a group that generally has any greater personality than that of the Personnel group. You should have a real personality, a real desire and a real urge to help people. If you have not that desire to raise people up to a higher standard of living, you will not accomplish the best results.

If you would come to the Frigidaire Corporation, I don't believe you would find a safety poster in our plant. I don't believe that you would find safety literature in our plant. I don't believe you would hear any definite lectures or talks on safety, but our work is entirely that of building men, building people, as well as Frigidaires.

We have two jobs in Frigidaire, and you fellows in your own plants have two jobs, that of building the product that your company makes and building people. We feel that if we make a few big people, a few real directors, a few safety men, all the rest will follow. We believe that is true. With the great personality that the safety men possess and should possess, with all the great personality the employment men should possess, still there are (as Dr. Myers said in the meeting in the Power Press Section the other day) some who have a greater desire to use authority than to be humble and get people to do things because they want to do them. Too many, like the traffic cop, would rather just say "Stop" than point the way.

If you have not read Van Dyke's "School of Life" you should read it. That is one of the books we recommend to all our foremen in Frigidaire—read things you can apply to your work the next day. No doubt every man here does a certain amount of reading, and I am wondering what you read? Whom do you visit with at night? I venture to say that if this morning it had been announced that Henry Ford or Mr. Chrysler or Mr. Sloane, or any one of the great industrial leaders was to speak here, you would have crowded in by the hundreds to hear him. But did you ever stop to think that Mr. Ford, Mr. Chrysler or Mr. Sloane would probably have traveled all night, as I did Sunday night, and maybe would have come in here with a headache, feeling tired and everything but his best, and that probably you would have gotten about half of what you expected to get?

But you can go to your room any night, you can sit in your own home, in an easy chair, and pick up the book "The Five Automotive Giants of the World," about Ford and Chrysler and Sloane and many other industrial leaders. You can pick that book up and sit in a big easy chair with your old soft slippers on and visit one of them when they are at their best.

Now I ask you—what do you read at night? The murders and suicides and baseball? Yes, we should read a certain amount of that, but how much of it can you apply to your job on your safety work? So we ask at all times in our plant on our program of educating men, not only on safety but to make bigger, better men, we must read more. This has been my experience that we can learn from these books, periodicals and booklets many lessons, if our mind is open to these good lessons.

I remember one of the first lessons I had, by one of the greatest bosses I have ever worked for—and I might say that I am fortunate for I have three bosses, Mr. Fordham, Mr. M. M. Roberts and I would not fail to mention Dr. Harry Myers, who has been the greatest inspiration and help to me in personnel and safety work of any man I know of.

My first idea of safety was this, "I will show them and tell them where to get off" and I started to post notices which read, "Starting today and from this day on and forever, anybody found guilty of violating a certain safety practice will be discharged at once." And I would sign my name, "H. L. Sain, Safety Director."

You know how it is. You put it on the bulletin board, then you look at it, feel pretty chesty over it. Tomorrow morning you go over to it again and wonder what all that scribbling is on it. Well, I found such remarks as "Bologna," and "So is your Aunt Emmy." What has happened? You have challenged the man, and when you tell him not to do a thing that is the very thing he is going to attempt to do.

Don't challenge the man. Take this one little item or quotation and remember it and take it back to the plant with you. In the autobiography of Benjamin Franklin—and I might say we have some 200 copies in the plant—Alexander Pope gives a little quotation, and this is one of the finest things I have ever learned: "Men must be taught as if you taught them not and things unknown proposed as things forgot." And whenever we can get that attitude and not come out with this power and this authority, then I believe men are going to follow us, and certainly no man will follow another unless he can to his personal benefit.

The little article I mentioned from Van Dyke's book is this: "I like the teacher who not only shows me where he stands but how he got there and who can encourage and equip me to find my own path through the mist of books and tangled thickets of public opinion."

So, if you attempt at any time to use your authority as you go through the shop to show the people where you stand, and you fail in your attempt to show them how you got there, you have missed the greatest opportunity of your life.

I would like to say in finishing, "Above all things let's be careful about the printed matter, the things we put out in the shops for the men to read." Ask yourself the question, "How many people ever read it?" A teacher in school one day asked the children, "What is poverty?" A little boy in the front of the room popped up and said, "I will tell you what it is, Teacher; it is hell." She said, "Sonny, aren't you ashamed of yourself?" He said, "Ma and Pa gave that definition of it and I guess they know." The Teacher said, "Sonny, you look it up in the dictionary and tell me what it means." He said, "Teacher, if the dictionary don't say that poverty is hell, it is wrong."

Now, no one can kid you people into believing any thing else but what if you had a couple of hundred or a couple of thousand dollars more than you have, that you wouldn't be happier than you are. But nevertheless there is another kind of poverty than that of going hungry, or a physical poverty. There is a mental poverty, there are mental poorhouses, and whenever you get out literature be careful how you put it out and when you put it out and where you put it out. Ask yourself the question first of all, "How many people actually read as much as the headlines in the evening paper?"

We have just five rules of safety in our plant, in the entire book. The first

rule of safety, which I believe is the thing that has accomplished more than anything else in the Frigidaire Company, is to be clean and orderly. The second rule is to take care of property and materials. The third one is to never wear gloves or loose clothing while working around moving machinery. Does that mean a drill press or screw machine? It means your washing machine in your basement at home or any moving machinery. I got the first idea on that working at Stoddard-Dayton's in Dayton, Ohio. A man got his necktie caught on the pump shaft of an automobile and if it had not been for brute strength or a rotten necktie, his head would have been twisted off. The next rule is, "Always wear eye protection while working where there are flying particles." This does not mean just sawdust or dust. It means any place where there are flying particles. The last is "Never oil or clean machinery while it is in motion." This means any kind of machinery. The only amputation we have had in possibly two years' time was that of a colored man cleaning machinery while in motion. The machine dragged the rag in the gear and crushed his index finger and then we showed ourselves up, as we usually do. Today we marvel at our shortsightedness of yesterday. The machine was running to the right and all we had to do was to reverse it and run in to the left. Now a can cannot get caught.

I never like to pass up the thing that awakened me, and has wronged men in all industries in regard to safety. You can never make any shop safe in terms of Safety Directors or Safety Engineers. You can never clean up the plant in terms of janitors. You have got to put the responsibility where it belongs on the other fellow's shoulders; you can't carry it all yourself.

The thing that awakened me on safety four years ago was one of the saddest experiences I have ever had in industry. An old man who had been a punch press operator for forty years got all four of his fingers taken off. I had that old, cocky egotistical attitude at that time and when the Works Manager sent his Secretary to me and asked for a report, what do you suppose I said? "The dumb son-of-a-gun. Let him get his head cut off. He has been working on Punch Presses forty years and don't know how to operate one yet." In about ten minutes Mr. Fordham, one of the greatest leaders I have ever worked with in my life, walked up and said, "I understand you had another serious accident." We had plenty of them, every week. I said "Yes, Mr. Fordham, we did." He said, "How do you account for that?" I told him the same story. He looked at me a few minutes and patted his hands back of him and he said to me, "I tell you, Mr. Sain, what I think is wrong in this Punch Press Department. I think it is a lack of supervision." Right square on the end of the nose! You know what kind of picture I had—Friday when I got my envelope I could see, "This is your last day."

No, that is not what happened. They wished the job on me to take the old gentleman home to his wife. That is something that I never forget. I went home that night and sat down and rocked and rocked and was accused by my wife of being everything but sane. But I said to myself, "If accidents are a result of lack of supervision, we have had our last accident in the Punch Press Department. That is about three and one-half years ago and we have not had an amputation since that time.

So I ask you, in your own work, in talking to your foremen, get the picture over to them not in a dogmatic way, not in a sense of authority, not in a way that you are going to make them not want to do the thing, but teach them as though you taught them not. And then follow up the proposition and then I believe we can point to that one thing—lack of supervision is responsible for the accidents in our factories today.

Now we are going to ask Mr. Phillip J. Bowen, Foreman, Annealing Department, Michigan Steel Corporation, Detroit, to speak to us.

What's It All About? The Foreman and Safety

By PHILIP J. BOWEN

Foreman, Annealing Department, Michigan Steel Corporation, Detroit, Mich.

Caesar, I think, uttered these words, "I came, I saw, and I conquered." Words to me are fruitless, but the sincere and undaunted efforts of any individual along any line will never go amiss, if he be sincere and have the courage of his convictions to do that which he thinks is right, and for the uplift of his fellowmen.

I am here today because I am sincerely in earnest relative to this great movement, and that earnestness has grown out of twenty-two years of actual service in the great steel industry of America. I have had the privilege of observing this movement from its inception in just a few small industries to its present position of effective and successful effort in almost all of the nation's leading industries. Effective in its policies and successful in its aims for the preservation of human life and limb.

I believe the slogan "Accident Prevention" has been the means of arousing millions of industrial employees from a spirit of lethargy and indifference to that of careful and cautious execution of their daily duties in the mills.

We must not forget that the medium of advertisement has been a great factor in this matter. Illustrated lessons placed upon the bulletin boards in the various plants with the cartoons have conveyed to the mind of the individual worker the aim and purpose of this great movement against industrial hazards. And there is still much need for some agency to awaken us to our great responsibility along this line.

That reminds me of a Greek who, after passing the required examination at Ellis Island in New York, started upon a search to find a suitable location for a lunch room. Finding the desired spot he took a walk down one of the busy streets of Old New York and observing the many signs advertising the various places of business, he stopped and read one which said "Meals Served at All Hours." Then another "Open Day and Night." He scratched his head, turned and walked back to the place that he had leased for his future business, bought a can of paint and a brush. Prying the lid off the can, dipped the brush into the paint and inscribed the following on the window, "Me No Sleep Too." He had caught a true vision of what was needed in order that he might keep pace with the time. We must do likewise lest we fail.

I: From the Viewpoint of a Foreman: This question can only be answered when we know the true attitude of the foreman toward this great life and limb saving crusade. But I am today taking for granted that all foremen are sincere in their efforts, otherwise they would not have been chosen by the executives of the various industries to serve in that capacity. Therefore, the foreman if he lives up to his calling, can be classified as a true representative of the company, the mediator between the company and the employee, or in other words he is the safety-valve in his department. He is an outstanding figure and should be an example to his men, who are placed under his personal supervision.

Today as I make a survey of this body of industrial representatives and employees I assume that I am looking into the faces of some that are serving as production managers, employment superintendents, or safety engineers. I would not be foolish enough to try to give you any set rules that you must apply in all branches of industry, because what might be profitable in one line of work might not be practical in another, but I would say that the application of good horse sense plus a little cooperation on the part of the foreman and his employees will accomplish a great deal toward the salvation of human life and limb. Past experience has proven that. If I only had the time to produce to you some facts concerning the thousands of industrial employees, who have become

physically incapacitated by accidents brought about by indifference and carelessness on the part of their fellowmen, if I could only picture to you some of the agony and humiliation brought about by that damnable "I don't care spirit," that in itself would be sufficient reason why you and I should stand and work for accident prevention.

II. *Humanitarian Standpoint:* When I speak from this viewpoint you may say that I am sentimental or weak kneed, but I am not. I am far from being such. But I do believe that there is a vital relationship existing between the home and the industrial life of our nation and one cannot exist without the other. An employee that is a good provider or a good husband and father will also be found to be a good employee. That fact cannot be denied. What I am trying to get at is this—accident or injury of any nature is a stunning blow to the home and the dependents of the employee. Have you ever had the misfortune of being called to the home of a friend or a relative who had been fatally or seriously injured, and then have the heart breaking experience of watching the expression upon the faces of those loved ones? Words cannot describe the sorrow and anguish of that home. Then think of the other conditions which confront them, such as financial responsibilities to be met by a mother and little ones, which may lead to poverty and starvation.

It is not only the thought of being the object of suffering and charity, but to see the home ties broken by a condition which by a little effort on the part of others might be remedied or eradicated.

III. *The Foreman's Responsibility:* In my early remarks I classified the foreman as a safety-valve or a true representative of the company. Therefore I can consistently say that the foreman is in one sense of the word directly responsible for whatever happens in his department. Especially the safety and training of his men.

The greatest aim and desire of every good foreman should be efficiency in his department, because if he has an efficient organization he will have the biggest asset for obtaining the best possible results. This, in my estimation, is: *producing the largest quantity of the very best quality of material at the very lowest cost.* In order to reach this ideal condition it is needful that the foreman in charge get a true vision of his great responsibility. If he does that he will immediately adopt and place in action a safe and well organized plan of working instructions to govern his men at all times.

The first big step is that every foreman know his men. Knowing your men means that you understand thoroughly their temperament and characteristics. Above all put forth your best efforts to gain their confidence by being consistent in your daily practices. For instance, don't harp all day about playing safe in the execution of your commands, then turn around and do something yourself which is not safe and against the working regulations of the safety director. If you do, you are only destroying that which you should be trying to create, "The Spirit of Cooperation." Mr. Foreman, you are writing a gospel, a chapter a day, by the deeds that you do, by the words that you say. Your men read what you write, whether faithless or true, so what is the gospel according to you?

Make a thorough survey of your working equipment each day at the beginning of the day's work. See that all working implements are in good, safe condition before your men start operations. It may mean that you should be on hand half an hour or so earlier but that will have a striking effect upon the morale of your men. It will show them that you are really sincere in your efforts to safeguard their lives and that you are interested in their welfare. Give them some little thing to do, hold them responsible for the inspection of some machine and it will help to create an interest in this great movement. Remind them that accident prevention means that immediate attention must be given to all injuries no matter how small. They must be treated at the First Aid station by the

attending nurse or doctor. The company has placed it at their disposal and it is your duty as a foreman to see that they take advantage of its services. Continually impress upon their minds the need of being cautious and considerate of others as well as themselves. Show them that the company has proven their sincerity by spending thousands of dollars for safety devices and medical attention in their behalf. Appeal to them for cooperation in using these things to the best advantage. Make yourself the information bureau.

This will give you an organization to meet the needs of the present competitive industrial system that demands economic production.

CHAIRMAN SAIN: I am always interested and pay very close attention when I hear anybody mention spirit. Gentlemen, I wish we had about an hour extra this morning, so we could talk about the spirit of the plant, the thing we need today to make them more agreeable and pleasant places in which to work. Spirit is such a vital subject that I wish every foreman's club, every safety organization, every fraternity, every church or whatnot would take up this subject of spirit in their fall and winter meetings.

I am wondering if you know what spirit is, the spirit of the plant. How particular people are in buying a piece of machinery, how particular they are to get a motor that will carry that machine at the right speed, will carry the load as it should and how important electricity is to run this motor! And spirit to the man is just as necessary. Still, how little we think of that when we go to hire the man.

Dr. Myers told of our program of employment. The first place in creating the right spirit of helpfulness and the atmosphere of agreeableness is right down in your Employment Department. Before a man is ever hired in the Frigidaire Corporation, he gets a talk pertaining to: "Do you know how to work?" Do you know that most people in this country do not know why they should do good work? Create that right atmosphere and they will work, for the good of the company and not with the spirit of trying to get even with that "son-of-a-gun" in the employment office.

I think from what our speaker had to say we should be able to take on some real information, some real points and carry back into our factory with us these things. Unless you do take the things back into your shop and put them to work, your time here has been little more than recreation. You have not even paid six per cent of the expense account that your boss is making up for you.

I realize there are some high-powered men here, men who hold down very responsible jobs. A lot of you drive high-powered machines, too, I suppose, but no matter how high-powered your machine might be you have to stop some time to take on gas. So I don't know of any better place to take on some high-test gas than here at this meeting from the talk we have just had. The storage battery that you brought with you should go back charged to the brim.

Mr. Kettering some time ago was asked by one of the professors of a university to interview a lad recommended to them as the smartest lad ever turned out in the Engineering Department. Mr. Kettering interviewed the lad and turned him down. A few days later he met the professor and the professor said, "What is the matter; wasn't he smart enough?" Mr. Kettering said, "My God, I never met a man who possessed a greater amount of knowledge, but there is a difference between knowledge and intelligence. With all his knowledge, he did not have the least idea of what he was going to do with it. We could go to the book store and buy a set of Encyclopedias that contained as much knowledge as he had for \$75."

So when you go back to your shop with this knowledge box crammed full of ideas, they are not going to amount to a thing unless you can put them to work right down in the plant. I have often said this, that eating without digestion is the same as reading without reflection. Unless you will reflect on all these good

talks you are hearing this week, it will be the same as though you would eat meals and they did not digest.

I would like to ask how many Baptists there are here. (Several hands were raised.) Then you can tell your buddies what I mean when I tell this little story. In Church one Sunday they were having the Baptist immersion services and the Minister was telling how you had to be immersed in order to be saved. Two little youngsters were sitting in the front row. Well, when they got out of Church and started for home, the little girl said to her little brother, "The kittens we have and the Mamma cat have never been baptized; we will have to dip them." So they got a bucket of water and took the little kittens and dipped each one down in and then got the old cat and tried to dip her. But she made such a fuss that they could not immerse her. So the little girl said, "That old cat does not want to be completely immersed." The little boy then said, "Well, just sprinkle her and let her go to hell."

Now, I want to thank the brother very much who just gave us the talk and I am going to call on one of our good old friends. He is a real friend and a real worker in safety, and Mr. Cotcher has a message this morning that I believe we will all appreciate. I want to present Mr. Cotcher.

Safety Through Contests

By E. H. COTCHER

**Supervisor of Safety, The Murray Corporation of America,
Detroit, Mich.**

So much has been written on this subject and it has been discussed so thoroughly that it is difficult to offer anything new for your consideration. However, I shall give a brief outline of my own experience and observation from which you may get some new thoughts. I hope you will pardon the personal touch but we are all better off where we confine our remarks to something of which we know at least a little by our own observation.

The problem of the safety supervisor, whatever his title may be, is very largely one of selling; selling the management on the one hand as to the need for the program, and selling the rank and file on the other hand as to the benefits which they will receive. The safety contest is properly a part of that selling campaign.

Last year we heard Mr. Loney, of the Fisher Body Corporation, tell how they use cash bonuses as an incentive to foremen in accident prevention. We also heard Mr. Williams talk about the attitude of considering safety to be a part of the foreman's job, making it unnecessary to offer any particular reward for a good performance. The one stressed the financial side of the question while the other subordinated the financial consideration to some extent. There is of course, considerable merit in each of these programs as they seem to meet the need in their respective companies.

We are taught in our salesmanship courses that practically all men react to one or the other of two motives or to a combination of the two. The motives are vanity or pride and cupidity or love of money. Let us call these the pride motive and the money motive. If you are to sell an idea to a man or group of men you must appeal to one or both of these motives. Of course with women you cannot go far wrong if you stress the vanity or pride motive, although some of the ladies pride themselves on being hard boiled. The "gold digger" type is interested in the money motive and you must appeal to that motive to win her favor if you consider it worth winning.

If you are dealing with a plant manager or department head you are safe in praising his plant or department before you get around to suggest improvements

which may be needed. If he is cold to this appeal, show him what accidents are costing and how much can be saved by cutting down the loss.

If I seem to have digressed from the subject of contests, there is a reason, as all of these remarks will serve to illustrate my reasons for favoring the type of contest which I shall explain.

All contests appeal to the pride motive in that they appeal to the desire of every man to rank well with his associates; to grade up well in comparison with other managers, other superintendents or other foremen. From my experience it seems possible and desirable to combine the usual appeal to the pride motive with an appeal to the financial motive as well. Let us see how this can be done.

In all contests between departments or plants of different sizes and engaged in different types of work we must apply some handicap or differential as a means of making fair comparisons. This is sometimes done by setting up a "bogie" or allowance, expressed in hours lost or by comparing the present performance with past records of the same department, or by some other means of evening up the start in some way, so that the race will be even and the result will be accepted by the contestants as a fair comparison.

The method which appeals to me as most effective is the bogie or allowance expressed in dollars. By using the manual rates promulgated by the insurance interests as a basis we arrive at a base rate covering the nature of the work for each unit in the contest. Say that the manual rate for sheet metal stamping is \$2.10 per hundred dollars of pay roll covering compensation cost and insurance loading. In my work I should take one sixth of this rate, or thirty-five cents, as the allowance rate as we are only going to use the pure cost to charge against the allowance and we want to make it low enough so that it will be a real accomplishment to keep the costs below the allowance rate. At the end of the first period to be reported we multiply the rate of allowance by the number of hundreds of dollars of actual pay roll to obtain the allowance for that period. Thus if the pay roll amounts to \$25,000 and the rate is 35 cents, 250 times .35 equals \$87.50, the amount of the allowance for the period. Had the payroll been \$87,500 and the rate 10c, the allowance would have been the same. The rate represents the severity of the exposure and the payroll shows the extent or amount of exposure. The allowance, being in dollars and cents, is much more understandable to the average man than any statement of ratios or hours lost. Shop men are accustomed to measuring their departmental efficiencies in terms of cost and such a method fits into the scheme of things.

Against this allowance we charge the cost of compensation and medical treatment, making no charge for minor cases which do not have any costs. Perhaps you question this method. Some would charge every lost time case. My reason for recommending the elimination of the minor cases is so that we may not discourage men reporting to the First Aid as may be done if we include the minor cases. We must avoid this as, if men stay away from the First Aid to avoid charges against the department, we may get some severe infections from that neglect. If we make it clear that the minor cases reported do not penalize the department we avoid this danger.

With such a set-up the contestants are competing against each other and also attempting to keep within their allowance. The unit or contestant carrying the heaviest load, represented by the largest allowance, getting by without any accident cost is the winner. Units are graded in accordance with the percentage of allowance used or percentage saved.

Contests to be of real value must be actively supported by the management. If they are not, they soon lose their appeal and are of little value. As to the rewards to be given those winning and those effecting a saving, opinions vary. Some favor a direct cash award proportional to the savings. Others incline toward prizes such as watches, etc. I shall not attempt to argue in favor of either plan.

I think that those of us who have had experience with properly managed contests will agree that the contest offers the finest kind of medium for selling the safety idea and that they will repay the effort expended.

If you are operating a contest or expect to operate one, I recommend that you study the matter carefully to make sure that you are getting the greatest possible good out of it and if you conclude that you are not, try to sell the management on letting you put the right kind of pep into your contest so that it may go over properly.

As to how to choose the contest and how to arrange the presentation of awards, it is recommended that a dinner be held at the end of the contest period and the awards handed out at that dinner. Some managers may not be sold on this plan but it certainly is a fine way to demonstrate managerial interest if you can put it over. If you are turned down on this plan, you must devise some ceremony such as having a committee from the unit relinquishing the trophy take it to the new winner and deliver it with the proper courtesies and have a few remarks by the heads of the two units.

It is recommended that your study of the question include the reading of Safe Practices Pamphlet No. 67, of the National Safety Council series, for suggestions on publicity, special stunts for scoring and other items coming under the head of maintaining interest in safety.

CHAIRMAN SAIN: If you fellows didn't know anything about safety contests before, you should now. Mr. Cotcher has given me several very good points.

I liked Mr. Cotcher's statement about getting on their wave length. If that is the thing necessary in your plant, I would say, do that thing, have paid contests.

In Frigidaire, we have 450 foremen and group leaders who belong to our Foremen's Club. I am sure that down there, right today, we have 450 safety directors working in the plant. Unless you can have the good will of your men, and have every foreman working for you as a safety director, then you have not done the right job.

How do you present safety to your foreman? How do you enter his department? What do you talk to him about? My experience in learning how to approach a man came from my old instructor and helpmate, Mr. Myers. He called me into his office one day and said, "Sit down." I sat down alongside the old boss. He said to me, "I understand you have a boy over in Columbus at school."

I said, "Yes." When he began to talk about the kiddies—I have two of them in Dayton—then he got right on my wave length, and I pulled the chair right up close to the old boss.

He said, "I understand the boy is getting along very well. I was talking to a friend over in Columbus, and he told me the boy was coming along fine." I felt still better. "I understand that he is in an apartment by himself, that is, with three or four of the Dayton boys."

I said, "Yes, he has a little apartment. It doesn't cost any more. It is a big expense, however, and it ties me down pretty tight."

He said, "Wouldn't it be nice if you could make a little more money to help bear that expense?" Then, I knew there was something coming. He said, "There are a few things going on down in the shop that if you can correct there will be no limit as to where you can go on the job." I felt fine. He certainly got on my wave length.

How do you fellows go out into the shop? I would like to give you a little quotation that I use frequently. What have you in the way of quotations? What have you memorized? Don't any of you tell me that there aren't times in your life when you feel like you are going backward? Isn't that right? You are not always going forward. You sometimes go in reverse. I would suggest that you memorize a few quotations. A little brain athletics sometimes does us a lot of

good. I don't think there are many of us that have memorized anything since "Twinkle, twinkle, little star."

When I go down into the shop to see one of the foremen, I say, "So-and-so has been up to the dispensary three or four times with a minor injury. I suggest that you get the picture over to him in the right way, and let him see what you have in mind, and he will wear the eye protection. Nobody wants to wear them. They all get a headache or hurt their nose. They don't wear the eye protection because we haven't gotten the picture over to them, haven't been a good enough salesman." He threatened to bawl the man out. Then, I gave him this little quotation: "A man who is worthy of being the leader of men will never complain of the stupidity of his helpers. These things are a part of the great game of life. To meet them and not go down before them in discouragement and defeat is the final proof of your power."

I just have one other thing in mind. Out in Seattle a sales manager got his group together. He told them that free labor was the thing that made the difference between the man who succeeds and the man who falls behind in life. The things that men do before and after working hours, the things that they do that they don't get paid for, and the things that they do that they don't have to do are the things that make them get more pay. He said, "A toad has the simplest method of locomotion of anything in the world. He gets up and he sits down. When you go out of here, go out into the field and get up and stay up. Don't be like the toad. That is the only way in the world that you can make a mark for yourself."

Until we can do the thing that we don't have to do with as much energy as we do the thing that we have to do we will never make a mark in life.

I would like to call for some questions or discussion on the first subject, "What is it all about? The foreman and safety."

L. R. SCHUYLER (Lycorning Manufacturing Company, Williamsport, Pa.): I would like to ascertain if they have taken up the foreman's safety discussions in various foremen's meetings along with production. Is it deemed advisable?

MR. BOWEN: I believe, as a foreman of practical experience, that it is the duty of the foreman to picture the production end to his men. The life of every industry is based on production. The existence of that plant, the steadiness of its operation depends on the production record of the plant. It is the cardinal principle of industry.

MR. SCHUYLER: Do you work with this safety program through the foreman? For instance, if you find a man that is grinding without goggles, would you go to the foreman and tell him that one of his men was grinding without goggles, or would you walk up to the man and explain to him why he should wear goggles?

MR. BOWEN: There is a little quotation I left out of my address that every foreman should realize.

You are writing a chapter

By the deeds you do,

By the words you say.

Men read what you write,

Whether faithless or true.

What is the gospel according to you?

I consider the safety director my greatest friend.

In our particular industry, there are rules and regulations governing each department. We know that in the machine shops, in the foundries, that it is not good practice to work at any grindstone of any description without eye protection. When you have instilled into your men the essential need of protecting the eye, the arm, and the limbs, you have no need to tell them about the use of goggles. That is why I impressed the fact that if a man is brought to any foreman from the employment office, it is his duty as a foreman to impart to the new man that

knowledge relative to the use of goggles or any safety devices that are used in that department.

CHAIRMAN SAIN: I think that is a very satisfactory answer.

If you were going down through your departments and you saw a fire starting in one department, you wouldn't hunt the boss and tell him there was a fire. I think a man operating a machine of any kind without the proper protection should be told about it. I think his attention should be called to his disobedience of the rules right then and there.

If you were a workingman grinding on an emery wheel without your goggles on, how would you want the fellow to present the thing to you? Put yourself in the other fellow's place. I say to you, whoever asked that question, it is the very thing that I am preaching and putting more time on than anything else. That man wouldn't be grinding without goggles on if he had a good foreman.

MR. BOWEN: Don't you think that the attitude of the department, where one employee tells another employee to do something, has a tendency to create a spirit of opposition? Don't you think the spirit of a department should be built to that extent, where each member of that organization should have confidence in each other, and should be used in approaching the individual instead of running to the foreman?

CHAIRMAN SAIN: That is the story.

Haven't we seen the executives we admire? We say to ourselves, "It just seems so easy for him." He makes the right approach. He gets the facts and presents them in a way that the men want them.

I might say in that respect that the man working right here should be responsible for the safety of this man next to him, and so on down the line. In our plant, we have that very well organized. We have organized what we call the human safety guard. Every ten men in Frigidaire has a group leader, a safety leader. I can go into a department, most any department, and say to the department head, "Get your safety men together," and he will have them together in a few minutes. I don't want to talk to them particularly, I just want to see if he has his group organized. We make these group leaders members of the National Safety Council. Every fellow wants to do good. Every man in this world wants to do well in life.

L. E. AVERILL (Packard Motor Car Co., Detroit, Mich.): I think one of the most effective things that we have had in protecting our eyes is, as you stated, holding the foreman and the job setters responsible for the safety in their departments. I often find in walking through our departments that the foremen and job setters are mighty busy in the increase in production and changing new models and so forth, and are not giving quite the amount of time they should to the question of safety.

We have had the same experience as every other large manufacturer in losing eyes. Last year, we went ten months without losing an eye. We thought we were going to go through the whole year without having an eye injury. This year so far we haven't lost any. We lost one last year, and five the year before.

In trying to sell this idea, I have tried every conceivable thing that I could imagine. Now, I carry a couple of glass eyes in a little box in my pocket. If I see one of our employees grinding without goggles (I have, by the way, one blue and one brown glass eye) I go up to him and open this box and say, "How do you like the looks of that thing?" He probably will say, "It doesn't look good to me." "How would you like to wear it? We keep it in the office for fellows who grind without goggles. They look pretty good, but you can't see through the darn things."

I will bet money that the next day if I go through the department and if that man is grinding he has his goggles on.

CHAIRMAN SAIN: That is a real example of getting on the wave length.

If there is no further discussion on this particular subject, we will pass over to the subject that Mr. Cotcher talked about, "Safety through contests." I know there is just a lot of things that many of us want to know about safety through contests.

HAROLD MOORE (Wallys-Morrow Co., Elmira, N. Y.): Mr. Cotcher said in his address that they only included major accidents. Do you mean by that lost time accidents, Mr. Cotcher?

MR. COTCHER: In our particular contest, we include only accidents where the time lost exceeds one week. That is a rather arbitrary way of expressing it, but our purpose is to avoid anything which might tend to keep the man out of the first-aid room. I am always afraid if we get too fine, get down to charging these little accidents, that only lose a few hours, there will be a tendency not to report them. You can make that lost time limit anything you please.

J. P. HAIGHT (U. S. Aluminum Co., Edgewater, N. J.): I would like to ask Mr. Cotcher whether he thinks that a certain type of safety contest is effective indefinitely or whether it is necessary to frequently repeat them?

MR. COTCHER: I think that a little variety has to be introduced. It is logical that after you have made the same appeal for several different periods you have to introduce some new ideas. Those new ideas can be introduced in various ways. You can vary your form of award or you can vary your methods of figuring a little, but probably the essential idea will have to remain the same.

MR. AVERILL: I presume Mr. Cotcher was speaking about interplant contests. I am particularly interested in an interdepartmental contest. In our plant, the hazards in the departments vary. In some departments they wouldn't have a compensation case in a year. These departments, therefore, would be winning the contest continually. How would you take care of a contest of that kind? Would you count their minor accidents or slighter injuries?

MR. COTCHER: Sometimes you have departments so small in comparison with others, and the nature of the exposure so slight that you really can't afford to let them enter the contest as single entries. In that case, you have to bunch a few of them together. If you have a productive organization, you have got to balance the size of your contestants somewhat.

Take, for instance, the concern with which I am now employed. We have one plant that employs approximately five thousand men. There are large divisions in that plant, a hundred superintendents. We enter them as though they were separate entrants. We have outlying plants which go down to a total employment as low as one hundred and twenty-five. We have some miscellaneous departments that are more or less unattached. We are compelled to bunch some of those together some times, even though the supervision is not in common. We have several different shipping departments that have independent supervision. We bunch those all together in one general materials handling classification, because, as you say, if we allowed a small department with non-hazardous work they would win the contests indefinitely. The big trouble, I find, is that certain departments will have a tendency to come to the top. We charge any expense, any outside expense that arises. You will find most departments sometime during the six months will have some kind of an accident that will send a man outside of the plant for treatment. If they don't, then I think the answer is to bunch them with some other departments. That is a problem, and it must be met as your circumstances require.

R. E. NEWCOMB (Brewer-Titchener Corp., Cortland, N. Y.): I would like to ask Mr. Cotcher who has the say as to how these small departments will be bunched? Do you take the department head into consideration and counsel with him or do you just arbitrarily bunch him with some other department to equalize that experience?

MR. COTCHER: We figure out what we have to do to make it balance. We then get the approval of the manufacturing head and sell the idea to the department head as to why it had to be done.

It is true in effect that you do have to arbitrarily set them up. Your salesmanship comes in in not letting the fellow know it is done arbitrarily. Lots of times you can put an idea over by going to a man and making a casual remark on any particular thing that you want to sell to him, especially if he is the type that insists on its being his own idea. You can just drop the hint and go away and let him alone.

MR. NEWCOMB: Do you find any reaction on the part of the workmen in the different departments on account of their not getting any reward themselves individually?

MR. COTCHER: Yes, and it is unfortunate that in an organization as large as the one I have in mind, it is impossible to give any great reward. I know of one other organization that was a little more liberal in supporting their contests, and they gave for the winning department a dinner at the expense of the management. Every member of the department was a guest at this dinner. That probably is the ideal way of doing it, if you can get that much support.

MR. NEWCOMB: The Wallys-Morrow Company have a way of doing that. I would like to have Mr. Moore tell how they work it over there.

HAROLD MOORE (Wallys-Morrow Co., Elmira, N. Y.): We started with the idea of making every man or woman in an individual department his brother's keeper. We thought the purpose of departmental contests was to keep that department out of the black list. We divided the plant into two divisions. The first division was actual manufacturing machine work and in that group we also included the maintenance divisions like the millwrights, the electricians and the sheet metal men, the carpenters, because we believed their job, from a hazardous standpoint, was equally that of the man who operated a machine or who worked in a drop forge. The other group consisted of those men in the shipping department, stock chasers, and all departments not actually engaged in machine operation. We made the same division for the night men. There were four groups.

The basis was that in the department that went through in each group with the best record, every member of that department should receive some sort of a token as a memento of the occasion.

In practice, it worked out this way: That there were quite a number of departments in each group that went through without a single lost time accident, and consequently there were in the first edition something like 40 per cent of the men who got prizes. If a department had a single accident, that is, a lost time accident, meaning an accident that meant the loss of more than the shift in which they were actually working, it put that department out of the race for the whole of the four months of the competition.

We chose four months because four months happened to represent what we call the peak of our business.

For the benefit of you fellows who are interested in the eye business, let me tell you any eye case that necessitated the operator going over to have it taken care of by an oculist other than our own first-aid, that department was eliminated from competition. Before the competition started, we let the foremen know what the records were for the previous months. Since we started this competition—we have one every year—we have cut down those overtime cases by 70 per cent. Why? Because every overtime case, every oculist case, arose from nearly one thing, the man wasn't sure whether he had a piece of anything in his eye. He felt something. He thought it was out. He didn't bother any more about it. During the night it troubled him. The next morning he came in and there was the beginning of an ulcer. Our first-aid department, which is not presided over by a doctor but by a registered nurse and a first class superintendent will not handle

cases of that description. The result was that a man would come in to the first-aid room and have his eye taken care of.

Any department that had a lost time accident or an overtime case, lost out in the competition. The first year, we had about 40 per cent of the departments that went through without an accident. The average cost of the individual prizes has been about \$1.50. By going into the wholesale market, we have been able to get something that was nice and something a fellow thinks a lot about. We let the Workmen's Safety Council decide what they will have for their prizes. We always put the prizes in a showcase somewhere in the center of the plant where everybody can see them. When the thing is over, the foreman of the division who is the connecting link always in all this safety work, distributes the prizes. The men have their choice of five things. The presentation of the prizes is made by the manager of the concern, who hands a bunch of the prizes to the foreman and the foreman distributes them to the men in the division.

That is roughly how we handle the safety competition. It does away with one of the points one of the speakers brought up. If it is a bill fold the man has won, he can show it to everybody. It has engraved on it: "Wallys-Morrow Co., Safety Competition, 1928. Winner."

CHAIRMAN SAIN: That is a real plan. The thing that it shows, at least, is that there has been a lot of hard work put back of it. We haven't heard yet from Cyrus Rath of the Reo Company.

CYRUS J. RATH (Reo Motor Car Co., Lansing, Mich.): I don't know whether I have anything to say. A safety contest is an unknown thing in our factory at the present time. We haven't had one in years. We used to have them. I can't add any further information to what has been given.

CHAIRMAN SAIN: Does anybody else have any discussion? I believe Mr. Williams, our Chairman, probably could give us some light on this subject of, How to compensate or how to take care of the departments where the men might probably show a little inclination to be dissatisfied by not being taken into the payment plan.

A. M. WILLIAMS (Chrysler Corp., Detroit, Mich.): The question was asked here a short time back: How do you take care of the department where the hazard is so much greater than possibly in the average department throughout the plant? It has been a hard thing to deal with. In every department, you have two variables. Your one variable is the number of men under the supervision of a given foreman. Your other variable is the degree of hazard on the particular job in that department. One way that has been worked out successfully and carried on for the last three years and has finished twelve consecutive competitions is by taking the insurance rating on each trade. You can go to your insurance company and get the rating on any particular department. For instance, your stores department, receiving and shipping department, you can get from your insurance company the rate on that particular work. Then, you can take your sheet metal stamping, if you wish, and get the pure rate on that. Then, you can take your transformation of bar stock, castings and forgings, all of your machine operations in the transformation of that stock, and use your rate there. You can break it down and get a basis to work from. The experience that you are drawing from, the insurance companies' figures, is so broad that it is pretty nearly as fair a yardstick as can be used.

THOMAS D. LAW (Oneida Community, Ltd., Oneida, N. Y.): I am wondering how many people here really use the preventive accident charts in any contest that you hold? In other words, I have heard quite a lot about not charging the minor accidents. I wonder just how they do it. In a small department where there is less hazard there are minor accidents which should really be charged in

the contest to make it a good contest. A minor accident that is not reported to an emergency room is a preventive charge against that department, and a preventive charge is made such that that foreman is going to be sure that every man that has a minor injury goes to the emergency room. We have tried that for the past two years, and it has worked out 100 per cent. In all our contests, I charge every case reported to the emergency room by the actual cost of the accident or the emergency work. I would like to hear if anyone here uses that system.

CHAIRMAN SAIN: Does anyone here use that system?

I might say that I am very strong with Mr. Cotcher on what he had to say about the minor injuries. It is too easy to break down the employee's willingness to go the medical department. We do like Dr. Myers said yesterday, it is just plain two and two, I look for the facts and I don't fool myself. Don't kid yourself, because there are a lot of foremen right down in the shop that are going to say to a fellow that gets a lot of scratches some pretty hard things, and the next time he is going to say, "Before I will listen to that fellow hawl me out again, I will not go to the medical department." As a result, he is going to get some infection and it is going to terminate in a lost time accident. I agree with you that it is a very good plan to keep a record of all of them, but then it is facing that thing of breaking down that willingness and that wanting to go to the medical department.

L. R. SCHUYLER (Lycoming Manufacturing Co., Williamsport, Pa.): In reply to the gentleman's question on first-aid attendance, we have tried any number of ways to cut down the minor accidents. We know that minor accidents are eventually the cause of a man losing anywhere from two days to possibly a month or more through infection. It is very essential, as we all know, that a man report to the first-aid department for the slightest injury as long as the skin is broken. We have found that antagonizing the men and chasing up the fact that they reported to the first-aid department so many times during the past week or month, that they have that tendency to say, "Well, if they are going to call me down every time I go to the first-aid department, I am not going any more." Consequently, you have a monkey wrench in your gear. He is going to tell the other fellows about it.

We also found if you don't have the person in the first-aid department who uses the proper technique in the approach of a patient, you are spoiling an awful lot of good work. A man came to me one time and said, "I went up to the first-aid department and I thought they were going to bite my head off. I didn't do anything to the attendant."

The way we have been handling it recently, is that we make out a weekly report of the accidents going to the first-aid department. That report is cut down into departments, and every general foreman receives a copy of the list of accidents that happened in his department that necessitated going to the first-aid department for treatment, and also those accidents that required outside medical attention.

When this was first inaugurated, we found some of the general foremen posting these communications on their bulletin boards. I took the matter up with them at once, knowing that it was going to do a whole lot of harm if it continued. I told the foreman that they were not sent that communication for general information, that it was their own individual communication and they should use it to the best advantage. Consequently, we are now receiving a great deal more cooperation from the general foremen.

In the words of one of the foremen, "When I receive your communication on the accidents in my department, I look them over, take the worst accident and then study the individual operation, find out why or how that man could possibly have received that accident. If I find it was the fault of a mechanical part of the machine, I have it rectified. If I find it was lack of knowledge on the part of the operator, I give that operator further instructions." We don't advise the

foreman to bawl a man out because he got hurt. I have gone up to men time and again on emery wheels, new men who hadn't received the message as it was given, and have just shut the power off. He then looks around to find out why the power was shut off on his emery wheel. Then, you give him a little friendly talk and you have the man sold on wearing goggles.

We ask these hard boiled characters, so to speak, to wear the goggles with the strap that go around back of the head. Of course, we tell them. "When you are not using your goggles, you can easily push them up on your forehead out of the way." There is no tendency to have any eye strain and it isn't necessary to wear them all the time.

On the weekly reports, all accidents coming to the first-aid department, we give that over to each individual general foreman and then under it tell him in addition how many dressings his men received in the department during that week.

CHAIRMAN SAIN: As safety directors, we run into people who, when you go down to the department and ask them to do something, will always say, "Who, me?" Did you ever run into that group of fellows that are always saying, "Poor me." They "poor me" themselves to death. Then, did you ever run into that fellow that when you handed him some work to be done says, "Count on me."

There are three types of people—who me, poor me, and count me. What group do you belong to? I would like to go into each one of them in detail.

There are three other things that are going to keep you out, three "in's" that are going to keep you out—indecision, never can decide on a darn thing; intolerance and indifference. There are three "in's" that if you don't get busy on, out you go.

Of the three, there is only one I want to speak of and that is indecision. Write up a plan and then work your plan. That person that hasn't any plan is going to be like the June bug that came out of Mr. Cotcher's pocketbook. Indecision—be sure you know where you are going.

The biggest thing in the world is this: How are we measuring what good we are doing? We don't know how many accidents we prevented last year. We know how many we have had, but we don't know how many we have prevented. The thing I am afraid of is that some of us possess one of those failing characteristics that Dr. Myers spoke of yesterday, laziness, egotism, unconcern. What one there is liable to get us in bad? Due to the fact that we can't tell how many we have prevented, there is no way in the world to measure that. Laziness is the one that may get us in trouble.

My last word to you is, don't be like the toad, get up and stay up.

ADJOURNMENT

October 3, 1928**A. M. WILLIAMS, Chairman****Supervisor of Safety, Chrysler Corporation, Detroit, Mich.**

The second session was called to order at nine-fifty o'clock by the chairman, A. M. Williams.

CHAIRMAN WILLIAMS: Before we go ahead with the regular program, we will have our business session and election of officers. However, that will not take very much time.

The chairman's report will be rather brief. The secretary's report will show what has been accomplished in securing new members and maintaining the interest that has kept together the old members.

In working out our program for this Congress, you will notice that we have given a small portion of it to each of the outstanding things to be considered in a well rounded safety program. Years ago we were pretty mechanical in the safety game, bringing out the educational, and now we are splitting up some of the educational activities.

I have this one illustration that I always carry around in my mind. Back in my boyhood days, we had one outstanding character of the neighborhood, a well read university man, a carpenter, and with him was his only boy. This boy grew up to manhood and always worked with the father. He had just as good a mind, had just as good an intellect, and did just as good work as the father. The father did all the planning and laying out of the work. The boy possibly gave here and there a suggestion. The thing that I want to get across is that the father dominated, the father's mind was the dominating mind. It was his mind that did the planning. When the boy was about forty years old, the father died and left this boy stranded financially and mentally. The boy finally died in the poorhouse. That part of that boy's mind with which he did his thinking and planning had simply atrophied due to the fact that he hadn't worked at it.

The human mind is like the human body, if you exercise by lifting, the muscles with which you lift become strong and you can lift a good big load. If you never exercise those muscles, they waste away. The functions of the mind are the same, only you can't see that atrophy, you can't tell it is there, only by contacting with the mind. In our physical examination rooms we examine a man physically and if we find that one side is atrophied, we say, "Why this man is not using this arm or this shoulder. There is something wrong here someplace." Usually we find some deformity that didn't show up readily. We have the left side in the fellow to compare with the right, and we can tell instantly whether atrophy has taken place. But when it comes to comparing the mental with the physical, unfortunately we haven't two sides to compare. You can't cut your subject off at the collar and tell whether he has exercised what he has above his collar or not.

A man may be well read. We know lots of them. I think all of you can call to mind men who read a great deal, but that is all they ever do with it; they stop right there. The receiving section of their mind is splendid, but when it comes to that section of the mind where they turn that material over and think of it, it is atrophied.

Are we approaching in industry through our safety activities and our other activities, the point where we are letting those things in our employees atrophy, shrivel up through lack of use? Are we pampering them a little bit too much by guarding against this and guarding against that? Don't misunderstand me, I am not driving to the point possibly you think I am, that we shouldn't guard, because we should. However, at the time we guard, the guarding should be in connection with the

development of that part of the employee's mind that we want to develop to keep him alert and on his toes.

In other words, the safety program that we have been driving at this year has been aimed to be a well-balanced program, giving to each its appropriate weight, as we saw it.

The growth of the Automotive Section will be taken care of in the report of the secretary.

The next order of business is the report of the Nominating Committee. The Chairman is Mr. Dunnebacke.

Report of the Nominating Committee

By A. F. DUNNEBACKE

Chairman

The Nominating Committee consisted of Mr. Nelson of the Nash Motor Car Company, Mr. Corbett of the Chandler Motor Car Company and myself.

We rather appreciate the seriousness of a Nominating Committee because the success of this Automotive Section depends upon the selection of your officers and the work that they do. Our deliberations were guided to a certain extent on the activities of the officers this past year. We considered also the precedent that has been established in this section of advancing past officers to higher positions. We have considered also advice from the National Safety Council as to the activities of different members in the National Safety Council and have considered representatives of such companies.

We have considered also the question of geographical location in the working out of the activities of the Section. There is necessarily three or four meetings each year. It sometimes works a hardship to come from distant points to attend the meetings of the officers. If there are not sufficient members present at those meetings, it is difficult to do real constructive work. I say this because you may criticize the committee and some of its members because you might think we are centralizing the officers geographically. If there is that feeling, just remember that that is done solely for the purpose of insuring a complete attendance of all officers at the meetings that are called during the year. We have gone over the matter pretty thoroughly, and I want now to submit to you the slate that has been selected by that Nominating Committee.

Conforming to our precedent of advancing officers, we have suggested the name of Mr. E. H. Cotcher of the Murray Body Corporation as your Chairman. Mr. Cotcher was Vice Chairman last year.

We have selected Mr. H. L. Sain of the Frigidaire Corporation of Dayton as Vice Chairman. Mr. Sain was your Secretary last year.

For Secretary of the Section, we have selected Mr. H. L. Fracher of the Detroit Steel Products Company. Mr. Fracher has done unusual work in connection with the Detroit Industrial Safety Council, and we know from his activities in the Detroit area, that he will make you a very splendid Secretary.

For Chairman of the Poster and Slide Committee, we have selected Mr. M. J. McCarthy, Fisher Body Corporation, Detroit, Mich.

For Chairman of the Publicity Committee, we have selected Mr. C. W. Bishop of the Lycoming Manufacturing Company, Williamsport, Pennsylvania.

For Chairman of the Statistics Committee, we have selected Mr. P. J. Brand of the Pullman Car and Manufacturing Company, Chicago, Illinois.

For Chairman of the Engineering Committee, A. F. Dunnebacke, General Motors Corporation, Detroit, Mich.

For *News Letter* Editor, we have selected Mr. C. M. Dotterer of the Graham Paige Motor Car Corporation, Detroit, Michigan.

There are two Committee Chairmanships we have left vacant pending advice and consultation from the new officers. They are the Chairman of the Program Committee, and the Chairman of the Membership Committee.

The Executive Committee will consist of the officers of the Section, the Past Chairman of the Section and one or two outstanding people that we feel we can call in to the sessions for consultation and advice. Your Executive Committee will be the officers, and Mr. A. M. Williams, the Past Chairman, and Mr. L. E. Averill of the Packard Motor Car Company, Mr. J. S. Burns of the Reo Motor Car Company and myself.

The committee wishes to submit the slate and ask that you accept it.

CHAIRMAN WILLIAMS: Gentlemen, you have heard the report of the committee. What do you wish to do with it? Are there any other nominations?

L. R. SCHUYLER (Lycoming Manufacturing Company, Williamsport, Pa.): I rise, since I hear no other nominations, to move that the report of the Nominating Committee be received, and that the Secretary be instructed to cast the unanimous vote of the Automotive Section for the officers as nominated.

(The motion was seconded and carried.)

CHAIRMAN WILLIAMS: We will now have the report of the secretary on the growth and so forth of the Automotive Section during the year.

SECRETARY SAIN: I think Mr. Dunnebacke was very much justified in his argument there about having the men located in a locality where they can attend the meetings. If you had a record of the meetings we have had in the past year, you would realize it is very important to have them geographically located. There was about as many absent as present at most of the meetings. I don't care to read over each of the meetings in detail.

I think the thing we are most interested in is the membership of this Automotive Section, how many new members we have taken in, how many cancellations there have been, and what we have at the present time. During the year, we have taken in fifty-five new members. I think a lot of credit should go to our Membership Committee. There have been nineteen cancellations, with a total membership at the present time of two hundred and ninety-three.

I think that the field is very rich, there is room for a great harvest. What we need in the coming year is a committee that will call on the different prospective members for the Automotive Section. There is a very short space there to the three hundred mark. With the cancellations we might have in the next year, I don't see any reason why we shouldn't go to three hundred different companies represented in the Automotive Section next year.

CHAIRMAN WILLIAMS: Before turning the chair over to the new chairman, I want to extend to the old committee members, all of them, my sincere thanks for the cooperation they have given me. I want also to extend to the new officers the hope that they will have the same, and give the same as I have experienced in the past year. Mr. Cotcher, will you take the chair?

(Chairman-Elect Cotcher took the chair.)

CHAIRMAN COTCHER: I am very proud to have been elected chairman of a section like this. I noticed, in looking over the reports of the National Safety Council, that we are next to the largest industrial section, and that we got the most new members last year. If the new officers and the new Executive Committee can do as well and make as much progress during the coming year, there is no reason why we can't stand at the top of the list. I feel that we should all be highly complimented in being given the direction of such a very vital and live section.

I am not going to take any more of your time with comments. I conceive the duty of a chairman to be principally to introduce the features of the meeting. We have such a very fine program for today that we don't want to waste any time in oratory.

The first feature of this morning's meeting will be a demonstration of the manu-

facture and application of pyroxylin lacquer. The explanation and demonstration will be given by Mr. E. G. Richardson, Chief Chemist of Berry Brothers of Detroit. Mr. Richardson!

Manufacture and Application of Pyroxylin Lacquers

By E. G. RICHARDSON

Chief Chemist, Berry Brothers, Inc., Detroit, Michigan

In a discussion of the manufacture and application of pyroxylin lacquer, it will be interesting for us to consider first the derivation of the name, and to review briefly the principal lacquers of other civilizations. We can then take up the raw materials entering into modern industrial lacquers; and the methods used in their fabrication. The important methods of application will be dwelt on; and finally a consideration of the hazards involved in the manufacture and the application.

The phenomenal increase in the demand for pyroxylin lacquers is borne out by government statistics which show a production of some thirty million gallons for 1927. This is contrasted with the same report which does not show separate classification of lacquers up to and through 1923. Lacquers may be divided into three classes, which refer to the method of application viz.: spraying, brushing, and dipping. They may also be classified as automobile, furniture, industrial, toy, etc., which refer to the type of coating work they are best fitted to perform. These lacquers are all essentially the same, differing only in some detail of the formulation, or quality of raw material. The term "Lacquer" has simmered down in the last several years so that now it is generally taken to mean a nitrocellulose or pyroxylin base coating material. Formerly, and to a small extent even today, any quick drying coating for protective or decorative purpose could be marketed as a lacquer, if considered desirable from the sales angle.

Ancient history records the use of lacquers. The derivation of the word is the Hindustani "Lakh" which means hundred thousand and refers to the swarms of insects which fasten themselves to host trees in the forests of India, Siam, and Burma, and in the course of their life cycle produce a resinous incrustation. This resin is gathered and after suitable refining becomes the well known shellac of commerce. Shellac varnish was our first lacquer. The earliest written reference of the use of shellac as a coating material is dated 1590; and states that lac was collected for use in making varnishes for the imperial palace.

We frequently hear reference made to Egyptian and Chinese lacquers. The early Egyptian material was a vegetable resin dissolved in any solvent then available, such as oil of cedar. The coating had no outstanding merit and should not be confused with the bitumastic paints used to protect the articles unearthed by present day archeologists. On the other hand, Oriental lacquers are still produced and used today, in much the same fashion as they were centuries ago. These lacquers of China, Burma and Japan consist of evaporated and treated sap from the tree *Rhus Verniciferox*, which is in the same botanical family as our poison ivy. The sap takes on a dark sirupy nature and when spread as a film requires exactly opposite conditions for favorable drying than do our American varnishes. The Chinese lacquer, or Ningpo varnish as it has been dubbed by English speaking residents in China, will dry only under high humidity atmospheric conditions, and, if applied during the dry season, long cloths saturated with water must be hung from the ceiling of the drying room. Many coats are used in building up a finish and each coat rubbed smooth; a process extremely long and tedious, and entirely impractical in any of our American finishing rooms. An unusual peculiarity which would bar the use of Chinese

lacquer in America, if it were practical otherwise, is the fact that wherever it comes in contact with a white man's skin, a rash similar to poison ivy begins, which will often spread and prove serious. This poison property is lost, however, when the lacquer has been allowed to dry sufficiently long. The material is very beautiful and durable and worthy of considerable respect as a finishing scheme, even though impossible in our western civilization.

Origin of Modern Pyroxylin Lacquers

Modern pyroxylin lacquers had their beginning with the issuance of an English patent in 1856 covering a solution of cellulose nitrate in ether-alcohol mixture. Such a lacquer had very limited use and small progress was made until 1881, when a patent was issued covering the use of a solution of cellulose nitrate in amyl acetate. The price of fusel oil, from which amyl acetate was manufactured, increased rapidly and the extensive use of lacquers was thwarted by the high prices for suitable solvents. We might not even today have suitable lacquer solvents at reasonable prices but for the war of 1914-18. Our principal supply in this country today comes from a plant which was originally started for the manufacture of acetone used by the English government in making their cordite. Butyl alcohol or butanol is a by-product from the fermentation process used in the acetone manufacture. Large stocks of the by-product were accumulated and after the war an outlet was sought for this dormant material. Co-incident with this development, the powder people found themselves with large stocks of surplus smokeless powder and processes were developed whereby the nitrogen content could be reduced to the range of 11.8 to 12.5 per cent, which range gives a material soluble in alcohol esters and is not sufficiently high to produce an explosive product. The nitrated cellulose or soluble cotton used in the lacquer industry is not guncotton and cannot be detonated by concussion.

Soluble cotton is used in the lacquer industry, because of the fact that it is soluble in the esters and the alcohol esters, which are suitable vehicles for spray application. If a lacquer were attempted with guncotton, acetone would have to be used as a solvent, and when the lacquer was sprayed, probably most of it would dry before it got to the work, and that which dried on the work would be so white from brushing that it would serve no good purpose at all. Therefore, the high nitrated cotton cannot be used even in lacquer manufacture.

By itself when dry, it will burn with about the rapidity of celluloid. In the lacquer as used, however, other materials are present which retard the fast burning characteristics, and we find that the pigmented lacquer films are no more rapid in combustion than many oil enamel or color varnish films. With the development of processes for conversion of smokeless powder into soluble cotton there was also the interesting development of a process whereby the viscosity of the dissolved material was so reduced that it was possible to get as high as forty ounces of cellulose nitrate into a gallon of solvent and still have a workable lacquer; whereas, with the early nitrocotton not more than six or eight ounces could be dissolved without obtaining a solution so thick that spreading by means of brush or spray was impossible.

This is really the basis of the modern industrial lacquer, because if we had a low solids material, it would take dozens of coats to give a film thick enough to give normal, reasonable durability. Varnish of a high-grade order contains as much as sixty-five ounces of solids in a gallon. So, you see, the present day industrial lacquers do not approach the varnishes from a film thickness per coat aspect. But, they are certainly far improved over the lacquers that were available when the first patent was taken out in 1881.

The lacquers for industrial and domestic use are manufactured today by

processing together in suitable proportions solutions of nitrocellulose, resins, flexibilizers, pigments and solvents. Lacquer nitrocellulose is made by treating purified cotton linters with nitric acid and sulphuric acid. From 5 to 14 per cent of the finished lacquer is soluble cotton. The process is stopped at the proper point and the cotton thoroughly purified by washing. Gun cotton is made by a similar process but the nitration is carried much further. The resins used in most cases are varnish gums such as Ester, Kauri, Congo, etc. They impart adhesion and gloss. The flexibilizers (or plasticizers) are either oils or non-volatile organic chemicals which were previously developed as camphor substitutes in celluloid manufacture. Such materials are tricreylphosphate and dibutylphthalate. As the classification implies, these materials impart flexibility and ductility to the lacquer film. Pigments used are, with few exceptions, the same as employed by the paint and enamel industry in recent years. They include zinc oxide, lithophone, and titanium oxide for whites. Lead chromate and basic lead chromate give yellow and orange colors, respectively: prussian and ultramarine blue produce many shades; pigments called chrome green, consisting of mixtures of prussian blue and lead chromate, give all varieties of green; iron oxides make dull shades of red, and when brilliant red shades are desired it is necessary to resort to dye stuff precipitated on inert white base. The organic colors, while brilliant and beautiful, are fugitive and result in lacquers of poor light fastness.

Solutions of the cotton and gums are made by adding solvents to them, either in agitator tanks or pebble mills. The pigment may be ground directly in the lacquer in pebble mills or may be ground on paint mills in the plasticizer portion of the lacquer, and subsequently stirred into the lacquer. From the manufacturing angle this is the most important phase of lacquer fabrication for a tremendous amount of mechanical work is required to thoroughly wet the pigment with the vehicle and reduce it to "enamel fineness." Tinting operations to secure the exact shade follow and are both tedious and costly. Finally, the lacquer must be cleaned by passing through a centrifugal clarifier which removes all dirt and large pigment particles and makes it possible for the lacquer to produce a smooth, even film when properly applied.

Lacquers Applied by the Spray Method

The bulk of the lacquer manufactured today is applied by the spray method. Spray equipment manufacturers are constantly improving the designs of their apparatus, so that lacquer coatings may be applied quicker and better, with less wastage of material as fume or spray dust. Local and state ordinances require that spray operations be carried out in properly ventilated booths. Booths are of many designs but all are constructed for the same purpose, which is the confinement and removal of fumes and spray dust. Compressed air at pressures of fifty to one hundred pounds per square inch is used to effect atomization of the lacquer in the spray gun. The lacquer supply for the gun is put under five to ten pounds pressure in pressure tanks in one type of equipment while another type depends upon the pressure head developed from an elevated bucket or drum. The first is referred to as pressure feed and second as gravity feed. Almost without exception pigmented lacquer supplied to the consumer is too viscous for application without thinning. The pigment will not settle as hard or cake as readily during the shipping and storage period in heavy bodied lacquer, as it would in thin lacquer. This situation necessitates mixing or thinning tanks in conjunction with the spray equipment.

Dip application of lacquer is only used on small articles and there is no necessity for large quantities of lacquer in the dip tank at any one time. Flacoating with lacquer was thought to have great possibilities a few years ago, but with one or two exceptions it has been given up as impractical at this time. Hand

brush application of lacquer is used industrially on small parts. It is the principal method of application of household lacquers. The hand pump spray which had been advocated for household use has proved tedious and ineffective. The quantity of lacquer sold for household decoration is insignificant when compared with the amount consumed by industries.

The advent of large scale lacquer manufacture and application presented new hazards, but not as was first thought, more serious hazards than had been experienced with varnish and enamel. The quick drying feature of lacquer causes any material not striking the work during spray operation to settle as a loose, fluffy powder. If poor housekeeping is permitted, quantities may accumulate making a very serious fire hazard. The fluffy powder is easily ignited and if a vibration or gust of air suspends it in the air in sufficient quantities, an explosion can result. This is true of any combustible material in powder or dust form, and we occasionally hear of grain, coal and even sugar explosions. Frequent cleaning of booths and stacks removes any possibility of dust explosion.

Explosions Rare in the Spray Booth

A vapor explosion is impossible in a properly operating spray booth as the concentration of thinner vapor is far below the explosive range. A paper published by the author's laboratory in *The Journal of Industrial and Engineering Chemistry*, for February, 1928, reviews the "Explosive Properties of Lacquer—Solvent Vapors." It was found that the vapor concentration in the air of typical industrial spray booths was of the order of one-one-hundredth of the amount necessary for an explosive mixture. Many samples were drawn from exhaust ducts while spray guns were operating a full capacity. These were then transferred to an explosion chamber equipped with a spark gap. In all cases it was found impossible to get an explosion.

Lacquer in mixing or dipping tanks is readily ignited by application of a flame, but, on the other hand easily extinguished by closing the lid or by water, foamite or carbon dioxide. The flash point of lacquer is approximately that of shellac and its burning characteristics are similar to those of oil varnish. Rags saturated with oil, varnish or paint will frequently ignite spontaneously and were often the cause of fires in finishing rooms. Rags saturated with lacquer will not ignite spontaneously and the use of lacquer has given us relief from this very serious hazard.

Lacquer solvents and diluents with the exception of benzol are not toxic. Numerous investigations on this matter have exonerated all except benzol. Alert to the situation, the lacquer manufacturers have eliminated this undesirable constituent from their formulae, except perhaps in a few cases of special purpose lacquers. In such instances, proper precautions should be taken both in manufacture and application to guard the workmen from contact with the fumes.

When the advantages of our modern pyroxylin lacquer became evident, it was truly remarkable how quickly the old established manufacturing and finishing room equipments and procedures were changed over to make way. There is a possibility that some time in the future pyroxylin lacquer will be supplanted with a synthetic resin lacquer possessing similar qualities but with more advantages. But as pyroxylin lacquer is still here, it behooves those of us who are connected with the manufacture or application to continue to learn ways and means of overcoming its faults and shortcomings.

CHAIRMAN COTCHER: To more thoroughly cover the subject of lacquer, the Program Committee has arranged for formal discussions before we invite general discussion. The first phase of that formal discussion will be led by Mr. H. L. Miner, of the E. I. duPont de Nemours Company, Wilmington, Delaware.

Discussion of Mr. Richardson's Paper

By H. L. MINER

Manager of Safety and Fire Protection, E. I. duPont deNemours Company,
Wilmington, Del.

Mr. Richardson certainly covered the subject of the manufacture and application of lacquers in a very comprehensive manner.

Before taking up the different phases of the problem I want to touch upon certain very important characteristics mentioned by Mr. Richardson. Most people have the idea or impression that pyroxylin lacquers or solutions contain large quantities of nitrocellulose or pyroxylin or soluble cotton. Mr. Richardson stated this morning that, generally speaking, the amount of nitrocellulose in these lacquer compounds was from 5 per cent to 15 per cent. I imagine that about 10 to 12 per cent would be the average; just sufficient pyroxylin to act as a binding agent in the finish and prevent oxidation.

A very interesting phase of the problem was raised a year or so ago as to the probable effect of the pigment or color used in lacquer compounds upon flammability or the decomposing tendencies of the residue. One chemist in Philadelphia stated that he felt that certain pigments either due to composition or color might lower the ignition temperature or decomposing temperatures. The Underwriters Laboratories recently tested pigments of five or six different colors, and while there was a few degrees temperature difference in their decomposing or ignition points, the variance was so slight that it was not worthy of note.

Another important phase of the problem, and one not well understood, is the effect that one or two per cent nitrogen has upon the burning characteristics of the nitrocellulose, as was very vividly demonstrated this morning.

During a recent survey in North Carolina, a committee went over the spraying operations in a chair factory. They were spraying ordinary white oil base enamel which did not contain any nitrocellulose. It was a continuous operation. The chairs went into the booth where the spraying was done and were then carried on a trolley system back into the drying room. We found about a quarter of an inch of a milk-like powder on the floor. We took it outside and, when thrown into the air, it ignited, and a blast fire occurred. Any material that is subject to oxidization, if suspended in the air as a dust cloud introduces flash fire or explosion possibilities.

I want to read part of a statement that appears in the 1928 issue of the Fire Prevention Year Book. It is called *The Red Book*. This book is published by Hough and Lawson in Baltimore. They publish several stock fire insurance periodicals. For the past three or four years, they have made it a point to include in their Year Book an article on pyroxylin lacquers. And for the past two years, they have carried the model ordinance suggested by the National Board of Fire Underwriters.

Mr. Lawson came to me several months ago and asked for an article on pyroxylin lacquers. I suggested that either he or some reputable insurance representative make an unbiased survey of the situation and publish the findings in the Year Book. I would like to read their findings, because they are very interesting, and have a bearing on the subject under discussion.

I want you to understand that I am not presenting this with any idea of mitigating the fire hazard or the need of taking proper precautions or anything of that nature; but just to show you that even in the insurance field, where there has been so much hysteria during the past few years, they are gradually gaining knowledge and are readjusting their viewpoint to the more practical common sense basis.

The article starts: "The wide-spread use of pyroxylin lacquer is a result of that quantity production prized by manufacturers for its cost-reducing equation. Pyroxylin lacquer is not a comparatively new product and the compressed air method of spraying dates back to 1890."

"During the World War the use of the spray method extended very rapidly until today it is the accepted method of applying quick-drying lacquers, paints and varnishes. Probably because of the very rapid spread of the spray method there was little time for exhaustive research work on the part of anyone but the manufacturers of pyroxylin and, as a result, the use of pyroxylin lacquer was classed as very hazardous when, as a matter of fact, this lacquer is not more inherently dangerous than other paints and varnishes and less dangerous than the cheaper varnishes and paints. The really important hazard lies in the method of applying it and this is a hazard which can be corrected. The purpose of this article is to clear away misconceptions and to stress to insurance companies, to manufacturers using the spray method, to fire prevention committees, fire chiefs and the public generally the necessity for better housekeeping in manufacturing plants. This bettering of conditions can be advanced if insurance companies would heavily penalize the indifferent and careless users of spray methods and reward, with lower rates, those manufacturers who installed approved spray booths, who kept the booths clean and free from vapors and residue and who provided adequate fire extinguishing systems in their booths and plants."

The article then goes on to say: "There has hardly been any problem in recent years so perplexing to fire prevention bodies and to chiefs of fire departments as that of the widespread use of the spray method of applying quick-drying flammable materials and there has hardly been a commercial product so generally misunderstood as pyroxylin lacquer. Many misleading articles concerning it and the hazard of its use have appeared in the technical and trade press. It is now developing that pyroxylin has been heavily and erroneously penalized."

"The most important development is the general recognition today that pyroxylin lacquer is no more inherently dangerous than is any other paint, lacquer or varnish and not as dangerous as the cheaper varieties."

"The next big development lies in the important fact that the hazard in the spray gun method of applying lacquers, paints and varnishes is largely a matter of house-keeping on the part of the users of the spray method."

"Discussing these questions before the State Firemen's Association of Texas on June 15, this year, Mr. H. E. Newell, engineer of the National Board of Fire Underwriters and an expert on flammable liquids, said this:

"No other subject has evoked so much discussion in the last decade as has the spray application of flammable finishing material on a wide, or quantity production scale. Similarly, no other subject within the scope of fire prevention effort has been so misunderstood and in numerous instances singled out for unwise and unjustified regulation. Reflection for a moment will prove that this is true."

"Neither the use of pyroxylin lacquer nor its application by the spray gun is new. Aside from its use in connection with lacquer, the spray gun is an old invention. As far back as 1893 it was in use and was employed in that year for the exterior painting of the World's Fair buildings in Chicago. If this is true, the question that naturally arises is, why all the agitation and warnings at this late date? The answer is easy to find. The spray application of flammable finishing materials on a wide scale or in connection with modern quantity production is relatively new, being a development of the past few years. During this period, in connection with this process there have occurred several disastrous fires, one of which involved the loss of many lives. In the case of the latter it so happened that the finishing material being used was pyroxylin lacquer, hence the publicity which followed served to emphasize the use of this material and to indicate it as

akin to dynamite and smokeless powder. Indeed it has been referred to as liquid dynamite, the inference being that shock or concussion in its immediate vicinity would cause it to detonate or explode. Of course this is absurd and untrue.

"Now, as everyone knows, the National Board of Fire Underwriters is an organization composed of representatives of virtually all of the largest and soundest stock fire insurance companies. Through its various committees it functions in many ways, not the least of which is its activities in fire prevention work. Its engineers are the best in their respective lines and it is largely through the National Board, its committees and engineers that standards for fire prevention and protection are equitable and sound.

"Another national organization whose activities are entirely devoted to fire prevention is the National Fire Protection Association. It, too, functions through committees and engineers. Its committees, however, are composed of men actively engaged in industry and commerce. They are experts, are business executives of the highest type and recognize, more than does the average layman, that the annual fire waste of the country is one of its very heaviest economic burdens. They labor unceasingly to reduce this burden.

"It is, therefore, most important to know that the National Fire Protection Association has gone on record as having reached the conclusion that the hazard in spray painting lies in the process used rather than in the material.

"On July 20, this year, the editors of the Fire Prevention Year Book wrote to Mr. Robert S. Moulton, technical secretary of the National Fire Protection Association, asking for statistics relative to the number of pyroxylin lacquer fires in the United States as compared with other paint and varnish fires.

"Answering this letter, Mr. Moulton replied:

"The difficulty in attempting to compile any statistics of this character is that the original inspection reports very frequently do not indicate the nature of the material sprayed. We find that the same plant will spray successively ordinary paint, shellac, varnish and pyroxylin lacquer, it sometimes being difficult in an individual fire to state which material was involved in the origin of the fire.

"We have reached the conclusion that the hazard involved resides primarily in the paint spraying process rather than in the particular material sprayed. There is doubtless a difference in hazard between pyroxylin lacquer and the other materials sprayed, but this difference is a comparatively minor one.

"In this connection you may be interested to know that a number of serious fires supposedly due to the use of pyroxylin have been, upon investigation, found to have been due to the spraying of ordinary shellac or varnish. It is also to be noted that substantially the same fire prevention precautions are called for irrespective of the material sprayed."

"Here we have the two national bodies most actively concerned in the question of fire hazard in entire agreement as to the outstanding fact that it is the process and not the material which introduces the hazard in paint spraying.

"In his letter, Mr. Moulton mentions the probability of a difference in hazard between pyroxylin lacquer and other materials sprayed. There is a slight difference. Lacquers involve a dust hazard, removable by good housekeeping. Paints, varnishes, etc., involve an entirely different hazard—that of spontaneous ignition. Mr. Newell, in his talk before the Texas firemen, discussed that particular phase of the question. He said:

"The principal materials used for this purpose (spray painting) include paints, enamels, varnishes, pyroxylin lacquers, oil stains, shellacs and mixtures of these materials.

"Pyroxylin lacquer, ready to apply, contains pigments, resins and flexible oils, thinner or solvent, and nitrocellulose, the latter averaging about 12 per cent of the total content. The solvents, or thinners, are in the alcohol class and vary consid-

erably; they include alcohol, amyl acetate, toluol and various other hydro-carbons too numerous to mention.

"The nitrocellulose used in pyroxylin lacquer, in one stage of its manufacture is pure nitrated cotton and as such would be explosive if allowed to dry; it changes its nature and loses this characteristic just as soon as it is dissolved in a solvent, hence a can of lacquer is no more explosive than a can of paint or any other finishing material. This fact should be recognized and remembered, especially by those liable to be called upon to fight fires in establishments where pyroxylin lacquers are used or stored. There should be no more hesitancy or fear of entering such establishments at times of fire than in the case of buildings containing paints, varnish, etc. It is well to remember also that water is the most effective medium for extinguishing lacquer fires. Pyroxylin lacquers, because of their quick drying properties, involve a dust hazard when applied by the spray method. That portion of the dust which is nitrocellulose may decompose when subjected to moderate heat and give off flammable gases.

"Paints, varnishes, enamels and similar oil type finishing materials contain turpentine as a solvent, but many low grade paints contain naphtha or gasoline. Linseed oil or other oxidizing agents are used to promote drying and this creates the hazard of spontaneous ignition. Some enamels contain quick drying agents, and these, when applied by the spray method, also involve a dust hazard.

"Thus, so far as the general hazard is concerned, there is little difference between paints, varnishes, enamels, shellacs, etc., on the one hand, and pyroxylin lacquers on the others. Lacquers involve a dust hazard; paints, varnishes, etc., as a rule do not. Paints, varnishes, etc., involve the hazard of spontaneous ignition, but lacquers as a rule do not. Lacquer thinners or solvents are generally more volatile than those of paints, varnishes and enamels, but on the other hand, as stated previously, many of the cheaper paints employ gasoline and naphtha for solvent purposes and these are more volatile than many commonly employed lacquer solvents.

"The storage and handling of these materials has caused no serious concern, hence it is apparent that we must search further for the cause of the hazard which we know exists.

"Any of the finishing materials mentioned, be they paints, varnishes, enamels, shellacs or pyroxylin lacquers, when finely atomized in a mist-like form promote vaporization. When discharged from the spray gun this very result is obtained. If thoroughly adequate ventilation is not provided where the spray gun is continuously discharged, the vapor and residue therefrom will spread throughout the room, the latter depositing on ledges, radiators and other places of easy lodgment. If there are open lights or other sources of ignition in the vicinity of the vapor a flash fire occurs.

"Thus it is apparent that it is the method of application and not the material used which is mainly responsible for the hazard. This fact was fully realized by the N. F. P. A. committee which recently completed a brochure on this general subject. To quote the committee:

"While paints, varnishes, enamels and lacquers differ somewhat as to make up and hazard properties, they all represent a similar hazard when applied by the spray method and should be similarly protected."

"The fire record verifies the correctness of this statement. While three large lacquer fires occurred in Detroit, Grand Rapids and Philadelphia, 11 large fires over a period of three years occurred in connection with the spray application of paints, varnishes and enamels in the southern furniture industry. The following are indicated as the principal conditions resulting in fires:

"First, broken electric lamps and other electrical defects.

"Second, result of careless cleaning of booths, fans and motors with highly flammable solvents.

"Third, improperly arranged or designed equipments of booths, fans and motors used for removing vapor laden air.

"The second and third causes might well be grouped and redesignated "poor housekeeping." Failure to maintain clean and orderly conditions in the vicinity of the booth has also facilitated the spread of many of the fires which have occurred. The importance of good housekeeping in connection with the spraying process is urgent and cannot be overstressed.

"Another feature of pronounced importance, indeed one that affects housekeeping to a considerable degree, is the effectiveness in removing vapor and dust laden air from around the article being sprayed. The principal object of the exhaust system is to properly remove the vapors and residue from a designated area. It is in this respect that ventilation is related to housekeeping.

"Thus, assuming direct means of ignition are eliminated, good housekeeping and adequate ventilation stand out as the cardinal features upon which mainly rest the safe operation of the spray method of application. These are by no means the sole precautionary measures necessary. Of equal importance is adequate fire protection supplemented by isolation or separation of the process."

"From the above it will be seen that freedom from the heavy burden imposed on manufacturers using the spray gun method of applying finishing materials lies in improving housekeeping. By 'housekeeping'—a term familiar to virtually all business men—is meant that cleanliness which insures freedom from carelessly caused fires, the installation of improved spray booths and devices which reduce the hazard to a minimum, and the installation of approved automatic, semi-automatic or manual fire extinguishing apparatus to hold, or extinguish such fires that might occur in spite of all precautions.

"That housekeeping was the really important factor, after all, was early recognized by the manufacturers of pyroxylin lacquers, by the members of the American Paint and Varnish Manufacturers' Association and by certain regulatory bodies. But it was not so recognized by the general public, by the layman, nor even by certain scientific men who had made little or no research work. Too many persons had accepted as facts erroneous statements based on an evident lack of knowledge. This was brought out last December in a report printed in *The Journal of the Society of Automotive Engineers* when a member said:

"Few problems in the industrial world in recent years have attracted so much attention as the application of finishing materials by the spray method. No other problem has developed so many diversified opinions, many of them entirely erroneous, largely based on personal conclusions without sufficient knowledge of facts. These statements or conclusions have been responsible for either over-emphasis of the fire and the health hazards involved, or slighting and mitigating the hazards so that proper precautions have not been taken."

"Getting back to the hazard of bad housekeeping, which, after all, makes up the major portion of the hazard of the spray process, the National Fire Protection Association, at its annual meeting in May, this year, at Atlantic City, adopted revised regulations on paint spraying and spray booths which are designed to meet present day needs."

The importance of good housekeeping and the need of adequate ventilation has been touched upon in a number of your meetings. Mr. Richardson mentioned the fact that the solvents and diluents used in lacquers today are non-toxic, benzol having been eliminated. But, should some of the diluents or solvents be toxic to a minor degree, the ventilation necessary for control of the fire hazard or removal of the vapors will adequately take care of any toxicity of the solvents.

The latest pamphlet or brochure covering the spray application of flammable finishes was published by the National Fire Protection Association last spring.

"These regulations are of more importance to the fire insurance companies and to inspection and rating organizations, all of whom are thoroughly familiar with

them. Copies of these regulations may be obtained from the National Fire Protection Association, 40 Central Street, Boston, Massachusetts, or the National Board of Fire Underwriters, 85 John Street, New York City.

"Of utmost importance, however, to fire marshals, fire engineers, fire prevention bureaus, and to fire preventionists in general are certain good practices based upon and in conformance with National Fire Protection Association standard regulations for refinishing shops. These were prepared by a special committee of the National Fire Protection Association after a thorough investigation of the entire subject. This committee was composed of H. E. Newell, engineer of the National Board of Fire Underwriters, and also chairman of several other committees of the National Fire Protection Association; W. D. Milne; H. L. Miner; Benjamin Richards; A. T. Nuckolls, and M. J. Thompson."

The report was unanimously approved by the committee, by the association and published in pamphlet form. It covers the hazard in detail, and outlines the necessary precautions to be taken. It also includes diagrams showing proper installations and installations of spray booths as well as covering the spray room hazard in the refinishing shops where cars are painted or finished in pyroxylin solutions.

CHAIRMAN COTCHER: This discussion wouldn't be complete without someone representing the users, someone who has made a rather thorough study of the subject, and your Program Committee has arranged to have this side presented by R. E. Abbott, Director of Fire Prevention of the Fisher Body Corporation.

MR. ABBOTT: I was informed by the council that they would prefer to have no prepared talk made for this morning, but rather an extemporaneous discussion. I assume that the formal discussion is supposed to continue by comments or criticism on what the former speakers have stated.

I think the subject has been very thoroughly covered by Mr. Richardson and Mr. Miner. Not very long ago, one of our prominent university professors was asked how it was he talked upon so many different subjects and was very conversant with the facts concerning the various subjects. The gentleman said to him, "You talk to doctors and you seem to be thoroughly familiar with medicine and medical terms, and you talk to lawyers and you are very familiar with legal terms and facts. How is it that you do that so ably?"

He replied, "Well, that is very easy. When I talk to doctors I talk upon law and when I talk to lawyers I talk upon medicine."

I think in a great many of our meetings along this line, that has been about the case. We hear technical papers read and discussed which it is hard for a safety man in the plant to discuss later and apply in his work in the plant. I think this morning we should be particularly grateful to Mr. Richardson for bringing us a very happy combination of the technical along with the practical knowledge of the subject under discussion.

There are one or two points I made a note of which I think are worthy of a little further attention. I was very glad to see Mr. Richardson make the demonstration here concerning the nitrated cotton and its relation to the solvents. I think a number of us will agree with me that in the early introductions of lacquer, there was a great deal said upon the subject of guncotton, and the demonstration which Mr. Richardson has given us was very fine on that point.

Sometime ago I addressed a meeting of the fire department in one of our southern cities. In the course of my talk, I had a sample of lacquer and I poured some of it out on the table, set fire to it and extinguished it with a glass of water that was on the table. After the meeting was over, the chief of the fire department came up to me and said, "That is the finest thing that ever happened before these men."

I said, "Why?"

He said, "There isn't a man in this room but what would have thought if he dropped some lacquer on the floor it would blow up the building."

That is the mistaken idea concerning guncotton which a great many people have. The demonstration which Mr. Richardson gave us of the difference between guncotton and its explosive qualities and the cotton which he used as it is used in pyroxylin finishes was worthy of your note. In other words, when it is in combination with the solvents, it is not as explosive as dry nitrated cotton. I think there has been a great deal of misunderstanding on that point.

Another important point is the danger from the explosive qualities of the vapors. There has been a great deal of misunderstanding on that point. It seems to be the idea in the minds of a great many people that the vapors were just somehow bound to explode. Experience in the field has taught us, as Mr. Richardson told us, that there is little danger if there is anywhere near adequate ventilation.

Also on the point of spontaneous ignition, which Mr. Miner touched on, there has been a great deal of misunderstanding. I think I am correct in stating that unless the residues of these materials are combined with other materials such as in your spray booths or other places of application, where they are mixed with oils or the residue from other products, that there is little possibility of spontaneous ignition from the dry residue.

Mr. Miner also mentioned or touched upon the point of the hysteria that existed probably up to a year or two years ago concerning this subject. It is true that a great many articles have been written, and a great deal has been said that was not authentic on this subject. I recall very distinctly that after the Briggs fire in Detroit, a report went to one of the municipalities from the officer who investigated the fire that the material being sprayed was 90 per cent guncotton and 10 per cent toluol. That report went into print and received wide publicity. I don't know that I could blame some of the engineers of the insurance companies after reading such an article if they did get hysterical. The demonstration this morning has clearly shown you where the misunderstanding has crept into the subject concerning guncotton.

L. R. SCHUYLER (Lycoming Manufacturing Company, Williamsport, Pa.): I would like to know the best method of housekeeping in lacquer booths to remove the residue from the booth.

MR. ABBOTT: That subject is dependent somewhat upon the extent of the operation. It is true that there are some spraying operations which are involved in small booths or small articles being sprayed, where a washdown system is not essential. If the installation is properly installed, and you have the proper equipment, they can be very well taken care of by a dry cleaning method.

In our plants at the Fisher Body Corporation, we employ almost exclusively now what is known as the washdown system. The booths, the ducts are equipped with open sprinkler heads, and the water is turned on at the close of the day, and the ducts and the booths are thoroughly washed down, assisted by hose streams, if necessary. Our experience with lacquer since this system was installed has been very favorable. We have had less fires over the same period of time from pyroxylin finish operations with this method than we ever had with paint and varnishes.

It is true that the floor space required and the time required to produce an article to a finish under pyroxylin has been reduced by about two-thirds. Take, for illustration, an automobile body. Under the old method of paints and varnishes, it required about twenty-one days for a final finish, whereas with pyroxylin it is finished in seven days. That reduces floor space and makes it possible to maintain good housekeeping conditions, because of the nature of the dry residue of the pyroxylin finish, whereas with paints and varnishes we had a sticky, adhesive residue, and it was almost impossible to maintain good housekeeping.

There is just one other point that comes to my mind along the lines of your question. I think it is folly to install equipment in a plant in which good house-

keeping is impossible, and then go down and tell the man in the plant that he must maintain good housekeeping conditions. If new ducts and booths have been installed, we tell the men down in the plant that they must be kept clean, that they must remove this residue and so forth at the close of each day's operations. We have gone into that phase of the subject and have gone over our equipment and seen that the equipment was so arranged that good housekeeping was possible. That may be an angle that will interest some of you people here.

We have had some minor fires and one or two of some proportions in the country that was caused by the cleaning operation. We analyzed the country over and this was the result, that all the fires that had occurred up to that time were due to one of two causes, either the lack of proper cleaning or improper methods of cleaning.

MR. SCHUYLER: Do you use soap on the walls?

MR. ABBOTT: We are using some of the various soap solutions that are on the market for the interior of the booths. In the ducts, we put no coating at all. In the booths, the soap solution seems to facilitate the cleaning and makes it a little more rapid. There is a little labor saving item there to be considered.

DEWITT RAPALJE (Fire Prevention Engineer, Railroad Insurance Association): Mr. Richardson's paper was certainly most interesting and instructive. It is just part of the educational campaign that has to be carried on to acquaint the public and the users of pyroxylin finishes with their nature and with their proper handling.

I do, however, want to speak on this subject as an engineer of a fire insurance organization, because some reference has been made here in the discussion to hysteria on the part of fire insurance engineers on the lacquer spraying problem.

I think we are just as much in danger of letting the pendulum swing the other way and telling the public in general, or giving them the impression that there are no new fire hazards, that there are no new installation problems, that lacquer is just the same as paint and varnishes—"all you have to do is to always be careful." I rather fear that some of the comments that have been made at this meeting might lead the unobservant to draw that conclusion.

In the particular end of the fire insurance industry which I am connected with, fire prevention on steam railroads, we have not felt any hysteria over the nature of pyroxylin finishes. We have not gotten excited over the fire hazard of the material, but we have recognized the fact that we have a large educational problem on our hands, to educate the users of pyroxylin finishes on steam railroads to a proper handling and proper installation when lacquers are sprayed.

I will say right now the job is nowhere near over, because the railroads have been very lax in taking up modern processes. They are, I should say, three or four years behind the automotive industry in painting practices. Right now, they are at the stage that the automotive industry was three or four years ago. The absolute ignorance that is evidenced by some railroad paint foremen and car shop superintendents on the modern finishing processes is astounding.

It is not only a question of housekeeping. Mr. Richardson referred in his paper to the fact that it was remarkable how quickly finishing rooms were altered to accommodate the new processes. That may be true; I think it has been true in the automotive industry. They were eager to install the proper equipment. The problem was a serious one of production. I am confident that it is not true at the present time on steam railroads. There are cases of large railroad systems using pyroxylin finishes without any study or provision for ventilating systems.

It isn't only a question of housekeeping, it is a question of equipment, different equipment necessary for pyroxylin lacquer spraying than that used for hand-painting. The educational work is still before the underwriters and it is still before the manufacturing end of the industry, to show the user show the process should be installed and how it should be used.

Mr. Miner has given probably as much attention to this whole subject as any man in the country. He has been working on it for a good many years, both through the industry and through the National Fire Protection Association. He has called your attention to the recent brochure of the National Fire Protection Association on spray painting. If every user of pyroxylin finishes would follow out the instructions that are contained in that product of the National Fire Protection Association there would be no further fire hazard problem. The result would be just as Mr. Abbott pointed out in his own plants, that the fire hazards of painting and finishing would be reduced, because the safe practices, if adopted, will make lacquer finishing work a far safer process than the old paint room was.

The trouble is it takes years and constant and continuous work to educate the users of any process up to modern methods. I want to make these few remarks because I don't believe that any so-called hysteria has been on the part of the intelligent officials of the stock fire insurance companies, and I know it has not been on the part of the mutual fire insurance companies. The work that the insurance companies are doing and the publicity which they are giving to this subject is entirely educational, to get for the users the proper installations when spray finishing is adopted.

On the steam railroads this is a very live topic. The American Railway Association had its convention a couple of weeks ago in Montreal, its Section on Equipment Painting. There were all kinds of committee reports introduced at that three-day meeting. Everyone of them before they got to the end of the report got into a discussion of the lacquer finishes. That was the live topic before those men. A great deal of educational, helpful work was brought out in that meeting.

Next week, the Railway Fire Protection Association, a younger brother of the National Fire Protection Association, holds its annual convention in Cincinnati, and the same topic is coming up there, because when the railroads take up lacquer finishes—and I personally am convinced it is just a matter of time when every railroad in the country will be using pyroxylin finishes on all its rolling stock—as they are beginning to now, they are going to be one of the largest users of pyroxylin finishes in any industry.

CHAIRMAN COTCHER: I don't think any speaker this morning desires to create the impression that there are no dangers in the application. I think we are all in agreement that there can be very serious dangers if the proper precautions are not taken.

MR. MINER: From Mr. Rapalje's attitude, I feel that perhaps some of you may have gained the wrong impression. You will recall that before I mentioned that two of the insurance company representatives were there, I stated that I in no way wished to mitigate the hazard introduced through the spraying process. There were hazards there that should have been protected.

I do challenge Mr. Rapalje on the question of hysteria. I have been through it for the past five years, and I know just what it means. If it were possible for me to divulge certain confidential information that I have received in the past six months, I could very readily disprove his statement. Some of the conditions under which these so-called serious fires took place were frightful. It wasn't a case of there not being information available covering these hazards, it was a case of the process suddenly creeping in on the manufacturing interests; and I think I can safely say that even the insurance interests themselves didn't appreciate the conditions that existed, neither did they in a number of instances that I am thoroughly familiar with, take up the question of the carrying out of their own regulations.

I can safely make this statement: That had the regulations existing at the time of these serious fires been complied with, in essential details, the serious fires would never have occurred.

I do want to make the plea, as I have in the past, to all manufacturers, whether

they are stock or mutuals, that they take the regulations or suggestions of their insurance carriers, analyze them and carry them out in full. The spraying brochure which I mentioned is in line with both stock and mutual insurance practices. If you will follow that brochure you can bring about safe conditions.

A. M. WILLIAMS (Chrysler Corporation, Detroit, Mich.): There is this, of course, that when we change from one kind of paint to another, we find our hazards and the things to be watched for changed. Am I right, Mr. Miner and Mr. Abbott, in saying that the dry residue we accumulate in large quantities around steam pipes and other places where the temperature may be raised to around two hundred degrees that spontaneous combustion can take place?

MR. MINER: I wouldn't call it spontaneous combustion. It is not considered good practice to have even wooden floors in contact with heating pipes. As an old insurance inspector, I have been making the same recommendations for the past twenty-five years. When you go into a factory and see clothing on the steam pipes, you always ask that the pipes be cleared and kept free from combustible materials. The residue of pyroxylin finishes has certain decomposition tendencies and should not be allowed to collect or remain upon steam pipes or other heating devices.

MR. WILLIAMS: We can then in our safety inspection of our plants emphasize the one point of housekeeping, especially with temperature.

MR. MINER: Regardless of what is being used.

MR. WILLIAMS: In the burning of a dry residue is there danger from the smoke?

MR. MINER: Not if it is burning.

MR. WILLIAMS: During the time it is burning?

MR. MINER: No.

L. R. SCHUYLER (Lycoming Manufacturing Company, Williamsport, Pa.): Are you having much trouble with lacquers poisoning a man?

MR. MINER: That is outside of my line. I can say this, however, that some lacquers are super-sensitive to certain solvents. For example, in the paint industry, you will find some workers that are seriously effected by turpentine. Generally speaking, the diluents and solvents are not of an irritating nature.

J. T. HAINES (Wagner Electric Corp., St. Louis, Mo.): I would like to know whether the friction from chipping the residue will cause an explosion or a fire?

MR. MINER: If you strike a spark, it will ignite.

CHAIRMAN COTCHER: We will proceed to the question of housekeeping. Your committee has divided the subject of housekeeping into three general heads. They have arranged with Mr. R. G. Knutson, Commissioner of the Industrial Commission of the State of Wisconsin at Madison, Wisconsin, to discuss the general topic of housekeeping. But as Mr. Knutson seems to have gone A. W. O. L., the next division of the subject is that of "Production Stores." That subject has been assigned to Mr. J. L. Juhl, Superintendent of Planning of the Chrysler Corporation of Detroit.

Competitive Housekeeping As a Means of Reducing to a Minimum Lost Time Accidents

By J. L. JUHL

Superintendent of Planning, Chrysler Corporation, Detroit, Mich.

Building automobiles is the business of our company. Our engineers are responsible for what we build, our sales department is responsible for how many we build, and our manufacturing department is responsible for not only how we build, but how safely we build. The handling of material is so closely linked with

some manufacturing activities that it is very difficult in some cases to discern where material handling leaves off and manufacturing begins.

The department I represent in our corporation is what is known as the "Planning Department." The responsibility of having sufficient parts available and the proper handling of material is the function of our department.

It is my purpose to cover certain phases of safety in material handling, but before I do this, it is best that you are given a brief outline of how the planning department functions.

In our general offices, we have what is known as the "Central Planning Division." Each plant within the corporation has its own planning department. The central planning division acts as a managerial clearing house on all engineering and sales information that is to be passed on through to the manufacturing division. It is through this medium that the individual plant planning departments are kept advised how to outline and control their activities. The plant planning department is directly responsible to the factory manager.

The respective plant planning department in every case is responsible for the following:

- (A) Material engineering specification records. Through means of the particular group controlling these records, all interested departments in the manufacturing division are kept advised on schedule and engineering changes.
- (B) The requisitioning of material requirements against the purchasing department.
- (C) The releasing and scheduling of materials against supplying vendors purchase order.
- (D) The scheduling of finished parts to be machined or stamped within our own plant from raw material, such as castings, forgings, bar stock and sheet metal.
- (E) The proper receiving of material, as well as correct disbursing and handling is a part of the planning function. We are responsible for both productive and non-productive materials from the time the requisition is issued until the material is actually consumed.

Various methods have been adopted in the cause of safety in material handling. At our plant, we have adopted a means of reducing accidents and lost hours, by getting our foremen and men directly interested in a monthly competitive inspection. Honorable competition in every line of endeavor stimulates and brings out the best. Competition coupled with necessity makes possible the highly developed industrial organizations that are known to the world today. From the time that history gives us any record of civilization, up to the present gigantic industrial development, competition has played a most important role in the affairs of men throughout the world. Through competition, better peoples, better governments and better communities have developed. By the same token, industries have improved, and with improved industries, better and safer methods of manufacturing and material handling have come to the front.

Until approximately fifteen months ago, material handling at our plant had come in for more than its share of criticism. In our department, we held safety meetings, read papers on the subject of safety, had talks given regarding safety, and all persons present at these meetings left with the avowed determination that accidents would cease; but regardless of the excellent intentions, accidents still prevailed in great numbers. Accidents and lost hours had been increasing at an alarming rate. We all knew that some other means had to be adopted to make material handling safe, but what course to pursue was questionable.

A committee was appointed to investigate the situation thoroughly. This committee consisted of four planning department executives. Various methods were

discussed, and finally after considerable deliberation we decided to attempt an end to unnecessary accidents and lost hours through a competitive scheme. We all knew that competition had existed in the safety movements between plants within our corporation and had shown excellent results, so we decided that competition within the departments controlling the material handling would accomplish the desired results. Immediately following our decision to enter into a competitive scheme we set out to draft up a necessary set of instructions governing such a campaign.

In the first place, we procured from the plant engineering division several sets of blue prints showing the plant layout. These layouts were divided into given areas. To each area a material foreman was assigned. He was to be held strictly accountable, not only for seeing to it that material was at the proper place at the proper time, but seeing to it that the material was handled safely at all times. The general appearance of this given area was chargeable to the material foreman. It was expected that he would work with production supervisors and foremen within that area to maintain shop appearance that the corporation might well be proud of. In other words, every material foreman was to train himself to look at his area through safety glasses as well as production glasses.

Our next step was to get the responsible material foremen together with the committee, and lay out before them our proposed means of cutting down compensation money and inefficient methods. All questionable points were brought up for discussion and before the meeting was dismissed we had every foreman giving us his enthusiastic and whole hearted support.

The day following this meeting we got each material foreman responsible for a given area together with his men, to see what the reaction was to be with the men. They were more than willing to give us their best efforts and support. We explained to them in no uncertain terms what would be necessary if we were to successfully combat the evil of lost hours resulting through poor housekeeping.

We stressed the following points:

- (1) The necessity of a clean shop.
- (2) Why material should be piled carefully, whether on floors, skids, racks, or what not.
- (3) Why certain commodities should be piled a given height.
- (4) Why aisles should be kept clear with all material inside the white lines.
- (5) Why electric truck and tractor drivers should reduce their speed.
- (6) Why the receiving department should remove all nails from opened boxes and kegs.
- (7) The absolute necessity of keeping skids properly lined up in order to conserve the greatest amount of floor space.

We further explained to them that any known hazard within their area, whether directly a material responsibility or the responsibility of some other division, was to be brought to the attention of the department head, who in turn could take up the proposition of eliminating the hazard with the safety division.

When it was made known to them that the plant had been divided into given areas and that a competitive inspection was to be given, they accepted the proposition much the same as a game. We all know that any real sportsman in any kind of a game, plays to win, and so we found this proposal of competitive housekeeping and safety ready to be adopted with but one point not yet cleared away, it had not been covered with our plant safety organization, but I need not say anything else other than it was enthusiastically accepted by them.

An inspection committee was appointed. It was decided that there would be one inspection held monthly. This inspection to be held sometime within the first ten days of each month, the foremen and men not to know the definite time for this inspection. The inspection committee was made up from executives within the

plant but outside the planning organization. This committee consisted of three men, one from the safety department, one from the manufacturing division, and one from the time study and efficiency department. When this inspection was made, the planning superintendent, material supervisor and his assistant accompanied the committee. The respective material foreman responsible for his area in the shop accompanied the committee while making the round of his particular territory. It was the responsibility of this foreman to bring to the attention of the committee any hazards in his division, regardless of where the responsibility lay.

After one or two monthly inspections, the production men became very enthusiastic and took steps to keep their part of the shop in ship-shape form, so that an inspection could be had at any time. In other words, both material and production foremen instructed their men to be ready for the inspection any day.

It was possible through the inspection for a given division to get a report rating them 100 per cent. The table for computing percentages was based as follows:

Safety	30 per cent
General appearance	20 per cent
Cleanliness	20 per cent
Efficiency	20 per cent
Accomplishments	10 per cent

The 30 per cent or safety element was based on lost hours.

Cleanliness and general appearance are closely allied, and are each rated as a 20 per cent inspection factor. These have to do with the actual stock lineup and appearance generally.

Efficiency, we listed as a 20 per cent item. This has to do with the time allowance against group bonus, production hold-ups because of stock shortages, etc.

Accomplishments we rated at 10 per cent. This has to do with progress made in the way of correcting known hazards that existed at the last general inspection.

The foreman responsible for the area receiving the highest monthly percentage was to be presented with an American Flag and also a banner, which read—"Material Honor Banner—General Efficiency."

It was to be possible for one department to keep the flag and banner an indefinite period of time, provided the percentage figure over the other divisions could be maintained.

This campaign started in June, 1927, and has been working successfully ever since. We discovered many interesting things as a result of these inspections.

These monthly inspections not only proved to be of decided benefit to life and limb, but also worked out very advantageously from a material standpoint. Below, we list certain conditions that results:

- (A) Aisles were kept open.
- (B) Material was properly piled.
- (C) Damaged equipment, such as racks and skids went to the repair department without delay.
- (D) Rusty material practically eliminated because material turnover was being carefully watched.
- (E) Salvage and obsolete material cleared the departments automatically.
- (F) Sheet steel piled the proper height.
- (G) Elimination of overloaded skids.
- (H) Installation of "Stop" and "Go" lights at main aisle intersections thus eliminating one of the worst hazards in our plant.
- (I) Floor space, which continuously has been at a premium in our plant, owing to increasing the scope of our activities, was used to the maximum capacity because material was properly piled and skids and containers properly lined up.

Numerous additional improvements could be mentioned, but time does not permit.

After two monthly inspections, certain of the foremen were asking that Vendors be instructed to send in containers that were safe for handling. A campaign was then instituted whereby materials were sent into the plant in containers that could be readily piled and handled. This was accomplished after considerable effort, but we now find our vendors very ready to cooperate with us. For an example, items such as bearings were being shipped in to us in containers weighing anywhere from five hundred to one thousand pounds. These we found impractical and unsafe for handling, both the size and the weights were reduced so that bearings could be handled easily. What is true of the bearings is true of some thirty other commodities giving similar trouble.

By getting vendors to cooperate with us in reducing the size and weight of certain containers that proved hazardous, we eliminated one of the greatest sources of lost hours. By the greatest source, according to our records, I refer to accidents to the leg and foot. Overhead hoists have now been installed to handle practically all of the remaining heavy containers and commodities, thus eliminating excessive back strains and the hazards of falling material while being handled.

Our monthly inspections gave us a physical insight into our stock conditions. We discovered many items on which our inventory was excessive. These became so numerous that we set out to revise our entire bank on both purchased finished and items fabricated within our own plant, and, as a result, to make a long story short, we showed a material turn-over at our plant that we believe ranks with any manufacturer in the country. And material turnover after all has considerable to do with safety. Excessive banks mean more handling—more handling means that there is just that much greater possibility for accidents. It is our purpose to place nothing in stock rooms save sheet steel and few of the large commodities, such as axles, radiators, fenders, etc. We for the most part handle from the freight car or truck to the point of consumption or primary operation. We eliminated all production material stock rooms better than a year ago.

I wish to give you a few figures that show better than anything else what has been accomplished through our safety efforts. In 1926 we had the following statistics:

	Hours Allowed	Hours Used	Hours Saved
1st Quarter	1,210	585	625
2nd Quarter	1,755	990	765
3rd Quarter	1,759	18,787	—17,028
4th Quarter	1,221	3,124	—1,903
Total year, 1926	5,945	23,486	—17,541

So in 1926, against 5,945 hours allowed in the various departments of the Planning Division, we utilized 23,486 or approximately four times as many as we should have consumed. This certainly was anything but a good record. In the third quarter, during the month of August, 1926, we had a death chalked up against us, an electric truck driver subjected himself to the hazards of a wet incline, he lost control, nothing more need be said other than when he arrived at the hospital he was found to be dead. Electric trucks, or jitneys as they are commonly called, have caused numerous accidents in our plants. As mentioned before, our safety department now has this very well under control, having "Stop" and "Go" lights at all the main intersections throughout the plant. All inclines are now equipped with tread plates, which no longer permit drivers losing control. To assure ourselves that we were procuring capable men, we instituted the practice of giving all jitney drivers a thorough examination prior to accepting them for the position for which they were intended. Each man hired to do this particular work is given a very thorough examination. Since starting this practice, jitney accidents have been

reduced to a minimum, and it is with the greatest feeling of pride that we state that not a single lost hour has resulted since starting this examination, through carelessness of an electric truck or jitney driver. Mr. Williams, our safety supervisor, brought with him to this safety Congress, a quantity of booklets covering questions asked when giving the jitney drivers their examination. In addition to the set of questions, he also has a complete set of rules and regulations for all operators handling trucks, tractors and jitneys on company property. He will be glad to furnish these to anyone desiring them.

When the year 1927 was ushered in, every man in our division was determined this was to be a year without excessive lost hours, and as few accidents as possible. Just the mere desire to prevent accidents was not sufficient. Before the year was half gone, we had another death to our credit, this time because a truck had not been made securely fast at our loading dock. In pushing a heavily loaded rack of fenders on the truck from the dock, the rack caught on the floor of the truck, and instead of pushing the rack on to the truck, the truck was being moved forward. The man pushing was not looking up, and therefore did not realize that the truck was being moved forward. As a result the fender rack fell to the ground, and in so doing, a man was caught and crushed between the dock and the rack. In addition to this, we had numerous accidents of various descriptions, chiefly confined to the foot and leg.

Our records for the first half of 1927 are as follows:

	Hours Allowed	Hours Used	Hours Saved
1st Quarter	714	1,134	—420
2nd Quarter	1,607	17,163	—15,556
Total first half, 1927	2,321	18,297	—15,976

Our 1927 start was certainly no improvement over the year of 1926.

It was in May, 1927, that the death at the loading dock occurred. In June, 1927, we started our competitive clean-up. The records for the balance of 1927 are as follows:

	Hours Allowed	Hours Used	Hours Saved
3rd Quarter	1,701	261	1,440
4th Quarter	808	0	808
Total last half, 1927	2,509	261	2,248

A foot accident on the 13th day of September caused us a loss of 261 hours. This was the only lost time accident from June 20, 1927, until March 5, 1928, or 261 lost hours in a department with an average enrollment of 550 men over a period of eight and one-half months. From September 13, 1927, to March 5, 1928, gave us 172 consecutive days in which we experienced no lost hours. Prior to our campaign we had experienced lost hour accidents every few days.

In 1928 from January 1st to September 1st we reported the following:

	Hours Allowed	Hours Used	Hours Saved
1st Quarter	1,446	1,620	—174
2nd Quarter	2,629	108	2,521
7/1 to 9/1/28	1,820	360	1,420
Total 1/1/28 to 9/1/28	5,895	2,088	3,807

The 1,620 hours reported in March, is the result of the loss of a finger on the steel roller leveller. In June, after having gone 96 more days, we had another accident in our sheet metal plant, where a man was cut by a piece of salvaged steel. This loss resulted in 108 hours. During the month of August, we had minor foot accidents that resulted in 360 lost hours.

During the year 1926 the Planning Department did not experience a single month without a lost time accident. The same is true in 1927 up until our competitive safety campaign started. So far in 1928, we have the following months with no lost time accidents: January, February, April, May, July.

The loss of the finger is the only accident of any real consequence so far this year. We realize, however, that any accident, no matter how unimportant at the outset may prove extremely costly and serious.

It will also be of interest to you to know that during the first eight months of 1928 we handled as much material as we did during the entire year of 1927. During the first eight months of this year we handled 33 1/3 per cent more than during the year 1926. During the year 1926 our records show that we unloaded approximately 6,500 freight carloads of material. In 1927 we unloaded 7,300. During the first eight months of 1928 we have unloaded more freight cars than we did during 1926, and within 500 of the entire 1927 figure.

The results obtained from this competitive safety campaign have proven conclusively to us that the method adopted for eliminating lost hours is well worth while, and if it works in the Chrysler Corporation, there is no reason in this world why it will not work in other automobile plants as well as any industrial plants where material handling is so important a problem to the safety of all concerned.

CHAIRMAN COTCHER: We will go on to the next subdivision of the discussion of material handling, that covering "Manufacturing Departments," which is to be discussed by Mr. J. B. Gibson, Safety and Health Division of the Western Electric Company, Chicago.

Good Housekeeping in the Manufacturing Department

By J. B. GIBSON

Safety and Health Division, Western Electric Company, Chicago

A few years ago, a president of an eastern university invited a prominent New York minister to speak at chapel on Sunday morning, and the visiting clergyman naturally inquired how long he should preach. The president being somewhat of a diplomat did not wish to give a definite answer. But when the question was again asked the university president said that he did not know how long he should speak, but there was a tradition at the university that no souls were saved after the first twenty minutes. I am not planning to break any traditions today. In fact, I will try to conclude my few remarks before the noon whistle blows.

I have attended the last seven Congresses of the National Safety Council and do not recall that in any one of these conventions the question of housekeeping has been left off the program, either at a sectional or at a general session. This in itself is evidence that housekeeping is a factor that must continually be kept in mind in any successful accident prevention program.

Undoubtedly you will agree that we like to see good housekeeping in our home and that we enjoy our meals at a table where clean linen, clean silver and food well served are the rule rather than the exception. I do not see how we can expect in our factories to have a workman turn out a high quality product if the environment in which he works is not up to the highest possible standard.

Assuming for the moment that a workman is careless, untidy and shiftless in his home surroundings, isn't it within the realm of probability that if we can give him a neat, clean shop, with adequate aisle space, clean machines, and scrap picked up from floors as quickly as possible, we may develop that workman to the point where he may rise to the level of being a neat and orderly individual? In the same way, if we have a promising type of workman coming into a dirty factory,

where the chips fall as they may or where his hands may be brushing against iron filings on the bed of the machine, no matter how he may try to battle against it, his morale is going to break down before very long and he is going to go along with the crowd.

Housekeeping goes back to the old principle that there is a place for everything and everything in its place.

In our Monday luncheon where Dr. Harry Myers of the Frigidaire Corporation spoke, he emphasized again and again that in his company, and I believe in the other divisions of the General Motors Corporation, one of the most important rules is that the workman shall be neat and orderly.

The particular phase of the subject that I was asked to discuss, that of the manufacturing departments, involves the handling of materials from department to department, from machine to machine, and sometimes from workman to workman. Let us assume that the stock has been drawn from the stores and is in the departments about to be processed. Of course, if your plant is modern, recently built, and equipped with an up-to-date layout, your problem of housekeeping is relatively simple. But there are in the United States any number of companies with buildings that were built in years gone by. However, they still make a satisfactory return on the investment and we have been obliged to live with the old conditions in the present day when efficiency and elimination of waste are the watchwords.

The closer we can come to running a job through the shop in an orderly manner, that is from department to department and machine to machine without any slack or overlapping, the nearer we get to the goal of efficiency. Frequently we have to put up with conditions as we find them, remembering, however, that good housekeeping depends to a large extent upon the individual workman, the supervisor, and the support you get from the management.

Dr. Myers remarked that he did not think the answer to good housekeeping rested on an ability to hire more janitors. With such sentiments I heartily agree, because, as you know, hiring one more janitor or hiring ten more janitors increases your direct expense by the total salaries of those ten janitors. That item is thrown against your budget, it enters into the cost of your product, and puts you at a disadvantage with your competitor in a field where competition is keen.

It seems to me that we can achieve more substantial results by adopting a policy of hammering at the subject day after day, interesting the workman, selling your supervisory force and getting them to expect just as much from the workman as he may expect from the supervisor.

In transporting material from department to department, it has been the experience of the company with which I am associated, that electrical trucks are doing a great deal of valuable work. I was interested in the last speaker's remarks that although electric jitney trucks a few years ago caused trouble, at the present time as a result of their thorough study and analysis of the causes, accidents have been reduced. We have had a somewhat similar experience. Fortunately, we have had no serious accidents. We had some minor accidents with the electric trucks in the early days. But they have since been developed to the point where they are safe to operate and function quietly, efficiently and at a reasonable cost. The electric truck eliminates that irritating noise you get from dragging metal containers along the floor with hooks. Moreover, you do not have from electric trucks the hernia possibilities that you get from pulling trucks.

If any of you men are foremen, and I imagine several of you are, don't you agree with me that we have had on too frequent occasions considerable difficulty in getting adequate space in our departments to store materials after they have come from the stores and are waiting for machines. I don't know how your departments are lined up but I have seen in any number of places spare parts piled up in aisle space. You talk to a supervisor about it and he says, "I know, I just put them there; in five minutes we are going to run them through." However,

those five minutes are being repeated all through the day and the parts are a real hazard since they interfere with the passageway through your aisles.

Until within the past few years planning engineers have generally paid more attention to a layout, getting the machines lined up, getting ready for production, than they have to helping the foreman to take care in his department of his surplus stock.

We also have to face the problem nowadays of setting machines pretty close together, especially in the small shops, where increased production and limited space present problems all their own. Perhaps you first set up a battery of machines close together. Then you move or take out one machine. Such a rearrangement changes the entire safety picture. In removing one machine you may expose parts of the next machine which are hazardous to the workman or the passerby and which opens up an entirely new guarding problem to be solved without delay.

The last speaker brought up the question of containers, especially metal containers which you need to inspect frequently. Watch out for the burrs on metal containers where the top part is bent over and roughened. Containers can be overloaded. In fact, they frequently are. Of course it is hard to determine just when a container is overloaded. But with overloaded containers you have all the probabilities of serious accidents, damaged or defective material, and all such items that do not help when you are striving to get out your product at a low cost.

We have adopted a method whereby electric trucks carrying material in metal containers pile these containers one on top of the other, four tiers high. Each container is so designed that it fits on top of the one beneath. The automobile factories have used this method for some time. We are finding it very successful and have had no trouble with tipping or loss of material.

Another point we should be interested in is that of the disposal of scrap. Until recently we have been so interested in getting the parts in process through the shop that we have not paid much attention to this item. As a result, scrap piled up around the machines results in cuts, scratches and possible infections unless prompt medical treatment is given. Where your scrap is in long strips we have solved a large part of the problem by using take-up reels.

We have also found that where stock is run through machines in lengths and the machine that is working the particular stock is on the aisle, the end of stock may project into the aisle. One of our employees developed a so-called semaphore, which can be attached to the iron pipe guard rail and is marked with black and white squares. I think an illustration of it appeared in the last issue of the *National Safety News*. Such a device gives ample warning to any person coming along the aisle.

I recently visited the plant of the American Can Company at Maywood, Illinois, and found there a most interesting mechanical conveyor system which took the scrap away from the machines, down along the side of the building, out through an opening and into freight cars without any human hands touching the scrap itself. This is certainly one of the most up-to-date developments so far as I know in the handling of scrap material.

Now, the condition of floors is important, especially where trucks are used. Electric trucks, of course, can handle a heavier load than the truck manually operated. If an operator of such a truck hits a floor with a depression in it, or if you have a concrete floor with broken patches, you still have the possibility of your truck tipping material all over the aisle and into nearby machines.

I was interested in the last speaker's remarks about the stop and go signs at the intersection of aisles in his plant. We have worked out the plan of one way traffic on certain aisles in order to speed up the transfer of material from department to department.

Machines located along the main aisles should be guarded, usually by pipe guard

rails. Sometime ago, I was in a factory and saw a battery of machines along the aisle with the back of the machines facing the aisle. The machines themselves were adequately guarded so far as the operator was concerned, but along the aisle the working parts in the rear of the machines were exposed. There were gears, there was everything there to encourage a serious injury.

Another point in which we are interested and which affects housekeeping is good lighting conditions. A foreman might well argue that it is very difficult for him to get any better lighting conditions because the plant maintenance department is responsible. However, the wheel that squeaks gets the most grease, and if the foreman finds he has a poorly illuminated location, he can usually get the proper kind of cooperation to take care of his complaint.

I came here today not only to talk but to learn. In conclusion I would like to ask this group two questions, the answers to which I am still seeking. First, what is the answer to slippery floors in a screw machine department. There is oil on the floor, and therefore the floor is slippery. We have tried everything possible, but we have not got as yet a one hundred per cent satisfactory answer.

The second point and one which always starts a discussion, is, What do you do to prevent spitting on the floors?

With those two questions, I rest my case.

CHAIRMAN COTCHER: I am mighty sorry that our program run along to the point where we had to squeeze both Mr. Juhl and Mr. Gibson, because they had both of them very pertinent topics.

Mr. Gibson left us two questions, the first of which was about the slippery floors.

A. F. DUNNEBACKE (General Motors Corp., Detroit, Mich.): I walked through the Brown, Lipe Chapin plant some three years ago with a wad of chewing tobacco in my mouth. I was afraid to spit, because every time I came to an entrance there was a little sign, about six by fourteen, saying, "Spot the spitter." I was in that plant three hours. I really carried it around three hours because I was afraid to spit. That is an idea for you.

MR. GIBSON: That was an accident hazard you had.

We have painted the corners on the stairways white, but we find, after going through in four or five days, that they are no longer white. I was wondering whether anybody had that experience. I know that education is the final answer, but I am looking for a stop-gap.

L. R. SCHUYLER (Lycoming Manufacturing Company, Williamsport, Pa.): In reference to these questions, we have had all kinds of experiences in trying to eliminate the spitting hazard. We have painted the corners white. We also went to great expense to paint the whole shop white for better illumination. We haven't yet found the answer to the "spitter" problem.

We have in the assembly department of our plant taken up the matter of slippery floors. After having tried numerous preparations including sawdust and cinders to take up the oil, we have put to work anywhere from four to six janitors or laborers who go about with scalding hot water and a certain percentage of Oakite. All they do day in and day out is scrub the floor of our assembly department. They keep that floor thoroughly clean. In that way, we have eliminated the slippery hazard. We have found that it also has a tendency to limit the spitting bug. A man who sees a clean floor does not want to besmirch it by spitting on it. That has been our experience.

J. T. HAINES (Wagner Electric Corp., St. Louis, Mo.): We did practically the same thing as Mr. Schuyler. We charged the foreman with that extra expense.

S. N. SMITH (Singer Manufacturing Company, Bridgeport, Conn.): We have, we think, eliminated the spitting hazard about as well as any factory you can go in to. I think I supplied the National Safety Council with our system some five or six years ago. We furnish cuspidors. We made a study as to where they were

used the most. If a man uses the cuspidor, he has a new one to use every day. It is a metal cuspidor. We have racks that hold six cuspidors. They never touch the cuspidors with their hands.

CHAIRMAN COTCHER: I am told that one of the plants in Detroit furnishes cardboard containers with sawdust or wood waste in them and sells them at about one cent apiece and then they collect them and burn them and say the b.t.u. value of them pays the cost of handling them.

ADJOURNMENT

October 4, 1928

E. H. COTCHER, Chairman
Supervisor of Safety, The Murray Corporation of America, Detroit, Mich.

The third session was called to order at nine forty-five o'clock by the chairman, E. H. Cotcher.

CHAIRMAN COTCHER: As I said yesterday, I conceive it the chairman's duty to do the introducing and not the talking. I am going now to introduce the first feature of our program this morning, which is going to be staged by Mr. A. F. Dunnebacke, of the General Motors Corporation.

Introduction of the New Employee

By A. F. DUNNEBACKE
Safety Director, General Motors Corporation, Detroit, Mich.

At a recent meeting of General Motors officials in the city of Flint, Mr. Sloan, President of the General Motors Corporation, used these words:

"The value of General Motors as measured in the market today is approximately \$3,500,000,000, whereas the value of the corporation's assets is \$850,000,000, the difference, or \$2,650,000,000 is the value established by the public for the corporation's goodwill."

It is a little strange, isn't it, that the president of the largest organization in the world values goodwill at over \$2,500,000.

What is goodwill, in the sense that Mr. Sloan used the term? When he used that term goodwill, he simply meant the kindly feeling and the attitude of the public toward the General Motors Corporation; its products and the conduct of its business. When he used the term goodwill, he meant the enthusiasm, he meant the loyalty and he meant the friendly feeling of the employees toward the corporation. When he used the term goodwill, he meant the pleasure on the part of employees in general who work for the corporation in being a part of it. That is what Mr. Sloan meant by goodwill, and he values that at \$2,500,000.

I claim that participation in a company safety program, an employee's desire to take part in that program in a plant is goodwill.

Who is responsible for setting up in the mind of the employee this spirit of goodwill that is so valuable? It is every man who has contact with a man from the time he asks for a job at the employment office until that new employee is put to work. It is the employment manager, it is the medical examiner, it is the clerk who takes the man down to the job, and it is the foreman. Those are the men who are responsible for setting up in the mind of the new employee this asset of goodwill.

There are a number of subjects that are called to the attention of a new employee when he is hired. There is the question of the insurance plan, there is the question of savings and investments, and there is the question of safety. This is a safety meeting. I am going to emphasize the question of safety as a part of this goodwill.

I could tell you in so many words how it is being done in some plants, and I could tell you in other words how it is being done in other plants, to show you what I think is the wrong and the right way of conducting the new employee from the employment office to his job. I think we will get a better conception of it if we put it on in the way of a little act.

I am going to put on two little acts. They will not take long. In those acts, I am going to try to show you one of the wrong ways of handling a new employee and what is the proper way. I am going to be assisted in this act by Mr. Ted Meisner, of the American Can Company, who is going to take the part of the new employee, and Mr. M. Kroger of the Chevrolet Forge Company, who is going to take the part of an employment clerk. Personally, I am going to take the part of the employment man and of the foreman.

In putting on these two little acts, we are going to leave a lot to your imagination. You will have to imagine an employment office here. You will have to imagine a clerk in the employment office at a desk over here. You will have to imagine that you are down in the production department, and you will have to imagine a drill press or some other machine here.

We will now show you what we think is the wrong way of handling a new employee.

The new employee has gone through his medical examination. He has been accepted for employment and he is being written up in the employment office. The play will start from the time he is written up until he gets down on the job.

In the Employment Office

EMPLOYMENT MANAGER—Well, I'll send you down to the boss now and don't forget there are dozens of men here every day looking for your job. *(The employment manager then calls to a clerk who is slouching in a chair, feet up on the desk, smoking a cigarette and reading a newspaper.)* Hey, Smitty, come here.

SMITTY—Yah, just a minute.

EMPLOYMENT MANAGER—Take this man down to Jackson.

SMITTY—Alright, come on.

(Smitty starts away to Jackson's department followed by the new employee. Smitty pays no attention to him but talks with the employees on the way, kids several female flapper employees, and approaches Jackson's desk.)

SMITTY—Hey, Jackson, here's a new man.

(Smitty then turns to the new employee.)

SMITTY—There's your foreman.

FOREMAN JACKSON—So you're the man they hired for me, are you? Whatcha done and what d'ya know? Never mind, I'll find out what you know. Come over to this drill press. I want you to run this machine. Here is the stock. Here are your tools, and here is your blue print. Now, let's see if you can cut the buck.

NEW EMPLOYEE—Gee, that fellow sure hates himself. This is some joint. Treated like a dog in the employment office, brought up here by a rough clerk and meet about the toughest type of a foreman I ever heard of. I think I will get out of here while I am all together.

MR. DUNNEBACKE: Now, gentlemen, we feel that that is a fairly accurate way in which the employment is still being handled in some plants. Maybe we have overdone it.

I think one of the greatest weaknesses in American industry today is the failure of the management, from general manager to foreman or straw boss, to properly appreciate the value of the first hour of contact between a new employee and the company for whom he is starting to work.

The greatest opportunity for establishing goodwill is in this first hour. There is no time when the new employee's mind is so impressionable as in this first hour. There is no time when it is so easy to set up in his mind a confident, kindly and friendly disposition towards the company, as in this first hour. There is no time

when he is more susceptible to instructions, when he will take more kindly to your advice and instructions. I feel that that is one of the greatest weaknesses in American industry today, the fact that the management of our plants, our personnel directors and our employment men do not fully appreciate the value of that first hour, that a man is with a company.

Who is the man who has the opportunity and who is responsible for setting up this spirit of goodwill? It is every man who has contact with the new employee from the time he asks for a job until he is at work on the machine.

It is reported that one company finds it good business to pay an intelligent middle-aged man a salary of \$5,000 per year to instill goodwill into the new employee's mind by properly conducting him from the employment office to the foreman.

We will try to put on a sketch showing what we think is the proper way of handling a man. Bear in mind that the man has been written up and is being conducted to his job.

Another Kind of Employment Session

EMPLOYMENT MANAGER—Now, Mr. Thompson, before I can sign you up, you will have to read over this book of instructions. This is our book of safety rules, general shop and factory rules, and we want you to read that over, before we send you down into the factory.

NEW EMPLOYEE (*Handing the book back*)—I think I understand what it is all about.

EMPLOYMENT MANAGER—You have to keep this. You will notice here on the back is a little receipt. Will you please sign that so that we will know that you have read it over and have received a copy?

Now, Mr. Thompson, I am going to send you down to Mr. Jackson. Mr. Jackson is the foreman of the department in which you are going to work. I think you will like him very much. He has been with us eight or ten years, and we feel Mr. Jackson is one of the best foremen we have. I am sure you will enjoy working for him. Mr. Smith!

MR. SMITH—Yes, sir.

EMPLOYMENT MANAGER—Mr. Smith, this is Mr. Thompson.

MR. SMITH—I am very glad to know you, Mr. Thompson.

EMPLOYMENT MANAGER—Mr. Thompson has been hired for Mr. Jackson's department, and I wish you would take him down and introduce him to Mr. Jackson.

MR. SMITH—With pleasure.

EMPLOYMENT MANAGER—Just a minute, Mr. Thompson. I wish you would come back and see me in a couple of days. I want you to realize that this office is always open. I would like to know how you are getting along. I would like to have you keep in touch with me. Come up any time and talk things over.

NEW EMPLOYEE—I will. Thank you, very much.

At the first aid room.

MR. SMITH—This is our first aid department. You will recall the safety rule book stated to come up here for every injury, regardless of how slight. You will notice it is well equipped and is in charge of a competent registered nurse.

NEW EMPLOYEE—I hope I will not have to use this place, but I am glad to know where it is in case I do.

At the company store.

MR. SMITH—This is one of our three stores, Mr. Thompson, where employees can purchase tobaccos, candy, soap, gloves, safety shoes. All the revenue of

these stores goes into our welfare fund. They are open fifteen minutes before starting time and during the noon hour.

At the foundry department.

NEW EMPLOYEE—Mr. Smith, what is that department over there?

MR. SMITH—That department on the far end is our foundry department. Every man in there has a pair of goggles on. It may not occur to you, but one of our shop rules is that every man in that department that is doing any grinding or chipping or any kind of work where he may injure his eyes, the company demands that he must put on goggles for protection. You won't find any man in there working without goggles.

At the safety banner award.

MR. SMITH—Do you see that banner up there, Mr. Thompson? We have a committee in this factory which makes a monthly inspection of this whole plant and awards that banner to the department that has the cleanest, most orderly, and safest department. This department has won it twice so far this year. I am telling you, they are proud of it. It is worth having.

NEW EMPLOYEE—That's a fine idea. That accounts for this department looking so nice and clean.

At the drill press department.

MR. SMITH—Mr. Jackson, this is Mr. Thompson, who has been hired for your department. Good-bye, Mr. Thompson.

NEW EMPLOYEE—Thank you very much, Mr. Smith.

MR. JACKSON—Come up, Mr. Thompson, and take a chair. Are you living here in the city?

NEW EMPLOYEE—Yes, sir.

MR. JACKSON—Are you married?

NEW EMPLOYEE—Yes, sir.

MR. JACKSON—Any children?

NEW EMPLOYEE—I have two children.

MR. JACKSON—How old are they? Are they in school?

NEW EMPLOYEE—One is eight and the other is eleven. Yes, they are going to school.

MR. JACKSON—Do you own your own home?

NEW EMPLOYEE—Yes, sir. I am buying one on a contract and have it about half paid for.

MR. JACKSON—Have you ever worked in any other plant here in the city?

NEW EMPLOYEE—I worked for the Central Machine Parts Company.

MR. JACKSON—How long?

NEW EMPLOYEE—Seven years.

MR. JACKSON—That is a pretty good record. What line of machinery are you most familiar with?

NEW EMPLOYEE—I have specialized mostly in drill press work.

MR. JACKSON—Are you used to working to pretty close limits?

NEW EMPLOYEE—Yes, sir.

MR. JACKSON—Familiar with blue prints?

NEW EMPLOYEE—Yes, sir.

MR. JACKSON—Micrometers, test gauges and so on?

NEW EMPLOYEE—Yes, sir.

MR. JACKSON—I suppose you have been over our safety rule book?

NEW EMPLOYEE—Yes, I have read it over. I am not altogether familiar with it as yet.

MR. JACKSON—I want you to get very familiar with it. You will have a little time during the day, and I wish you would read it over until you get quite familiar

with it. This company is doing a lot of work along safety lines. We are having a contest in our shop, and my department has a good record so far. I should hate very much to have you get hurt and spoil our record.

NEW EMPLOYEE—I will do all I can to help you win that flag I saw on my way down to this department.

MR. JACKSON—That is fine.

Let us go over to this machine. I want to show you the job you have been hired for. I want you to run this drill press, Mr. Thompson. This part which you will machine is a clutch hub. You will notice the first operation is simply a rough boring operation. The second is the drilling operation, and the final operation is the reaming. Your stock from here will go down to the next machine on the conveyor. I am going to run through a few pieces for you and then I am going to have you run a few. (*Demonstrating.*) I wish you would run a few of those, Mr. Thompson.

Mr. Thompson puts on a pair of gloves.

MR. JACKSON—Wait a minute. Wasn't there something in the safety rules about wearing gloves on machines?

NEW EMPLOYEE—I believe I did see something about not using gloves on machines. I think I had better roll up my sleeves, too, before I start.

Mr. Thompson then runs a few pieces through the machine.

NEW EMPLOYEE—How does that look?

MR. JACKSON—I think you will get along on the job alright, Mr. Thompson. I will leave you now. If you do have some trouble, don't hesitate to come up and see me. (*Turning to Jones, a fellow employee.*)

Just a minute, Mr. Thompson. I want you to meet Mr. Jones. Mr. Jones has been in our department about six or seven years. Mr. Thompson is a new man coming into the department. I wish you would kind of take an interest in him for a few days and see that he gets along alright. Mr. Jones has been with us for six years. He knows all the ropes in the department. He will be glad to help you out anytime.

MR. DUNNEBACKE—Now, gentlemen, that is, just in a sketch, our opinion of what is the right way. I hope it met with your approval.

If you gentlemen will now kindly imagine yourselves a group of new employees, hired during the day, and who have reported to the safety director's office at five-thirty, I would like to speak to you as I used to talk to the new employees of a company for whom I formerly worked.

At this plant the management set up a rule that all new employees must report to the safety director at five-thirty, immediately after whistle time, on the first day they were hired and went to work. The company paid all men attending this talk one-half hour's time. Absences were reported next morning to the factory manager, and foremen soon were asked by him why their new employees were not at the safety meeting the night before.

The Safety Director Talks to the New Employees

"No doubt you men know why you are here tonight. You are here to have a little safety talk. This company wants you to come through that entrance gate in the morning happy and healthy. It wants you to have a pleasant day's work and it wants you to go out of that gate every night back to your homes and your families safe and sound. It would much rather have this than to have you get hurt, call an ambulance, take you to the hospital and then have some one from our welfare department get a car, go up to your home and tell your wife or mother that you were hurt and are over at the hospital. Yet, that is what is happening quite often. The ambulance driver knows that gate pretty well.

"We feel that we have one of the safest plants in the city. We compare our accident records with other plants and we know we have as good a record, if not better, than any other plant. The state factory inspector made a thorough inspection of this plant last month and only issued two minor orders. This company spends thousands of dollars every year to make this plant safer; it guards and protects every hazard. It has a safety engineer, medical department, first aid rooms. Our manager told me only last week that he would rather pay a hundred dollars any day to keep a man from getting hurt, than fifty dollars for compensation after he gets hurt. Now, that is the kind of a company you are working for and the kind of a plant you are working in. And yet, we killed men last year, we lost some eyes last year, some of our men lost fingers, and, as I said before, the ambulance still calls here. We will probably kill some this year and some will lose their sight and fingers. Who is it going to be? You? No person in this crowd can say definitely that he will leave that gate at night safe and sound. But, I can definitely say that according to the law of averages that we are going to have a certain number of accidents this year.

"What are we going to do about it? I said the company was paying thousands of dollars a year to stop accidents, and I know it would pay any amount I recommended if it knew the accidents would cease. But, fellows, the company cannot stop the accidents we are having these days. They could fill this factory full of all kinds of guards and we couldn't prevent ten per cent of the accidents. The accidents we are having nowadays can only be prevented by yourselves. They result from inattention, acts of carelessness, chances that men take. There is only one guard can prevent these and this guard is under your hat. The guard is to use your head and do a little thinking.

"Here are a few accidents. A carpenter took hold of a wire hanging down, gave it a yank, expecting to pull it loose from its fastening overhead. But, it didn't pull down. It pulled out of his hand, swung back and hit him in the eye. He has lost the sight of his eye. Could any guard have prevented that? Yet, he had a hammer in his other hand. If he had wrapped the wire around his hammer handle a few turns and then yanked, all would have been well.

"A few months ago a man stepped from the dock into an open freight car. As he stepped over, his foot slipped and he fell between the dock and the car, fracturing several ribs. Could any guard have prevented that? The trouble was that when he stepped over, he did not put his foot sufficiently into the car to get enough bearing under it to carry the weight of his body.

"Over in the motor plant a while ago, one man goosed another man. He jumped, struck his thigh against the corner of a work bench. An abscess set in and he was in the hospital two weeks, just because some damn fool thought he would be smart. Is there any kind of a guard to prevent such accidents? Horse play. Fool stunts.

"Now, those are just samples of some of the accidents that are happening. I am telling you that we can't stop them any more. The only way we can stop them is through your help and cooperation. That is the purpose of this safety talk.

"Did each of you get one of these safety rule books this morning? Everybody did. And do you all know what is in this book? Put up your hands all who do. Oh, fine, everybody. Now, be careful, fellows, before you put up your hand. I would only have to ask a few questions to show you you don't know what is in this book yet. I know you have read it, because the employment man wouldn't sign you up until you had. Would he? And, I know you have a fair idea of what is in it. But, you don't know every word that is in this book yet the way I want you to know it.

"There is only one reason I have for wanting you to know these rules and that is to keep you safe, not me. I don't care if you get hurt, it is only one more accident in the record, a few more dollars in compensation. That sounds rather hard-boiled, but that is not the way I mean it. What I mean is this; That if you get

hurt, you and your family are the only ones who suffer. Isn't that true? So, it is you who we are trying to protect. That is why I want you all to know the rules in this book, because if you know the rules and follow them you will be much safer than if you don't. I analyze every accident that happens here, to find out just what caused it, and here is my experience: That ninety per cent of the accidents that happen in this plant, happen because some one failed to follow the rules in this book. So, keep this book with you. Read it over once a day for a week and then once a week for a month. If each of you will faithfully do this, then you will know the rules, and if you follow them you will be safe.

"I am not going to take up each of these rules, but I am going to spend a few minutes on a few of them. First, this rule about going to the first aid room for every minor bruise or injury. You know, a lot of fellows think it is kind of sissy

Wotta Place!
**A messy shop hinders
 production and in-
 creases injuries**

to go to a first aid room, and when they get a little bruise or cut they brush the blood off on their overalls and say, "Oh, hell, that don't amount to anything," and go on with their work. Well, before night a few little bugs get in the bruise; over night they increase to millions and about the second or third day there is a nice case of infection that requires a doctor's care.

"Last year we had sixty-six cases of infection, and in some cases the doctor had to work pretty hard to save the finger or arm. Why? Because they thought it was not necessary to go to the first aid room. So, I don't care what you are doing, or where you are, the minute you have a break in the skin, go at once to the first aid room. If you don't, look out for your foreman. If he sees you he will make you go.

"Second, the question of clothing. We have nearly all of our dangerous belts and gears guarded, and do not have many accidents from getting caught in machinery. However, we have occasional accidents from the use of gloves. The rule is, that absolutely no gloves are to be worn around machines with revolving parts such as drill presses, lathes, milling machinery, grinders, etc.

"Here is a glove that was worn by a young man on a hand miller. It got caught in the milling cutter and he lost two fingers on his left hand. This young man, by the way, was intending to study dentistry. He hasn't any chance now, has he?"

"There are some jobs in this shop where we furnish gloves to men to prevent accidents. Men who are handling sheet steel and rough castings must wear gloves, but their use is absolutely forbidden on any machine unless your foreman and the safety director have studied the job and given permission to use them. Keep your sleeves rolled up to the elbow. Keep the flowing ends of your tie tucked in. Keep your overalls buttoned up tight around you, keep rings off your fingers, and wear safety shoes. We can sell you a pair of safety shoes at our stores that have more honest shoe value, more comfort than you can buy at a shoe shop, for more money; and in addition, they have safety for your toes. If you wear sloppy, thin, dangerous shoes, don't be surprised to have your foreman tell you to go to the store and get a pair of safety shoes.

"Hand tools: I am especially concerned about these mushroom headed tools. Here is a sample. You can see how that head is all burred over. Every time I hit that chisel, steel flies off and it may lodge in somebody's eye. It is not you that is getting hurt, but it is the fellow next to you. Watch your hand tools.

"On the question of goggles, I hardly know what to say. It is very, very serious. Sight is one of the most valuable of our five senses. Ninety per cent of the pleasures and happiness that come to us in life, and yes, some of the tragedies, come through the sense of sight. It is not hearing, nor feeling, nor tasting, nor smelling, but sight, which is the greatest gift. And yet, how little we seem to appreciate it and what awful chances some men take with their eyes.

"I shall always remember my grandfather who was blind in later life. Mother would take us to his home during vacation when we were kiddies. He would take us on his knee and pass the tips of his fingers over our face, our little bodies and say, 'This is Joe,' or 'This is Frank.' Many of you are fathers. Can you imagine anything more beautiful in life for parents than to watch their little kiddies grow up from babyhood through childhood into beautiful men and women in whom they see their immortality? Do you want to do this as my grandfather did with your finger tips? Vision is wonderful, it is precious, and yet, how quickly we can lose it. A flying nail, a flying particle from a machine tool, a bit from an emery wheel, a splash of acid or hot metal and the beauties of this life turn to the tragedies of darkness.

"We have set up in this factory the list of operations in which you must wear goggles; so, when your foreman tells you to wear goggles just realize that he is trying to save your eyesight.

"Here are a few samples of goggles that were worn by our employees and which saved their eyes. This pair was worn by a man who was cutting a nut from a bolt with a cold chisel. The last blow severed the nut. It flew, struck a panel, and bounded back in his eye. It broke the lens but saved his sight. This pair was worn by a man making babbitt hammers. Some of the molten metal splashed up and struck the lens.

"We have all kinds of collections. Here are some more. All of these were worn by fellows in regular work.

"If any of you are going to work in the press room, just remember there is only one safe way to feed a press, and that is to keep your fingers out from under the dies. We haven't got a job in the shop that can't be run safe and no man will be laid off in this shop for refusing to run a dangerous machine. Just talk each job over with your foreman and he will show you the safe way to run the job.

"I will not spend any more time on the rules. Your foreman will discuss these with you in detail. I have simply touched on some of the more important ones. Possibly I have scared some of you and made you think this is a dangerous place

to work. I do not want you to think so, for, as I said in the beginning, you are working in one of the safest plants in the city. Last year, under our group insurance policy, the insurance company paid claims on sixty-five violent deaths in the Corporation and out of these only sixteen were in our factories, the rest were in the homes and streets. So, you see, you are four times as safe working in our shop as you are away from the job.

"Here is last year's report of the National Safety Council, of all accidents in this country, and here is our company pretty close to the top of its section. I want you to feel that you are in a safe plant, that you are working for a company that is anxious to keep you safe, but at the same time I want you to know we are still having a few accidents and we can only prevent these with your help.

"In closing, let me say a word or two on cooperation. I get out a monthly report in this plant showing just how every department stands on safety, and every foreman is anxious to have his department at the top of the list. You can help your foreman. The only accidents we count are what we call lost time accidents. A lost time accident is one which keeps a man off on the next shift at which he was hurt. Today is one shift, tomorrow is the next. You could be hurt any time today, the nurse might bandage up your finger and send you home, but if you are back tomorrow you are back on the next shift. It is not a lost time accident and does not go into the record. I mention this, because so often men like to take a day or two off and they use a slight accident as an excuse for being away.

"Then, too, I want you to cooperate with me. Any time that anyone of you see anything that you think is dangerous or may cause an accident, just call me over, when you see me in the shop, or call your foreman and say, 'What do you think about this? Don't you think we ought to have a guard on this?' We do not do everything that the men suggest, because we have to use good judgment and commonsense, and we only install guards when our experience shows there is no:

only a possibility of an accident but also a probability. But when you call our attention to these things, it shows us that you are back of us in our safety program, and that is what we want. We want every man in this shop to take an active, personal interest in his own safety and in the safety of his fellow-man.

"Safety is just a habit. When you drive your car, you never stop to think to use your clutch or brake pedal, you just do it automatically. So it is with safety. If every day you give a few thoughts to safety, if when you are piling your stock you say, 'No, I guess I will pile it the other way, it will be safer,' or if when you go to jump over the conveyor you say, 'No, I guess I will go down to the gate,' or if when you see an upturned nail you step on it and bend it down, you will soon do these things unconsciously; you will have acquired the safety habit.

"We have made a wonderful record in this plant since we have been doing safety work. We have cut the number of accidents nearly seventy per cent. We feel that we are pretty safe, but, as I said in the beginning, we are not satisfied; we are still having too many, and we can only hope to make further improvement through the cooperation of every man in this plant, with the management to make this a one hundred per cent plant."

CHAIRMAN COTCHER: I feel sure that after you get the Congress transactions and read over and analyze this talk, you will appreciate even more than you have now the fundamental psychology behind it.

Does anybody want to ask any questions of Mr. Dunnebacke before we proceed?

JAMES F. HENNESSEY (State Insurance Fund, New York City): I would like to ask Mr. Dunnebacke to what extent they get the cooperation of the men to wear the goggles?

MR. DUNNEBACKE: We attempted at first to do it through kindness and reasoning with them. We had fair success. In my experience, the use of goggles is something that you can't play with. The more I see of it, the more I realize that we have got to get down to a hard-boiled discipline. It is a case of saying that you *have* to wear goggles, and if you don't you don't care to work for us. My experience in safety work is beginning to teach me that that is the only thing we can do on goggles.

JAMES S. HENNESSEY (State Insurance Fund, New York City): Do they have any trouble with the foreign speaking help relative to having them obey the rules?

MR. DUNNEBACKE: The question of language is present in all our plants. All of our people are English-speaking people. However, this program can be varied to suit the different nationalities of a plant.

MR. HENNESSEY: The reason I ask those questions is this: Of course, in our work here in New York, we have a great many small shops, and one of our hardest propositions is to get the cooperation of the men to wear goggles. We go in and sell the employer the idea of providing the goggles. I have gone into plants where they have had serious eye injuries, and notwithstanding that fact they complained of a certain type of goggle. I persuaded the employer to buy a goggle that would suit their needs. On many occasions thereafter when I went into that plant, I went right into the chipping room because it was near the gate and there I would see the men wearing the goggles under their hat. That has happened time and again. I have pleaded with the foreman, I have pleaded with the employer to enforce those rules.

I imagine from Mr. Dunnebacke's statement here that it all depends upon the employer, how far he is willing to go to enforce the rule. The employers claim in these small shops in New York that their greatest trouble is getting the cooperation of the non-English-speaking people. I don't know why it should be when there are so many accidents and so many serious ones which affect the eyes. I

would like to know what other people are doing, and how far they go to enforce the rule of wearing goggles.

L. R. SCHUYLER (Lycoming Manufacturing Company, Williamsport, Pa.) Relative to the use of goggles, I might say that we don't have all our men wearing goggles yet that we want. The last speaker said we try to get the goggles through the milk of human kindness and in some departments where we have straight grinding, that is, grinding directly in front of the emery wheel, we ask the men to try the lightweight large goggle without the side protection at first. But, of course, in the event that the man is doing snagging and work of that kind,

I have gone so far as to try four and five different types of goggles on. I have even sent to San Francisco for goggles to try and get anything that might possibly be able to convince the man that it is all right. After a man has had three or four different kinds of goggles fitted on him, he rather gets ashamed of himself; he can't find any more excuses to make for not wearing them. That is one of the ways that we get around him.

I would like to ask the last speaker, the relation of the employment department to the old employee. What becomes of the old employee when he can no longer safely carry on his regular occupation?

MR. DUNNEBACKE: In the General Motors Corporation, the executives of the corporation are realizing that that is one of the most serious problems that is facing them today. They are making an intensive study of the question. It is a personnel problem and it is a managerial problem that I don't think I am capable of giving you a good answer to. Some of the industrials are not in favor of pension systems. I think the proper idea is that in a man's lifetime as an industrial worker, management should give him every opportunity to lay up and to provide an income for his later age. There are a certain small majority of men we can take care of. It is one of the biggest problems that is facing American industry today. I am not in a position to answer that.

A. L. THOMPSON (Du Pont Company, Gibbstown, N. J.): Speaking about goggles, did it ever occur to you gentlemen that they have to be adjusted to the particular individual? You must remember that you buy goggles in wholesale lots, and you give them to a man and they are uncomfortable. Very seldom does the man take the trouble to adjust that goggle to his face. If you will take time to adjust the goggle, you will find it easy to get the man to wear them. I think that has been one of the drawbacks in getting the men to wear the goggles.

MR. BIRD (Fisher Body Corp., Pontiac, Mich.): On that question of goggles, I instruct all the new men coming in that if they have any difficulty with the goggles to stop me on my way through the shop. Almost every day I am stopped by at least one man who is having difficulty. I get him straightened up right then. If necessary, we try a half dozen different kinds of goggles on him. Just the day before I came up here, one of the men said he was having trouble with his goggles. I looked at them, and saw they were bent. I straightened them out for him.

CHAIRMAN COTCHER: We will pass on to the next topic. We are going to have some short discussions, and the first one is on the subject of "Rehabilitation."

Mr. Owen T. Flynn of the Fisher Body Corporation will discuss this topic.

MR. OWEN T. FLYNN: Mr. Chairman and Gentlemen: In accepting the invitation to address you on such an important subject, I am going to make use of my status as an invitee and also due to time limitation, will read from prepared data in order to insure accuracy.

Rehabilitation

By OWEN T. FLYNN

Department of Industrial Relations, Fisher Body Corporation, Detroit, Mich.

In introducing a subject of such far-reaching importance, I will first introduce myself and my connections. Anything contained herein is my personal opinion, and on that basis I will proceed.

I am in charge of the department of industrial relations of the Fisher Body Corporation, Division of General Motors, at Detroit, Michigan. My duties deal with labor trouble, welfare; and our medical department, employment, compensation and safety departments have their respective heads which do not come in range of my activities.

After many years dealing and associating with industrial workers while actively participating as a unionist, the writer decided that he could render a greater service by changing his course, but not his destination.

Dealing directly with the workers, the writer believes that to a great degree he has re-established that lost personal contact which was lost when industry went through transition and entered the machine age.

The word "welfare" is in the constitution of the United States of America, and no one associates it with charity or dole systems. Recognition of the equities of all partners in the big game of mass production, and render service accordingly, is my conception of welfare.

Rehabilitation is a word very little understood, due largely to its infrequency in every-day use.

The problem, as I see it today, especially in the United States, is not one of production alone, but of more units of production per man-day. If I am correct, the problem is divided into two parts; one dealing with the installation of modern machinery to reduce costs, or the material side; and the other dealing

with individual efficiency and reward, or the human side. I will deal with the human side, because I believe it is most important.

It is so, because no matter how scientifically equipped, wonderfully located, or beautiful the plant may be, it is quite valueless without men. Recognizing this side of the industrial picture, one of the largest, if not the largest motor manufacturing concerns in the world, claims it is just as much interested in the employees' welfare as it is making money; and to prove same, it gives the employees an insurance protection in case of accident, sickness or death, with liberal provisions for permanent disability, and encourages its employees to avail

themselves of a co-operative savings and investment plan which will, if accepted, provide amply in days when old age prevents them from working.

It goes further in recognizing the equities of its employees and at great cost has made their plants a safe place to work. The safety department contributes these benefits, and gives some other people something to brag about. It also provides first class surgical and medical care in all industrial injuries, but not withstanding these wonderful achievements, has recognized itself as a part of our great commonwealth, and has come to realize that restoring injured employees to a working, self-sustaining basis and prevent them from becoming state charges, is also full appreciation of equity.

During the war, the topic or subject of rehabilitation was very much in evidence, and to prove that it is worthy of its name the United States Government, through its Congress, passed the Rehabilitation Act, it was signed by our president on June 2, 1920, and thereby told the world that she recognized equity, and that maimed and injured people had to have vocational rehabilitation. However, this act does not provide for the direct organization or administration of vocational rehabilitation by the Federal Government, but does provide for financial assistance to each state in proportion to which its population bears to the population of the United States. Provision for each state is at least

\$5,000.00; providing, however, that each federal dollar is matched by a state dollar. The appropriation for 1920-1921 was in the amount of \$750,000.00 and I believe \$1,000,000.00 each year since.

Opportunities of returning disabled men to industry is difficult, especially during depressions, and according to state men, the depressions are due to labor-saving machinery and gradual moving of country folks into the cities.

There are some 41 states operating under the Federal Act, and we in industry can reasonably expect the state to rehabilitate cases of major nature. Now it behooves us to take care of those less seriously injured by setting up a method of our own. The Fisher Body Corporation has set up such a department on the following tentative basis:

It is a department divorced from other departments and managed by a production man, who pays attention to an employee's disability; and a psychiatric nurse, who sees to it that the medical director's directions are carried out to the letter. Only candidates whom the medical director and industrial director pass on go there for employment.

The doctor will use his own judgment on all entrants, with the possible exception of the few who carry on production when there are no medical cases.

Small operations have been set aside for production in this department.

It is strictly against our set-up to allow same to be an old men's home.

I will now attempt to show you where rehabilitation comes into our own industrial picture.

How States May Secure Federal Aid

1. It must accept provisions of the Federal Act.
2. State should empower and direct the state board for vocational education to cooperate with the Federal Board for vocational education in administering this act.
3. Provide for a plan of cooperation between the state board for vocational education and the state board, department or commission administering the State Workmen's Compensation Act, if state has such an act.
4. Provide for supervision and support of the work.
5. Appoint the state treasurer as custodian of all such allotments.

Time prevents me from going very much further, but I must at least call your attention to the following: Under our compensation laws, some states provide for the purchase of artificial appliances, and are as follows:

Massachusetts	Utah	Arizona
California	Minnesota	Washington
Nevada	Wisconsin	Illinois
Maryland	Oregon	

In conclusion, I must point out that the industrial surgeon, when amputating, should make such an amputation with a view in mind of an artificial appliance being desired by the patient and fitted to the stump. Makers of artificial appliances complain of their inability, to properly fit an appliance to a stump that is too long, and often a re-amputation is necessary if the patient is ever to be satisfied.

Time is long since up, and if the chairman so permits, I will try to answer questions, but will refuse to discuss cases, only on the basis of viewpoint.

Anyone interested in this topic can secure more information by writing to me at Detroit, and I will close, thanking you for your attentiveness.

JAMES F. HENNESSEY (State Insurance Fund, New York City): New York also provides for the purchase of artificial appliances.

MR. FLYNN: When was that added to your laws?

MR. HENNESSEY: I don't know when it was added to our laws. I know in the various cases where I have had a compensation and medical fee, it has also included a surgical or artificial appliance. I do not know that the State Fund pays for it.

MR. FLYNN: They can do it if they want to, but it is not a law.

MR. STEEL (Singer Manufacturing Company, Elizabeth, New Jersey): The New York State law was changed and went into effect July 1st of this year.

MR. FLYNN: The last publication I have here written by the government is Bulletin Number 126. If you gentlemen want a copy of this, you can get it by sending twenty-five cents to the Bureau of Documents, Washington, D. C.

I have just returned from the convention of the National Rehabilitation Association at Milwaukee. Nobody attended that meeting except Government and State officials. I happened to be the only industrialist. I was invited by the Federal Board. It was the most interesting four-day meeting I have ever attended. There are a lot of people as close as I am to industrial matters. I didn't know the Government was doing the work they are doing.

MR. BIRD: What measures, if any, have been taken to instruct industrial physicians in regard to where amputations should be made, having in mind appliances?

MR. FLYNN: There was very little done in that direction. However, in a trip yesterday through this Institute for the Crippled and Disabled, the director in charge told me that student doctors and student surgeons are making weekly trips through there with that very thing in mind.

The average man, after he is injured and loses a member of his hand or foot, wants an artificial appliance long before the stump is ready to receive it. There are plenty of ambulance chasers around to sell him one. If you have an injured man in your plant who wants to buy an appliance, buy it through the State Department of Rehabilitation. They have a contract with these appliance makers, and they guarantee to make it serviceable. The State will live a whole lot longer than either you or I will.

MR. BIRD: I have in mind a major case where a man had both hands cut off and faced reamputation with all the tragedy that had already occurred in that man's family; that was a terrific shock to that family, facing possible death, of course, again unnecessarily through physicians not being informed when the time is right and appropriate. I certainly think that this organization should go on record as proposing through any possible or feasible means that instruction where amputation should be made should be included in the university curriculums of our medical schools of the United States.

Double Duty Guards—How to Get the Most Out of Them

By H. E. MILLER

Safety Engineer, Chevrolet Motor Company, Detroit, Mich.

It has been my privilege occasionally to talk to groups of men on topics of interest. I know that this topic is one which carries a lot of interest to all who are enrolled on the roster of those who serve their God and fellow-man in this great humanitarian movement of safety. I hope I shall be able to do justice to the subject, and be able to leave with you a few thoughts which will be of value when you leave this Congress and take up your endeavors in your several localities.

As a prelude to this discussion, will you permit me to diverge just a little and make a comparison of present day methods with those of a decade or so ago?

Several times in the past three or four years I have heard the remark passed that the human element is being more and more forgotten in industry. I do not agree with this statement, and an analysis of present day working conditions will prove conclusively that this is untrue, and that more actual study is now given to the betterment of man's working conditions than has ever been the fact before. This is emphasized by the fact that nearly every employer has one or more persons to whom are delegated the sole duty of looking after the safety of these employees, and those who for economic reasons are not able to go that far, with very few exceptions have made safety part of the duties of some responsible party in the organization.

Compare this condition, if you please, with the conditions in all industries some 20 or more years ago. Some of the old timers in this audience, will, I believe, verify the statement that in those days man was not valued as highly as a good mule. Man was only thought of as a necessary evil that could be replaced by stepping to the gate and whistling or crooking a finger. A mule, however, was on the par with a little tin God. He had to be brought a long distance and trained carefully to do the job assigned to him, and then he was guarded religiously to see that he did not get hurt, and that he was not taken sick; for if either of these things took place, he would be out of the service for a time, and that would result in a terrible loss; therefore nothing was overlooked to guard him and keep him on the job. Nothing, except in very rare instances, was done to protect the man-power in the plant from either sickness or accident.

I remember an incident in a Pittsburgh steel mill, which, as I recall it, happened about 18 years ago. At that time this particular mill had a narrow gauge railroad track running from the pig yard in to the furnaces, and the cars were hauled by a single mule, there being about two ton of pig in each car load. On this particular day I saw the mule skinner misjudge his distance, and back a car load of pig off the end of the track at the turn table, and when it dropped it pulled the driver and mule down into the pit on top of it. The car was badly damaged and both the driver and the mule were hurt. The pig gang got the driver out, laid him out on the ground and then spent about 25 minutes getting the mule out. They found the mule had to go to the veterinary but they forgot all about the man who was still lying on the ground. I was finally able to get the gang boss to send a couple of men to help get the man to a doctor. The mule was found to have several minor injuries to his hide and not much else, so he was able to be back on the job almost immediately, but the man, when examined, was found to have a broken collar bone, a dislocated shoulder, a broken wrist, three broken ribs and severe contusions all over his body, and he was laid up in the hospital for 19 weeks. The best part of this however is yet to come, and that is that when the subject of protecting this dangerous condition was brought up, the pig yard boss' reply was that he thought something should be done as it was too hard to get good mules.

Now doesn't that make a great picture? No worry as to the condition of the man but worried to death for fear they would lose a mule.

Today, thank God! this condition has changed, and man has been raised to his proper place, and now is considered far more valuable than the most expensive piece of machinery or equipment. It has only been a very few years since industry began to figure the value of the human being and how best to protect him from injury and death, but in those few years, thanks to men of the caliber of Judge Gary, such rapid strides have been made that almost the first thought of the executive, when buying new equipment, is "What guards are provided and what will we need to make this machine safe for use?" I know of plants, lots of them, where a new piece of equipment cannot be ordered until the general manager, the assistant manager, plant superintendent, master mechanic and safety engineer sit in conference and actually specify what the manufacturer shall provide in the line of guards for dangerous points, so the machinery will be received fully guarded and

no delay will be occasioned through waiting till guards are built. In other plants I know of, they will not let the power be turned on till every dangerous point is fully guarded.

Now, let me ask you this—How is it with you? Do you get this cooperation in your plant?

If you do not, there is something wrong with you or your executives, and you should bend your every effort toward getting it. Without it you cannot hope to gain the confidence of your employees, for they will gain the impression that you have not the whole-hearted support of your management, and further that the management is only interested in putting guards where they are compelled to. You will never gain the necessary confidence of the men with this idea prevalent.

This brings me to the main part of my topic, which refers to, "Getting the most out of mechanical guards."

This subject could have been worded a little differently to express the real import of the matter. That wording I believe should have been, "Selling the Employee on His Own Safety and Protection Through Design, Construction, Application and Use of Mechanical Guards."

There are many angles to this important subject, and a lot of them I will be unable to touch on in the space of time allotted to me, so I have selected the four most important, and will discuss them in this order: Design, Construction, Application and Use.

Care in the design of guards is vital, for, if improperly designed, they may be clumsy both to handle and look at and that nearly always, if on production machinery, results in handicapping the operator or workman. Such handicapping, you all know, will be disastrous, especially in shops where so many men work on a bonus, or piece-work, basis, for it will directly react on the pay check, and when that happens you can rest assured they will exert every influence toward removing the handicap. This is logical and has been proven in many different types of factories.

In designing, therefore, there are many things to be considered, chief of which are: (1) cover the dangerous point; (2) make the guard as small as you can and eliminate protrudance into aisles or runways and tie in as much as possible to the contour of the machine; (3) exclude as far as possible any encroachment on point of actual operations; and (4) consult the operator and job foreman for their suggestion as to design.

The first three are very important but the last is, to my mind, the most important. To a lot of you this may sound like bunk, but listen—the point is that unless you get your suggestion from the man who is running the machine you are not putting up the kind of guards that will get the cooperation of the workman himself. In other words, unless you do go to the workman when a guard is contemplated, and get his ideas you will be erecting something which, from your view-point, will probably do the work, but practically it will be causing inconvenience to the operator, and when you cause this you will find your guard doing duty as a floor covering or helping to hold up a post in the middle of the plant most of the time. When you seek the reason for this you will get no explanation from anyone except the answer, "I guess the night turn took it off, for it was off when I came to work this morning." But if, when you plan to build a guard, you ask the operator for his ideas, he will nearly always make a good suggestion or two and if you follow his suggestions, even partially, you are forging a chain which will compel him to leave the guard in place. That way lies protection.

Let me illustrate: A couple of years after I started in safety work, I had formed the opinion that my experience qualified me to design a guard just about as well as anyone, and consequently when an occasion arose one day to lay out a guard for a machine I proceeded to do so. I had it made up according to my own ideas, and had it installed and said to myself that it was a darn good piece of work.

I noticed, however, that the operator was not very enthusiastic about it. But, in my egotistic way, I gave him no thought, as I could not see that there was a thing the matter with my guard. A few days later I found my beautiful piece of guarding a total loss, for someone had "accidentally" removed it for some purpose, and while it was lying beside the machine, something heavy had, again "accidentally," fallen on it and it was ruined. Again I did not use good judgment but had another guard made up along the same lines, only to have it meet the same fate. Then I began to realize that all this was happening because someone did not like the thing. Then I went to the foreman and the operator and asked them what was the matter; and the three of us checked this job and the operator showed me more in a few minutes about guarding that job than I could have found out alone in a week. I followed his ideas on the next one, and when it was installed it stayed put; and by the way, I happen to know that that guard is still in use after several years duty.

After that experience I have carefully followed the lead I got then, and when I find a place where a new type of guard is necessary I first study the job myself, then I get the foreman to suggest his ideas, and then I go to the operator and ask him for any suggestions he may have that will help in designing a guard for his machine. I often find that his suggestions follow the ideas already incorporated but more often I get a different slant on the job than I have been able to get from my own study. Following this, the total of the ideas of the workman, foreman and myself are consolidated into a design, and we then proceed to have the guard made up. It is a fact that, by following this procedure, whether the operator is able to give any new ideas or not, I am having the contact with him which has the psychological effect of selling him the safety thought, and from this on he is constantly watching not only his own job but various others in the immediate neighborhood and his suggestions are very often extremely valuable.

Some of you may not think I gain much by such a procedure and that I may even forfeit the respect of the employee by it, but I am here to say that I have never found a case where I have lost a bit of the man's respect. And here's another angle, after I have asked their aid in designing a guard I cannot recall a time or a case where any of these enlisted safety men have had to be cautioned a second time on any matter pertaining to their personal safety, nor do I have a record of any of them having been injured from the enlistment date on. So I claim that very often we can all sacrifice our so-called dignity and get hand in hand with the mechanic, the production man, and the laborer and profit from it to an unlimited extent.

As to the construction of guards, let me say that there are very few hard and fast rules or ideas to follow, as this is a good bit like building a house, for you have to judge your construction from many angles. Let me explain this in a few words: if the guard to be built is to cover a remote place where there is little, if any, traffic passing and is on a machine where there is very little chance for frequent repairs and where the operator is only required to go at infrequent intervals, then let your guard be of very light material, preferably metal, bent to shape and set in place. But if your guard is in the direct opposite location, that is, where there is lots of traffic, both foot and motorized, and is subject to bumps and jams, or is liable to be removed due to frequent machine repairs, then, for goodness sake, build it of heavy gauge metal-rivet, or weld the seams, reinforce the sides with steel ribs and fasten it in place with heavy machine bolts or cap screws and you will find that you will not need to replace it for a long time as it will stand a lot of abuse.

Never, except in very rare cases where nothing else will do, should you use cast metals for guard construction, for that type does not stand up. The lightest taps or blows will frequently break them, and that necessitates replacement or a

welding job, which always increases your operating costs, and in the latter case usually results in a very unsightly appearance.

Then, to tie in construction to double duty guards, let me say that a guard lightly built will not stand up and in a short time becomes misshapen and ragged, and one that has been welded looks terrible; all of which detracts from the general appearance of your factory and has a great bearing on the safety of your employees, for a man who works in a slovenly looking shop rapidly loses all pride in himself and his work and as he becomes careless in his appearance, he also becomes so in his actions and accidents and personal injuries result.

Therefore my whole discussion on construction can be expressed this way; build your guards of rugged material, build them along the lines that conform to the contours of the machine without encroachment on production, and build them ruggedly.

In discussing the application and use of guards let me cite an experience of a few months ago in Detroit, when, on invitation, I went to pay a visit to a large plant. The Safety Engineer of that plant is well known to you and we made quite a trip of it and I enjoyed it greatly. There was, however, one incident that reacted unfavorably on me and I haven't been able to forget it. On entering one department, and while standing beside a machine, I noticed a set of spiral gears uncovered and running at high speed within 18 inches of the operator's hands. On looking around I saw the guard or gear cover lying on the floor near the operator, and it was filled with sawdust and you can guess its use. My friend noticed it, too, and began to ask questions and learned that the guard had been off for several weeks, that the operator had asked that the gears be guarded but the foreman had made no attempt to have it replaced. This safety engineer then proceeded to give the operator a call down for using the guard for a cuspidor, but did not say a word to the foreman about the guard being off. I learned that the operator had been on that job for about three months and as we left him I overheard him say to his neighbor: "Who is that anyway?" The reply was, "Why that's the safety man." And the first operator remarked, "Well, I never saw him before."

Do you get the picture as I do? Do you see the thing as I do? Was this safety engineer handling his plant properly, when a man could be working there three months without knowing him? Was the foreman sold on safety when he would knowingly leave so flagrant a violation of all safe practices in existence? How could the safety engineer accomplish anything by criticising the operator and letting the foreman go without censure? Wouldn't it have been better to have called the foreman right then and insisted that the guard be cleaned out and replaced at once, and that this condition be overcome and never again allowed to exist? And lastly, wouldn't the engineer have strengthened his position a lot with the operators, by showing them that he was only interested in their welfare and would put up a fight for their protection? You can answer these questions for yourselves, but I'll wager your answers will coincide with mine, and that you will agree that this man went at things wrong end to; for it is a fact that the operator can only get done what the foremen will do for him, as far as the mechanical side of things is concerned, but that they will do a lot for you if you will only take the time to show them that you are working for their interests.

This incident illustrates the necessity not only of proper installation but of proper and continuous inspection to see that they are being properly used and brings out the point that when you have designed and ordered a guard of any description everyone in the immediate neighborhood is aware of the fact and it is therefore imperative that you leave no stone unturned in obtaining prompt construction and immediate installation. I have seen cases in plants where the guard was built and taken to the machine but due to high production schedules it was felt that the machine could not be shut down long enough to install the guard with the result

that the guard lay on the floor for several days before it was put in place and I have heard the operators ask why in blazes it wasn't put on. It is a fact that the majority of operators are intelligent men and they cannot reconcile our statements that we are working for their protection and safety and yet will allow a guard to be left uninstalled after it is ready to be put on. Therefore, let me emphasize that when a guard is ready it should either be placed on the machine at once or kept clear out of sight until the time arrives for installation, otherwise you will get adverse sentiment which will react unfavorably.

As to the use of a guard, you can only determine whether it is being properly used by constant inspection. I have gone into plants of many kinds for various reasons and through these have discovered there are only two classes of safety engineers; the ones who are constantly in the plant and are known to everyone, and the kind who are seldom in the plant and are known to only a limited number of employees. If you will permit, I am going to theorize at this point in this way: I feel that the theory of safety engineering is tied up with the constant and careful analysis of each unit of your plant. You can go around the outside of the department following the aisles and see very little of what is going on but if you will get into the middle of your department for only a few minutes you will find more actual hazards existing that should be guarded than you can find in a week by walking around the outside and you will find that if you do enter and travel through the departments everyday, you will have any number of employees stopping you and pointing out what they consider dangerous conditions and will be able to get more actual results than in any other manner.

In this same theorizing I want to ask you a question and that is: How many of you actually consider yourselves as useful mechanical guards against accidents in your plants? This may sound like a queer question, but let me say that through your constant inspection efforts and analysis of hazards you are making of yourself a useful practical and mechanical guard, and you are building a mental chain around each and every employee. He will take pride in seeing that there is never a guard missing from his particular piece of equipment, and will be constantly mentally alert not only to the guarding of hazards of a mechanical nature but to the guarding of his own mental hazards.

This all leads to this thought: that in the real analysis we can only get safety among the employees, by selling the idea of self protection, but when they have bought the idea they will bring you added suggestions of ways and means for betterment of conditions; and, while many of these will be useless, there will be plenty that can be used, and those you can use will just be added means of securing more and more safety amongst the men.

I had the privilege some time ago of looking over the minutes of a general safety committee meeting of a large automobile manufacturing plant which gave me some very good corroborative evidence on this subject. In this meeting they were comparing the accident record of Plant "A" (which was being completely guarded) with that of Plant "X" (which, except for extremely dangerous points, was being practically left out of the guarding program) and I believe this was being done with a very definite idea in mind. Some one from Plant X could not see why they were being discriminated against, and asked for reasons. The gist of the safety director's reply was that Plant A was only having about five per cent as many accidents as Plant X, but the reason for this was that the foreman and workmen in Plant A had embraced safety as part of their duties, and were so interested in it that they were continually requesting guards for dangerous places, and that the management was giving them these guards as their contribution to the general safety and well being of the men, thus helping to keep up the interest of all employees. In Plant X, however, the foremen or men had not become imbued with the safety idea and were not making any pretense of trying to protect themselves and they were not ready for the inauguration of an intensive

guarding campaign. He enlarged upon this by saying that his inspectors were simply devoting their time in Plant X trying to increase the employees' interest in their own safety and trying to get them in a frame of mind where they would begin to see the light and start asking for some protection, and when that day arrived the company would be ready and anxious to get their guarding program under way.

The safety director further stated, in answer to a question as to why the safety inspectors did not ask for guards, that the inspector's job was purely that of arousing interest in safety, and acting as a friendly advisor and aide to the plant supervision, and that it was the duty of supervision itself to ask for guard protection. In other words, he stated that putting the guards in to arouse interest was just putting the cart before the horse. I am heartily in accord with this idea and I believe his stand on the subject is a direct support to what ideas I have been trying to pass on to you.

Now let me summarize just a little and I am through. Consider this, that safety is a means of increasing efficiency, and an efficient man is nearly always a safe man; or you can put it this way: safety and efficiency are the true direction of man's mind to his work. This being true, guarding then must be a part of efficiency as well as safety.

Therefore, as I see it, to get the most duty out of mechanical guards, let the workman in on your studies, take well into consideration all that he may offer, combine it with your own knowledge of proper methods of construction, build your guards of materials that will stand up under long usage, make your installations accessible but permanent. And last, but greatest of all, use your guarding activities as a means of impressing safety so indelibly on the employee's mind that he will unconsciously become safety conscious and will himself, mentally, guard by his actions those points where mechanical guards cannot be applied, or that if applied would be absolutely worthless. All of these things will help you to sell to the man the idea that all you and he are doing will react to his benefit through saving him injury and pain and you will not only enlist his aid in keeping the guard in place and in good condition, but you will make of him a true disciple of the gospel of safety, which he will preach throughout the shop and it will be the means of eliminating accidents and their causes, and accomplishing this is, to my mind, the only way of securing double duty from your guards.

CHAIRMAN COTCHER: I am sorry, but shortness of time makes it undesirable to stop here for any discussion.

We will now take up the next topic, which is "Mechanical Safeguarding." This is to be discussed by Mr. George Thompson of Detroit.

Mechanical Safeguarding

By GEORGE THOMPSON

Detroit Insurance Agency, Detroit, Mich.

What is meant by mechanical safeguarding? I would say it is protecting machinery so that the operator will not be injured. In other words, it is providing a protection by some mechanical construction that will substitute for the skill and judgment we expect the operator to possess. That is really a fact.

In Lansing, Michigan, I gave a talk on mechanical guards and constructed a plant on paper, so why not construct a plant here and put in it some of our machinery?

I am not going to dwell on building requirements as that is confined to location, various locations having certain requirements that they feel necessary in buildings. For convenience sake, we will use the square type. It will be one story,

basement, with a gallery, virtually a two-story structure, which is similar to most of the plants which you work in.

We, of course, will have a fireproof building, with cement reinforced floors in the basement, the main floor, and self-supported gallery with ventilated slab roof. That again is just about what we use.

We must have a separating wall, a fire wall, if you please, separating the office from the factory, and the exits in the wall are to be equipped with approved fire doors. The building is also equipped with sprinklers and hose, also hand extinguishers, some soda and some chloride.

The building is to house one hundred men, so we must provide exits for these men, and will provide fireproof exits and stairways of the approved type. We must have at least two, one on each side of the building. We must be sure that these exits are kept clear at all times. We must see that they are not only clear in the plant but also clear to the public street.

We must also keep the stairways lighted, and the source of power for these lights must come from a source other than our own, so that these lights will always be illuminated. This is important. This was proven beyond a doubt at a recent fire, both as to the fire stairway and lights. The lights were burning three days after the fire was out and the debris had been removed. The stairways were serviceable even after all of the debris had been removed. In fact, they had to be torn down. It proves conclusively that fireproof stairways, well lighted, are the proper thing to have connected to your building.

The doors must open outward and all exits must be marked so that in case of extreme movement our men will know how to get to safety. This is also important. Why do we say a fireproof door? These tin doors are just wood-like inside of them. Why do we want a door of that kind? Why not put up steel? Let me tell you something. A blast of flame of enormous intensity and four of these doors exposed to that flame constantly, and even though the interior of the door was completely disintegrated, and within twenty feet of that doorway was textile material that a slight amount of heat would have ignited, the material was saved. Don't discourage the use of a tin door just because it is tin, because when the Board of Fire Underwriters set up that standard for the fire door, they did it for a purpose. The fire door is no good, you know, if someone puts a brick in the corner of the doorway and keeps the door open. It isn't any good at all if it is blocked open. A door is meant to do two things, open and close. A fire door is meant to do two things, open and close, and stay closed when it is subjected to fire. So, let's provide our buildings with fire doors.

Stairways: This is very important. Equip all stairs with slip-proof treads and hand rails, with landings. These landings must not be more than twelve feet apart. I would suggest six feet as preferable, as this will give us an angle of rise of about thirty degrees. This is a pleasant non-tiring rise, for as you know we must conserve the energy of our men.

I don't know whether you realize the importance of a stairway in a plant, but if you have to walk up and down five stories in a building, two or three times a day, even you yourself will find it rather tiring. But if that stairway has the proper slant, you will do it all day long without any particular effort.

The nosing should also be given attention, and should not over-hang the riser more than one or one-and-a-half inches. Why? Did you ever hear of a person falling up a stair, or falling down when they are walking up the stairs? I have. I find it was caused by the toe catching under the nosing. You experience the same feeling that you do when you reach for the top step when you come home late at night from a lodge meeting or something of that kind, and you reach for the step and it isn't there. I dare say there is not a man in this room that can tell me how many steps there are in the stairway of his home, yet you are using them every day. It is just that unconscious fact of the stairway being there, the

familiarity of going up and down that makes it a safe stairway for use. We don't stop to count the steps, and neither does the workman stop to count the steps. Therefore, if you will give him a stair that is as near foolproof as possible, you won't have the accident of falling downstairs; and falling accidents, by the way, are the greatest cause of injury in the United States today. Falling is one of the big things that contribute to our accident frequency in the United States.

The hand rails on the stairs should be made of not less than one and one-half inch pipe and should measure thirty-six inches from the center of the tread to the top of the rail with another rail eighteen inches from center of tread, measured at right angles to the tread.

We must not forget the gallery. This must also have a rail and should be forty-two inches high with an intermediate rail midway between the floor and the top rail, with a riser every six or eight feet. We must also have a toe board. I have found that a four or six-inch board is sufficient. I don't believe in making the toe rail rigid. I have found, by taking the toe board and putting a pipe champ on it to fit the riser on your rail, that then if it is necessary to move it for cleanliness or for some other purpose, you can merely slide the champ, clean out from under it, taking out the waste material that may accumulate around the ledge, and the moment it falls back in its place it is done. It is not rigidly fastened.

We will have an elevator. We will have one of the approved types. We will have the top hinge of the elevator or top section of the elevator hinged, so that if anything protrudes into the car and the car moves it will open and drop closed, when the obstruction is passed; also if it should be dislodged it will fall on top of the car instead of on the operator. That in many of our plants is disregarded. They are usually made across the shaft to open up and come down, and usually they don't come down. If this section across the front at the doorway entrance to the elevator is made so that it hinges and can stay up, if anything projects it will turn up and drop down underneath it. If it has dislodged that part, then that part will come down and land on the elevator.

Let me speak about the boilers in your plant. They get the least amount of attention of anything you have in the plant. Boilers sometimes explode. Very little thought is given to protecting the men from burning, or scalding.

The boilers will have safety valves properly set and exhaust outside of the building. We will have gauge glasses protected and instant reading devices installed so that our fireman can readily tell his water level. We will also have double blow-off valves that can be locked, also that we won't injure anyone inside the boiler when cleaning and inspection is necessary. Our boiler doors will also have latches so that in case of leaking flues or water getting into our fire box the steam will pass out into the chimney instead of blowing the fire doors open and scalding or injuring our fireman.

The turbine will have a governor and the generator will have breakers and rubber matting will be used on the floor in front of our control board. This will also be railed off.

We will now install our machinery. As we are going to use some machine shop equipment, we will have transmission.

We will locate our motor overhead and drive to the transmission line from here, and we can go to our countershafts and down to the drills and grinders.

The drive belt on our motor may break and fall, so we will enclose the drive belt with a hanging rack strongly built, so that if the belt fails it will drop into the hanger and do no harm. We will also put a belt catcher at the end of the motor pulley so that if the belt slips off the pulley the hook will catch it. The rack under the belt should not have a wood or metal bottom in it. I would suggest cross rods spaced twelve inches apart. Why? Because a wood or metal bottom accumulates lint and dust and presents a fire or explosion hazard, so why create one when the open construction is safer and cheaper?

We will enclose our down belts at least six feet from the floor, one side we will have removable. We will use set screws but they must be the socket head or safety set screws, and while the old millwright does not like them, we know that they are the best because they are safe.

We are going to have some ladders. We will equip our ladders with safety feet. We will have the rungs not less than one and one-half inches thick. They will be spaced not more than twelve inches apart. On our step ladders, we will have rungs on one side and steps on the other, or perhaps rungs on both sides, as occasion may demand. We will equip our straight ladders with hooks. I have found the best place to put these hooks is about one and one-half feet from the top, the extreme end of the ladder.

You may say, why do that, why not put it on so you hook it on the shaft? In many of our plants today the old type of transmission is still in effect, and the man goes up to put a belt on. He climbs up the ladder and throws it on the pulley. Possibly the pulley is making 1,300 to 1,500 revolutions per minute. The belt is anywhere from three to five inches. A man may have loose clothes and get caught. I say a foot and a half advisedly for this reason: Your hangers are very rarely over thirty-six inches on the extreme; there are more of them twelve to eighteen inches; so that you will have plenty of head room between the shaft and the ceiling. Put the hook a foot and a half down and when you hook it up, the man has an opportunity to take the rest of that ladder to act as a guide, a brace for him to hold himself in throwing that belt on.

On our drill presses we will enclose the gears and drive belts and rail off the rear guards, and we will instruct our operator that he must not wear loose clothing or finger rings.

Milling machines: Our milling machines will have their moving parts enclosed, and we will instruct our operator to use a brush to remove the chips, and he must also be instructed regarding loose clothing, gloves and rings.

Shapers: Our shaper has its drives enclosed and a rear pan long enough to cover the extreme travel of the ram, and we will instruct our operator to wear eye shields to keep the hot chips from his eyes.

Our lathes must be of the quick change type, so that the gears will be enclosed. We must also enclose our latch pins. I don't know whether you boys have come in contact with that very much. The latch pin is that little latch that you pull out when you want to throw out the back gears. Many a man thoughtlessly puts his hand on the bearing and throws the belt on and the pin comes around and a finger is gone. It is usually either torn off or it is mutilated in such a condition that it has to be removed. It costs about fifty cents to enclose this pin to a lathe.

On our planer, we will see that the apron is enclosed and filled-in, so that no one will reach for tools when the bed is moving and possibly break their arm. That has been done many times.

We will have a grinder or emery stand, so we will use grip tight washers and enclose the wheels so that not more than one-third of the wheels are exposed. We will adjust the tool rests as close as possible to the wheels, and we will equip the stand with glass shields, that are adjustable, as we do not want emery in our workmen's eyes. We will also have a tool grinder, and we will warn our operators that they must wear goggles when using this tool. These tools will also be equipped with an exhaust system.

Why do I bring up the matter of tool rests? Well, you have heard the old story that a burnt child is afraid of the fire. I have been burnt. I was just about as hard-boiled a tool maker as ever came down the pike. If twenty years ago someone had come to be and talked safety, I would have said: "That is some more of that stuff; spread it on the lawn; I don't need it." I had to hang

around and work in plants, supervise and all that sort of thing for a considerable length of time before I realized that we were not making mechanics like the old type mechanic. Production wouldn't permit it. Specialization was a rule of the day.

Some years ago, I was doing missionary work or emergency work, and did something that I had no business to do. It took a quarter of an inch of that finger off. I started to grind a washer on a grinding machine, and the rest was too far back and the washer went in and so did my finger and it ground off enough so I could pull it out. It served me right. I had no business to do it; I knew better than do it. It made a safety man out of me. If I am fool enough to take that finger and lose a quarter of an inch of it to do such a fool thing as that, what can I expect of other men who maybe haven't quite as much intelligence as I have. It is up to me, it is part of my job to tell that man what he may expect and then to mechanically safeguard that machine to the best of my ability. I haven't done my job, and you haven't done yours unless you have done the same thing. That is the reason I talk mechanical safeguards up to a certain point.

Let us go out into the production department, and as we propose to use both wood and metal in our product, we must keep our metal division separate from our wood division. In our metal division we will have a row of drills, some turret lathes, a miller or two and a square shear, power type, as we have described the guard for drills and lathes and know what they are. We must now provide protection for our shearmen. As we drive our shear with an individual motor, we must next enclose the fly wheel, which is rarely done on shears. I would do it, however. This should be entirely enclosed with solid or one-half inch mesh and have one side removable. The treadle should have a board protecting it, so that falling objects will not release the clutch and cause an injury. Also, we will fill in the arches on the hold down with a metal shield loosely held in place and having a vertical action of about one-half inch, so that if an operator gets too close to the cutting edges it will at least warn him of his danger before he meets with an accident. We will also warn him to use a metal pushing tool when he is cutting close to the line. We are called upon to have all of the wrinkles out of our metal parts, so we must have a spring hammer or bumper, and so we will enclose the spring action, then if the spring should break it will fall to the floor and not injure our men.

Punch presses: I am not going to start anything on punch presses this morning, because we could talk all next week on that little thing. But, you can bet we will enclose our fly wheels and operate them with two-handed devices. (A lot of you won't agree with me on that.) We will also feed all of our dies with tongs or spuds, as we will not allow our operators to place their hands between the dies. Of course, we will enclose our blanking dies and use slides whenever we can, and if we must use the treadle we will put a shield over it so that falling objects will not trip the press and injure anyone.

We have a nail keg full of those tongs about every two or three weeks. They cost us thirty-five cents, and we can buy a whole tub full of new ones for one finger. It doesn't do the die any particular harm.

We will also use a board hammer and we must have a pulley catcher and enclose our boards, put on a treadle guard, shield out back action and use baffles for scale and chips. Our men will wear goggles. On our furnace, we will use a water curtain, and the counter poise on our furnace doors will have limit chains and pins.

In our wood department, we will have several machines. One of them will be a mitre saw. It is driven with an enclosed motor. As we will use it for ripping as well as cutting gains, we must use several types of protection. When ripping, we will use a splitter, a shield, and a dog for kick back. When we are

fitted with a Dado head for cutting gains, we will put an over-hang on our cross rail so that the cutter head will not be exposed when the work has passed over the head. On the cross cutting, we will also use the over-hang. If we are cutting blocks, we will open the throat plate and allow the blocks to fall through the table into a box.

Yes, we will need a shaper, so we will make our protection in the form and fit the form with handles. Our clamps will be provided with latches so that they will lock in place. We will also use heavy steel shields and adjust them so that the form will pass freely under them. We will instruct our men to wear goggles when operating these machines.

Our saw tenonner we must enclose and use baffles so that the piece removed will not be thrown out in the aisles.

We will equip our boring machine with a stripper or holding form, and we will instruct our operator that he must not reach in under this protection at any time. Our jointer has a cylinder head, and it is shielded with a fan or slat shield. On our planer, we will have a kick back so adjusted that it will always keep the block or board in the rolls.

Our band saws will have the wheels enclosed, and we will provide a deep slot for the return side of the saw. We will also attach a head guard to the guide roll bracket, so that when cutting close to the line, our operator will not injure his head.

We will have a horizontal or bull shaper. Our men will wear leather aprons to protect them from splinters. We will have a dust proof room where we will spray our paints, so we will equip our booths with an exhaust of the impulse or injector type. The motor will be located outside the booth. The booths will be fitted with temperature release valves, and our men will wear respirators and wash down the booths every day. When necessary, we will scrape the side walls with brass or copper scrapers. We will warn our men to keep everything clean.

As our product is now finished, we will pack and ship it and send it on its way.

Now It Is "Up to the Management"

Now, gentlemen, our next step in the control of this plant is up to the management. What are we going to do about safety? I would suggest in our plant that we have a safety committee of four men, one to be our manager, one to be the factory superintendent, the assistant superintendent and the foreman and our maintenance man, he to be our inspector. We will expect him to check the following items:

Fire hazards and fire equipment; floors, openings, walls; elevated runways and platforms; pressure apparatus; electric equipment; railings, toe boards, ladders; elevators and hoisting equipment and gates transmission equipment; machine hazard, guards, belt; general conditions; first aid; lighting; goggles, respirators; material storage, toilet facilities, hand tools; and we will expect general suggestions.

We will hold a safety meeting once a month. We will review this report and outline what our activities for the next month are to be. That is a very important thing to do. If you put a ship on the ocean and just start it sailing, it will, of course, eventually get somewhere, but that isn't the destination. But, if you will outline and chart a course that you are going to pursue for the next month, you have something to hit at and you have something to endeavor to obtain. That is the reason I put that thought in there.

Men, there is nothing in this talk I have given you, so far, that you cannot do; there is nothing unreasonable. If you have not started, start now.

CHAIRMAN COTCHER: The next discussion is of Safety Committees by H. L. Fracher.

Safety Committees

By HOYT L. FRACHER

Personnel Manager, Detroit Steel Products Company, Detroit, Mich.

The many years of successful operation of "Safety Committees" in the industries of the country is sufficient evidence of their importance in the development of industrial accident prevention programs. The general benefits to be derived from the operations of a successful safety committee are too well known and appreciated to warrant our spending time in the discussion of them.

Our problem, assuming that we accept the premise that safety committees are desirable, is to develop that type of safety committee which meets the requirements of our specific problems.

Safety committees generally may be classified under three broad operating methods: First, the "Employee's Safety Committee" whose personnel includes only workmen. This type of organization is usually found in the larger industries where it forms but one group in a series of committees. Secondly, there is the "Management Safety Committee," comprised of only three persons holding supervisory positions; and lastly, the "Combination Safety Committee," which includes both workers and representatives of management.

The fact that all the types of committees and combinations of committees have staunch advocates is testimony to the fact that no one particular organization plan is all-inclusive. A careful analysis of the purposes to be accomplished by the organization of a safety committee is necessary to the establishment of a proper type of committee.

While safety committees are a great help to plants employing a safety engineer or safety director, I believe that the greatest work can be accomplished by safety committees in plants which are not large enough to employ a safety engineer. I want, therefore, to confine my remarks to the operation of a safety committee which is functioning in a plant of about 900 employees not employing a safety engineer.

The personnel of this committee includes the plant engineer, who is chairman of the committee, chief electrician, chief tool designer, employment manager, one superintendent, two assistant superintendents and the personnel manager. You can readily see the spread of experience that is gathered in this group. This committee has no sub-committees or employees' committees, but invites four foremen and four employees to meet with them at each of their meetings, asking the employees and foremen for their suggestions. These men are also invited to the next meeting to allow them to see what has been done with the suggestions that they made at the previous meeting. In this way we feel that we are creating an interest and making safety missionaries out of each one of the men who attend the meetings. By this method in a comparatively short time a considerable number of key foremen and key employees are brought in contact with this committee and in increasing numbers form the basis of contact for the promotion of our safety program.

If I should attempt to point out the greatest single factor in the success of our committee it would be this: That the committee has final authority on the matters it considers and due to the makeup of the committee recommendations are put into immediate effect. The management had given this committee authority to make improvements for safety up to \$2,500 without referring it to the management for their O. K. This situation brings about two conditions which, to my mind, are the backbone of the successful operation of a safety committee. First, the authority to order desirable recommendations to be carried out; and second, the means to put these recommendations into effect immediately.

Suggestions submitted to the safety committee by foremen or workmen are acted upon promptly and if, in the opinion of the committee the recommendation is not a practical one, the person who made it is advised why his plan could not be accepted. We believe this procedure, combined with the prompt carrying out of accepted recommendations, is very necessary if we are to secure the cooperation and interest of the entire organization in our program. The man who conscientiously and sincerely makes a safety recommendation is entitled to a proper explanation of why the suggestion is not practical, if such is the decision of the Safety Committee.

In conclusion, I just want to restate the two points which I believe to be of greatest importance:

First—Careful analysis to secure the proper type of safety committee organization for the work to be accomplished.

Secondly—Sufficient authority for the safety committee to enable them to properly and promptly execute desirable recommendations.

CHAIRMAN COTCHER: I know you are all here to hear Dr. Myers. I am not going to wait any longer. I now introduce Dr. Harry Myers of the Frigidaire Corporation who will talk to us on, "What Are You Going to Do About It?"

What Are You Going to Do About It?

By DR. HARRY MYERS

Superintendent of Personnel, Frigidaire Corporation, Dayton, O.

Some time ago at a foremen's meeting in a certain city, the program was very, very long. They had a lot of entertainment, gymnasts of one kind or another and lots of humorous things. Finally, I was supposed to talk. I said then to the chairman, "Let's declare an intermission of five minutes and get a rest."

The chairman said, "Aren't you afraid most of the men will leave?"

I said, "If they do, it is because they would rather leave than hear me talk. In that case I would rather they would leave for they are not interested in what I am going to say."

Just let me throw out this hint while I am on that subject. If you are having foremen's meetings of any kind in your city or shop, and you are having somebody come to talk, do not have a lot of miscellaneous entertainment before you have the main address. Do not fill up your program with a lot of vaudeville. Today, it seems to me, a lot of men who are managing meetings imagine they have got to have a lot of vaudeville of some kind to attract people. If they do, then I pray you, let that vaudeville come after the principal address. Maybe that will hold the crowd all the better. Do not ask a speaker to approach a very tired audience. Remember this, the average foreman gets up early, and is tired and ready to go to bed by nine or nine-thirty. If he is too tired, he can't possibly follow the speaker and he can't possibly get any good out of what he says.

My subject is "What Are You Going to Do About It?" When the program committee gave me this subject, I thought it a rather queer one. But if I do say anything which reminds people that things must be put into action, then I am very glad, for unless you act on any idea, will you not agree with me that it amounts to nothing? Will you not agree with me that this whole convention, so far, will not amount to anything unless you take certain things out of here and go home and do them? If you do not take some things out of here and go home and do them you will have been just a bill of expense to your company. Certain it is, if you will take what has been talked over here this morning or any particular part of it, starting with the splendid subject "The introduction of the new employee,"

which was so cleverly presented by Mr. Dunnebacke, it will repay any organization to pay for your time and expense here. And this is only one small part of this great Congress. Many other splendid meetings have been held, so I am just wondering what are you going to take out of all this, and what are you really going to put to work in your plant?

Well, there are a lot of things you are not going to do, because you have a closed mind, and you really didn't get the picture of what was being discussed. There have been a lot of things talked over here in this Congress to which you have said, "Hell, I know better than that; that isn't so." It is the same thing that you encounter in many other meetings. You read or hear many things that you automatically can never do anything about because you keep the idea out of your head with a closed mind.

I wonder what type of an individual you are? I wonder if you are one that people can approach and feel that they are getting their idea over to you, or if you are a man with a closed mind. You have been up against those people, haven't you? Perhaps you have oftentimes gone up against your boss when you have felt just like a rubber ball going up against the side of a big building. You know absolutely when you went there that you wouldn't make any impression because you couldn't even get your idea inside of his skull.

Oh, if we will only recognize this fact, that no idea can possibly do anything for us until it gets into our mind. It all starts from up here in the brain. Mr. Sloan, President of General Motors, is constantly stressing the importance of an open mind if we are going to progress and Mr. John Patterson's favorite slogan was, "We progress through change." Yet this change seems difficult for most people to make and there are two distinct things down in our bone marrow and down deep in the marrow of the race that tend to close the mind. I wonder if anybody can tell me what they are? These two things will guarantee that you won't carry anything in particular out of this convention. Yes, these two things will guarantee that you won't handle a bigger job. They block the progress of the race and thereby block your own progress. They are the tendency to resist the new and the tendency to resent criticism.

Resisting the New and Resenting Criticism

There are a lot of things that have been discussed in this Congress, that you are not going to do anything about for you resisted the idea because it was new. This is a trait of the human race. That's why we say so many times, "Oh, it can't be done." Do you agree with me?

If you want to read an interesting book, read Henry Ford's "Today and Tomorrow." If you do read the book, read that particular chapter, "It Can't Be Done," and see the number of things that were proposed in that organization that people said couldn't be done. One of the most interesting that he cites is that somebody said plate glass couldn't be made in a continuous stream. I want you to follow me carefully. I am going to quote the book almost verbatim. He said: We felt plate glass should be made in a continuous stream. We consulted the glass experts of the world and they told us that it could not be done. Then, we put a group of men to work at it that never had been in a glass plant, and they did it.

What a lesson, ladies and gentlemen! I ask you, is it not a peculiar circumstance, to have somebody come along who has never really been in our line of work and show us how to do something that we said "couldn't be done." I think it is due to this fact, that as we go along, we accumulate knowledge or information of two kinds, that which is true and that which is not. Every once in a while you accumulate more knowledge on the subject that is not true than is and you are

then on dead center; worse than that, you are in reverse. Then, somebody coming along who knows nothing about it can tell you how to do it. But he will have an awful time getting it into your head.

The Outside Opinion

I am just wondering now if you, as safety experts (I don't care what division of safety you are in) are wise enough to get that outside opinion. I was so glad to hear Mr. Miller's paper where he said he goes to the men on the job and gets their ideas. I am just wondering if you do that thing or if you are one of those experts that know it all. I heard the definition of an expert the other day. He is an ordinary man away from home. Some say he is a worn-out fountain ex-purt. That is pretty deep; you have to think that over.

Anyhow, if you are an expert, you don't know it all. One of the wisest things that John Patterson, that great man who did so much for the industry of America, ever said was: "I go to school to every one I meet." I wonder if you do. I wonder if you want the outside viewpoint, I know this: A man from the outside can many times show us things that we are stumbling over. We are too close to them. In fact, it is easy to get so close to a thing you cannot see it.

Just the other day I had my coat off, and Harry Sain, a good friend of mine, said to me, "I think your collar button is too long." I felt for it, and found that it was pushing my collar out, and I had never noticed it, and just think how close I was to it.

The other day my brother Al came to visit me. As I was shaving, he said, "Just leave your brush out as I may want to use it." A little later he yelled out, "What kind of a brush have you got?" I looked to see what was the matter. I will tell you honestly, until that moment I didn't notice that that shaving brush which was once long had been worn down to a stub. I had been too close to it—twice a day.

Isn't that peculiar? It is indeed easy to get so close to a thing that you don't see it and then anybody who is on the outside can come in and tell you about it.

We say to all visitors who come down our way, "Don't tell us just how fine things are; we think those things ourselves. We want especially to know about the things we can improve." This then, always gives us the outside view point.

There are going to be a lot of things mentioned in this convention that are not going to be registered in your plant, unless you have an open mind.

The Open Mind

How, then, can we develop an open mind? This is of greatest importance to all of us.

I wonder if you realize that everything starts from up here, and possibly because you are not doing a good job along this line is due to the fact that this isn't acting right for you.

Glenn Frank, President of the University of Wisconsin, mentions these four points of a fine acting mind: first, humility; second, curiosity; third, courage; and fourth, responsibility. Note how he has them lined up.

Humility, really makes for open-mindedness.

Curiosity, means you actually want to know; the very fact that you are sitting at a meeting this morning, have come to New York, indicates that you want to know something; you are showing that.

Third, courage means you will follow a new idea, even if it upsets all the old ones you had; courage when somebody down in the plant whom you thought never had an idea comes to you with a good idea that you adopt—that takes more courage than to lick your weight in wild cats. If there is anything that closes our

minds, it is when somebody comes to us whom we thought never had an idea in his head, and now has a good one. How we hate to acknowledge that that fellow has a good idea! That takes courage.

Now, responsibility, the fourth thing, the thing that, after you get the idea, after you have courage enough to see that it is right, makes you put it to work. The responsibility that is going to rest upon you to leave this meeting and do something about these things back in your plant.

I don't think I ever heard four points lined up finer than that. If you have an open mind you are going to get a lot out of this meeting. If your mind is closed, there will be a lot you won't get out of it. I am afraid there is going to be a lot lost unless you review some of the things you have heard.

Taking Notes

There is going to be a lot of things that you are not going to do in your plant simply because you are going to forget what was said in this convention. I am pleased to say that at the various meetings I have been in, I have seen more note-taking than any other convention I have ever attended. That is a marvelous sign, people taking notes so that they won't forget.

There is another fine thing you can do, and that is, you can order a copy of the transactions of this congress. I am just wondering how many of you are going to put to work what these fine people who are sitting here are taking down. Some day I am going to ask them how they do that stuff. Did it ever strike you how marvelous that is? I don't know if I will be able to learn it; I may be too dumb. It is one of the most interesting things I have ever seen. Now, I just wonder if you will order a copy of the transactions, study them, and do the things you read. This, by the way, will enable you to benefit by the sessions you were unable to attend.

Do you see what we have discussed so far? We have analyzed a group of things that you haven't done because of the closed mind or perhaps because you are going to forget it. And now let us say that you haven't got a closed mind, that you have it in your notes, or you are going to read it in the proceedings. What are you going to do about those things which you do remember and of which you say, "Yes, that was fine; that will make my shop a better shop,"—what are you going to do about these things?

Well, what have you done about the things to date which you have admitted would make you a better safety director, foreman or manager? What have you done about those things? Here is a question I am very fond of asking of large numbers of people. I have asked it of thousands of people. The answer I get is fairly accurate. What per cent of things you hear or read and admit will make you better and more of a success in life, what per cent do you do? It would be interesting to take that census right here this morning. After taking it with tens of thousands of people, the per cent is just about as good as poor beer. And mark you, I mean Dayton beer and not Detroit or New York beer. There is a difference I am honest about it. The per cent runs from one-half to one per cent. You think that over quietly when you get back home. Ask your wife about it—she may have some pretty good notions on it—and see how you stack up. Then, remember this statement: *That my value is governed entirely by the amount of supervision I require.* Do you get the force of that?

That is why you don't do more than you do, because there is nobody to go along and make you do it. If somebody gets a hold of you and makes you do a thing, that is supervision, and this is what costs money. That ties in exactly with Elbert Hubbard's idea of initiative, "The world bestows its big prizes both in money and honors for but one thing, and that is initiative." What is initiative? I'll tell you it is doing the right thing without being told. But next to doing the

thing without being told is to do it when you are told once. In other words, with the least possible supervision. Hubbard thereby divided the world into three classes, those can do things without being told, those who have to be told once and those who have to be told more than once. The successes of life lie in the first two classes, and the failures of life lie in the third class. Examine your own life and examine the men who work with you, and you will see that this statement is true.

The men who can do things without being told always have good jobs. They are also the last men to be laid off. The men who fail or the men who have poor jobs, are the men who have proved themselves undependable or those who have to be told more than once. You make the application, and see if it isn't true. Every time you have to be told more than once you have joined the failure class on that particular thing. If there are enough of those instances, you do belong in the failure class and you fail and you lose your job.

My value is governed entirely by the amount of supervision I require. If you can take the things out of this meeting and put them to work, it means that you are doing it with a very little bit of supervision and great will be your reward; you will be a success.

Now, let us go a little farther, let us go to the plant. Let us say you are home. Can't you feel yourself walking into the plant? I wonder how many ideas you will still have with you. When you get there and you still have a lot of good ideas, look out. I wonder whom you are going to see first. Of course, they are going to ask you about the Safety Congress. They probably think you had a good time and didn't bring back any new ideas. Maybe you never brought back any information before. Fool them this time. Make the old G. M. smile.

You are back home, you still have some good ideas. You are going to start talking to somebody. Suppose that fellow frowns, for he hasn't the inspiration of this convention. Can't you see him, can't you feel him? That is a tough moment, and that is going to be the deciding thing. There isn't anything that so decides your status as just that proposition. Can you go up against opposition and handle it? Or do you wilt and wither?

I am not pausing particularly for emphasis or because I have run out of talk, but I am pausing because I want you to think about that feeling you are going to have. A lot of you are going to be up against it. Maybe your management is not sympathetic with this thing. How long can you carry this atmosphere and this inspiration that you have got out of this convention? The man who goes up against any type of opposition and gets the thing done, is a live wire. Let me say this: Unless you can go up against whatever opposition you are going to meet, once again this convention is going to fail for your plant. Great is the responsibility of anybody who is the point of contact between an idea and putting that idea to work.

I want you to think about the obligation that is on you, on anything that you are doing when you are the point of contact between the idea and getting it done.

The men in the plant are going to miss a lot of this thing if you fail for any reason, any that I have named or any that we are talking about right now.

Good Teachers

Let us say you have a wonderful plant, and that the folks are waiting for you to come home. You are going to give your various reports to the different committees. Now what? Are you going to be able to present this thing in such a way that that crowd wants to do it? A lot of my good friends sitting in this meeting who have heard me before know exactly what I am going to say next. It brings in this biggest and hardest job that every one of us is up against, and that is the job of teaching others. This is the hardest job you have.

I wish we had two hours to talk on the art of teaching. I am wondering if back in your plant there is an atmosphere of teaching. A visitor came to our plant the other day and paid us a very high compliment. He said, "Of all the plants I have been in, there is more of an atmosphere of teaching around here, more of the atmosphere of college, than any place I have been in my life."

That is the highest compliment that man could have paid our institution. Yes, we try to have an atmosphere of teaching throughout the place. If any of you are interested in this particular phase of our work down there, we will be glad to send you some literature describing it, namely a book, "You and Your Work," which might possibly help you.

How few good teachers there are in the world. If you don't believe it, look over your own life. Some time ago I addressed the State Teachers Association. I guess I was pretty rough. I said to them, "In the last ten years I have talked to a good many groups of people but I have never talked to a group of teachers, and yet I am perfectly at home with you, because your problem is mine and mine is yours. I am just wondering now how many of you are good teachers and how many of you are punk." They all looked at me expectantly. I said, "On the law of averages, most of you are punk." (Are there any teachers here?) I said, "If you don't believe it, look back over your own life and see how few good teachers you ever had." Isn't that so? What does it mean? It simply means, ladies and gentlemen, that the principles of teaching bring to the surface certain elements that are very difficult to find in people.

I wonder what your idea of a teacher is. My idea of a teacher is somebody who can stimulate and direct others. A teacher should provide the inspiration and the enthusiasm. I was interested this morning in hearing the number of times the various speakers say, "You must tell them; you *must* do this." I am wondering if you can say "must" and still be interesting. I want to tell you right here that I have found very few people who can ever say "must" or make a demand that are ever interesting. There is just something about everyone of us the minute we have got to do a thing, somehow or other we don't like to do it. Let me say in all sincerity, that if you are going to go home with any of these ideas and are going to put them over by virtue of your authority, look out! That again will decide your status and the spirit of your organization more than you will ever know. Yes, that will decide your status in life, it will decide the type of man that you are.

In Ingersoll's Tribute to Lincoln there is this tribute to him: "Nothing discloses real character like the use of power. It is easy for the weak to be gentle. Most people can bear adversity. But if you wish to know what a man really is, give him power. *This is the supreme test.* It is to the glory of Lincoln that having almost absolute power, he never abused it except on the side of mercy." Did you ever hear anything more beautiful? Now don't say "must" too hard. Try to be interesting. Don't use your authority too quickly, anyone can do that and no one likes to have it used on him. Somehow or other we don't like to have people make demands on us. Let us try to make this whole program interesting. If finally you fail in that and you have got to say "must," say it, but at the same time admit that you have failed to be interesting, the greatest indictment that can be given against you as a supervisor of any type. Do you think that sounds right?

I wonder how you stack up back home. I wonder if you are interesting. How many interesting people do you know? I wonder if anybody but your wife thinks you are interesting. I say that in all sincerity too. Do you make work interesting to others so that they really want to do it?

There are three thoughts I learned from Mr. Kettering one time on the subject of teaching. I can never go past this point in teaching without laying down these three points. I remember my first work in Frigidaire. My boss told me that Mr. Kettering was going to come in to a class I was conducting, for he is inter-

ested in all sides of development, material or human. Right in the middle of the class one day in he walked. He didn't know what I was talking about. He listened to me for a little while. I happened to be talking about instructions. He jumped to his feet and said, "Do you mind if I talk a bit?" In the next half-hour he told me more about teaching than I ever knew before. I want to pass this along to you and I want you to review it frequently.

The plea I am making is, don't use your authority first; use it last if you have got to. Andrew Carnegie gave us eight words that if he gotten the race to see would have done more for the race than all of his libraries. They are contained in his autobiography, and if you haven't read it, and most of you haven't because I find very few people who have, you should; on page seventy-four, you will find a description of the time that Andrew first had authority. He was put in as a superintendent for two weeks. He abused his authority terribly. Later on, Andrew Carnegie, the great man, the philanthropist, as he looked back over it, saw where he was wrong and comes out and tells us where he was wrong and ends up with these eight words: "Only experience teaches the supreme force of gentleness." "Isn't that wonderful?"

Most people seem so afraid of having an agreeable and pleasant shop. Unless there is an atmosphere of agreeableness and a spirit of helpfulness in your organization, the two biggest factors in production are killed off.

Square that all up now with Mr. Kettering's idea on instruction.

Mr. Kettering's Points on Teaching

Mr. Kettering says you are apt to be poor teachers because instructions tend to degenerate, they do not propagate. You can't tell a man a thing just once and then think it is going to be done. You have got to check up. Instructions themselves tend to degenerate, and the individual, of course, being an ordinary human being forgets and gets lazy and many other characteristics enter that stop the thing.

Second, you are poor instructors because you are apt to teach the last thing you learned and not the first. And that poor fellow is learning it from the other end like you did years ago, I honestly believe this: That in all the things you have got to instruct, if you will go back in your own mind and see what was hard in that thing to you and put special emphasis on that, do special checking on that particular thing, you will clear up many things to the fellow you are trying to instruct.

It is only natural that as you go along and teach ideas on any type of thing, that you are apt to teach the last thing you learned. We are poor instructors because we can't remember how dumb we once were. Nature is very kind to us. It is a very protective thing. If we only could remember that, I am sure we wouldn't be so egotistic.

Mr. Kettering's third point is, "You are poor instructors because you are poor actors." You don't like to do your stuff over and over again in an interesting and entertaining way. He said, "Last night, I went to see Ed Wynn, and he is doing the same darn fool stuff he did three years ago, and yet I sat there and laughed my head off. I thought, What has that cost Ed Wynn to be doing that thing in such an interesting way for three years?" Can you do it three times in the plant and still be interesting? Isn't that a great point? Maybe that is the difference between yours and Ed Wynn's salary. Because he can do the same things again and again and again and still be entertaining.

Can you do whatever you have got to do in that interesting way again and again and again? Or, do you fall back immediately on your authority that you have got and say, with the face of a dill pickle, "Do it this way!"

If you have an open mind, if you receive ideas, if you won't resist the new,

if you won't resent criticism, and if you will carry these ideas back to your plant, and if you can then meet whatever opposition you encounter and go straight along with it and make these subjects interesting and entertaining, I know the greatest possible success can come to you and to yours. And that is the wish I am making for you, and I hope you are making it for me.

ADJOURNMENT

SEVENTEENTH ANNUAL SAFETY CONGRESS
NATIONAL SAFETY COUNCIL

Aircraft Sessions

First National Aeronautical Safety Conference

Under Joint Auspices of

*The Daniel Guggenheim Fund for the
Promotion of Aeronautics and the
National Safety Council*

October 4 and 5, 1928

PROFESSOR ALEXANDER KLEMIN, Chairman
The Daniel Guggenheim School of Aeronautics
New York University, New York City

The first session of the Aircraft Division at the Seventeenth Annual Safety Congress, devoted to a consideration of "Structures and Materials in Relation to Aviation Safety," was called to order at ten o'clock by the chairman, Professor Alexander Klemin, of the Daniel Guggenheim School of Aeronautics, New York University, New York City, who introduced the speakers, as follows:

Structural Analysis and Design in Relation to Commercial Aviation Safety

By T. P. WRIGHT

Chief Engineer, Airplane Division, Curtiss Aeroplane & Motor Co., Inc.

In order that aviation may continue to expand and may more rapidly attain the position in our modern civilization which all of us who are actively engaged in its development feel confident it will eventually reach, it is necessary that the public in general become actively interested in its use. This interest must be concentrated on the possibilities of the airplane as an every day carrier of men and goods, and not as means of providing an afternoon of thrills. I believe the most important single feature connected with airplane transportation which can so convince the public, is assurance of safety comparable with that which exists in other means of transportation. Although statistics are frequently cited by the aviation enthusiast, dealing with thousands of miles traveled per fatality and like figures, up to the present time the average man has not been convinced, and probably rightly so, that it is safe to travel by air. Rather than attempt to prove a doubtful case, it is, I believe far better to buckle down to the task of considering all phases of the safety problem, with view to eliminating sources of danger which exist in air

transportation as rapidly and as completely as possible. The urgency of such action emphasizes the importance of the present National Congress on Safety in Aviation.

Safety, by definition, is freedom from danger; any state which is non-hazardous. We cannot expect to witness a truly air minded country until its people are convinced that when traveling by air relatively great freedom from danger exists. Plenty of uses for the airplane will spring up, once its safety is proved. Every indication is that potentially aviation is an economic necessity.

Types of Danger Which at Present Exist in Aviation

The following list classifies the types of danger which now exist in air transportation. The list has been drawn up after studying reports in which the causes of airplane accidents in this and foreign countries have been carefully analyzed. A per cent is given to each item, as obtained by averaging the results appearing in these reports.

(a) Forced landings away from a suitable airdrome or emergency landing field, caused by engine failure. Twenty per cent of all accidents are brought about by this cause. This classification includes engine failures caused by breakage or non-functioning of the engine proper, or of the systems connected with its operation, such as the fuel, ignition, cooling, lubricating, distribution or carburetion. Approximately the same percentage of failures occur in each of the above sub items. The remedy for this source of danger is in providing more dependable power plants; in using multi engined airplanes, capable of flying with one or more disabled power units; and in providing more landing fields throughout the country.

(b) Errors of judgment of the pilot.

Fifty-three per cent of the accidents are marked against this cause. It should however be realized that it is frequently extremely difficult to decide just to which one of a number of contributing factors a given accident should be credited. The pilot may be credited with an accident brought about by design deficiency. Such faulty design may consist of the presence of instability, deficient control or excessive landing speed. It can however, be argued that the pilot realizing these qualities in his airplane, should so fly his ship that accident would be averted. In any event, the remedy for this potent source of danger appears to be better training for pilots and the production of more easily flown airplanes.

(c) Acts of God and miscellaneous causes.

These include chiefly accidents caused by the elements, such as severe storms, lightning, fog, ice formation, etc. Nineteen per cent of the accidents recorded are listed under this heading. The remedy would appear to lie in the establishment of more meteorological stations accompanied by facilities for disseminating the information there collected. Radio will undoubtedly play an important part in accomplishing this end.

(d) Structural failures.

Under this heading are included all accidents brought about by structural failures of the airplane proper, including wings, fuselage, landing gear, tail controls or propeller. Strangely enough, only 8 per cent of the accidents are brought about by this cause. Additional importance should however be attached to this 8 per cent, when it is realized that the percentage of fatal accidents herein is high. The adverse effect on morale of a structural failure is tremendous. It is the type of failure, more than others, which tends to create fear in the mind of the average person witnessing or reading about such an accident, thereby deferring the time when that particular person will

become air minded. One comes in contact in other walks of life with fatalities by lightning, by storm, by errors of judgment in personnel or by other causes which can be associated with items of the preceding classifications. It is however, distinctly novel and unpleasant to say the least, to think of being a mile up in an airplane when the wing drops off.

Having described briefly the general problem of commercial aviation safety and the types of danger which are present, I will now discuss in more detail the last item listed, namely, structural failure, including within the discussion a description of the stress analysis made in developing a design. The object of a stress analysis is to assure the existence of an adequate factor of safety, thus insofar as possible eliminating the source of danger: structural failure.

General Theory of Factor of Safety in Airplane Design and Description of Stress Analysis Methods

The necessity for economy of weight in the airplane structure has an importance in aviation which is unrepresented in the older engineering arts, such as in the construction of buildings, bridges or machinery. As a consequence of the greater stringency of the requirements, it is necessary in preparing a stress analysis for an airplane structure, to make common application of theorems and formulae of comparatively rare usage in the other branches of engineering. The two ever present and essential considerations which it is necessary for the structural engineer to keep before him when designing the airplane structure, are therefore weight economy and structural safety. Realization of the former assures the production of a design which will permit of carrying a relatively large pay load; without the presence in the design of the latter quality however, few if any of the planes so produced will find a market. Any aeronautical engineer has to constantly compromise in developing his design. This necessity for weight economy means first of all, the selection of a low factor of safety, lower, for example, than employed in the designing of bridges and buildings. Greater attention must therefore be paid to the loads to which the internal structure is subjected.

No other vehicle of transportation is subjected to such a variety of changes of motion, as the airplane. Consider, for example, the evolutions gone through in performing a loop or roll. The basis of all rules for stress analysis work in airplane design, is the load factor. This term is peculiar to aviation, and consists of the increase of loading on the airplane wings, when performing a given maneuver, over the normal unit loading which maintains in unaccelerated horizontal flight. For a given type of airplane, it is therefore first necessary to consider what maneuvers it is reasonable to suppose will be executed in it when completed. The next step is to ascertain what load factors can be present during these maneuvers. This last load factor is then increased so as to provide what is known as a real factor of safety.

The distinction between load factor and real factor of safety is extremely important and must be constantly borne in mind. In the older branches of engineering, the largest load which is likely to occur on a given structure is determined and a factor of safety obtained by using this load as a basis for the design analysis and then reducing the strength of the materials employed by the amount of the factor of safety. Ultimate stresses in the material divided by the working stresses in design gives the factor of safety. For bridges, buildings and the like the factor of safety is about four to five. In airplane design it rarely exceeds two and is frequently used at one and one half. This factor must take care of possible defects in material and workmanship; of design inaccuracies; of errors in assumptions and of depreciation. The justification for the use of such a low-factor of safety in a structure such

as the airplane, where freedom from danger is so important, is the extreme care used in selecting load factors; the refinements used in preparing stress analyses; and the care used in selecting and inspecting and testing the materials. It is unfortunately true however, that all the painstaking care of the designer and engineer in improving performance through low weight obtainable in part by use of low-basic load factors, can be nullified, and the whole art in a measure set back, by unthinking pilots who persist in violently stunting airplanes not designed for the purpose; and no commercial airplane based on standard Department of Commerce requirements, is so designed.

Let us next consider the magnitude of the loadfactors which maintain during several maneuvers, remembering that the load factor is the increase in loading over the amount present in straight horizontal flight.

In the following maneuvers, which are used in military airplanes, and which are not usually, if ever, essential to the operation of commercial planes, the accelerations or load factors are approximately as follows:

Dive	3½
Roll	4
Loop	4
Spin	3½
Sharp, pull out from dive	5½

These values were obtained on military airplanes tested with an accelerometer mounted in the plane when maneuvered at Langley Field by test pilots of the National Advisory Committee for Aeronautics. The high speed of these particular planes was approximately one hundred twenty-five miles per hour. It is theoretically possible to obtain higher load factors than the above, the limitations being the power of controls present in the design, the amount of balancing of controls, and the strength and endurance of the pilot. Remember the pilot has the same forces acting on his internal organs that are acting on the wings of the airplane. The point at which a man loses consciousness varies for individuals, from about four or five load factors to as high as seven or eight. The following load factors are present when maneuvering a commercial airplane:

Sharp vertical bank	3½
Bumps (rough air)	2½

It is therefore apparent that in setting the designating load factor for an airplane, considerations of future use and size enter in. A small maneuverable sport plane will obviously be subjected to more severe maneuvering than will obtain for a heavy passenger or freight transport. It may therefor be reasonable to suppose that load factors of the order of four may actually obtain in the former case, and of two and one half in the latter.

The Aeronautics Branch of the Department of Commerce has established regulations governing the load factor requirements for the design of commercial airplanes. The regulations list requirements which differ for various types depending on gross weight and power loading or weight in lbs. per horse power. In each case the load factor varies inversely with the function. The following are the Department requirements which I believe to be well chosen:

(a) Airplanes weighing 2,500 lbs. or less; the load factor varies from $7\frac{3}{4}$ for a power loading of 10 or less to $6\frac{1}{2}$ for a power loading of 20 or more.

(b) Airplanes weighing 5,000 lbs.; the load factor under similar power loading variations to those given above ranges from 5.9 to 5.

(c) Airplanes weighing 12,500 lbs. or over; the load factor under similar power loading variations to those given above, ranges from 5.1 to 4.5.

For other weights than the specific ones listed interpolation is permitted. Assuming that the figures for *obtainable* load factors I gave above are correct (namely 4 for a sport plane and $2\frac{1}{2}$ for a transport) it is apparent that the above regulations permit of a factor of safety ranging from about 1.6 to 2. It must be emphasized that these factors of safety are low even for the basic maneuvers and corresponding load factors assumed. They will become dangerously low and in fact disappear and thereby make structural failure almost inevitable, if more severe maneuvers than those considered as legitimate for commercial airplane use are attempted. Commercial pilots should be impressed with this fact. Others interested in the progress of aviation should realize and disseminate this information as much as possible, as it will admittedly be a difficult task to restrain pilots, particularly those who have had military flying service, from stunting commercial ships.

The load factors just described represent requirements for the design of the wings under high angle of attack condition. This is the condition which usually governs in maneuvering and is used as a basis for comparing the strength of different designs.

Let us now consider some of the conditions other than high incidence and the type of loadfactor applying to parts of the airplane other than the wings. The other conditions investigated in designing the wings are low incidence, corresponding to high speed flight; inverted flight, diving and roll. Under these varying conditions the center of pressure moves along the wing chord thus designing the front beam and truss under one condition and the rear beam and truss under another. The high incidence condition designs the front beam and has the factors above noted. In the low incidence condition, factors are used which are 65 per cent of those for high incidence, with a minimum of 3. Under this condition the rear beam is designed as the center of pressure moves back. For inverted flight and diving, factors are used that are 40 per cent of those which obtain for high incidence with a minimum load factor of 2. The diving condition frequently designs the drag truss. The rolling condition is based on a differential load between the right and left wings, caused by aileron deflections, and designs the cabane system members in a biplane.

The fuselage is designed by the loads transmitted to it from the wings under the above conditions, and in addition by loads from the landing gear, tail skid and tail surfaces. It is also necessary to investigate the fuselage for the effect of propeller torque and so called nosing over condition. The ailerons and horizontal tail surfaces are designed for a loading in pounds per square foot, ranging from 30 to 20 depending on the airplane weight. The same system is applicable to vertical tail surfaces, the loadings however being but 75 per cent as great. The loadings for ailerons and tail surfaces above described are based on pressure distribution tests with real factors of safety included comparable to those which obtain for the wings. The landing gear is designed for load factors ranging from 6.5 to 4.5 depending on airplane gross weight, and under the following main conditions, viz., level landing, 3 point landing, level landing with side load and braked landing. A drop test design requirement is included for landing gears and tail skids. This requirement governs the design of the shock absorber system, and is based on a free drop ranging from 24 to 18 inches depending on airplane gross weight. It is also necessary to analyze the control system. In this case the requirements are based on loads derived from the control surfaces or from the pilot, as the case may be. All details and connecting parts require analysis and design conditions for propellers are likewise laid down. It is thus seen that every part of the airplane is structurally analyzed, specific conditions of design based on tests or experience, being furnished in each case.

**Methods of Obtaining Load Factors for Analysis Assumptions and of
Checking Accuracy of Design Analysis**

Above I alluded to accelerometer tests. A brief statement concerning such tests appears in order. An accelerometer is an extremely simple instrument, consisting merely of a weight mounted on a spring, with a recording device for obtaining the amount of weight movement against the spring resistance, when the weight is subjected to accelerations. Obviously, knowing the weight movement between zero load and its' own weight, when mounted in a maneuvering airplane, the weight movement to the proper scale will record load factors or accelerations directly. It is essential that, as new types of airplanes are produced, they be subjected to accelerometer tests, thus keeping analysis assumptions abreast of the progress made in aerodynamic design, particularly as regards development in control surfaces.

It may be anticipated that, in spite of the utmost vigilance, designs will occasionally be constructed which will fail structurally during severe maneuvers. This brings up the second source of information to be used in studying propriety of load factor assumptions, viz. the study of accident reports. This is perhaps the ultimate consideration, as it represents the realm of experience and actual practice which will always be a step ahead of theory in any science. After sufficient facts have disapproved a given theory, it must be modified to account for the fact, thus giving us a revised theory for future use, with accompanying assurance against a repetition of the type of accident due to the initial set of causes.

Next let us consider the methods used in checking the accuracy of our analysis. There are many uncertain factors which are involved in structural analysis and design, which may vitiate the results obtained by even the most refined methods. Some of these are structural complication; design of detail parts; form factors of structural shapes; strength of materials; fatigue. It is therefore highly essential throughout the period when the structural analyses are being prepared and also after completion of the airplane, that the theoretical conclusions be supplemented and checked by static tests. Before considering in more detail the nature of such tests, a brief statement will be given regarding the uncertain items which make it necessary to check the design by tests.

(a) *Complicated Structure*: It is frequently necessary in developing a design to complicate it further than is desirable from the standpoint of structure only, by the introduction of redundant members, eccentricities and secondary stresses. Analysis formulae are apt to become so involved when taking full theoretical account of these factors as to render them unusable from the practical standpoint, even for the application by airplane structural engineers, who, as before mentioned are far more familiar with refinement of design analysis than are men performing similar functions in other engineering fields. This makes necessary the adoption of approximations which require static test for verification.

(b) *Detail Design*: The design of fittings and follow through parts from one major unit to another, is at once difficult and uncertain. The likelihood of errors creeping in is further strengthened by the very number of such parts and the complication of loads entering each. Improper design of detail parts is, probably the most potent cause of structural failures. The old axiom, "a chain is no stronger than its weakest link" is peculiarly applicable to the airplane structure, wherein the "links" are so different one from another and so complicated both as to design and loadings. In the field of detail design, static tests are, not only desirable, but essential in order to insure structural integrity.

(c) *Form Factors*: Each structural shape has a form factor, by virtue of which failure occurs at lower loads than are indicated by straight application of theory. A wooden "I" beam will fail at a lower load than will a rectangular beam theoreti-

cally designed for the same load but neglecting form factor. The same condition obtains, but accompanied by a different form factor in the case of wooden box beams, riveted duralumin beams or extruded duralumin shapes. Tests only can determine the magnitude of this form factor. As the art is progressing rapidly, bringing about the use of different shapes in almost every new design, no standardization of shapes, with accompanying form factor tables has yet been extensively accomplished, so that static tests during development are essential.

(d) *Strength of Material:* New materials or combinations of materials are constantly being advocated and used. Before adoption of these, extensive tests are necessary in order to assure the adoption of proper strength values in designing with their use in view. Tests are also necessary to check the current strengths of established materials, although these more properly are an inspection function. Tests to assure the efficiency of joints made by welding or other means must also be made.

(e) *Fatigue:* It is well known that all materials, to a greater or less extent, fail at a load lower than the ultimate under normal static application, when such load is repeated or reversed through a long period. There is, however, a fairly definite stress value, below which an infinite number of repetitions can be imposed without causing rupture. This fatigue or endurance limit is particularly important in airplane structures, where vibrations are present. Therefore, parts which are located in the structure so as to receive vibration must be specially designed for the purpose with endurance limit in mind. An example of this is duralumin propeller design. As the fatigue limit of duralumin is of the order of 12,000 lbs. per square inch (as against 55,000 ultimate in tension) and as propellers are subjected to extremely severe vibrations throughout long periods, it is obviously necessary to keep the unit stresses well down to the fatigue limit. The same conditions should be considered in the design of many other members such as wire pulls, motor mount clips, etc.

Several factors have now been described which make it necessary to supplement theory by tests. Let us now roughly classify the tests involved. These are as follows:

- (a) Structural tests of parts to determine satisfactory strength from considerations of loading, of fatigue and of joining.
- (b) Inspection tests to check unit strengths of materials.
- (c) Drop tests of landing gears and tail skids, to check the design from the stand point of shock absorption in landing.
- (d) Propeller whirl test, required because of the complications involved in propeller stress analysis.
- (e) Sand load tests of completed airplane wings and control surfaces to check detail design and basic assumptions made in the stress analyses.

In conclusion under this heading I wish to emphasize that static tests are of extreme importance and must not be neglected. Unfortunately they are costly, for which reason I fear they are not receiving the attention particularly in Commercial Aviation which they merit. Where it is not considered possible from the standpoint of cost to conduct major tests to destruction, frequently it is desirable and legitimate to carry on a proof test to a load of the order of 75 per cent of the design load. This type of testing is now common practice in the case of wires and may be applied to the sand testing of wings and other surfaces if carefully carried out. In such cases danger exists that some parts will be stressed to a point which is higher than their yield point, thus imposing a permanent set and perhaps making them unfit for use. It is however readily possible to properly proof test surfaces and thus assure a slight real factor of safety.

Refinement of Theory and Computations Used in Airplane Stress Analyses

The last discussion emphasized the desirability, and frequently the necessity of supplementing the theoretical analyses by structural tests. Perhaps in gaining the point at hand, the impression has been left that confidence is lacking in the major stress analyses which are made on every design. If such is the case, I hasten to rectify my position by restating the idea appearing early in this paper. In no other branch of engineering is refinement of theory and computations carried out to such lengths as obtained in airplane stress analyses. I doubt if more than two of the previously mentioned eight per cent of accidents attributable to structural failure are caused by the rupture of main members such as beams or struts. The greater proportion of such failures are due to the breaking of detail parts of joints or improper follow through, which is the particular source of trouble most readily discovered by the static test method.

In airplane stress analyses, the fundamental principles of statics, beam theory and strengths of materials which practically complete the required information in analyzing structures found in the older engineering fields, are supplemented by many refinements, such as the elaboration of the ordinary three moment equation to take care of combined bending and compression, known as the Berry formula. Methods of least work and deflection are frequently used also. In addition to the above type of theory refinement, sight should not be lost of the great number of loading conditions which are investigated for each part of the airplane. At the present time considerable attention is being paid to the theoretical aspect of wing flutter and vibration synchronization. I think we can justly be proud of the cleanness of the record as regards structural failures and of the accurate analyses and advanced methods of computations used in designing our airplane structures.

Materials Used in Airplane Structures

The subject indicated by the above heading merits a discussion of far greater length than can well be inserted within a paper of the scope of the present one. However, for the sake of completeness and at the risk of getting slightly off the subject, the principal materials now used, with some mention of their relation to stress analyses, will be enumerated.

(a) *Wood*. This material has been extensively used in the past, although at present its general use is on the wane. It has a high strength weight ratio and is cheap in small production but is not looked upon as of ultimate major importance because of uncertainty of supply, variations in physical properties, inspection difficulties and deterioration in service. However for use in wing beams on fairly small airplanes, it still predominates and will for some time to come. It will probably disappear eventually from general use, as it has in other engineering structures.

(b) *Steel*. This material has the advantage of reliability of physical properties, and for heat treated alloy steels, a good strength-weight ratio. It is at present extensively used for fuselage structures, landing gear structures and miscellaneous fittings. To some extent it has been used for wing beams and more often for tubular beams of control or stabilizer surfaces. It is difficult to predict the extent of future use, although it is certain to maintain its present position and probably increase in importance. Elimination of corrosion is a real problem, particularly for seaplane use, but a satisfactory solution may eventually be presented. Although at present the extensive use of heat treated steel is not looked upon with favor, the future tendency will probably be toward its being used more rather than less extensively. Aside from the fundamental advantage of high strength-weight ratio, heat treated alloy steel has among its physical aspects one which is particularly

advantageous, namely small disparity between ultimate strength and strength at yield point. In a structure such as the airplane where the real factor of safety is low this quality is particularly important, as its presence in a structural material in such a case insures against stressing any part above the load at which a permanent set will take place, a condition which must be guarded against.

(c) *Duralumin.* The predominate advantage of this material is high strength-weight ratio: It is coming more and more into general use both here and abroad and will, I believe be even more extensively used in the future. Its greatest enemies are corrosion and low fatigue limit, although it may be confidently expected that the problem of the former will be solved, and in the case of the latter, no fear need be held if parts are so placed in the structure as to be relatively free from vibration, or if vibration is present, proportioned so as not to be stressed above the endurance limit.

(d) *Composite use of materials.* Although at present many designers prefer structures which are all or practically all, of one material it is probable that in the future, in general, airplane structures which make use of several materials, each chosen as best suited for the particular portion of the structure in which it is used, will predominate. Even now, when a careful study is made of a particular part in regard to function, loading, location, etc., some particular material will automatically suggest itself as being most suitable. Granting this to be the case, it seems inevitable that composite construction will ultimately be generally adopted, as economy of weight is certainly basic in airplane design.

Conclusion Adequacy of Present Analysis Methods

Present analysis methods, such as are recommended by the Department of Commerce as well as the Military Services, are fundamentally sound, giving little cause for adverse criticism. It is also believed that, at least until more standardization of design has developed, there will be little need for change in general methods or elaboration of formulae employed. In so far as fundamental adequacy is concerned, the stress analysis of Airplanes is on a par or ahead of other phases of Aviation. This of course is logical, as the principles involved are derived directly from fundamental methods used by the older branches of engineering. More refinement however, is employed in their application. The soundness of present methods is indicated by the relatively small proportion of accidents due to structural failures, with an even smaller percentage brought about by failure of main truss members. We must not, however, rest on our oars, but must rather watch carefully for signs of error in our methods which may be indicated by such failures as do occur. The greater stress should, however be placed on the analysis and testing of detail parts.

Possibilities of Improvement in Structural Reliability and Safety

In the main structure attention must be given to the necessity which may later become apparent of raising required load factors due to a gain in maneuverability brought about by aerodynamic design improvement. Such condition may quite conceivably arise from the increasing tendency to provide larger control surfaces, properly balanced to relieve the pilot of excessive stick forces. It should be realized, particularly by pilots, that with such control as above mentioned, it is possible to cause the collapse of any airplane designed to present requirements, if the maneuvers attempted are too violently executed. Under these conditions accelerations can probably be imposed which will cause structural failure in advance of rendering the pilot uncon-

scious from the same cause. This brings before us two considerations which require future attention:

First, there must be a closer coordination between the aerodynamic and structural engineers; between the wind tunnel and the stress analysis. By realizing and making use of this coordination, it will be possible to define in advance just how violently a given design can be maneuvered with impunity. A military airplane recently failed in flight during the performance of a violent aileron roll. (The crew made safe parachute landings.) The design of the particular ship had just been changed from its general type of which a great number had been flown and maneuvered safely with the utmost violence. The changes consisted in increasing appreciably the aileron area, and balancing the ailerons at the same time. After the accident, wind tunnel tests were made and analyzed and the structure re-investigated with the result that it was shown that with a stick force well within the strength of an ordinary man, it was possible to cause cabane strut loads far greater than present requirements would make necessary. The result is of course a new set of regulations governing design conditions for roll. Similar coordination in the future may be expected to bring to light other inadequacies in load factor requirements. Other design improvements may arise which will permit a reduction in the severity of design requirements, as for example those recognized by the Department of Commerce in the case of landing gears using oleo shock absorption. Lower factors are here required than are necessary when rubber or springs only are used.

Second, there must be a greater realization on the part of pilots of the limitations of their machines. Each design type must be used only for the purpose intended. It is obviously unreasonable to expect a large transport airplane to withstand the stresses imposed by pulling sharply from a steep dive, whereas a similarly executed maneuver in a pursuit ship would be entirely in order. Pilots should be made to realize that one reason for lower load factor requirement in large, heavy airplanes, is that they are not intended for use in maneuvers that are at all violent. In fact the Department of Commerce does not include within the load factors specified, a sufficient factor of safety to permit the execution of really violent maneuvers in any of the classes defined.

The greatest reduction in accidents due to structural failure will come about by giving closer surveillance to the design of detail parts and fittings. Such part must be properly analyzed, supplemented by carefully conducted static tests. There is a real need for improvement in this field. A recent series of failures on two or three commercial types were directly caused by obviously improper design of fittings. Particular care must be exercised in the design of details in eliminating eccentricities which may not only adversely effect the fitting itself, but also cause secondary stress in main structural members of such magnitude as to render them under strength. Follow through and avoidance of redundant members are principles often violated. More attention should also be given to possibilities of failure due to fatigue and to the allowance for proper bearing area on parts subject to wear. The proper checking of detail design takes a considerable time to perform, and it is therefor important that in laying out development scheduels, sufficient time be allowed so that this important phase may be given proper attention.

The last item which I would like to mention in connection with improving structural reliability, is personnel. At present there are not sufficient competent airplane structural engineers available to meet the demand of a rapidly expanding industry. This situation can only be remedied by turning out men from the universities who are well grounded in applied mechanics and structures. Heretofore these subjects have in general been slighted in the aero-

nautical courses available to such an extent that the industry was able to obtain men better equipped to conduct airplane stress analyses from graduates of civil, architectural or mechanical engineering courses, than from aeronautical courses. Far better results would be obtained were it possible to secure aeronautical engineers with a proper ground work of the structural subjects.

The four main sources of improvement which we may expect in the future, and which will make Aviation safer from the standpoint of structural integrity, are, therefore: coordination of aerodynamics and stress analysis; more general use of static testing; application of sound engineering in the design of fittings and supply by our universities of aeronautical engineers better grounded in the basic principles of structural design and analysis.

Inspection of Airplane Structures and Materials in Construction and Operation

By EDWARD P. HOWARD

**Chief, Air Regulations Division, Aeronautics Branch, U. S. Department
of Commerce, Washington, D. C.**

The invitation to present a paper before this Congress is an honor greatly appreciated. The general subject of Inspection of Airplane Structures and Materials in Construction and Operation is considered under five principal headings, the first being:

Selection of Materials for Commercial Aircraft Construction

The following remarks are not made in an attempt to thoroughly cover this broad subject, but apply only to that phase which is directly related to the safety of aircraft operations.

Such things as cost and adaptability to particular design problems are only touched upon incidentally and insofar as they affect safety. This cannot be construed, therefore, as a comprehensive study of the selection of materials for aircraft design. It is hoped, however, that it will serve to point out the major items which must receive consideration in order to insure dependable and safe air transport.

Omitting, then, all other aspects of the situation, the safety of aircraft materials depends upon three major items. These items are: first, the initial physical properties of the materials; second, the effect of fabrication methods employed in the construction of the aircraft; and third, the effect on these materials of service operations of the completed aircraft.

The initial physical and chemical properties of structural materials should be known to a certainty. An airplane is designed upon the assumption that the materials employed possess definite specified strength properties. If these properties are not actually realized, the airplane will not have the strength and ruggedness necessary to meet all the service conditions that will be imposed upon it.

A great deal of spruce on the market is vaguely labeled "airplane spruce." Specifications as to specific gravity, grain formation and soundness should be adhered to.

In the case of steel it so happens that the market is flooded with so-called "commercial" steel, which is being purchased for use in aircraft. This grade of steel may possess any physical properties below those of S. A. E. specifications 1020. Its physical properties and chemical composition are not guaran-

teed to the purchaser. It is, consequently, cheap and popular. Airplane designers working with steel tubing and steel plate fittings almost invariably assume that 1020 or 1025 steel will be used, and design the member sizes accordingly. If the manufacturer purchases a cheap grade of commercial steel without specifications and static tests he not only lowers the strength of his airplane, but may actually make the machine a distinct menace by unwittingly including members which are brittle or soft, or which contain segregated grain structure and weakening impurities. It is absolutely essential that the full importance of this situation be realized and that definite purchase specifications be combined with a rigid inspection system to insure the construction of safe aircraft.

Drawn steel shapes, such as tubing, are subject to a number of defects which are difficult to discover and which may become serious in the airplane. Hair line cracks, "pipes," and variation in wall thickness, are some of these defects. A crack will open up when the cracked member is subjected to a compressive load and may cause the member to fail. If materials of this nature are selected for use these inherent flaws must be given due attention.

Heat-treated aluminum alloy castings lend themselves readily to odd and complicated shapes but must be used with discretion. They must be of such shape as to reduce to a minimum the possibility of hidden blowholes and like imperfections. Because such imperfections cannot be entirely eliminated, a generous amount of excess material should always be provided in addition to that calculated as necessary for the required strength. Bolt holes which are subjected to reversing loads will, in general, give unsatisfactory results in aluminum alloy castings unless the working bearing stress is very low. Otherwise, the holes will elongate under continued pounding and will induce a failure in the surrounding material. The recommended procedure is to use these castings at points of minor importance where failure will not wreck the airplane. In such places they will be found to be economical and of comparatively light weight and will give good service if properly designed.

With increased production it will be possible to use with decided advantage a hitherto overlooked type of fitting, i. e., that type which is forged. Aluminum alloy and some steel alloys lend themselves very readily to forging and produce fittings which are more reliable, neater in appearance, and in quantity production, cheaper than the present welded type of steel plate fitting.

From the standpoint of fabrication methods, there are a number of factors to be considered in the selection of materials.

If parts are to be joined by welding, the selection of materials is immediately limited to those which weld satisfactorily and still retain sufficient reliability and strength.

Aluminum alloy, for example, welds beautifully but becomes soft aluminum during the process and retains only the strength of soft aluminum.

All steels are somewhat annealed during a welding process, but some are effected more than others. Chrome-molybdenum steel of S. A. E. specification 4130 is probably injured less than any other commonly used alloy steel and is consequently very desirable for members and parts upon which little or no machining is required. This material possesses such high strength properties when heat-treated that it is extremely difficult to machine and form in the heat-treated state. If annealed first and heat-treated afterward, it produces fittings of great strength and reliability. This process is somewhat expensive, however, and sometimes difficult in view of the distortion coincident with heat treatment, hence it is not widely used.

In the matter of fittings it might be noted that the present almost universal practice of forming complicated shapes by welding together flat steel plates has almost nothing in its favor except comparative ease of design. The exces-

sive amount of welding usually necessary, produces burned and distorted material and induces internal stresses that might be of any order whatsoever. These internal stresses cannot be allowed for in design except by providing ample excess material. This consideration is either forgotten, or if taken into account, results in excessive weight. In cases where the internal stresses are of sufficient magnitude, they will result in cracks which can be detected before the fitting is installed in the airplane, allowing the fitting to be scrapped. If such cracks do not appear until after the airplane is in operation the chances are great that they will not be noticed and they may cause a serious accident. This is one case where a rigid inspection during construction is of little or no avail, the only remedy being extremely careful design and first-class workmanship. Such a remedy is, of course, only partial, but will usually result in an airworthy structure.

Another important consideration is the amount of cold working necessary in the formation of the various members and parts. Heat-treated aluminum alloy has to be worked carefully and bends provided with ample radii to preclude cracking. It is usually difficult, if not impossible, to make the forming operations upon annealed material and heat-treat afterward. In designs, therefore, which necessitate violent cold working or sharp bends, aluminum alloy cannot safely be used. The flanging of small holes in aluminum alloy sheet is a source of cracks, and consequent unsatisfactory members.

The effect of airplane operations in actual service is another major consideration which governs the selection of aircraft materials. There have been cases, for example, in some of the small aircraft, where soft bolts or pins were used for hinges on control surfaces. After some hours of service these bolts were so warm that the control surfaces were loose and subject to fluttering. In some cases the bolts were worn nearly half-way through after only about 50 hours of operation and were in danger of breaking completely. This illustrates the necessity of providing both ample bearing surface at hinge points and hard surface material which will resist abrasion.

Another serious situation is found in the corrosive influence of the elements upon aircraft materials. This is particularly true of aluminum alloy, which must be carefully protected. There is some choice in this matter. One product called "Alclad" is an aluminum alloy with a surface layer of aluminum and is extremely corrosive resistant. If the plain alloy is used there are several types of surface coating available. The electrolytic "Anodic" process is in general use and gives good results. Paints and varnishes can, of course, be used and are satisfactory so long as the surface is not removed by abrasion. This type of protection requires constant care and re-application on the part of the operator and is consequently not so satisfactory as a more durable coating.

Steel must also be protected, although the situation is not so imperative in this case because of the slower action of corrosive elements. Paints and varnishes prove quite satisfactory.

When wood is used the action of moisture on glued joints is detrimental to safety and these must be protected by varnish or its equivalent.

To summarize, then, the selection of materials for aircraft construction is guided by the physical properties required for strength, the necessity for obtaining materials of comparative freedom from imperfections, the methods of fabrication to be employed, the nature of the loads which will be applied to the part in question while in operation, and by consideration of the corrosive and deteriorating action of the elements.

The next phase of this subject to be considered is:

A Recommended Method of Inspecting Airplanes During Construction and Assembly

Inspection under this heading resolves itself into four classifications. These are chemical tests, physical tests, constructional inspection and general assembly inspection.

Chemical tests can only be employed successfully when materials are purchased in accordance with definite specifications. Purchase specifications are, however, imperative if the completed airplane is to actually incorporate the safety factors deemed essential by the designing engineer. Cases have come to light, for example, of manufacturers who were using low-carbon steel bolts in the belief that those bolts were nickel steel. Chemical test inspection should be a routine matter of examining a sample from each lot of material received in order to ascertain its accordance with the required composition and to eliminate the possibility of such a dangerous situation.

Since engineers will be charged with determining the strength properties essential to all of the materials which are built into the airplane, it becomes a simple matter to perform routine physical tests on samples of all material received. Usually these tests need only determine the tensile strength and elongation of tubing or sheet material because these properties give an accurate index to compressive bearing, and shear strength. In some cases, bending tests are required in order to ascertain the malleability of certain materials.

Simple tensile tests on fabric and shear tests on sample glued joints should be regular procedure.

In many cases, it is advisable to proof load all special parts such as wire terminals, although it will usually suffice if occasional parts of analytically indeterminate nature are tested to destruction.

If the manufacturer feels that the volume of his business is not sufficient to warrant the added investment of a static test machine, he can purchase the services of a commercial laboratory at small expense. In any event, inspection by static test is essential to safe aircraft production and such a system must be installed in every factory if we are to progress beyond the blind, groping stage.

Other physical tests which are not so recurrent or essential consist of impact tests, immersion tests and corrosion studies. All three of these may be classified with tests of complete airplane units in that they will seldom or never be employed by an inspection section, but will usually be made for the purpose of obtaining design data.

Visual inspection is an art, or science, which requires skilled workmen whose duties are many and varied. It includes both qualitative and dimensional inspection of all the materials and parts which constitute the complete airplane. All inspection, however, covers three definite fields. These are: first, inspection of materials entering the factory; second, inspection of parts and small assembled units; and third, inspection of the complete airplane assembly.

Much material received at the factory cannot or need not be subjected to physical or chemical tests, but can be examined visually with satisfactory results.

Wood should be checked for specific gravity, grain formation, freedom from knots, and soundness before being placed in stock. Metal tubing and sheet should be checked for gauge thickness and freedom from pits, cracks and other defects.

In the matter of constructional inspection, there are as many specialized functions as there are types of construction. In general, however, the inspector will examine parts for accordance with the subject drawings and for defects of workmanship and assembly.

In welded construction the welds themselves must all be examined to determine that satisfactory fusion has been obtained. In addition, the assembly must be inspected for signs of burning, cracking and distortion.

The inspection of welds can be satisfactorily accomplished only by personnel who have had long training in that particular phase of aircraft construction. A good weld depends upon the perfect coordination of so many factors that anyone of a fairly large assortment of defects may appear. These defects, of course, are not always serious so that it becomes the duty of an inspector to determine the character and degree of any variation from perfect fusion.

A weld may be ruined by improper proportioning of the oxygen and acetylene in the torch flame, by using too broad a flame, or by laying the welding material on the joint without sufficiently pre-heating the parts to be joined. Each of these types of imperfections produces its own characteristic effect upon the completed assembly.

If the welding flame used has contained too great an amount of oxygen in proportion to acetylene the steel around the joint will show an oxidized or burned effect. The outer surface of the steel adjacent to the weld will be scaled and pitted. This is the worst type of poor welding that will be encountered.

A carbonized weld is produced when the welding flame has been provided with insufficient oxygen. The excess carbon produces an effect which is usually but faintly discernible, in which case it is not serious. A slightly carbonized weld is but little less efficient than a perfect one. If the welder has used too large a tip on his torch the effect will be a large area of annealed material adjacent to the weld and some burned material in the immediate neighborhood of the joint. This type of weld can be detected by the bluish cast of the material within a radius of an inch or inch and a half of the weld.

If, on the other hand, the parts to be joined have not been sufficiently pre-heated, the welding material will not form a smooth fillet at the joint and will have quite definite rounded corners, showing that fusion has not been obtained. Where this is the case, the joint will have very little strength.

These remarks apply particularly to oxy-acetylene welding, that being the method in most common use. Electric welding is usually more dependable and is not subject to as many defects, with the result that it is beginning to replace the torch method and will probably continue to do so as fast as the industry becomes acquainted with its advantages.

In wooden construction, the inspector looks for splits, poor glue adhesion and poor workmanship.

A glued joint should be looked upon with suspicion if some of the gluing has not been squeezed out at the sides of the joint. This would tend to indicate either that insufficient glue had been used, that the glue was allowed to become too hard before pressure was applied, or that the joint had not been adequately squeezed.

The necessity for using proper glue and gluing practice cannot be too highly stressed. Casein glue, for example, is more widely and improperly used than any other kind. This glue must be used within four hours after mixing to produce the desired results. The mixing, itself, is an operation which requires considerable care as it is essential that there be no lumps in the glue and at the same time, that the process of stirring and dissolving the lumps introduces no air bubbles or foam into the mixture. A foamy glue will produce a joint that is marked with air pockets and consequently lessen the efficiency of the joint, while one which is lumpy will prevent an even pressure over the surface of the joint and thereby prohibit adequate adhesion.

In riveted construction the most recurrent flaws are cracked or misshapen

rivet heads. Holes may be out of place and too near the edges of parts or the rivet squeezing might cause cracks to appear around the hole. An aluminum alloy rivet might be used in place of an iron one, or vice versa.

The soldering of wire terminals, the serving of cable terminals and splices, the sewing and fastening of fabric and the quality of brazed joints are a few of the miscellaneous constructional details which require inspection.

The next and final phase of inspection concerns the major assembly units. The purpose of this type of inspection is to insure that all units are properly assembled.

The clearance between bolts and bolt holes is a commonly overlooked point that should be covered at this time. At points of reversing load the life of an airplane may be said to vary, within certain limits, inversely as the clearance allowed for connecting bolts. If these bolts are loose they will pound out the holes in a short time and so distort the fitting as to create a dangerous situation. It is essential that such holes be reamed to close limits if a serviceable airplane is desired.

The inspector will also ascertain that all nuts are properly safetied to prevent their backing off and that clevis pins are all fixed in place by cotters. He will check the tautness of tierods and wires and will see that they are taped at points of intersection to prevent chafing.

Another very important point that appears to be a common difficulty at the present time is the chafing of moving members against fixed parts of the structure. For instance, if the aileron control tube were allowed to rub against drag wires or wing ribs, it is natural to expect that after some hours of service the control tube might be so badly worn as to be no longer safe and require replacement. Such a condition has actually existed and should, of course, be prevented by the designer. In any event, however, an efficient inspection system will prevent the designer's error becoming serious.

The power plant installation is an important part of the airplane and is sufficiently complex to merit a great deal of the inspector's time, but as this subject is covered by another paper it will not be discussed here.

Final inspection is given the aircraft after complete assembly. This should not be superficial in any sense of the word, but particularly thorough with attention to parts that require safetizing and to the working of the control system. An aircraft should not be test flown without the factory inspector's final approval and a stamp or tag denoting its service status affixed.

To summarize briefly, an efficient factory inspection system can be divided into three distinct groups whose functions are more or less sharply defined.

The first group will examine incoming materials and will combine chemical and physical tests with visual inspection.

The second and largest group will inspect detail construction and workmanship, and the third group will conduct assembly inspection.

As any one of a thousand details may be fatal to aircraft safety, it is essential that all points be covered and that the aircraft industry realize the futility of attempting to manufacture satisfactory aircraft without a staff of efficient inspectors.

In order to promote safety in aircraft operation, the Department of Commerce has developed an inspection system which provides for a rigid inspection both in the factory and during operations.

This system consists of an Engineering Section for the purpose of checking stress analysis and design data, an Inspection Section to carry on inspection in the factory and the field, a Liaison Office to coordinate the work of these Sections, Supervising Inspectors, Factory Inspectors and Field Inspectors. Chiefs of Sections and Liaison are located in Washington; the subordinate groups are all in intimate contact with the industry in the field.

Materials and specifications are accepted which conform to those of the United

States Army or Navy, the Society of Automotive Engineers or other recognized standards.

Although approved specifications as to materials should be adhered to, it is obviously impractical to develop general design specifications, as in the military services, that would be applicable to the many types of commercial aircraft. There are, however, certain stipulated requirements to be met by a manufacturer of commercial aircraft, propellers or engines, before his product is considered eligible for an Approved Type Certificate. These requirements serve not only as a guide to the manufacturer, but also provide definite limits of safety to which his product must conform.

Discussion of the practical application of a Federal inspection system inevitably leads to consideration of the personnel involved. A factory inspector must possess particular qualifications:—previous experience, ability, good judgment, and sincerity of purpose. He must be familiar with both general and detailed methods of construction from the blue-print to the finished product. His recommendations and reports are forwarded to the Chief of Inspection Section in Washington.

In order that some details may be checked in operation, field inspectors are sometimes notified that certain parts be watched under operating conditions. This information often proves of particular value to the manufacturer.

Although Government and private inspectors work independently, there should be a unity of purpose and complete cooperation between them. Such dual inspection system will not only result in a saving of time and money to the manufacturer but will also give assurance to all concerned that the machines produced are structurally sound.

The Federal factory inspector first definitely ascertains whether the raw materials as used by the manufacturer conform to the materials assumed in the original design of the aircraft. This includes metals, woods, glues, material coverings, protective coverings and all other materials incidental to the fabrication of the aircraft.

Stock is checked over and its specifications noted and checked against the purchaser's invoices. Samples are chosen at random for a determination of their physical and chemical properties and static tests are made at frequent intervals.

Constant inspection is made during the various stages of fabrication of the aircraft. The methods used, the workmen, the workmanship and the machinery are all under careful scrutiny. Details of design and physical dimensions of the airplane parts are checked to see that they conform to drawings.

The next to be noted are the materials used by the manufacturer in guarding against corrosion. This applies to the outside surface of internal members, the inside surfaces of dural and tubing members, and the protective covering on the external surfaces of the aircraft.

The Air Commerce Act of 1926 requires that all aircraft engaging in inter-state commerce be licensed. Since airworthiness is one of the pre-requisites to license, a given airplane which satisfies other Federal requirements becomes eligible upon passing the final inspection.

Licensing is facilitated by the Government factory inspector's assigning commercial license numbers to machines as they come off the production line.

When an aircraft is ready for delivery, the inspector accepts, in proper form, an application for this license in the name of the owner. He then installs in the license holder, clearly visible within the aircraft, a temporary license card. This authorizes operation pending receipt of the permanent license card issued by the Department of Commerce from Washington, D. C. This application for license, together with the inspection report, is forwarded to Washington for record and the aircraft is ready for service.

The next subject to be considered is:

Operations Inspection

In operation, after license, the Air Commerce Regulations require that the aircraft be subject to the following series of inspections which assure its being kept in an airworthy condition. The owner or licensed airman must satisfactorily complete the first three inspections while the latter three are completed by the Federal inspector.

Daily Inspection:

After an aircraft is licensed and between the times that it is inspected for airworthiness by a Federal inspector, the owner is charged with the continuous duty of maintaining it in a good and proper state of repair. The owner, or a licensed mechanic, must give the aircraft a line inspection at least once within each 24 hours preceding flight and the result entered in the log book over the signature of the person making the inspection. This inspection covers the control system, landing gear, propeller, motor and accessories, together with a warming up test, instruments, fuel and oil lines, cooling system, fuselage open to visual inspection and accessible rigging.

Inspection after 100 Hours of Operation:

After each 100 hours of flight, the airplane must be given a "periodic inspection" by the owner or operator and the result entered in the log book by the person making such inspection. This is a more detailed inspection to ascertain the condition and state of repair of the engine installation, propeller alignment, complete control system, fuselage complete, and main plane assembly.

The Quarterly Report:

This report serves as an excellent check on operations of the aircraft and previous inspections. The pilot's personal log book may also be used as a further check on operations. The owner or operator of every licensed aircraft must keep a navigation and engine log book and quarterly transmit to the Secretary of Commerce a navigation summary report in duplicate, showing the number of hours and the approximate number of miles the aircraft has flown during the quarter, the duration and the use of each engine, the engine installation and repairs, and the plane structure and rigging changes and repairs. Both aircraft and engine log books are required to be in the airplane when it is away from its home airport.

Accident Reports:

The Department of Commerce requires that all accidents in the operation of licensed aircraft be reported without delay. After repairs have been made following the accident, the owner makes a full report of the kind and extent of repairs. It cannot then be flown again carrying passengers for hire or reward until it has been inspected by a Federal inspector and found to be airworthy.

Relicensing:

Upon the expiration of the term of an existing license, the aircraft may be relicensed after it has been inspected by an inspector of the Department of Commerce and found to be airworthy.

The inspections covering operations made by the owner or operator are for his protection and the protection of passengers carried by him. For this reason, he will generally make these inspections to the best of his ability. In many cases, however, due to the owner's unfamiliarity with the subject, lack of time, stress of operations, or costs, he may neglect repairs, which though seemingly unimportant at the time may result in later damage, or injury to personnel.

Suggestions from Operations Inspection as to How the Manufacturer may Increase the Structural Reliability of the Airplane

In the performance of his duties, the field inspector is especially well qualified to make recommendations toward improving the structural reliability of the airplane. In his practical flight test with many applicants for pilot's licenses, he will have flown most types of commercial aircraft. His detailed inspections covering nearly all types will have included many inspections of some one type.

In many cases, inspectors have found serious defects in structural design that, though not apparent in the original drawings nor detected during factory inspection, appeared after operation in the field. These defects are followed through until the difficulty has been remedied. In several types of light planes, inspectors have found that wheel spokes were soon loosening under service. Stream lining was removed from the wheels on the occasion of each inspection of these planes, thereafter, in order that the spokes might be examined. In nearly every case, the owner was not aware that such a condition existed, having reasoned that his plane was too new to need an inspection of the spokes. Again, through constant inspection of types, inspectors have found that the rear fuselage construction of a certain type of plane is such as to make inspection of the rudder wires and the elevator push-pull rod exceedingly difficult.

Investigation showed that controls were interfering and not receiving proper lubrication. Subsequent inspections of this type of plane indicated that this condition existed in all models.

In this particular case, the inspector suggested to the manufacturer that an inspection panel be added to future planes to permit proper inspection of control units at that point and also to allow maintenance during operation. It is quite obvious that parts which are inaccessible will not receive the attention that they should, but that such parts when inspected and serviced occasionally will give better service than those which are not.

The cases mentioned are only a few of many found in the field during inspections. It is only through continuous inspection during operations that such defects are discovered and suggestions made to the manufacturer which enable him to improve his product.

In his daily personal contact with many operators and mechanics the inspector obtains opinions from as many points of view, and taken collectively this information passed on to the manufacturer may be of much benefit to him.

In his investigation of all accidents of a serious nature, the inspector occasionally finds it advisable to send some parts of the damaged airplane to the Bureau of Standards for analysis. The manufacturer is, of course, advised of the findings, and without this investigation it is doubtful whether such information would ever have been available to him.

In most cases, it is quite apparent that the manufacturer does not at the present time have enough contact with his product after it has been sold and sent into operation. His present volume of sales does not warrant his having field personnel for the purpose and his dealers are too few and his planes too widely scattered for such information to be gathered and returned to him in time to be of value.

It seems evident, therefore, that only with a complete system of inspection both in the factory and in the field will it be possible for the manufacturer to obtain all information essential to his increasing the reliability of the airplane and only then when regulation is provided which guarantees a definite standard of safety.

Suggestions as to How the Operator May Maintain the Structural Reliability of his Craft

By selecting the best possible maintenance and operating personnel; by using the best of materials for servicing and repair; by a thorough inspection system; through proper maintenance methods and through adequate housing facilities.

In the operation of aircraft it is vitally important that the best of personnel be selected. This holds true for the success of any enterprise, but it is especially true in Air Transportation. Mistakes made by personnel must be detected and eliminated before damage results. The mechanic must not only be thoroughly qualified for his work, but must be entirely dependable as well.

Good maintenance requires that equipment be taken care of before it actually needs attention. The aircraft should be "serviced" at the completion of a day's work. Such details as completely filling the fuel tanks so that condensation does not result is only one of many known to a good mechanic. The craft should be cleaned at the first opportunity, removing mud, oil or grease from the covering. Servicing is completed by cleaning and adjusting the engine and its accessories and making such changes in the aircraft as may be necessary. Detailed inspection is usually completed before the next flight together with a warming up of the motor and a check of the instruments. In operation, the use of the best oils and greases is not only cheaper in the long run, but also results in increased reliability.

Engine and aircraft log books should be accurately kept. The latter is a record of operations and shows inspections and overhaul, as well as parts replaced during any given period.

Housing is also important in maintaining good equipment. Hangar facilities should be provided to keep the aircraft out of the weather whenever it is not in use.

Summarizing briefly, the selection of materials should be carried on with the utmost care. An adequate inspection system should be maintained in the factory and by operators in the field, and the manufacturer should be kept constantly advised concerning the result of operating conditions upon his product.

It may be thought that the Federal inspection system, although not outlined in detail, is nevertheless over-stressed in this paper, but as it has been arrived at only after much experience and careful study it is considered a worthy guide to private practice.

In closing, it is urgently recommended that factories that have not already done so, institute their own inspection systems, following the general principles laid down in this paper, that inspectors employed report directly to the manager of the plant and not to a foreman or production manager, as they should not be influenced in any way by a tendency to speed up production at the expense of rigid adherence to safety standards. It is my opinion that insofar as material is concerned "inspection" is virtually synonymous with "safety" and that in the last analysis practically all material failure can be traced to faulty inspection.

Commercial Airplane—Structural Reliability from the Operator's Point of View

By WESLEY L. SMITH.

Superintendent, Eastern Division, National Air Transport, Inc., Cleveland, Ohio

Structural reliability in commercial airplanes has gradually increased, due to our advance in Aeronautical Engineering, so that commercial airplanes very seldom have structural failures in the air. This however, is not true of commercial airplanes on the ground, since most of our structural failures have to do with the

Airplane in landing, taxiing, or taking off. It is a paradox to say this, but it is nevertheless true, that if commercial airplanes or any other airplanes, never made contact with the ground, they would probably last forever. I might point out in this connection, that so called flying accidents are in the majority of cases not flying accidents, but accidents that happen after the flying is finished.

Structure of the Airplane

Let us consider the structural reliability of the commercial airplane, taking each important unit of that airplane in turn. Starting at the front end of the airplane, the first unit to be considered is the propeller. Propellers are very easily damaged in accidents, but the actual cases of structural failure are very few. In order to fly through rain and sleet and to taxi on fields whose surface is composed of cinders, sand or gravel, the propeller must have a metal leading edge from the hub to the tip of each blade, if the blades are of wood or of that composition known as "micarta." A propeller whose blades are of duralumin, needs no such protection, although it is subject to considerable pitting and wear from loose abrasive material that may be on the surface of a flying field.

Duralumin blades have a very good feature; that they bend instead of breaking. In any but the worst crashes, bent blades can usually be straightened and placed back in service, but this process is a difficult one which requires annealing, straightening and then heat treatment. There are not enough service stations throughout the country equipped to do this work, probably because the necessary equipment is rather expensive. The increasing use of this type of propeller, will probably provide the necessary business, so that there can be more of these service stations.

Some of these propellers that have duralumin blades, together with those that have micarta blades, have a steel hub and the pitch of the blades in the hub may be varied when the propeller is assembled. This is a good feature, enabling the same propellers to be used at maximum efficiency on engines of the same horse power, but in planes whose speeds, loads, and other operating conditions vary. This type of propeller, however, needs further engineering work on the steel hub. These hubs have a tendency to loosen after 1,000 hours or so of flying and means of locking the hub against this loosening is not satisfactory at present.

Cooling System

When the plane has a water cooled motor, the next unit to be considered is the radiator, and radiator leaks are structural failures which are quite common. These may be eliminated in part by properly mounting the radiator on shock absorbing material and by being careful not to pour hot water into a cold radiator when the temperature is below the freezing point. This latter procedure causes rapid and unequal expansion in the radiator, resulting in leaks.

In connection with the radiator, I might also mention the radiator shutters which are necessary, to properly control the engine temperature. If the radiator be mounted directly behind the propeller, considerable difficulty will be encountered with structural failure of the shutter blades. I have not yet seen an airplane with a radiator mounted in this position, which did not need to have the radiator shutters re-designed in order for them to stand the whip that they receive from the close passage of the propeller blades, at high speed. Shutters on the so called tunnel radiators or on radiators mounted above the engine, do not suffer such heavy casualties, probably because they are further removed from the propeller.

Where shutters are mounted on a nose radiator, the blades are usually too thin in cross section and have too great unsupported lengths to prevent flutter from the propeller whip.

These shutters must be controlled from the cock-pit and in flying under icy condi-

tions, they must be opened and closed frequently to prevent their freezing into a solid mass thereby causing the motor to overheat. The usual type of shutter control is not strong enough to stand this sort of usage or to exert enough force to break the shutters loose, should they freeze solid.

The Power Plant

Power plants are being discussed by others in this session, so consideration will be given here only to power plants as they relate to the airplane as a structural whole. The most common structural failure in any airplane is a power plant failure, though with our latest power plants when properly serviced, failures occur at the rate of about one for each 100,000 miles of flying. Most of these failures are not in the engine itself, but rather in the accessories; one of the most common ones being failure in the plumbing, which includes water, gasoline and oil lines. These sort of failures can usually be eliminated by the elimination of solid connections. If each pipe that connects the various parts of the power plant or the power plant to the airplane is broken somewhere in its length and a rubber hose connection inserted, or rather placed over a metal sleeve that covers the two ends of the pipe, these sort of structural failures are practically eliminated.

This metal sleeve should be brazed fast over one of these two ends and fit slightly loosely over the other end. This will prevent any rubber from getting into the lines, will permit the rubber to absorb the vibration, and does not reduce the size of the line, as do the more commonly used olives, which fit inside of the two pipe ends.

Air cooled engines eliminate the radiator and shutter troubles but all of the present air cooled engines are designed with the air intake directly under the plane. This feature makes it impossible to take off on snow covered fields, because the propeller fills the carburetor with snow. In the summer this location of the air intake causes a great deal of abrasive dust to go directly into the engine and causes excessive wear on all internal moving parts. We have found it necessary to add an air scoop through the top engine cowling and piping to the carburetor, to eliminate these troubles. The carburetors on air cooled engines need to be redesigned, so that the air intake goes through the top cowling instead of through the bottom.

Tanks

Fuel and oil tank leaks are structural failures, which do not occur as frequently as heretofore, when such occurrences were common. The complete mastery that the Industry seems to have attained in building these tanks out of aluminum seems to have practically eliminated this sort of a failure.

While it has not been proven by tests, it is very probable that the use of aluminum fuel tanks has eliminated a definite fire hazard that was present in steel fuel tanks. This of course is for crashes, where the steel is liable to send out a shower of sparks. We do know, that our Airplanes that are equipped with aluminum tanks have not had as many fires in crashes as those that had steel tanks, so that the saving in weight which the aluminum tank provides is not its only good feature.

Cowling

A very common structural failure, though not a serious one, is the failure of the various cowlings on any airplane. I have yet to see the airplane on which the cowlings themselves and their fasteners are strong enough to stand the wear and tear, that is their lot. Some of these cowlings fail purely from vibration in:

the air stream and others fail from their constant removal and replacement in servicing the airplane.

All cowlings should be designed as rigid units in themselves, so that their shape does not depend upon the way they are fastened to the fuselage.

Landing Gears

Since most of the structural failures of the airplanes occur on the ground, it would be natural to suppose that the landing gear would be the part to fail most often. This was formerly the case and it used to be a very simple thing to break any landing gear with a rough landing. The introduction of the Oleo Shock Absorbing Unit has practically eliminated landing gear failures. This unit which is almost universally used now on every modern airplane, absorbs and dissipates the first hard landing shock. Night flying operations with heavily loaded planes and high landing speeds, such as we now have in commercial aviation, would hardly be possible without the Oleo gear. The Oleo gear has, however, added new maintenance problems since the viscosity of any oil varies with the temperature. Proper maintenance requires the use of a light oil in winter and a heavier oil in summer, together with a periodic elimination of leaks.

For taxiing, taking off, and any but the first shock of landing, the landing gear must also have another shock absorbing unit, which may be either an air cylinder, a spring or rubber in either tension or compression. Rough frozen ground and the use of concrete run-ways, make the work of these units very hard. They usually do not fail, but may reach their limit, coming against some sort of stop and then transfer to the other members of the airplane, forces that they are not designed to take, with the result that we have structural failure where the landing gear attaches to the fuselage. The growing use of a smooth sod surface on airports will gradually eliminate these sort of failures. In general, there is need for more shock absorbing action in this secondary landing gear unit, to absorb the stresses involved while the plane is taxiing on rough ground.

Tires and Wheels

Tires and wheels are very important units of the landing gear. I believe it is safe to say, that wheel failures have been practically eliminated. Tire failures, due to structural failure in the tire itself, are also practically eliminated. Airplane tires are constantly exposed to the weather and get very little actual use, so that they do not wear out, but rather rot out from this constant exposure to the weather. The Oleo Unit in the landing gear has probably eliminated the great percentage of the failures that we used to experience in tires and wheels. Larger tires and wheels are now being used, than was formerly the case for the same load and this has probably done a great deal to eliminate these failures.

Ice Formation

The wing structure of an airplane is the unit that carries most of the load most of the time, and yet in these modern days of aeronautical engineering, wing structural failures happen probably less than structural failures in any other part of the airplane. If the airplanes have external wires in the wing truss, these are a constant source of structural failure in flying through weather conditions where ice forms on the airplane; the wires, being metal, radiate heat faster than does wood or fabric and as a result, these wires are the first parts of the airplane on which ice forms. This ice formation is seldom uniform, with the result that vibration results and these wires break, forcing the airplane down long before the weight of ice accumulated on the plane as a whole, would accomplish this result.

Each one of these wires is usually in duplicate on the plane, so that the pilot has some little time for his landing after the first of a pair of wires breaks. Were these wires not in pairs, we would probably have many serious accidents each winter. In night flying, it is rather hard to see broken wires and our pilots have many times completed trips by sheer good fortune, with part of the wires broken, and unconscious of this fact. Unless we can find some means of keeping this ice from forming on the airplane, it is almost a foregone conclusion, that airplanes whose structure requires external brace wires will vanish from the commercial field, where regularity of operation must be maintained regardless of weather conditions.

There is also a tendency in designing airplanes with external struts to make these of uniform section and thin wall, with the result that these struts are apt to suffer from vibration in flying under ice forming conditions, and also, such struts are apt to buckle in hard landings. More thought needs to be given to the design of external struts in airplanes, when these are necessary, to eliminate the failures that I have just mentioned. These struts need to be designed so that their cross section at any point is ample to meet the stresses that the strut may encounter at that point. The wooden struts that were in use before the tubular strut became common, were always properly built in this respect and never gave us the trouble that we have encountered with these tubular struts of uniform section.

The Fuselage

The advent of the welded steel tube fuselage and those of duralumin have practically eliminated what few structural failures there were in fuselages. Even in the early days of flying, there were few cases of structural failures in the fuselage. The new types of fuselage construction are however, much stronger and suffer a great deal less from crashes. They have the added feature that they are much easier to repair after a crash, than were the old stick and wire fuselages. There is the one thought however, that flying which depends on any sort of a magnetic compass or even the Earth Inductor compass, is handicapped greatly by the possibility of a welded steel tube fuselage becoming magnetized, even while the airplane is in flight, so that it seems that for this reason alone, our ultimate airplane will need to have a fuselage of non magnetic structural material.

The Tail Skid

The tail skid or tail wheel assembly is an equal sufferer with the landing gear in taking most of the punishment and hard usage, that is the lot of any airplane. Where a tail skid is used, structural failures on rough frozen ground are quite common. I am not aware of any tail skid unit that has yet been designed that meets the test satisfactorily in all cases. The addition of brakes to our airplanes makes possible the use of a castor wheel instead of a tail skid and I believe that the impending universal use of this wheel instead of the tail skid is going to eliminate the failures at this point. It is common, where a tail skid is used on frozen rough ground, to have the shock absorbing unit of the tail skid fail, or reach its limit, and for the forces then to cause failure in the rear end of the fuselage, because they are applied on members not designed to take such forces. The period of thawing and freezing that we usually get in Spring is the one in which we encounter these conditions of rough frozen ground. The ground is cut up by the landing gear and tail skid during the thawing period and these ruts freeze solid to cause all of our grief when the next freezing arrives. Proper maintenance of Airports might eliminate this, but the periods of thawing and freezing may follow each other within a few hours and the removal of all ruts from the flying field in this short period of time is well nigh impossible as well as almost prohibitive in cost. As the sod on our flying fields gets older and thicker, this source of structural failure will probably disappear.

Control Surfaces

Control surfaces very seldom suffer from structural failures in commercial airplanes that are doing ordinary flying. This has been so since the day of the first commercial airplane, but there is always the danger with control surfaces and even the wing structure itself, that some enterprising young aviator may attempt acrobatics such as only military airplanes are designed to stand, with resultant failure of either wings or controls. Commercial airplanes are designed with safety factors that are usually adequate for all commercial operations, but there will always be danger of structural failure, when pilots attempt military acrobatics with commercial airplanes. The Department of Commerce has taken a very firm stand on this point and very justly so.

Controls that are operated by wires, operating over pulleys, are apt to suffer from structural failure of these wires as they gradually wear in going around the pulleys. Proper maintenance in changing these wires at the first signs of wear will eliminate this, but the more proper way of doing this will probably be to design the airplane so that the controls will not operate by wires, which must pass over pulleys.

Fuel Tank Vents

One of the serious errors that is made in designing airplanes, is to leave the vents to fuel tanks exposed, so that they will easily become sealed with ice, or even dirt. We have had forced landings from such cases as this. All vents need to be placed so that they open into free air, but at the same time are protected against ice and dirt.

Conclusion

As a general thing, there is room for great improvement in the design of commercial airplanes, in providing more accessibility to parts that need service and replacement and also to parts that need frequent inspection, such as the various controls on the airplane. At the present time, our mechanics spend almost as much of their time getting at the things that they have to do in the daily servicing of the plane, as they do in the actual service work.

General Discussion

CHAIRMAN KLEMIN: The meeting is now open for a general discussion of these interesting papers.

JOHN BONFORTE (Airways Extension Superintendent, Department of Commerce, Washington, D. C.): I would like to ask Mr. Smith to give his opinion as to the proper location for a pilot in a passenger airplane.

MR. SMITH: The best location would depend on several things, where the passenger plane is to be used, and whether the plane has a single engine or several engines, and whether it is capable of sustained flight with one engine out of commission. I believe, first and foremost, that the pilot should ride ahead of his passengers, as a general thing. We should not be carrying passengers unless we are carrying them under conditions of the utmost safety, and if anybody should be injured it ought to be the pilot.

C. W. HALL (Hall Aluminum Aircraft Corporation, Buffalo, N. Y.): Mr. Wright brought up, without referring to it particularly, one feature of aircraft design that we have inherited from the time of the wooden structures, and that is, designing for ultimate loads rather than designing to yield points. Wood, of course, has no definite yield point, and the practice probably arose from that. But in going into metal construction there seems to be many advantages in designing

to a definite load factor which might be less than the nominal load factors in current use, and not stressing any part of the material over the yield points. That would certainly assure a perfectly definite safe condition up to the design loads.

It would also allow of a considerable amount of proof testing of finished planes. That would serve to check defective material and is not a very expensive thing to carry out.

Several references have been made to the corrodibility of the strong aluminum alloys. Of course, all common metals are subject to corrosion. I doubt whether we will ever have a common structural metal that will not be more or less subject to it. This year's experience in using the pure aluminum coated strong alloys under the name of "Alclad" is very encouraging in that respect. It seems to be almost immune from the troubles that we have been more or less used to. Mr. Wright also referred to continued use of wood for wing beams after other parts have been constructed in metal. It is sometimes suggested that wing beams are more difficult to build in metal, but I do not think that this is really true. Mr. Wright also referred to the likelihood of composite structures being used. In almost all other lines of structure we are getting away from combinations of wood and steel or Monel metals and steel or other combinations, which have all been tried out in yachts and automobiles. We are getting back to building our structures of a single material throughout, so far as it is feasible. I think the same thing is likely to be true in aircraft.

In Mr. Howard's paper there was some reference to the difficulty of forming aluminum alloys and the necessity for heat treatments intermediate to forming operations. It is not always appreciated that intermediate heat treatments on aluminum alloys are very much like those applied to other metals; that is, unless there has been quite a large amount of cold work done, one simply coarsens the material by intermediate heat treatment. It seems to me it is more logical in such cases to buy the material in the hard condition, not having been subjected at any time to a solution heat treatment, and give the solution heat treatment immediately before forming, rather than start with annealed material and getting through a beginning operation.

BURKE E. WILFORD (Philadelphia): I would like to ask Mr. Wright what method has been found of insulating vibrations from the fuselage.

MR. WRIGHT: With the water-cooled engines there has just been introduced in the mounting some rubber composition. This, I think, is not adequate. I think the coming thing will be an entire rubber insulated mount. Our recent efforts have demonstrated the practicability of this method, in that we have arranged our motor mounts so that they were entirely surrounded by rubber, and this seems to reduce vibration to a great extent. I think with more experimental work and development of more suitable grades of rubber the transmission of motor vibrations to the rest of the structure can be eliminated, and I believe it will be, probably within a year or two. But I think a great many of the most recently developed automobiles have entire rubber swathed engine mounts, and I see no reason why we shouldn't follow suit. I might add that wooden mounts have been used for minimizing vibration with great success. In lots of ways wood seems to be almost ideal for absorbing shocks. But, nevertheless, I believe that the rubber mounts will ultimately be used.

C. E. NOORDYN (Atlantic Aircraft Co., Hasbrouck Heights, N. J.): Mr. Howard stresses the superiority of chrome-molybdenum steel tubing in a paper devoted to safety. Of course, it is clear to engineers that as far as safety is concerned it can be attained with low carbon steels just as readily as with chrome-molybdenum steels. It is only a matter of the stresses employed. As a matter of fact, I have seen some cases lately which led me to think that there might be some disadvan-

tage to chrome-molybdenum. It seems to crack up in a different way in a crash. I have always felt that we probably learn more about airplanes in the examination of a wreck than from ordinary operation. I have seen lately a chrome-molybdenum fuselage which had a brittle appearance close to the welds in the section made of low carbon steels and several breaks a few inches or so away from the welds. Perhaps in fifty per cent of the cases they were a few inches away from the welds, and in the other they were in the middle of the column. In column failure the chrome-molybdenum is not of much advantage as there is little difference between it and the low carbon steel tubing in strength.

With regard to Mr. Smith's paper, I do not think he has sufficiently stressed the fact that in the latest type of plane, all the difficulty he has met through all those years have been very largely eliminated. Those things that he has described are absolutely the troubles that occur, and they are the ones that the designers who want to give the present purchasers the benefit of that experience have attended to in their latest designs.

R. A. FOWLER (Miller Corp., New Brunswick, N. J.): The designer may calculate a flying wire to take a certain load. But this does not necessarily mean that that wire is going to be sufficiently strong from the maintenance point of view. The designer of today should study very closely the maintenance problems of airplanes.

The question of load factor is certainly very important. The load factor requirements of the Department of Commerce are higher than the military requirements. From the military point of view, the high load factor is maintained by good work in the field. On the other hand, the designer of the commercial plane is confronted with improper maintenance on the field, which is due largely to the lack of competent personnel to carry on the inspection that this needs.

G. P. HERRICK (New York City): I would like to ask Mr. Smith if he feels that the position of the high wing or the low wing had any bearing on the reliability of the structure.

MR. SMITH: I will have to answer that by saying that on the New York-Chicago line we have had no experience with either high or low wing monoplanes.

CHAIRMAN KLEMIN: I would like to ask Captain Carroll what he thinks the safety factor of an airplane is at the present time.

THOMAS CARROLL (National Advisory Committee for Aeronautics, Langley Field, Va.): Load factors due to acceleration have been measured of as high a value as five and a half. We have actually measured in some of our experiments load factors as high as eleven, but this has been in relation to extremely high speeds. But it does seem that the factors which were given by Mr. Wright are those found in ordinary commercial practice. We, therefore, would have to consider our safety factor as one and a half or two.

There is one item that is interesting and that we have been working on, and that is the problem of ice formation and its solution.

The formation of ice on the plane is exactly as Mr. Smith has said, first noticeable on the wires. We have done a considerable amount of work at Langley Field in a study of that problem. By using altitudes to find the selection of proper temperatures and clouds to provide the proper humidity, and we have been able to collect ice almost at will. We also have a wind tunnel which enables us to collect ice on various surfaces. We are studying preventive measures, but it seems to us that the solution of the ice problem is largely in avoiding it.

We have found that ice collects in a region very close to thirty-two degrees Fahrenheit; it is only within a degree or two on either side. It is unusual that it occurs at temperatures other than those in very close proximity to that temperature. Therefore, it is our suggestion that all planes be equipped with an air temperature gage which is visible to the pilot and which will apprise him of the fact that he is in a dangerous temperature area, and then it is quite probable that

he will have a greater opportunity to look for clouds and fog. I believe we all feel that the avoidance of ice formation is the ultimate solution.

MR. SMITH: I would like to say to Mr. Carroll that we equipped one of our airplanes with a thermometer and found that we got ice when it was fourteen below zero and all the temperatures up and down. I think the problem is a deeper problem than you realize or than any of us realize.

LIEUT. E. DICHTMAN (U. S. Army, Dayton, O.): I would like to get the airplane designer to make the inspection of the airplane. He puts in little inspection doors that become dirty and that you can't even get your hand into. If the engineer would occasionally attempt to absorb the operator's viewpoint, attempt to conduct an inspection of the airplane, he certainly would be more intelligent when he got back to his office.

E. P. LOTT (National Air Transport, Inc., Chicago): There is one point which Mr. Wright brought up about the load factor in commercial airplanes. He mentioned that the load factor of two and a half can be expected in normal bumps in commercial aircraft and that three and a half can be expected in vertical turns. It seems to me that greater shock can be expected in rough air than one ever gets in a plane in vertical turns.

CHAIRMAN KLEMIN: I would like to comment on Mr. Lott's remark that he thought in bumpy air the stresses might be greater than in a maneuver. We have experimental evidence obtained by Lieutenant Doolittle that the stresses in bumpy air are nowhere near the magnitude it is possible to impose by violent and premeditated maneuver. I think the order of magnitude of the heaviest bump he got in a flight between Philadelphia and some place over in Pennsylvania was the order of two, whereas he got eight in getting out of a dive.

MR. LOTT: We have in some cases broken wires on ships in purely rough weather, and I don't recall any broken wires in vertical turns. I think the shocks brought on a ship in rough air are greater and do more damage than any smooth flying and vertical turns that could be carried out in ordinary service.

MR. WRIGHT: I think there is a good deal in the point that Mr. Lott brings up. It may be that in a biplane, if it is rigged rather loosely, so that the landing wires slacken up considerably when the wires are under a normal tension, that in bumpy air there is a whipping that causes a, perhaps, greater load than we realize. But, in general, I believe that the action of acceleration does not exceed two and a half in bumpy air.

There was one point I wanted to mention in connection with dirt and designer's inspection. I recently had the pleasure of flying across the country as mechanic and assistant pilot, and I am sure the company got a lot of good out of it, particularly in the matter of cowl fasteners.

There was a point which Mr. Hall brought up in regard to designing to the yield points in contradistinction to designing to the ultimate strength of the material, which I think is very well taken, although I don't yet quite see how it can be handled. It is also connected with the matter which Mr. Noordyn mentioned as to the desirability of alloy steel, and which I brought out in the paper is desirable because there is a smaller disparity between the yield point and the ultimate strength in a heat-treated alloy steel.

There is no doubt, as Mr. Hall brings out, that the factor of safety is directly connected with the yield points rather than with the ultimate strength, as almost any structure, if it is stressed to any great extent over the yield point, will give permanent set, which will cause loads in other members, not accounted for in design, and therefore cause failure.

I don't agree with Mr. Noordyn in regard to the use of chrome-molybdenum steel. I believe there is a real weight saving by using chrome-molybdenum steel, and it is going to come more into use in the future. It can be welded just as satisfactorily as low carbon steel, and I believe that the cases he cited were probably

peculiar to the particular welding rather than to the fact that they used chrome-molybdenum steel.

Regarding Mr. Howard's paper, I certainly wish to endorse the opinion that commercial firms should adopt inspection methods and hire inspectors to the same extent or almost the same extent that military manufacturers have been required to do in the past. I think the whole game is going to suffer very decidedly if the grade of inspection is permitted to deteriorate.

Someone voiced the opinion that likely government control over airplane manufacture would tend to increase rather than decrease. I think that would be unfortunate if that were to occur, but the best way that the commercial manufacturers can avoid additional government control is by adopting the proper inspection and design methods which should obtain in any structure as delicate as the structure of an airplane.

F. J. D. FULLER (White, Weld & Co., New York City): I am a layman and I want to know how safe the airplane is under the worst possible conditions to which I could subject it.

HON. W. P. MACCRACKEN, JR. (Asst. Secy. of Commerce for Aeronautics, Washington, D. C.): I will tell Mr. Fuller that not only is it difficult to find a common factor of expression of safety, but the unfortunate part of it all is that these engineers have different ways of figuring their factors of safety. That really makes it very difficult to reduce it to any common denominator which you can use in conveying the idea to the layman. All that we can do is to try to arrive at factors of safety which we believe will make the airplane safe, otherwise we don't approve it. But when it comes to the relative degree of safety between types of planes, it certainly is impossible to do it unless you take the only method that I know of that is infallible, which is the trial and error method; that is, drop testing your planes and testing the construction of every member and factor of it. When you do that you are going to increase the cost and tend to decrease improvements in design, because if the manufacturer knows that every time he makes an improvement in design that design has to be tested to destruction, he is not going to be so ready to make the improvement, for that is a very expensive method.

CHAIRMAN KLEMIN: Structural failure is very rare. If you follow the load factors as laid down by the Department of Commerce, the Department of Commerce approves your plane. You are reasonably safe in having under commercial use at least a safety factor of two and probably more. All planes designed by competent men and turned out by good manufacturers have about the same degree of safety. There is nothing much to choose between if they have passed the Department of Commerce.

Now, if you want to commit suicide in an airplane you can always do it by breaking the structure in a violent maneuver.

W. C. NAYLOR: One of the most important advances that I know of is the Oleo shock absorber. I have figured out the other day that if a plane is fitted with Oleo shock absorbers with a stroke of twenty-four inches, you can come out of a flat spin without hurting your ship, providing, of course, that the ship is not going too fast. An ordinary flat spin landing could be taken up by a twenty-four inch stroke. I have seen Oleo shock absorbers ride across frozen ground with a six-inch rut, and the riding qualities of the ship are one hundred per cent better with such shock absorbers.

I have seen the old type of tail skid going across frozen ground, and you hear a report like a rifle and look out and see the tail skid go shooting out across the field. The application of a tail wheel helps matters considerably.

Some of the manufacturers have gone even farther than that and have incorporated the Oleo with the tail wheel.

Mr. Wright brought up one very important point, and that is the application of rubber to the motor mounts. To date, I believe the Ford Company has used one motor mount incorporating four rubber supports. In other words, the steel motor mount as in use today has four cylindrical rubber mounts on each leg. Although this ship has not had a great deal of service, indications point that it will be far better than the ordinary fiber or wooden mount. In the smaller type ships, where four, five and seven cylinders are employed, that is particularly applicable. Vibrations produced by a five or seven cylinder engine are naturally much in excess of those nine-cylinder engines. Torque vibrations in particular are very excessive, and we have the problem of eliminating this vibration. The real trouble lies in the engine itself, and vibration should not be transmitted to the rest of the plane.

MR. SMITH: I would just like to say to Mr. Noordyn and the rest of you that it isn't all brief. We operate a regular schedule as near as anyone can do that, and we couldn't do that if we didn't have planes that we could use regularly. I mentioned a lot of things that are wrong. There are also a lot of things that are right. I think we are making progress in aviation, and there is nothing for anybody to get worried or excited about in our present healthy state of growth. It is just that we who are operating them want to see the perfect airplane, and I think we are getting it.

C. W. MORRIS (Student in Aeronautics, New York University): I would like to ask Mr. Smith one question regarding the tail unit. You spoke of using the tail wheel instead of the tail skid, and you also spoke of airports that have a spongy sod. Don't you think that when they do have a spongy surface like that, that we will have to use a wheel instead of a skid, because the skid is more liable to tear up the surface of the ports, particularly with concrete construction?

MR. SMITH: Of course the tail wheel does present a problem on the muddy field. In regard to the use of the tail skid on a sodded field, it is a matter of what sort of a shoe you put on that tail skid. You can put a proper shoe on the skid that will not disturb the sod. So far as the concrete is concerned, it has been my observation that most airport operators wish they did not use concrete.

ADJOURNMENT

Aerodynamics

DR. S. W. STRATTON, Chairman

President, Massachusetts Institute of Technology, Cambridge, Mass.

The Aerodynamics Session was called to order at two o'clock by Dr. S. W. Stratton, President of the Massachusetts Institute of Technology. Two papers were presented "The Desirable Aerodynamic Characteristics of an Airplane from a Safety Point of View" by Professor Alexander Klemin, and "The Desirable Flying Characteristics of an Airplane from a Safety Point of View" by Thomas Carroll.

Dr. S. W. Stratton in opening the meeting said:

"I have long been interested in safety engineering and have kept in fairly close touch with aviation, as a member of the National Advisory Committee for Aeronautics. During the war, and especially in the period that followed, we were appalled by some of the accidents that occurred and the committee undertook to encourage and promote safety in aviation in every way possible. This was not an easy matter. I remember quite well when even the safety council considered this as entirely beyond its province, although it has now taken it up with interest. Safety is the most important problem in aviation, and the greatest impetus that it has had is through the Daniel Guggenheim Fund, which is largely responsible for this meeting."

Desirable Aerodynamic Characteristics of an Airplane from a Safety Point of View

By ALEXANDER KLEMIN

**Professor of Aeronautical Engineering, Daniel Guggenheim School of
Aeronautics, New York University**

The aerodynamic characteristics of an airplane which are desirable from a safety point of view are clearly understood by designers, and the literature of the subject is extensive. In the following notes, an attempt is made to recapitulate these characteristics and to recall the various aerodynamic and design methods at our disposal to secure such characteristics.

Slow Landing Speed

Three or four years ago, opinion both in England and in the United States seemed to be that the airplane had for the time being reached the useful limit of speed. One of the British Civil Aviation reports announced the design of a freight carrying machine with a pay load of 8 pounds per horse-power which was to have quite a moderate rate of speed, well under 100 miles per hour. But at the present time, American planes of all types, whether small two seaters, four or five passenger cabin monoplanes, or large three engine transport planes, sell largely on speed and quite rightly so. High speed is the main justification of the airplane, and a most important factor in its economic success. To secure speed, high power, perfect streamlining and small wing

area are the three essential elements. In the race for performance, designers will always be tempted to increase the wing loading.

It can never be insisted upon too often that safety demands low landing speed.

To achieve low landing speed by very low wing loadings is undesirable. Low wing loading means decrease in top speed, larger dimensions in every way, higher structural weight, and increased cost of construction.

Low wing loading may also be highly undesirable in gusty weather. If the speed is low at the instant of landing, and a powerful head-on gust strikes the plane, there will be an instantaneous increase in lift which may raise the plane a considerable height above the ground. The subsequent drop may be highly dangerous. A plane with very low wing loading is also liable to damage when on the ground in high winds, although the experiences of a private owner of the English light plane, the Widgeon, recently described in *Flight*, seem to contradict this view. Other arguments in opposition to low wing loading may be readily cited.

On the other hand low speed is highly desirable when making an emergency landing, particularly in rough ground. There is no doubt also that slow landings will be far more welcome to passengers than landing at the speed of an express plane.

It would seem desirable to give a pilot the choice of either a moderately high speed or a very low landing speed by the incorporation of some device to increase the maximum lifting capacity of the wing.

In an article in *Aviation*, the author has discussed a variety of such devices, and in the light of subsequent information is even more convinced that the utilization of some such device is bound to become a matter of commercial practice in spite of the complication and increase in weight which may be entailed.

A classification of such devices includes: variable area; conversion of a monoplane into a biplane with very low gap/chord ratio; variable camber; an auxiliary tandem wing; a front slot of the Handley Page type either manually or automatically controlled; rear flaps; combinations of slots with variable area; the use of rotating cylinders in conjunction with an airfoil; prevention of boundary layer detachment by artificial suction or ejection of air; and the use of airfoils of very high maximum lift.

It is impossible to say which of these devices will ultimately be adopted, or whether other interesting devices may not be forthcoming. At the present time it would seem that the use of the rotating cylinder is impracticable. Varying the camber is a cumbersome process not justified by the comparatively small results achieved. Methods of suction and ejection are at present in the laboratory stage only. The use of rear flaps alone does not give a large enough increase in lift. Variable area wings give splendid aerodynamic results, and have actually been used with some degree of success in flight. The utilization of this aerodynamic device depends solely on the mechanical skill of our designers.

The use of the front slot alone, while it may be very interesting from the point of increase in lift, offers the drawback that this increase in lift is achieved at a very high angle of incidence. To take full advantage of the front slot it is necessary to design a stilt like chassis, which means an increase in weight and head resistance. The front slot in combination with a rear flap, may be made to give an increase in lift of nearly 100 per cent, and the use of the rear flap brings down the angle of incidence of maximum lift to quite reasonable values. Particularly when the front slot is automatic in action, the use of a front slot plus a rear flap (which also may be automatic in action) seems highly promising from the point of view of slow landing.

Short Landing Run

While there may be some difference of opinion as to the desirability of low landing speeds, there can be none as regards the desirability of a low landing run.

As we know, very satisfactory results have been achieved with wheel brakes, and their importance cannot be overestimated. When wheel brakes were first introduced it was thought that they would produce a serious danger as regards nosing over. In practice it has been found that a slight forward displacement of the wheels relative to the center of gravity is sufficient to obviate such danger. The forward movement of the wheels imposes a slightly heavier load on the tail skid, but apparently no difficulty is experienced in raising the tail off the ground. The provision of a small wheel at the rear of the machine avoids all danger of tearing up the surface of the airdrome when taxiing.

Entire reliance cannot be placed on the wheel brakes because the coefficient of friction with locked wheels may vary with different ground conditions. It is by a judicious combination of the wheel brakes and of aerodynamic characteristics that the best results will be achieved.

The use of air brakes is a clumsy expedient, although it has often been suggested. One suggested form is that of flaps at the sides of the fuselage, to be swung out and back at the instant of landing, by means of cable control. The area required is so large as to become impracticable. Swivelling struts have been employed on an Italian machine, but the extra air resistance they would give is too small to be really helpful.

A spoiler on the wing, however, in the form of a narrow flap placed on the upper surface of the wing at its center has been shown to be very effective in diminishing lift and increasing drag.

With a machine unprovided with lift increasing devices, the only methods available to the designer are diminish the landing speed by using large wing area or wings of high lift, or a combination of both, and to make the chassis of such length that the plane can be set down beyond the stalling angle. Beyond the stalling angle the lift drops off so that the ground reaction disappears, while at the same time the L/D of the wing diminishes very rapidly. There are obvious limitations to the extent to which these expedients may be used.

Landing directly from a stalled steep glide, so that a considerable portion of the velocity is vertical, and there is a large landing shock, is a powerful method of shortening the run, provided the undercarriage will stand it.

Where lift increasing devices are used much more powerful aerodynamic braking effects are obtainable.

For example if rear flaps are used, they may be depressed after landing to an excessive angle. A manually controlled slot would be held open, prior to landing and then closed. Both these operations would tend to decrease lift and increase drag.

In tests with machines equipped with flaps, the effect of flap manipulation on length of landing run has apparently been small, but with greater experience on the part of designers and pilots their breaking characteristics will be found to have real importance.

Fine Gliding Angle

The desirability of a fine gliding angle is obvious. With an engine failing suddenly on a cross-country flight, the gliding radius increases as the gliding angle diminishes, and therefore the chances of finding a suitable emergency field are increased. Another argument, however, for a fine gliding angle is often overlooked.

With a fine gliding angle, the angle through which the plane has to be turned before making a landing is small and the longitudinal control necessary is also small. The effect of misjudging the height on landing is less serious. A machine landing on a very gentle glide, without flattening out is not so liable to severe damage and nosing over, as one landing from a steep glide. The methods of attaining a fine gliding need not be discussed. They are mainly a matter of good wing section, and refined streamlining.

The author has had the privilege of wind tunnel testing a number of commercial airplanes in the last four or five years. It may be stated that the maximum L/D of such designs has increased roughly by one point in each succeeding year. A maximum L/D of 8 would have been considered quite a reasonable value for a single engined commercial biplane with open cockpit in 1922.

At the present time, a single engined enclosed cabin design, supported by a cantilever monoplane wing, with a cantilever chassis, careful cowling of the engine, filleting of the wing to the body, a well streamlined body, tail surfaces worked in nicely to the fuselage, tail skid nicely streamlined, shock absorbers entirely hidden in telescopic strut or body or wheel, wheels carrying a streamline cover, engine and accessories so designed as to lend themselves to a good nose, should have an L/D in the wind tunnel of at least 12. Nor should this high maximum L/D be accompanied by an undue increase in structural weight. Skill in structural design has kept pace with improvement in streamline. Tapered cantilever wings for example for machines of medium size should weigh no more in pounds per square foot than an externally braced biplane of the year 1921.

The De Havilland Tiger Moth, the Lockheed Vega, are but two of the many examples of refined streamlining in commercial craft which come to mind.

Further aerodynamic progress in airplane design, apart from the attempt to employ lift increasing devices on the wing, will lie in such detail refinement. In particular a great deal of progress may be expected from the use of in-line air cooled engines, completely cowled in, with well planned entrances for the cooling air and from a study of the air flow after it has entered the fuselage and is suitably guided to exits. A fruitful subject of research lies in the study of the nose of cabin machines, in reconciling aerodynamic requirements with the requirements of good vision. Interference between parts, wings and body for example, is also a subject of great possibilities for both wind tunnel men and designers.

We may venture the prediction that a commercial airplane of the future will be as carefully streamlined as a racer.

Good streamlining has other relations to safety besides that of providing a good gliding angle. Increase in speed is always helpful to safety, since gusts affect a machine less the faster it flies. Also with good streamlining, maximum speed can be maintained with larger wing area and consequently lower landing speed.

Steep Gliding

The value of a fine gliding angle is not disputed by designers or operators. Opinion is somewhat divided on the desirability of an aircraft being able to glide down steeply and slowly, with its nose slightly above the horizon. It is the author's opinion, after very careful consideration, that such a characteristic is highly desirable and will sooner or later be incorporated in the design of commercial airplanes.

There is one contingency which is dreaded in commercial flying, and that is being forced to land when enveloped in a dense fog.

In air mail work, the obvious resort is that of making a jump in a parachute. There are a number of jumps on record in such circumstances, and mail has been recovered under such circumstance, although the plane has crashed badly. In passenger air transport, with three or more engines, it is to be hoped that power

plant failure will never be encountered. But in the single engine cabin monoplane, engine failure in fog is bound to be encountered sooner or later; and resort to jumping on the part of the passengers is very improbable.

Under such conditions, an airplane which can glide down slowly and steeply, with its nose above the horizon, will furnish a very important degree of safety. From such a glide no recovery should be needed, provided a long enough shock absorber travel is provided. The plane should land in the very attitude of the steep glide, and providing the landing is made in any sort of open space, the chance of accident will be very much diminished.

The steep slow glide should also be very useful when an emergency landing is to be made in a small field with obstacles, such as trees or telegraph poles.

In such a case the pilot has several alternative plans that he can follow. He can glide down in a fairly steep dive, and flatten out to a high angle of incidence very rapidly just before reaching the ground. This may result in a "zoom" or in excess speed at a high angle of incidence, in which case the plane may float a long way close to the ground. Evidently such a plan is undesirable. Flattening out from the dive to only a moderate angle of incidence, means a two point landing at high speed. It is then difficult to apply the brakes violently, and the emergency landing field may again prove far too short for safety. Again the pilot may elect to make a perfectly orthodox landing, convert his steep glide into a gentle glide, and then flatten out to the conventional three-point attitude. This also may bring him dangerously near the end of the field. In the hands of a very skilled pilot maneuvers such as spiralling down tightly, fish-tailing, or side slipping may be resorted to. But we do not believe that such maneuvers are desirable when a plane is carrying passengers cross-country.

If the steep, slow glide can be achieved with control suitably maintained, we believe that it will offer the solution of a real difficulty.

Apart from the question of maintaining lateral control on the slow glide (which will be dealt with later), there are a number of difficulties in design to be met.

If the glide is steep, say 16 degrees to the horizontal, the vertical velocity is apt to be very high unless the stalling speed of the airplane is low, say round 38 miles per hour.

Therefore the steep, stalled glide is only likely to be of value if some lift increasing device such as that employed for slow landing is incorporated.

Even if lift increasing devices are used on the stalled glide landing, a considerable amount of vertical velocity remains to be dealt with. Therefore designers will have to provide a large shock absorber travel to prevent damage to the plane.

Yet another difficulty in the stalled steep glide is that of actually maintaining it.

The modern airplane if reasonably well designed has when trimmed for cruising, a powerful diving moment at high angles of incidence. This is as it should be and is a safeguard against stalling. In gliding beyond the stall, the diving moment increases rapidly because the center of pressure on the wings moves back. In wind tunnel tests it is frequently found that even when the elevators are turned up to their maximum extent, it is impossible to bring the machine up to the angle of incidence corresponding to maximum lift.

British full flight experiments indicate that even when the stabilizer is turned down at the leading edge to its fullest extent and the elevator turned up to the fullest extent, it is impossible, on many machines, to maintain steady stalled flight without moving the center of gravity back by the use of water tanks. Increasing the total area of the tail surfaces will not help, since the inherent stability of the plane is thereby increased.

Designers who wish to develop a machine capable of maintaining stalled flight will find it necessary to provide a rapid adjustment of the stabilizer through a larger angle than usual, and to increase the proportion of elevator to total hori-

zontal tail surface area. Such provision will also help in securing slow landing speed.

If a front slot and a rear flap are employed in a design, the difficulty of maintaining a stalled glide will probably be greater still because in such a case the wing becomes relatively more powerful in its lift and moment producing characteristics than the tail surfaces, and because rear flap depression may mean a backward movement of the center of pressure of five to six per cent of the chord. The probability is that when front slot plus rear flap are employed in a design, increased tail surface area will have to be provided, as well as rapid stabilizer adjustment and increase in the proportion of tail surface area.

Designers who wish to make their machines achieve a slow glide at 16 degrees or more to the horizontal will also find that the average machine is far too efficient at high angles of incidence. The L/D of the wing is likely to be 7 or 8 at maximum K_y and opening the front slot will rather tend to improve the L/D. Parasite resistance at low speeds is small relative to the wing drag, and the provision of air brakes is futile. To use a spoiler on the wing, such as discussed in relation to length of landing run is not sound; the spoiler may increase the drag, but it will also decrease the lift. We believe that for slow steep glide the use of depressed rear flaps will be found absolutely necessary, whether the front slot is used or not.

It may be interesting to recall that experiments by Anthony H. G. Fokker in a Fokker D VII and by Captain De Haviland in a Moth equipped with slotted ailerons indicate that steep stalled glides can already be realized on some machines without difficulty, and that the under carriages of current practice are already not far from meeting requirement.

Short Get-away Run

There is no argument possible as to the value of a short get-away run, and it is quite clear that our modern airplane still has far too great a get-away run. While calculations of the get-away run are not made frequently, the factors involved are quite generally understood. The requirements are

- (1) a low flying speed, obtainable by methods analogous to those necessary for getting low landing speed.
- (2) aerodynamic efficiency increasing the acceleration with a given thrust.
- (3) a geared down large diameter propeller.

It is quite clear also that a variable pitch propeller would be extremely useful in making a quick get-away.

Steep Climb

For military work rapid climb is absolutely essential. For commercial purposes, steep climb is much more important, since this means the ability to get out of a small field surrounded by obstacles. Observers at a flying field always misjudge the steepness of a climb. Particularly when a fast machine is climbing into a head wind, observers are apt to liken it to a helicopter. As a matter of fact, in calm air the angle of climb of an average machine is not likely to exceed fifteen degrees, and just skimming the top of a hangar is a spectacle too often witnessed at a flying field.

Lift increasing devices cannot be used to increase steepness of climb. Once the machine is off the ground, climb will be better with slot closed and flap in neutral, since the profile drag is thereby diminished and the induced drag is mainly a matter of span loading or aspect ratio, and for steep climb a large aspect ratio is most helpful.

Again climb depends on the weight carried per horse-power, and as in many other aspects of airplane design, lightness of structure is of prime importance.

Structural failures in the air are now so rare, that it is now probably more important to keep down structural weight and weight per horse-power than to increase weight. Large transport planes are not likely to be exposed to the high loads of stunting, but they may get into trouble when getting out of a field heavily loaded.

The greatest climb is obtained when there is maximum excess power. The steepest climb occurs on the other hand when there is maximum excess of thrust over drag. The maximum excess of thrust over drag occurs at a larger angle of incidence and lesser speed than those corresponding to maximum excess power. It might be well if designers of commercial planes placed a little more emphasis on this point.

For example it is conceivable that propellers could be specially designed for steepest climb, and not for maximum climb.

As for a quick get away, geared down engines, and variable pitch propellers may be very helpful, certainly more important than when maximum climb and not steepest climb is sought.

Stability in Normal Flying

The stability of free oscillation of the airplane has been well understood for many years. Securing such stability is mainly a question of the correct location of the center of gravity, of longitudinal dihedral, lateral dihedral and vertical fin area.

An airplane which is stable in small free oscillation, is one which when slightly disturbed from a normal flying attitude will return to that normal attitude without any controlling action by the pilot.

British practice has frequently been in the direction of pronounced stability, and British authors have always advocated stability. As early as 1913 we find records of experiments made by the British Royal Aircraft Factory, in which stable machines were flown hands off in rough weather for considerable distances.

German writers recommend only a moderate degree of stability, coupled with good controllability.

No advocates of unstable machines will be found anywhere, although military pilots may vote for a neutral machine, with great controllability and maneuverability.

For commercial machine flying long distances cross-country, a machine without pronounced stability may be particularly dangerous in foggy weather and will certainly be fatiguing at all times.

The exact degree of stability which a commercial machine should have is still an open point however.

Granted that a commercial machine should be stable, the pilot should always have at his command, controls powerful enough to overcome the stability of his craft under all circumstances. Particularly when near the ground, an excessively stable machine may try to take charge. One of the reasons why the Burgess-Dunne plane did not remain in construction is that it was so stable as to make landings and get-aways dangerous in rough weather.

There is another argument against excessive stability. A machine which is very stable may be quite safe, yet very uncomfortable in rough weather. Let us imagine for example that a plane has large directional stability, and suddenly encounters a powerful side wind. It will head promptly into the resultant wind, which will be the proper thing from a safety point, but not the best from the point of view of keeping a given course. A machine which is very stable longitudinally, struck

by an upward gust, will nose down more than a less stable machine, although the chances are that it will accelerate far less upwards. From the point of view of the passenger, it would appear that there is still a great deal of both theoretical and practical work to be done in regard to the degree of stability which designers should aim at.

Longitudinal Problem at the Stall

Pilots associate trouble at the stall with a spin, and have little recognition of the fact that there is a definite problem of longitudinal stability and control at the stall. Nevertheless there is such a definite problem, related to, but distinct from the problem of lateral control at the stall.

In a recent paper before the Society of Automotive Engineers, the author drew the following conclusions from a series of wind tunnel experiments:

- (1) Even when trimmed for steep climb, modern airplanes having the center of gravity far forward are stable at the stall.
- (2) With the center of gravity far forward, the tail surfaces carry a down load, even when trimmed for steep climb; therefore they are not themselves stalled when the wings fall.
- (3) The elevators do not cease to be effective at the stall. Turning the elevators down will increase the righting or diving moment even at very large angles of incidence for the main wing, partly because the tail surfaces are initially carrying a down load, and partly because of the downwash. Of course the elevators are less powerful than at high speed.
- (4) The righting moment or diving moment persists far beyond the stall of the main wing.
- (5) The backward movement of the center of pressure on the wings is a help rather than a hindrance to "unstalling."
- (6) With the modern longitudinally stable machines having the center of gravity at 30 per cent of the chord or thereabouts, there is not much choice between airplanes of many different design of tail planes or elevators.

With all these apparently favorable characteristics of the modern airplane it seems remarkable that any difficulties should be encountered at the stall.

All these considerations are based on static tests only. Analysis of the dynamic conditions is necessary, and a study of the longitudinal equations of motion at the stall.

When the wing stalls, the lift falls off and the drag increases, which reduces the speed. The combination of the two factors causes the path in space to be curved downward sharply. The inherent stability of the plane tends to lower the nose of the plane. But the angular rotation produced by the stabilizing moments may not be as rapid as the angular change of the flight path, so that the plane does not unstall. If the ship remains on an even keel laterally, a steep stalled dive may result. The correct action of the elevators is increasing the angular rotation of the plane, so that the wing may "catch up" with the downward curvature of the path.

From a study of the equations of motion, it would seem as if the following conditions were beneficial at the stall:

- (1) A large degree of inherent stability at high angles of incidence.
- (2) Large and powerful elevators.
- (3) Large horizontal control surfaces, but with a short arm from the center of gravity of the airplane. With short coupled large control surfaces, the stabilizing moment may be just as large as with a longer arm and smaller

control surfaces, but the damping moments are less. Therefore the stabilizing moment will tend to unstall the plane more rapidly.

- (4) Thrust line of the propeller well below the center of gravity. In case of sudden engine failure, a diving couple will at once be introduced with such disposition of the thrust line.
- (5) Wings with large camber, and large well rounded leading edge. Such wings, as shown by experiments in a number of wind tunnels do not lose lift rapidly at the "bubbling" point and therefore one important contributing factor to the stall disappears. Even wings of this design, however, increase in drag at the stall, so they are far from being ideal. Also wings of this type are apt to have either a low maximum K_y , or if they have a high maximum K_y to be very inefficient.

The slotted airfoil, particularly when automatic, provides a real safeguard against stalling, because it stalls at a higher angle of incidence than the unslotted wing, because it stalls at a lower speed for the same wing loading, and because, owing to the higher angle of incidence, the inherent diving moment at the stall becomes greater.

Characteristics of the "Canard" Plane

A revival, in Germany, of the "Canard" type of plane, with horizontal surfaces ahead of the main wing, is another attempt to improve longitudinal conditions at the stall. With the conventional design of airplane there is generally an increase in the slope of the moment curve when the stalling point is reached, because the center of pressure on the wing then moves back. With the "Canard" type of plane, the horizontal surfaces stall before the main wing. Therefore the sharp increase in the slope of the moment curve may be made to occur before the stalling point itself. The "Canard" type of plane has the further advantage; that a third landing gear wheel may be placed at the front end of the plane, thus providing an additional safeguard against nosing over, and facilitating the violent application of brakes.

We have discussed the problem of the stall under the apparent assumption that a stall there must be at times. In normal level flying, with a pilot of fair skill, and a machine having the generally desirable characteristics stated above, it is very hard to see why a stall should occur.

In rapid climb, and particularly on the steepest climb of which a machine is capable, sudden failure of the engine is very likely to produce a stalled condition.

Airplane manufacturers are apt to state with some degree of pride that their machines cannot be spun. We believe that what they should really state is that their machines cannot be stalled voluntarily, since a stall is a preliminary to a spin. Planes that cannot be stalled voluntarily are really deficient in elevator control. When they are stalled on the climb, such planes are likely to be quite dangerous.

Our general conclusion is that particularly when slots, a large degree of stability, and powerful elevator controls are available, there will be sufficient safeguard against stalling.

It should be pointed out here that the use of the front slot has another advantage in maneuver at the stall. The conventional and generally the best manner of coming out of the stall is to pull the elevators up so as to decrease the angle of incidence, making a dive with nose down the preliminary to recovery; with a slot which increases the lifting capacity of the wing at the critical moment, it may be possible to hold the stick back and make a steep descent with the nose of the machine above the horizon. This may be particularly useful when a stall occurs in climbing out of a field, and a steep descent in the same direction of motion is the best plan.

Anti-Stall Devices

At least two anti-stall devices have actually been used in the air. That invented by Dr. Rohrbach is described by M. L. Bramson as follows: "The object of Dr. Rohrbach's invention is to prevent stalling. He achieves this object by means of a horizontal vane stably suspended in the air-stream at the tail of the machine and adapted to control what might be called the gear ratio between the control column and the elevator in such a manner that the tail plane movement produced by a given movement of the control column diminishes as the incidence increases." Such a device is evidently a safe guard against an erroneous use of the elevator by the pilot. On the other hand, if the stall is due to engine failure on the climb, then the elevator control will be least operative, just when it should be most powerful.

The Savage-Bramson Anti-Stall gear is described by Mr. Bramson as follows: "The stall detector is a horizontal vane facing the air stream, statically balanced on a horizontal pivot and unstable with reference to the air stream. It has a free movement of about 7 degrees and the stops are so positioned that at normal flying angles the air pressure on the van is directed downwards; the vane therefore rests against the lower stop. On reaching the angle of incidence (say 14 degrees for a normal machine) at which the pilot ought to be warned that he is about to stall, the lift on the vane changes sign and the vane flicks up against the top stop through an angle of 7 degrees. This movement of the detector is utilized to operate a pneumatic relay, which in turn, applies pressure to a piston attached to the control column. This pressure represents a forward force of 7 to 20 pounds at the pilot's hand, depending on the size of the machine, and can be easily overcome by him if he so desires; but it is impossible suddenly to provide that extra pull backwards without knowing it. The pilot is therefore effectively warned, and if the circumstances are such that a stall would be obviously dangerous, he will comply with the hint and put the stick forward. When the incidence has decreased by 7 degrees the detector vane flicks down again and the pressure on the piston in the warning unit is released to atmosphere. The pilot then feels the sudden disappearance of the force previously applied and knows that he is well away (over 7 degrees) from the stalling incidence."

For a plane unequipped with the front slot, however well designed, there is no doubt that the Savage-Bramson anti-stall gear should be most useful. It is rather surprising that it has been so infrequently employed on American machines.

A plane equipped with manually operated front slots should be safer at the stall than a plane not so equipped. The pilot, when he finds his machine badly stalled has two immediate steps at his command. (a) pushing the stick forward so as to get the maximum unstalling moment from the elevator; (b) opening the slots so as to unstall the wing, and secure a greater lift coefficient from the wing. The two maneuvers should effectively prevent the path of the plane from curving violently downward in space. But with manually operated slots, safety still depends on the pilot. The Bramson-Savage should still be useful, particularly if it could be made to control the slots.

If a plane is equipped with the automatically operated front slot, the dangers of the stall from the longitudinal point of view are greatly diminished. In such a case the Bramson-Savage gear does not seem necessary. But it would constitute another safeguard nevertheless. Even though with slot open, flight at a high angle of incidence becomes comparatively safe, it is generally better to reduce the angle and glide down at a higher speed which always improves the controls.

Lateral Control at the Stall

The British have issued a large number of publications on this subject, and it

may now be said to be thoroughly well understood, much better understood than the longitudinal problem at the stall.

From a safety point of view it is probably much more important to check the spin at its very beginning than to design machines which come out of the spin very readily.

The following are the main contributory items of the incipient spin, following a stall:

- a. If the stall follows on sudden engine failure, the torque of the engine disappears. If it was balanced in normal flight by appropriate wash-in or wash-out of the wings, a tendency to fall off on one wing is always to be expected.
- b. When a wing is stalled, the rolling moment resisting roll disappears; there is more likely to be a moment producing autorotation.
- c. The roll will produce more drag on the low wing.
- d. The ailerons lose in rolling moment and their adverse yawing moment increases.
- e. The rudder is blanketed by the fuselage and tail surfaces, and may be not powerful enough to overcome adverse yawing moments due to the roll and the ailerons.

If the longitudinal conditions at the stall are only those of the usual machine, and the above unfavorable factors are found, we can see why it may be difficult to check the incipient spin.

The remedies for lateral difficulties can be indicated with much more assurance than the remedies for longitudinal difficulties.

For a machine not equipped with a front slot, or with slotted ailerons:

- a. The most careful design of the conventional ailerons, so as to give as little loss in rolling moment and as little adverse yawing moment as possible.
- b. A very powerful rudder. In normal flying too large a vertical surface introduces stability difficulties unless balanced by an appropriately large dihedral. A very large dihedral means increase in weight and decrease in performance. The American designers will have to give this question of oversize rudders very careful consideration. Wind tunnel tests frequently indicate that rudders designed from the customary empirical formulae are not powerful enough.
- c. Wings having a flat lift curve which may be useful even with some sacrifice in wing efficiency.
- d. The use of differential ailerons.

The use of symmetrical tip controllers floating in the air stream is to be considered very seriously. Theoretically they are every bit as promising as the slot and aileron controls.

The slot and aileron control has been proved, to the writers' mind, to be quite effective in maintaining rolling moment and reducing adverse yawing moments to a negligible amount.

A radical departure from the conventional designs of today cannot be urged too strongly in regard to the problem of the stall.

Turning in Restricted Areas

After an engine failure in climbing out of a field, it is almost a maxim that the pilot should go straight on, if there is any kind of a field ahead. Turning is considered, and quite rightly so, a dangerous invitation to a spin. If however the approaches to a field are quite unsuitable for landing, the pilot may be absolutely forced to make a gliding turn back into the field. It will be a great step forward if machines can be designed that can perform such a maneuver. Complete con-

trollability at slow speeds is again a requirement. Next the machine should be able to make a 180 degree turn with minimum loss of height. The subject has been considered by Moriatry and Glauert, among other writers. The height loss of the gliding turn as shown by Glauert is proportioned to $\frac{W K_a \csc \theta}{S K_l^2}$, where

θ is the angle of bank. The minimum loss in altitude occurs therefore when the angle of bank is 45 degrees, and K_a is a minimum which occurs very near the $\frac{K_l^2}{K_l^2}$

stalling attitude. It is advantageous to have a low wing loading, and a high lift coefficient for the wing.

Getting out of small fields may be accomplished by a steep climbing turn. Again complete control near the stall is required. Low loading per square foot, or high lift capacity, or both, and low power loading are desirable in order that the turn may be made with the smallest possible radius.

In practical flying, in fog and sometimes in clear weather, in avoiding collisions, safety may depend on the ability to make a very sharp turn. Again control at low speeds, low loadings and high lifting capacity will be helpful.

In the above paragraphs for low loading per square foot we may consider it feasible and desirable to use conventional loading with an automatic slot.

Spinning

It is impossible in this brief paper to discuss the spin adequately. From the now voluminous literature of the subject, it would appear that both in the spinning nose dive and in the flat spin, the following are helpful for recovery:

- a. forward position of the center of gravity.
- b. good aileron control at large angles.
- c. powerful elevator.
- d. powerful rudder, which is not blanketed at high angles of incidence.
- e. moments of inertia as nearly equal as possible about the three axes, so that precessional inertia effects may be reduced.
- f. wings not too susceptible to autorotation.

Conclusion

From this brief review of the desirable aerodynamic characteristics of an airplane, two striking facts seem to emerge:

The aerodynamic characteristics desirable for one element of safety are likely to be desirable for another element of safety.

The present state of the art is already such that a machine having the greatest possible measure of aerodynamic safety can already be designed.

The writer has the conviction that within the next two or three years an aerodynamically safe airplane is sure to be available.

General Discussion of the Paper

(After Prof. Klemin read his paper, the meeting was opened for discussion by the chairman.)

R. D. SMALL (Aviation Finance & Trading Co., Chicago): I would like to ask Professor Klemin to give us the status of the variable pitch propellor in respect to safety.

PROFESSOR KLEMIN: Its only relationship to safety is that a variable pitch propellor on the ground may stop the plane in a shorter distance and may also enable it to land more steeply. The difficulty is that these properties are most needed when the engine has failed. Therefore the variable pitch propellor, while likely to improve efficiency and climb, has only an indirect bearing on the problem of safety.

MICHAEL WATTER (Chance Vought Corporation, Long Island City, New York): Designers know very well that they are capable of solving the problems of performance, but, the case of stability is somewhat different. While longitudinal stability can be calculated, the designer has difficulty in solving the problems of lateral control mathematically.

General safety will only be achieved when the designer is able to control and calculate all the factors of stability. While spinning is an unnecessary and undesirable factor in commercial planes, in military maneuvering a certain kind of plane must be spun continuously and the pilot must be able to come out of this maneuver. The problem of spinning is very complicated and is of such vital importance that I would like to bring up a few points which are misinterpreted at times. There is undue stress given to aerodynamic factors in spinning, while it is the dynamic factors that are the main source of danger. In this regard I would like to suggest the use of the front slot on the tail surfaces. If the pilot should find himself in a spin and is unable to come out he could open the slot and, since the angle of attack of the plane is very high, I think the slot would give him the additional control necessary.

In normal spinning the angle of attack is around thirty-five degrees, and in a flat span it may be almost seventy degrees. The use of the slot on the tail surfaces would seem to be a logical thing.

In talking about stability and controllability, etc., I believe it is vital for designers to have definite factors to deal with and I would suggest that, while stability is more or less experimental, still we know by comparison just how to deal with controllability.

J. S. McDONNELL (J. S. McDonnell & Associates, Milwaukee, Wis.): I should like to ask if a plane which can land at thirty-five miles an hour is necessarily dangerous near the ground.

PROFESSOR KLEMIN: Not for an airplane which has high wing loading.

HARLAN D. FOWLER (Miller Corporation, New Brunswick, N. J.): I wish to thank Professor Klemin for mentioning my own development. I have been working on this device for twelve years. My device provides additional wing area when landing or taking off.

CHAIRMAN STRATTON: Professor Klemin mentioned the relation between the designers and the pilot. It is quite true that in the early days the pilots were very

skeptical of the scientific men; but now the gap between the designer and pilot is passing away. It is from the user of a device that we learn of its faults and it is for the laboratory man to correct them if he can.

We have with us this afternoon an example of the pilot who is interested in the development of the scientific side. The test pilot on the National Advisory Committee for Aeronautics, Mr. Thomas Carroll.

The Flight Characteristics of an Airplane from a Safety Point of View

By THOMAS CARROLL

**Chief Test Pilot, National Advisory Committee for Aeronautics,
Langley Field, Va.**

In the airplane of today, and of the immediate future, there is no quality which is so essential to the rapid success of aviation as safety. Speed, range, beauty and reduction in cost are important, but at the present time are entirely secondary.

We choose to approach the subject of safety in aviation without recourse to the fanciful possibility of hovering flight. We pass with only a remark on the truth of the safety of any flying machine which can arise and descend vertically, remain stationary in the air, and so forth. We feel that to discuss this particular phase of flying here, prior to its greater development, would be to devitalize an issue which is important and whose ends seem to be attainable with the more orthodox practices of the present time as a basis. Our consideration is, therefore, confined to airplanes as we know them, although we concede that their use will always incur certain elements of danger.

There are certain characteristics which all airplanes must embody to some extent. In order to be considered safe they must have all of them to some degree, although deficiency in one element may be effectively offset by superiority in another.

It is, of course, not our purpose to consider those qualities which are not flying qualities, but which contribute to safety, including structural strength, protection from fire, facility of maintenance and inspection, and so forth.

The flight characteristics of a safe airplane include the following: Stability, controllability, maneuverability, reasonably low landing speed, visibility, and comfort.

In defining these qualities, it is our intention to depart from or to elaborate upon the pure technical definition of the terms. Thus, stability may be considered as the characteristic of an airplane by which it tends to remain in constant steady flight at a speed within the cruising range and to return to that attitude if it is disturbed. This condition is generally referred to as the trimming speed and may be varied by the manipulation of the movable stabilizers or the elevator control. It is desirable that this variation in speed be capable of being carried down into the range near the stall and under later developments and improvements in design, to below the stalling speed. The importance of this is clearly discernible in any case. In level flight through "bumpy" air, should the airplane lack stability, it is bound to incite over-control by the pilot of lesser experience. Over-control in itself, must be regarded as a hazard, for it destroys smooth handling, induces flight with irregular, even though mild, acceleration, which from its involuntary constancy, disconcerts the pilot, creates a tenseness, and destroys his confidence in himself and in his airplane. Under such conditions he is less able to cope with the task in hand, even when no unusual occurrence, such as a forced landing, intervenes. Should such a thing occur, he is almost at its mercy in his weakened and uncertain condition.

Stability, at or near, and particularly when possible below the stalling speed, is an immense safety factor. When it is borne in mind that a landing is no more than a deliberate stall executed as close as possible to the ground, the value of stability is appreciated. Stability here may be negatively defined as the absence of any tendency to depart from the speed and attitude chosen by the pilot, which is most frequently manifested in a "falling off" on a wing due to lateral instability.

The next quality to be considered, controllability, is too frequently confused with maneuverability. It is closely allied with maneuverability, as it is, inversely, with stability. An airplane can hardly be maneuverable without controllability, but it is frequently controllable without maneuverability to a commensurate degree. The deficiency is found in excessive stability whether provided by large size or inherent stability characteristics due to other causes.

Controllability consists in two factors, the response to control movement, rotating the airplane about its axes, and, the reaction in the control system to the degree of force necessary to be applied by the hand of the pilot. An airplane which is responsive to the heavy touch of one pilot may be slow and unsatisfactory to one of more delicate touch. Again, while controllability may be slow, usually referred to as "sluggish," due to excessive stability, on the other hand, usually quick response due to oversized or balanced control surfaces without the impediment of stability, may be as unsatisfactory or worse, due to the condition which is often referred to as "flicky."

Maneuverability consists of a blending of stability and controllability which permits more involved maneuvers; as for example, a continued turn, either steeply banked or while climbing within a reasonably small radius, not to mention the more involved maneuvers of "stunting." Overloading in either wing or power loading detracts from maneuverability, as can be readily appreciated.

Reasonably low landing speed can not be defined in the abstract. It is entirely dependent upon the case. A speed which would be entirely adaptable to one case would not apply at all to another. It can be considered, however, that for all cases, landing speed which may be considered reasonably low should fall within the range of from 30 to 60 M. P. H. The behavior of the airplane while landing with regard to stability and positive controllability through the landing condition, is of much greater importance than any definite determination of what this speed should be.

Visibility, or more accurately, improved field of vision for the pilot, is of great importance from a safety point of view. It is usually considered only in the reduction of blind angles. It appears more important that certain ranges of vision, forward and down, particularly, should be definitely open. Forward vision while taxiing is very important and is too often neglected. Defective visibility while flying is one characteristic which often may be offset by good maneuverability permitting a zigzag course, but this remedy is, of course, inapplicable to commercial airplanes, particularly of the larger sizes.

The comfort of the pilot is not generally considered as a safety characteristic and yet it is readily imaginable, that a pilot who is cramped and uncomfortable can not be acute in the prosecution of his piloting duties, nor in his watchfulness for the hazards of collision, and so forth. Simply roominess is not comfort. Proper seat height, leg room, rudder and control stick position are of even greater importance. To explain, even though the actual seat and cockpit may be as comfortable as a fireside chair, should the control stick be centered so far forward as to require reaching, as is so often the case, the pilot, during a long flight, is very uncomfortable. The relief of heavy control forces by means of stabilizers or "bungees," rubber cord or springs is very important (and it must be considered that under some circumstances, any continuous force upon the control stick or rudder is heavy). Proper wind shielding, if the cockpit is open, is of very great importance.

The safe airplane is in itself of indefinite distinction. What may be properly considered safe in one instance is distinctly unsafe under others. While again, the airplane which is safe in one type of service may be clumsy and ungainly in another.

We will therefore consider two rather widely differentiated cases. On one hand, the private owner pilot of small or mediocre piloting experience and ability, who flies a small airplane intermittently of occasion and for pleasure only; and on the other hand, consider the operator of a large flight service who contracts to transport passengers and valuable express matter under the hand of a thoroughly skillful pilot. It is readily appreciated that the specifications for safety in these cases are at variance. The private owner pilot demands safety from the hazards of an unfinished piloting technique almost to the exclusion of any other source of danger with the possible exception of those hazards which are incidental to landing and taking off in such small and unimproved fields as he may possibly choose to use.

The commercial operator on a large scale must require of his equipment that it be capable of maintaining its schedule under any and all conditions. It is to be assumed that he has incurred no additional hazards in the selection of his piloting staff, that his pilots are thoroughly trained and experienced, and are capable to overcome routine difficulties. It is impossible to avoid bad weather and its attendant danger and his equipment must, therefore, be capable of surmounting unusually bad ground conditions at his terminal airports. It must be capable of flying through fog, and other bad weather conditions while on the course and particularly to cope with the ever attendant hazard of being forced to land at an emergency field due to weather conditions or from mechanical difficulty within his airplane.

Consider the case of the owner pilot. While it is, of course, appreciated that many of this class are excellent all-round pilots, it nevertheless, appears reasonable to suppose that many have had no experience other than upon their own airplane, which is frequently the one upon which they have learned to fly. From this point of view, it is also obvious that while they probably are thoroughly well acquainted with the characteristics of their own airplane, they lack the broadening influence of more general experience.

For the average case, it seems highly desirable that his airplane be a very stable one. This stability should be of a very high order longitudinally, laterally and directionally, that its pilot may be relieved as far as possible of the necessity of continually flying the airplane. The lateral stability is probably most easily secured. Longitudinal stability is hardly of greater difficulty, provided by movable stabilizers or spring loaded control surfaces which are variable with the speed of the engine and are not so complex of operation as to incur the possibility of their being neglected by the operator. Directional stability is not so frequently solved, although it appears that it is not more difficult through the provision of the same medium as in the case of the stabilizer and elevators. This provides an airplane which, once taken into the air to a desirable altitude and placed on a course, requires the minimum of attention. It is safe, therefore, under this condition, because, if its pilot will let it alone it will keep itself out of difficulties. Even in the case of fog flying or in other low visibility condition, this fact will remain true.

This covers the condition of low angles of incidence, but he must, of course, in climbing, increase the angle of attack and possibly unconsciously approach the stalling angle. Here it is of great importance that no unusually sudden break in the lift of his wings shall occur. The tendency of wing design, with and without auxiliary appliances, tends to provide him with this desirable quality. When this condition is met a very appreciable range of increase of angle of attack should be permissible without serious loss of lift, or of stability. A righting moment which tends to put the nose down and assume a safer angle of attack should be provided.

Sooner or later, while making a turn, climbing at a high angle of attack the tendency to stall and fall off will occur. No sudden break, which is characteristic of the start of the spin, must occur. It must be free from any tendency to the unintentional spin.

The controllability must be good but restricted, that is, small angular changes on any axis must follow control movement, but the controls, particularly the elevator, should be small in angular displacement, or undersized to the extent that brutal handling of the control will not suddenly incur such great changes of attitude as will be hazardous. This limitation of control is a most important safety factor in the case which we are considering, but it need not interfere with the desirable flying qualities of the airplane within its proper use in its class.

It should hardly be necessary to balance the controls to relieve the force necessary to be applied by the pilot. In fact, it should be borne in mind that it is important that a reasonable degree of resistance is extremely desirable in order that a pilot have the proper "feel" of the controls. If this is eliminated by balancing or other such means, it will induce over-control to a hazardous degree among pilots of this class, perhaps more than in any other.

These features connect directly with the maneuverability of the airplane. For the owner pilot maneuverability is entirely of secondary importance. It should be neither desirable nor permissible that it be capable of being thrown through any involved maneuver. Safety demands conservative flying of this class and with the combination of stability and controllability which we have considered, it may be flown through all of the simpler maneuvers gracefully and easily, while it will be at no time robbed of the ability to dodge obstructions or avoid collision should such a condition be imminent.

Speed range is of no great importance to the airplane of this class. It is difficult to believe that its high speed need be very great, say upwards of 90 or 100 M.P.H., but it does not appear that the owner pilots will be satisfied with maximum speeds of very much less than this figure. Therefore, abnormally low landing speed is hardly attainable. Landing speeds of 30 to 35 and possibly 40 M.P.H. must be considered conservative and safe for this class. Below 30 M.P.H. the landing speed must be considered abnormally low and desirable only when it can be obtained without interference with the cruising and maximum speed.

The landing characteristics are undoubtedly of the greatest importance to an airplane of this class. Whatever the landing speed may be, the lateral stability and controllability at high angles of attack in landing must be excellent. With the stability which seems possible on the latter design and the restriction of control which has been mentioned, it appears possible that an airplane can be provided at the present time with which in order to effect a landing, all that need be necessary to do should depend upon the proper selection of a point and altitude above a field, with regard to its size and the direction of the wind, where the airplane must be placed at a certain speed and from thence on all that is necessary to do is to throttle the engine and pull back slowly on the control stick and wait. The airplane will proceed to land itself. This is only dependent upon proper stability in the stalled glide and with limitation of the control which prevents an angle of attack higher than necessary for a stalled glide together with a landing gear preferably of the Oleo or pneumatic types which will sustain the shock of landing which need not be of unusual force. Wheel brakes add greatly to safety in any case and particularly in this one, providing as they do, greater ability to handle while taxiing as well as to prevent running into objects on the ground. Taking off with an airplane of this general specification should also be quite safe since the speed range will indicate the reserve of power which guarantees rapid acceleration, low angle of attack in the initial part of the take-off and rapid climb without the tendency to stall thereafter.

The visibility of the pilot should be as good as possible, both in the air and while taxiing. In general, it might be said that the poorer the pilot, the more desirable is good visibility. Still it would not be desirable that a poor pilot be placed in an airplane in which he had perfect forward visibility due to his being seated in the very forward part of that airplane, on account of the fact that he is thereby deprived of any visual assistance in lining up some parts of his airplane with the horizon. It is a matter of experience that most pilots of lesser ability are habitual "rocker-arm" flyers, those who line up certain forward parts, as the rocker-arms of their engine, with the horizon, using this as their sole guidance to maintain level flight.

The airplane should provide very considerable comfort for the pilot, as on account of his lack of experience he will be certainly more susceptible to the reaction of physical or mental fatigue than in the more experienced.

With these specifications reasonably met, the owner pilot should be provided with a safe airplane, certainly as relatively safe as ground transportation which is in step with the times.

We will now look to the opposite case; of safe equipment for the larger commercial operator. As we have said, the case is initially free from the hazards of a poor piloting technique. Errors in judgment by men is a condition which we may only hope to see reduced and never eliminated. There can, therefore, be no greater protection against these hazards, or no inherent qualities of an aircraft which would assist in the elimination of the hazard than faith in the selection of the personnel.

Of the airplane itself, we would say that it should be stable to a reasonably high degree. It should be as stable as possible to the limit of any possible interference with the control. This may appear to be an unnecessary or incongruous statement, but it is important to emphasize that stability in this case is only a virtue to the point where it affects the controllability to any appreciable degree. It is believed that well within this limitation of its stability, the airplane will have a marked tendency to maintain its course, which is highly desirable, if not indeed absolutely necessary, to assist the pilot to come safely through local areas of fog or reduced visibility which are bound to be encountered in this class of service. While the airplane should certainly be equipped with complete navigational instruments which naturally are of great assistance to the pilot in this instance, it is nevertheless true, that with an airplane of any lesser degree of stability, the pilot would be deprived of that "feel" of his ship which is provided by an airplane of positive stability and upon which he bases all of his control movements.

Good stability at low speed or with high angle of attack range is a positive requirement in this case. In taking off under conditions where the airplane is loaded to capacity and where the ground conditions are bad, as for example, where necessity demands that the take-off direction be to some degree across wind, accompanied with the further handicap of a soft field, the pilot may find that he is faced with the necessity of pulling up to his maximum climbing angle before he has acquired the flying speed which should be necessary for the maneuver. This possibility, of course, is based solely in the instance where he is confronted with obstructions over which it is necessary to pass. In this case, there is an absolute demand for stability of a high order which would prevent any tendency to drop a wing. If the stability is satisfactory in this case, it seems clearly evident that in the case of landing that no additional hazard would be incurred. Here, in general, with regard to stability, it can be said that it is of definite necessity which controverts the idea which we frequently hear expressed in approbation of commercial airplanes with the "pursuit touch." This might indicate neutral stability.

In the consideration of its controllability, it may be admitted that in general practice this is not necessary to a high degree; that is, for taking off from an air-

port, maneuvering only in large circles and holding a constant course over a route and effecting a landing after the manner of the take-off. But we must bear in mind the possibility of collision which may be averted by ready response to the controls, and it must therefore be considered that this ability is essential in the safe aircraft of this class.

Considering the ability of the pilots who are flying in this class of service, any amount of controllability which may be provided them will hardly be a handicap through the possibility of its engendering over-control. This does not include control action which is so light as to eliminate a positive reaction which is felt by the hand of the pilot. This reaction, as we have said before, is definitely important, and while it may permissibly be reduced, it must remain appreciable.

Since we are considering that maneuverability entails only sustained or involved maneuvers as opposed to the simpler movements which we are considering under controllability, it appears that in this class of airplane the maneuverability may be safely neglected.

The landing speed requirement in this class must be expected to be reasonably fast due to the demand for high cruising and maximum speed. Under full load conditions it should not be considered abnormal if the airplane land at 50 or 60 miles per hour and even up to 70 miles per hour maybe, in the light of current practice, entirely permissible. Practice and experience have developed that landing a large airplane at these relatively high rates of speed does not involve the difficulties which a smaller airplane would encounter at the same speed. The characteristics of landing in this class should only demand that the landing must be made in an orthodox, though skillful, way. For the comfort of the passengers, however, it should be regarded that the shock absorption of the landing gear be excellent, not only to absorb the initial shock of striking the ground, but also to absorb such rolling shocks as would otherwise tend to "bounce" the airplane in the air. Brakes are, of course, a necessity in this class.

In regard to visibility for the pilot, almost any extreme is desirable to provide him with the best that is possible. In the newer commercial ships of today this is quite well provided for, although some criticism may be made of the visibility in a single engine or trimotored airplanes where the pilot is placed immediately behind the center engine. Where this necessity exists, improved visibility on one side at least is secured where the pilot is offset from the center line of the airplane, and it is our opinion that good visibility on one side is better than mediocre visibility on both sides. This arrangement, however, may incur some difficulty in the visibility while taxiing, but since in this case when the pilot is placed to one side, there is generally another seat beside him which is almost invariably occupied, he may use the occupant of this seat to assist him in avoiding ground obstacles.

In this class of airplane, arrangement is frequently impossible which would provide rearward vision for the pilot, but where there is any possibility of providing rearward vision, it should never be overlooked.

The comfort provided for the pilot is of some importance, although to a lesser degree than in a case which involves a less experienced pilot, because, in view of his longer and broader experience, he will not only have been accustomed to the relative discomfort of the usual cockpit, but will also have discovered means of making himself comfortable even in view of these limitations. The placement of the pilot in the airplane is a subject of some disagreement. In an airplane which carries passengers, there can be little question that they are entitled to the position which may be the safest should an accident occur. This must mean that the pilot should be placed forward. But should the airplane be designed solely for the carrying of mail or express matter, particularly when it is to be used considerably in night operation, there can equally be no question that the pilot should be placed as far to the rear as is possible. Any detriment to visibility or any unusual position

in regard to his placement in the airplane is quickly overcome by the adaptable pilot, whom we may expect to find in this class of service.

And thus in the case of the commercial operator we feel, as we said concerning the owner pilot, that an airplane of these characteristics from the safety point of view, will be as relatively safe as other modes of transportation.

In the rapidly moving science of aeronautics, it is to be expected that the conditions which we have presented here will soon become insufficient. It is beyond the ability of the observer of today to predict the possibilities of the future, at least until such time as revised design provides us with materially different aircraft than we are now familiar with. Pending that time, it is our belief that airplanes bearing the specifications as they have been presented should be considered safe aircraft.

(After Mr. Carrol had read his paper, the chairman again allowed discussion to be opened.)

J. S. McDONNELL (J. S. McDonnell & Associates, Milwaukee, Wis.): I should like to ask the speaker if he considers a landing speed of 60 miles per hour for a two ton commercial airplane just as safe as a landing speed of thirty miles per hour for a two-seater light airplane in private use.

MR. CARROLL: Sixty miles an hour is a little high. Between fifty-five and sixty miles per hour would be a satisfactory landing speed for the heavy airplane and equally as satisfactory as thirty miles per hour for a light airplane.

WM. H. MILLER (Curtiss Aeroplane & Motor Co., Garden City, N. Y.): Landing speed should to some extent depend upon the reliability of the airplane. I consider that sixty to sixty-five miles an hour is too high a landing speed for any plane. No matter what wing is employed. I agree with Mr. Carroll that the speeds of commercial cargo and passenger machines may well be in the neighborhood of sixty miles an hour, whether equipped with slots or not.

W. C. NAYLOR (Stout Engineering and Finance Co., Dearborn, Mich.): I would like to ask Mr. Carroll what results were obtained in the tests, made at Langley Field last summer, on the P. T. airplane equipped with front slots.

MR. CARROLL: Most of us at Langley Field are not satisfied that all the possibilities of the slot, as built and installed on that particular airplane have been developed. But there is no question that the placing of the slots on that machine has given a different characteristic in stalled flight than that found in an unslotted machine.

In the experiments referred to, we could not find a large quantitative difference. But there was a qualitative improvement in the accomplishment of the various maneuvers of stalled flight.

One very definite result was a complete difference in the whole procedure of the incipient spin, once a spin was accomplished. While you are definitely out of control, the airplane seems to be controlling itself and carrying on a little better with slots than without.

CHAIRMAN STRATTON: Any further questions? If not, that finishes the program for the day.

I wish to express my great appreciation for the speakers who presented these papers and also the men who have entered into the discussion. I thank you very much for your attention.

ADJOURNMENT

Power Plant

HON. EDWARD P. WARNER, Chairman

Assistant Secretary of the Navy for Aeronautics, Washington, D. C.

The Power Plant Session was called to order by the chairman, Hon. Edward P. Warner, Assistant Secretary of the Navy, at 10.15 a. m. on Friday, October 5, who then addressed the meeting.

CHAIRMAN WARNER: It has been fashionable, and sometimes convenient for a good many years to place on the innocent and unprotesting engine the responsibility for poor maintenance or no maintenance at all, and for various faults of judgment on the part either of ground or air personnel. It is no news to anybody who has occasion to fly that a great deal can go wrong with an engine. There can be a great deal of power plant trouble without any immediate adverse effect on the safety of the aerial operation, but we can not go on having engine trouble indefinitely without serious consequences resulting to the aircraft and its occupants sooner or later.

Every pilot from time to time, and in fact at some time in the course of almost every flight, has to trust to his power plant. He has to rely upon its continued operation for his continued safety. We get so much in the habit of such reliance that we think nothing of it, but it is a fact that the pilot and the passengers are very much in the hands of those who design, build, install and maintain the engine.

That there are so few accidents wholly attributable to engine trouble is a strong testimonial to the high average of performance of the various classes of people concerned with the power plant from the time the design is started to the time the propeller is swung and the plane ready to take the air.

The lesson of safety so far as the power plant is concerned is reliability. We want other things, high performance, low power plant weight, small frontal area, ability to operate in all temperatures, and many other qualities. But when we think of safety, we must think of engine reliability. It must keep on running once it is started until the pilot cuts the switch, and running at substantially constant speed and power output until he varies the throttle setting.

Those who have been in aviation for a long time need no written history to prove that there has been an enormous progress in engine reliability in the last ten years, to which a great many people have contributed, but it would have been impossible to make that progress without constant study in a laboratory where the features of engine performance can be analyzed one by one, where difficulties can be broken up and considered separately, and without any danger to anybody.

The history of engine laboratory work in this country is very largely a history of the aeronautical power plant section of the Bureau of Standards which began its work when America entered the war, which has been carrying on continuously up to the present time and is now making all the routine type tests, virtually all, for the Department of Commerce. It is at the same time carrying on those various researches which date back to 1917 and their results have been incorporated in numerous reports published by the Bureau of Standards and the Bureau of Aeronautics.

The work of the engine laboratory of the Bureau of Standards is very largely due to Dr. H. C. Dickinson, who has been in charge of this laboratory for many years and who will present his paper "Laboratory and Service Tests of Engine Safety."

Laboratory and Service Tests for Engine Safety

By H. C. DICKINSON

Chief, Heat and Power Division, Bureau of Standards, Department of
Commerce, Washington, D. C.

Failures of the power plant, according to the best available data on civilian flying, constitute somewhat less than 20 per cent of the causes of airplane accidents. This, however, is about three times the percentage attributed to all defects of the plane, including aerodynamic qualities. Personnel failures and adverse flying conditions account for most of the remaining 75 per cent. Training, experience and improved facilities can greatly reduce accidents of this latter sort so that the individual pilot and the management of flying fields can contribute greatly to increased safety in these respects. As regards the power plant, however, those whose personal safety is most concerned can accomplish little in the way of improvement. It is doubly important, therefore, that every practicable means should be used to protect the pilot and his passengers where they cannot protect themselves, viz., in the matter of power plant safety.

It is probable, moreover, that faulty functioning of an engine has been a contributing, if not a primary, cause of many accidents attributed directly to personnel. This is especially liable to be the case with inexperienced pilots, of whom there must be many as civilian aviation gains in popularity.

Engines which have been developed through comparatively long experience in the hard school of military service generally have attained a good degree of reliability. However, this result has been attained by the gradual elimination of weaknesses developed in severe service; nor has the item of cost ever been a prime consideration either in the design and development of these engines or in their mounting in the plane.

For the commercial engine designed and built solely to meet commercial conditions, the situation is entirely different. There has not as yet been the same opportunity for gradual elimination of faults and causes of failure, since few of these engines have had so long a period of use. Moreover, the question of cost must necessarily be of much greater importance here than in military equipment. It seems inevitable therefore that for some time to come engines built for purely commercial use may be less reliable than those in military service, notwithstanding that engine reliability is at least equally important in civilian flying.

How, then, can safety be obtained? The title of this paper correctly suggests that laboratory and service tests can contribute to safety; but no matter to what length formal testing is carried, it can only contribute to safety, not assure it. This being the case the length and severity of tests are matters of compromise depending upon various factors.

The British Air Ministry was among the first to prescribe a type test as the basis for approving engines to be installed in licensed aircraft. The maker of a new type of commercial airplane engine must specify the main characteristics of the engine. The type test comprises the following: (1) a power curve test, (2) a 50-hour endurance test, (3) tests of slow-running and acceleration, (4) a high-speed test, (5) a high-power test, (6) a second power curve test, (7) a complete teardown inspection followed by a final one-half hour test at normal speed and 90 per cent full power.

In addition each individual engine manufactured is required to pass an official acceptance test of two hours duration before it is placed in service, and one engine in fifty is subjected to the type test.

The air commerce regulations of the Department of Commerce provide

that engines which have passed the regular endurance tests of the Army or the Navy will be approved for use in licensed aircraft and that all other engines submitted for approval will be tested at the Bureau of Standards. The present test requirements call for general specifications from the maker, including drawings of the engine, together with the log of a 25-hour preliminary run at at least one-half rated power. The test proper consists of (1) a 50-hour endurance test, (2) a power curve test, (3) tear down and inspection and (4), a flight test. However, the flight test is being waived in the case of engines which have a record of successful performance in the air.

Causes of engine failure may be classed for convenience somewhat as follows:

Seven Causes of Engine Failure

(1) Mechanical or structural failures, such as breakage or other injury to any of the major mechanical parts of the power plant, such as to cause its stoppage or a very marked decrease in power.

(2) Failure of the fuel supply, through stoppage, breakage of lines, exhaustion of the supply to the carburetor either from lack of fuel or failure of the main supply to reach its service supply tank.

(3) Failure of ignition due to any of the various faults or accidents which may prevent the production of igniting sparks in one or more cylinders.

(4) Failure of lubrication, which may occur due to faulty operation of the oil pump, of the supply system in general, or of the supply to some essential part, to the over heating of some part or possibly to the use of a lubricant of too high or too low viscosity.

(5) Failure of the cooling system to maintain safe operating temperatures, either from loss of cooling medium (in water cooled engines) or as a result of some fault in lubrication, fuel quality, ignition timing, etc.

In addition to the causes mentioned above, which are more or less directly dependent upon the design, construction and maintenance of the power plant, there are other causes of failure which depend more directly upon the operation of the engine.

(6) *Engine Speed.* Mechanical stresses increase rapidly with speed and speeds which are liable to cause failure may be reached by driving with open throttle, or by the use of too small a propeller.

(7) *Fuel.* Maximum cylinder pressures and corresponding stresses depend largely on fuel quality. The use of fuels which "knock" in a given engine may result in over-heating, preignition, spark plug failures and in extreme cases, major mechanical breakage.

Of the causes mentioned above, by far the most important two, as regards number of accidents, are the fuel system and the ignition system. These together constitute more than half of all accidents due to power plant failures in civilian flying. Next in importance come structural failures of the engine. Lubrication and cooling each constitute only 2 to 3 per cent of the causes of failure. Some 25 per cent of accidents due to the power plant are listed as cause unknown. In some cases the evidence is destroyed by a crash; in others failure is due to one of the causes enumerated above, such as temporary stoppage of fuel (vapor lock) or ignition; others may be due to such things as collection of ice in the carburetor or manifolds.

The bearing of laboratory and service tests on safety of the power plant depends upon the character and the limitation of such tests. Under laboratory tests we shall include the operation of the engine either on a dynamometer stand or torque stand or with a calibrated propeller, as well as special

laboratory tests of accessories, such as carburetors, ignition devices; etc. Under service tests we shall include operation of the complete power plant in a plane either on the ground or in flight.

Laboratory Tests

Laboratory tests can serve as follows:

(1) They determine the operating characteristics of the engine, such as power-speed range, fuel and oil consumption, consistency of operation, cooling requirements, etc. On these points definite information is had by a brief series of tests. Barring gross mechanical faults, the figures obtained should apply to any individual engine of the same design and construction. While this information has no very direct bearing on the safety of the power plant, it does determine the suitability of the engine for use in a given type of plane and for a given kind of service. It is, therefore, essential to the selection of a safe combination of engine and plane.

(2) Laboratory tests afford information as to structural safety and reliability. By running an engine for long periods at loads and speeds equal to or greater than those expected in practice, serious inherent mechanical weaknesses will probably develop into failures or show up on subsequent inspection in excessive wear, local heating, incipient cracks or loosening of threaded parts. On the other hand, such tests alone give little information as to the margin of safety of the structural design. Parts may be stressed too near their elastic limit, and might fail from repeated stresses if run for longer periods or at speeds somewhat greater than in the tests. The structural materials used may not be sufficiently uniform in composition or in heat treatment, so that occasional failures may occur, in service, although the individual engines tested did not happen to contain any faulty parts and successfully completed the tests. Thus laboratory tests alone on a very limited number of engines cannot give complete assurance against structural failures, but can very greatly decrease the chances of their occurrence.

(3) Laboratory tests may serve to point out faults in design which would lead to unreliable operation or failure after long use. For instance, a design may have obvious mechanical weaknesses such as points where stresses are concentrated, or parts in which the material is not well distributed for maximum strength. There may be parts liable to displacement or which may become loose, or parts too difficult to service properly. Some such faults are indicated by failure or incipient failures; others are noted on inspection by the members of a skillful and experienced test crew, even though no failure has occurred. Most of such faults have been eliminated from the engines which have been long in production, and they will be relatively rare in new designs drawn up by engineers of long experience in the aircraft engine field. These faults are, however, discouragingly common in the newer designs of commercial engines, many of the designs of which have had only limited experience with modern aircraft power plants. Careful testing and inspection are, therefore, of utmost importance in these cases.

As already pointed out, fuel supply and ignition are responsible for the greater number of failures and these are to some extent capable of independent test. Insofar as the fuel system is a part of the engine, laboratory tests of the engine should show up its weaknesses. Special laboratory tests can be used to determine whether the carburetor will function properly in all positions which it may assume in flight. Since the fuel supply piping on the test stand is usually different than that used on the plane, no useful information regarding this part of the fuel system is obtained by laboratory tests.

The complete ignition system, including spark plugs and wiring, can be tested independently of the engine if necessary, although the laboratory test of the engine should develop any very serious faults in ignition.

Usually the carburetor, ignition system and spark plugs are of types which have previously been used on engines of other designs so that their characteristics are known. Special tests, therefore, are necessary only when new or unfamiliar designs of these units accompany a new type of engine.

The discussion of laboratory testing so far has dealt primarily with what may be termed "type tests," i.e., rather exhaustive tests of one or a few engines of a single type, or sample engines of a production lot. There is another class of laboratory tests which is also of importance, i.e., condition or acceptance tests which involve the running of an engine for a comparatively short period of time to determine whether it is in satisfactory operating condition, followed by a complete disassembly and inspection. In fact tests of this sort are essential to check the condition of each individual engine before it is mounted in a plane. Such tests are required by the British Air Regulations and some others. Where these tests are not required under official observation, it is common practice, and should be universal practice to subject every new engine to a brief full power run with subsequent take down and inspection before it is finally assembled for service.

The object of a condition or acceptance test is to determine whether the fits, clearance and adjustments of the individual engine are correct and whether the fuel, ignition and lubricating system are in proper order. A tear-down and inspection of parts after a run for an hour or two at rated load and speed should reveal any serious defect in these items which might later cause a failure.

The same sort of tests also should be made on any engine which has undergone a major overhaul. A brief test should again be made after reassembling and before the engine is taken into the air. This final test may be made either in the laboratory or after the engine is mounted in the plane.

Service Tests

Service tests in which the entire power plant is operated in the plane in flight necessarily lack the accuracy of measurement and the detailed observations of engine condition which are possible in laboratory tests and for this reason cannot replace the latter, particularly where type tests are concerned. On the other hand, laboratory tests are limited in their application as they furnish information only as to the engine itself and not as to the character and reliability of the oil, fuel and water, i.e., the "plumbing" connections between the engine and the plane, the engine mounting or the general adaptability of the engine for service tests and inspection of the carburetors and fuel systems may indicate whether they will function properly under all service conditions. The conclusions thus reached should be checked in service.

The chief function of service tests, therefore, is to show whether the parts of the power plant which connect the engine proper with accessories mounted on the fuselage are reliable, i.e., whether the "plumbing," the wiring, if any, and the structural supports are properly designed and installed. So far as design and workmanship on these parts are concerned, much can be learned from careful inspection by experienced inspectors, particularly as concerns type installations.

From the nature of the case, the information as to the reliability of the power plant, afforded by flight or service tests, is of a rather uncertain and indefinite nature. In general, information is obtained only when some

failure or obvious fault is noted. For instance, one of the most serious faults to be detected by such tests is liability of breakage of oil and fuel lines. In fact, the latter is perhaps the worst single hazard of the power plant. However, provided the piping is of suitable materials and is properly installed, such breakages are largely a matter of chance. There is no assurance that a limited number of flight tests will show all weaknesses in design which still may result in relatively frequent failures. This is typical of most other things on which information is needed from service test results. For this reason flight testing of civilian planes is generally confined to type tests which may show up obvious weaknesses of a design.

While the results of formal flight tests are of limited value, data which only can be obtained in flight are of utmost importance. There is fortunately another means of obtaining these data, viz., by systematic analysis of the records of accidents and of power plant failures. In fact, this is probably the only means whereby the relative safety of different engine and plane designs, and their combinations can be definitely fixed. In order to secure and make available these data there must be full cooperation between the flying personnel, the management of flying fields and the Department of Commerce. With such cooperation, the accumulating data will afford an even firmer foundation for safer and safer power plant design and construction.

The present requirements of the Department of Commerce for airworthiness certificates for engines, should be looked upon as a first step only in securing such safety as can be had through governmental regulation. They set only a minimum standard which will doubtless be made gradually more rigid as commercial power plants improve. In the last analysis, however, safety will depend more on the knowledge, skill and honesty of the designers, production department and the individual mechanic than on any governmental requirements, no matter how rigid and well enforced they may be.

Crossing the Ocean by Air Craft

CHAIRMAN WARNER: Eight years ago there was a little group of people who thought that the obvious way of eliminating the cooling troubles of the aircraft engine was to resort to air cooling. Now we have enrolled among air cooling enthusiasts practically everybody concerned in aviation. The history of air cooling and of air cooled development in this country is summarized in the history of ocean flying. It is interesting to see what has been done in the way of ocean flying and what it shows us about engines.

I think I am correct in saying there have been during the last year six trans-Atlantic crossings by aircraft, including those on the short route, of the North Atlantic, not counting those of the South Atlantic. Of the six, five have been with Wright engines. There have been five complete or partial crossings of the Pacific. By partial I mean at least to the Hawaiian Islands. Of these five have been made with Wright engines, which is a pretty good testimonial to air cooling and to a particular type of engine which has a long history.

All of these remarks tie together because it was one of those bold pioneers in whose experience with engine design and air cooling the history of the Whirlwind engine is summed up, and who symbolizes from his own experience a very large part of the history of air cooling applying to aircraft engines. We are singularly fortunate in having the second subdivision of this general subject, "Safety Requirements of an Aircraft Engine and Its Installation," presented from the point of view of the designer and manufacturer, by Mr. Charles L. Lawrence.

Safety in Aircraft Engines and Their Installation

By CHARLES L. LAWRENCE

President, Wright Aeronautical Corporation, Paterson, N. J.

1.—Engine Design

A.—GENERAL ENGINE DESIGN: While high performance of aircraft engines in terms of weight per horsepower is of great importance, it is only of interest if the performance is obtained at no sacrifice of reliability, and many elements of design should be particularly considered from this point of view. It is useless to design aircraft engines on the assumption that they will always have expert care, expert use, high grade fuel and good oil. The manufacturer cannot stress too highly the importance of all these factors, but everyone knows that they will not always be possible. The fact that the engine will from time to time be abused must be in the designer's mind. In other words, the margin of safety must be such that minor defects in material and minor carelessness or ignorance on the part of users will not cause failure.

a.—Detonation: In order to obtain a reasonable performance every new engine must be designed for the use of at least as good a quality of aviation gasoline as is obtainable at most flying fields. However, the engineer must not overlook the fact that occasionally such fuel will be impossible to obtain and that the user will be forced to employ whatever fuel is available, possibly, a poor quality of motor car gasoline. This emergency sometimes happens under the conditions of a forced landing, where the full power of the engine may be required to leave the field, and where safe flying requires reaching a considerable altitude. The detonation arising in such emergencies must not cause failure of pistons or cylinders. As in other respects, the engine must be more or less fool-proof.

b.—Oils: Manufacturers of aircraft engines usually specify certain brands of oil which should be used in their particular engine, or at least give a specification of such oil. It has been my experience that most users of aircraft either through the sales talk of someone, or from the natural desire to experiment are always anxious to use some other oil than the ones which are recommended. The designer might as well face this fact in designing an engine and any power plant which can only operate satisfactorily with very special lubricants, is bound to be unsatisfactory, to the average run of airplane operators.

c.—Lubrication of Minor Parts: Nothing indicates the different degree of care with which aircraft engines are maintained in the field as much as the care and lubrication of minor parts of the engine. Some users are very particular about this, while others will allow the engine to run for a great many hours before attending to the lubrication of the less important parts. The lubrication of rocker boxes of air-cooled engines is a case in point. Some users lubricate these parts very frequently, while others are very careless about this, and, frequently, do not use the proper quality of oil. The designer must recognize this and so design the parts of the engine requiring outside lubrication that they will run for a long period without attention and if, on the other hand, they are lubricated too frequently, see that the oil does not leak out over the outside of the engine.

d.—Minor Defects in Material: Aircraft engines are designed on the assumption that a very high quality of material is used throughout, but in the manufacture of any product on a large scale, and even with the very best inspection, small defects of material, especially in the case of steel, are liable to occur. It is impossible to expect the material to be perfect and sufficient factors of safety must be provided in order to allow for the minor defects which will undoubtedly exist.

e.—Running at More Than Rated Speed: Another point which should be taken into consideration is the high speed at which some of the engines will be run in competition. Given a rated speed, for which the engine is guaranteed, it is certain that most of the competitors in a race or aerial tour, will run their engines considerably faster than the speed recommended by the manufacturer, perhaps for a period as much as twenty or thirty hours, and it is essential that the valve gear, connecting rod bearings, and other moving parts of the engine, shall be easily able to stand this overload. Otherwise, the engine will get a bad reputation and serious accidents may occur.

B.—DESIGN DETAILS CONTRIBUTING TO SAFE OPERATION

a.—Measures to Prevent Ice Forming in Carburetor: It is well known that in low temperatures, and especially under certain conditions of cold and humidity that ice will form in the carburetor of aircraft engines, and that even if this does not occur, the use of very cold air in the intake manifold tends to prevent proper carburetion with the consequent increase in the fuel consumption. There is a difference of thought on the best method of overcoming this difficulty, but it is certain that either heating of the intake air or the use of a hot spot between the carburetor and the engine or both are necessary for the proper operation of an engine in cold weather, or at high altitudes, and this problem must be satisfactorily worked out by the engineer before the engine is fit for use.

b.—Air Cleaners, etc.: Another accessory that must be provided by the engine manufacturer is a method of preventing sand or water getting into the carburetor. Under the dust conditions of some of our fields in the South and Southwest, so much sand may be taken into an engine as to completely destroy the major working parts in as little as fifteen hours of running, necessitating the entire replacing of cylinders and pistons. This is particularly the case in the type of radial engine having its intake at the bottom. In this case, it is necessary to equip the engine with some air cleaner which will catch most of the sand and dust. It is possible that an air intake at the top or at the side of the cowl will overcome this difficulty, although the V type of water cooled engine with the carburetor intake in the Vee is also subject to this difficulty, but to a lesser degree. Some simple form of air cleaner may be the ultimate solution. For use in seaplanes where the propeller stirs up a very considerable spray, protection against water is necessary, as otherwise, the engine will frequently draw in so much water as to foul the spark plugs. And in the case of a seaplane which has landed and is taxiing to its mooring or mother ship the salt spray which gets in through the carburetor will cause rust in the piston rings and valves guides.

c.—Ignition Wires: Another important detail that should be looked to is the chafing of ignition wires or their deterioration through heat or contact with oil. This presents no particular problem, except that the engineer must study the design of a suitable ignition manifold which will properly protect the ignition wires.

d.—Multiple Valve Springs: Another design detail which is desirable is the use of more than one valve spring to each valve, so that the breakage of a spring will not completely cripple the operation of that cylinder.

e.—Broken Valves: Another desirable detail is some method of preventing broken valves from falling into the cylinders. Although engines often have completed their flight with a broken valve in the cylinder head, the damage always necessitates the replacing of the cylinder and piston, and in many cases, causes a wreck of the entire engi: ..

f.—Dual Ignition: Partial failure of the ignition apparatus must be provided for by dual ignition. Possibly, not in the source of the current supply, but at least by the use of dual breakers, dual distributors and dual spark plugs. Inci-

dently, it is well known that dual ignition properly synchronized, produces additional power and to a certain extent overcomes detonation.

g.—Oil Strainers: The oil system must be designed so that no dirt or chips can get into any of the pumps. It is usually considered inadvisable to place a strainer in the suction line between the tank and the pressure oil pump. When the oil is cold, it may be impossible to draw oil through such a strainer into the pressure pump, and bearing failure may ensue from lack of lubrication. On the other hand, an oil screen between the pressure pump and the engine must be sufficiently large so that it cannot be clogged by dirt in the course of a few hours. Otherwise, the oil pressure will burst the screen and the dirt will all be discharged into the engine. The screen in the oil return from the engine sump to the scavenging pump need not be of a fine mesh, but is necessary to prevent large chips getting into the pump which might break or jam the gears. Needless to say, the oil strainers should be so located that they are easily accessible. The engine designer should use his imagination as to how the average aircraft builder will probably locate the elements of his engine mount and place the strainer in a position where it can be most easily removed. Otherwise, the strainer will be cleaned infrequently and the reputation and reliability of the engine will suffer.

h.—Rotary Induction: Up to now most aircraft engines have had the ordinary motor car arrangement of carburetor and manifold, usually not more than three or at the most four cylinders to one carburetor intake. Recently, rotary induction with all cylinders on one manifold has been adopted by some manufacturers. Rotary induction has the advantage of giving distinctly better distribution to all of the cylinders. But, on the other hand, the failure of a single inlet valve which may stick open, will greatly interfere with the operation of the remaining cylinders possibly stopping the engine although the rotary induction may be sufficiently powerful to force some mixture into all the cylinders in spite of the leakage around the stuck valve. In a military operation where one of the intake pipes is shot through by a bullet, a similar leakage would occur. With the old system as used in motor cars complete failure cannot occur. In the case of a nine cylinder engine, if a valve were to stick open, it would only incapacitate three cylinders connected with that manifold and the other six would continue to operate; however, the distribution and fuel consumption with this system is less efficient than with the rotary induction. The aircraft engine designer must balance the advantages and disadvantages of these two systems in laying out his engine, considering on the one hand the safety of the old system and, on the other hand, the better fuel consumption and the ability to supercharge of the more recent system.

i.—Accessibility of Accessories: A moment ago I spoke of the accessibility of oil strainers, but I wish to point out that all the accessories of the engine must be carefully considered with a sympathetic thought for the problems of the aircraft engineer who has to install the engine. Enough stress cannot be laid upon the important accessible accessories and influence upon the mind of the user.

2.—Engine Testing

A very natural tendency of many companies building the experimental engines of a new model is to exercise more care with the first engines, than with the subsequent manufactured product which often has also been modified for manufacturing reasons, with the result that the tests of the new model do not give a proper idea of the possible weak points of the manufactured engine. Such experimental engines generally are carefully built by the best mechanics with a certain amount of hand fitting and from carefully selected materials, and are tested under good conditions of weather, fuel, oil and maintenance. The tests, often, are not very severe, the intention being to carry on more severe testing later on

the manufactured product, but to pass some kind of a type test as soon as possible. This later testing is often delayed, due to lack of testing equipment, the necessity of testing other models, or false ideas of economy, so that the first information of the limitations of this particular design often come from the hands of users. It is a natural tendency of engineers to assume that the user is an ignorant person who "has abused the motor," thus, in their minds establishing an alibi.

A.—TORQUE STAND OR DYNAMAMETER TESTING

a.—Testing Under Conditions of Overload: Actually, the complete testing of a new model should be carried out as soon as possible after the first manufactured engine has been completed to find out all its weak points, both in respect to design and material, and also to check up on the unexpected and unexplained difference which nearly always occurs between the hand made engine and the manufactured one. Duration tests should be run at considerably higher speeds than at which the engine is to be rated, and, if the engine is equipped with rotary induction, by turning this into a supercharger so as to obtain a higher volumetric efficiency than is normally used, or in the case of an engine of the type having an ordinary carburetor and manifold, by means of an attached super-charger such as a Roots blower. High compression can also be used in these tests, though of course it is obvious that some anti-knock fuel will be necessary. Finally, runs at high speed accompanied by high mean effective pressure will give a test which will demonstrate any weak points that may exist and incidentally prepare for the development of future models. Another important test is a duration test using ordinary motor car gasoline to determine the amount of damage, if any, this inferior fuel oil will cause. Parts that are supposed to be oiled only occasionally should be given no lubrication during a long duration run, which can be combined with one of the other tests to determine the amount of wear this severe treatment will produce. Another endurance test should be run at a very lean mixture to determine whether it is possible to overheat the engine by this process. Nothing, in the case of air cooled engines, will show up a defective cylinder design more quickly than running with a lean mixture. And in the case of engines having a rotary induction system, where the distribution is very good it may be possible to lean the mixture to such an extent as to cause high cylinder temperatures. The piston and valves must be developed until they are able to stand this treatment.

b.—Testing to Check Design Changes: Frequently, changes in design are made which, to the engineers at the time, seem unimportant but it is surprising how often some apparently minor change will cause trouble where it is least expected and except in a change of the most minor description, it is good policy to run tests sufficiently comprehensive to insure that no change in the operation of the engine has occurred.

B.—FLIGHT TESTING TO CHECK OPERATION UNDER ALL POSSIBLE CONDITIONS

a.—Operation of Carburetor at Altitude: All manufacturers of aircraft engines should have at their disposal suitable aircraft with which they can conduct flight tests of the engines which they are developing. The importance of these tests is very great and unless they are carried on by the manufacturer it will devolve upon the unfortunate user of the engine to make these experiments for them. The most important flight testing of a new engine is carburetor testing at high altitude and checking the range of the mixture control. This testing should be carried on in conjunction with the representative of the carburetor manufacturer and may involve the design of whatever heating attachments are provided, and which I will touch upon later. Often, it will be found that a mixture control is

too sensitive or that it is not sensitive enough, and, in order to give the pilot proper control of the mixture it should be so regulated that the full throw of the mixture control lever will control the mixture through the range necessary for the operation of the motor. The fuel consumption curve should be checked under propeller load conditions, to be sure that no abnormal lean or rich spot occurs within the flying range.

b.—Hot and Cold Weather Testing: Until an engine has been in the air under conditions of both very hot and very cold weather, the engine manufacturer is unable to determine how it is going to behave. Conditions of both very hot and very cold weather are particularly important for the water cooled engine, and very cold weather for the air cooled engine. These tests will show the amount of radiator area which is necessary and the amount of cooling that will be required for the oil and whether the ventilation of the cowl is adequate, while very cold conditions will affect the carburetion and the entire lubrication system. These tests cannot be made in a few days, and the complete results can only be obtained through long months of intensive flying.

c.—Intake Protection Tests: While these tests are going on, other experiments should be made to determine whether the intake system is properly protected against dust and water with tests of various air cleaners, which may even go to the extent of producing an artificial dust by the slip stream of another airplane so as to simulate the conditions which obtain where a lot of aircraft are gathered on the same field.

d.—Exhaust Collector Experiments: Experiments with exhaust collectors are also very important. If these are not supplied by the engine manufacturer, which is a very desirable thing, they will be furnished by the airplane builder, and unless the engine manufacturer has complete data on the cross section area and proper design of such manifolds, it is certain that a lot of unsatisfactory attempts at manifold construction will be made by the airplane builders. Their natural tendency is to make the exhaust collector too small in cross section, causing back pressure, heating of the exhaust valves, and loss of power.

3.—Engine Installation

A.—Engine Mounts: In the installation of engines in aircraft, the problems are as many as there are different types of planes, but they all have certain features in common. The mounting of engines in aircraft and the structure by which they are held is properly a subject which concerns the airplane designer. Unless the mount is so designed as to properly withstand the torque reaction, the engine will vibrate, and carburetion will be bad.

a.—Torque Reaction: The engine mounting must be sufficiently rigid to withstand the torque reaction of the engine and this rigidity must be carried back into the ship until it is finally communicated to the wing structure. In the case of geared engines, this is a matter of no small importance, for in some cases, a poorly designed mount has been the means of condemning a perfectly good engine, when the real fault was with the airplane. I can recall at one time when I was building small three cylinder engines, scarcely any manufacturer installed these engines properly. When a strong enough mount was provided with a proper tie into the wings, the engines ran very smoothly.

b.—Engine Mount Design: It goes without saying that no member of the engine mount should be subject to vibration, nor should they, in the case of tubular mounts be subject to bending stresses. Yet I have noticed occasional cases in tubular mounts where some of the struts did not come together at the junction points, so as to form triangles everywhere, but were so separated as to cause considerable bending moments. Such design cannot help causing local stresses which may result in crystallization.

B.—FUEL SYSTEM

a.—Solid Construction: It is most important that the fuel system of all airplanes be properly engineered and designed with heavy gauge tubing and proper fittings of an approved type, such, for instance, as those used by the Army and Navy. The tubes must be properly supported at suitable intervals so that no vibration can occur and all fittings must be sufficiently strong so that the efforts of an energetic mechanic with a powerful wrench will not wreck them too easily. They must be laid out to avoid all vertical bends which might cause them to be air-bound and a new installation should be tested in every flying position before leaving the flying field in order to be sure that no airbound condition can exist.

b.—Suction Lines With Small Lift: All suction lines must have as small a lift as possible especially when tanks are nearly empty. Although they may operate properly at sea level, the suction may break down at high altitude if the lift is too great, and for this reason it is advisable to take advantage of gravity for the flow of fuel as much as possible. In any installation where fuel must be located well below the fuel pump, as in the hull of a flying boat, or in the pontoon of a seaplane, it is necessary to have a separate fuel pump located in the tank and driven by a flexible shaft, a windmill or an electric motor.

c.—Traps for Water: Enough stress cannot be laid upon the matter of proper traps to catch any water that may be found in the gasoline. The condensation of water in the tanks often accumulates in considerable quantities in or at the carburetor and unless caught in a trap will interfere with the operation of the engine, and in case of cold weather will freeze below the jets and prevent the flow of fuel.

c.—Protection Against Fire: In designing the part of the gasoline system inside the cowl, it is very important that the arrangement of pipes should be such that in case of a breakage of any part of the gasoline line, the consequent discharge can under no circumstance come near the carburetor inlet, either in the form of vapor or fluid. After such a breakage, the fuel in the carburetor float chamber will be quickly exhausted and will usually be followed by a backfire in the carburetor intake. If the air scoop is too near the gas flow from the broken pipe a fire may ensue. Carburetor air intakes located at the top or side of the cowl are therefore desirable, and should be air tight.

C.—OIL SYSTEM

a.—Protection Against Cold and Heat: A difficulty in the oil system of airplanes in cold weather is the sluggish flow of oil to the pressure pump and the pipe from the tank to the suction side of the pressure pump should therefore be of ample proportions. This, and all external pipes on the engine, should be adequately protected against cold by cowling with adjustable openings so that the oil system can be maintained sufficiently cool in hot weather and protected from the cold in winter. Cool oil will do more to insure a large number of hours between overhauls than any other one thing, except the exclusion of dust and proper inspection, and an oil cooler located within the cowl where the temperature can be controlled by shutters is a very valuable adjunct to any power plant.

b.—Reserve Oil Capacity: It must be remembered although the oil consumption of modern aircraft engines is very low under normal conditions, that through any condition of undue wear in the cylinders or through some failure of the piston rings, considerable clearance can develop within a short time with a consequent sudden increase in oil consumption. Therefore, the oil tank should be very much more than sufficient to supply the usual needs of the engine. Oil consumption of say .02 pounds per horsepower hour is usual, but the tank should be at least designed to take care of an oil consumption of .04 or .05 pounds per horsepower

hour. I have already spoken of oil strainers, but in this connection I again wish to bring home the point of having them easily accessible.

D.—COWLING

a.—Cooling of Crank Case: Cowling is provided on an engine in order to complete the stream line form of the fuselage, but must provide for proper cooling of the parts of the engine which are covered up. The general tendency, especially in the case of air cooled engines is to cool the head of the cylinders which are in the slip stream, but to neglect the crank case and cylinder barrels. The cylinder head cooling is of no possible interest if the other parts of the engine are allowed to get too hot and the proper supply of cold air must at all times flow inside the cowl, not only through large enough openings to let it in, but as is often overlooked, through just as large openings, to let the air escape. This air flow will also take care of the oil cooling and should be controlled by shutters.

c.—Cooling of Exhaust Collectors: The exhaust collector, whether it is supplied by the engine builder or by others, must be so designed that the air flow can pass on all sides of it, and that no spot becomes very hot. This is important, not only from the point of view of the life of the collector, but also as a protection against fires in a crash. The British have developed exhaust collectors where no part of the collector reaches a temperature sufficient to ignite the hot oil which might be projected upon it from the crank case at the time of an accident.

E.—CONTROLS

a.—Strong Controls: Controls shall be positive and strong so that a pilot can use, if necessary, considerable strength without damaging anything. They must be positive in both directions and free from play or vibration. It is very desirable to avoid all offset rods whenever possible, or if this is impossible, to provide operating rods of good diameter.

b.—Sensitive Controls: The controls shall have the proper degree of sensitiveness with leverages so worked out that the full motion of the control handle by the pilot produces exactly a full movement of the lever on the carburetor, magneto or other device.

c.—Standard Operation: Needless to say, all controls should have a standard direction of operation and be suitably and comprehensibly marked.

4.—Inspection of Aircraft Engines

a.—The inspection of aircraft engines, properly carried out, has more influence on the success or failure of any airline or military operation than any other single thing connected with flying. The personnel should be trained in the inspection of all details of the engine after specified numbers of hours and all this should be systematically carried out and nothing overlooked.

b.—Inspection Sheets: In order that this be done in the most efficient way without any possibility of error, all aircraft engine inspection should be suitably worked out on a printed chart, indicating exactly after how many hours of running each detail of inspection shall take place. In order that the chart may be comprehensive enough and worked out to cover the proper periods of time between inspections, it should be based on other inspection charts for the same engine already in use and should be submitted to the engine manufacturer for criticism. It can then be further developed by such changes as may from time to time appear best to the user. Mechanics should be given no leeway with regard to changing any of the system laid down unless officially approved by the management.

The third paper, prepared by Captain L. M. Woolson of the Packard Motor Car Company on "Field Service and Maintenance of Aircraft Engines" was read by Mr. G. J. Mead, Vice-President of the Pratt & Whitney Aircraft Engine Corporation.

Field Service and Maintenance of Aircraft Engines

By L. M. WOOLSON

Aeronautical and Research Engineer, Packard Motor Company, Detroit, Mich.

The general subject of field service and maintenance of aircraft engines admits of such broad interpretation that I am limiting my remarks to those phases of the subject which should be particularly apparent to the engine designer.

I have always claimed that a certain amount of actual operating experience in the field on the part of the designer, particularly with a new design of engine, is indispensable. Many engineers claim that such field experience is entirely unnecessary and state that if the engine is put through a standard course of ground testing that is all that is necessary. I have always been opposed to this viewpoint, as evidenced by the fact that I have participated in the initial trial flights of every new Packard aircraft engine during the past several years. In this fashion it is possible to anticipate and avoid considerable field maintenance work which would otherwise become necessary and it is this thought that "prevention is better than cure" that justifies the following remarks under the heading of this paper.

Considering first of all the questions involving the durability of the engine, it has been shown in the past that even the most strenuous ground testing does not bring into play some of the forces brought about in actual flying. Typical examples common to many different makes of aircraft engines are found in timing gear failures, for example. Such failures in the air are undoubtedly brought about by crankshaft torsional vibrations which are not present in ground testing either on the dynamometer or with test clubs. Supercharger drives have also given trouble in the air in a relatively few hours, whereas duration tests on the ground failed to reveal any weaknesses.

Then again, take the question of accessibility. We all appreciate how important an item this is in reducing the cost of operation and maintenance and yet it is very difficult to criticize an engine from this standpoint when on the test block. Certain important parts of the engine which must be accessible, such as gasoline and oil screens, may be very inaccessible after the engine is installed in the plane, and a simple change in either the engine or plane design may overcome this difficulty. Similarly, engine controls may need revision in location after the engine has once been installed in a plane and the proper action taken by either the engine or plane designer before quantity production is started will save countless hours in the field later.

Then again, the question of proper functioning of the engine in the air can never be foretold with certainty. Influence of the slip stream on carburetion, engine pick-up after a long glide, and ice formation in the carburetor under critical conditions of atmospheric humidity and temperature are simple instances of questions which arise in actual service and should be settled satisfactorily by the engine designer so as to avoid service troubles later.

In many cases it has been customary to rely solely on the test pilot's report as to the behavior of the engine in flight and to believe implicitly his diagnosis of possible troubles. Even the judgment of the best of pilots is by no means infallible and in many cases the pilot is more concerned with the handling of the ship than the action of the engine, so that the proper thought is not given to those

characteristics of engine operation, in which the engine designer is vitally interested.

In this connection I recall a rather amusing incident when the pilot insisted that a certain engine was developing roughness at regular intervals and he was convinced the engine should be pulled out for examination. Accompanying him on a flight I found that the roughness came in as reported, but it was due to tail flutter, certainly far removed from the engine!

And lastly, the engine designer gains invaluable experience from riding behind his engine. Frequently this brings about rather insignificant appearing changes, but nevertheless changes of vast importance from the safety standpoint. For example, a forced landing from the breaking of an oil line rigidly attached to the engine will develop a modification to the engine oil connection which forces the plane builder to install a flexible hose connection at this vital point. Or similarly, experience with fire in the air due to the breakage of a gasoline line fastened rigidly to the engine and free to vibrate between the engine and firewall will make the engine designer sit up and take notice and provide a connection on the engine which permits of nothing else but a flexible connection to the airplane piping.

To state that all engine service troubles were due to the engine designer and were preventable, of course, is going too far, but there are innumerable cases where service troubles or delays can be avoided by minor changes in design. As an instance, many engines have been designed to require a special propeller hub wrench which is naturally too heavy to carry around with the ship and frequently cannot be found around the hangar. A few years ago some bright genius made a propeller retaining nut which was tightened up by means of a 1-inch bar passed through the nut. This design has been extensively copied and deserves to be, for the simple reason that it is no longer necessary to look for a special wrench, but merely for a round bar, which can be easily located practically anywhere.

Another bane of the service man's existence is the lack of uniformity in the sizes of hexagon nuts, plugs and screws used around an aircraft engine. The result is that his kit of tools must include wrenches for a great many sizes which differ perhaps only by one-sixteenth inch measured across the flats. It would frequently happen that the addition of a few ounces in weight to an engine would result in reducing the number of various sizes of hexagons so that the saving in weight of several pounds in wrenches to be carried could be attained.

Another question on which there is a wide variation of opinion and which should be settled in the interest of conserving the service man's time is the matter of safetying bolts, nuts, screws, plugs, etc. Years ago it was considered essential that everything should be either cotterpinned or safety-wired around an airplane engine. Nowadays a more liberal attitude is adopted, and while everybody is agreed that parts inside the engine should be cotterpinned or safety-wired in an approved fashion, the same procedure is not usually adopted on parts outside the engine which are visible for inspection.

So far as my personal opinion is concerned, I do not believe that either cotterpins or safety-wire are really essential on any fastenings outside of an engine. It is certainly true, however, that from an inspection standpoint it is much more satisfactory to look over a job and see the cotterpins and safety-wire installed in an approved fashion rather than have to judge by the appearance of or actually try a wrench on each bolt or nut to be inspected. From the service man's standpoint, however, both cotterpins and safety-wire materially lengthen the time necessary for making adjustments or repairs and consideration should be given to eliminating such locking means wherever considered practicable.

Another question worthy of serious consideration is that of brass or steel plugs entered into threads cut in aluminum. There are a great many places around

an airplane engine where such practice is countenanced, and I am referring, of course, to such plugs as are removed for inspection or repair purposes from time to time and not studs which are anchored in aluminum and not intended to be removed. For example, carburetor strainer plugs are almost invariably screwed into aluminum, and should a careless mechanic get the threads slightly crossed or should the parts be put together without the proper compound on the threads there are very good chances of spoiling the whole assembly through damaging the threads. I believe that such instances represent cases where the demand for light weight has gone too far, and I think that steel or brass inserts should be invariably used in the aluminum to avoid the damage to soft threads. A possible exception is in the case of spark plug threads in aluminum cylinder heads of air-cooled engines, and it would be very interesting to gather some statistics as to how satisfactory such construction has proven in the field.

Although engine designers are fighting weight increases at every turn, it is believed that the provision of permanent lifting eyes or hooks on an aircraft engine are warranted. This perhaps might not apply to well organized transport lines which are well standardized on their equipment and have all their shops supplied with standardized lifting devices, since in such cases carrying around the extra weight of the lifting hooks, theoretically at least, robs the plane of that much pay load. However, in the case of the privately owned plane or the independent operator it certainly would seem advisable to have such lifting means permanently attached to the engine.

These few remarks have been offered in the hope that they may help in some slight measure to bring about an improvement in the much needed co-operation between the man in the field who is operating and maintaining aircraft engines and the engine designer. Good constructive criticism on the part of the field man, pointing out how simple changes might improve accessibility or durability, would be a fair exchange for the engine designer's assistance in providing such aids to the service man as have been briefly touched upon. Co-operation between the engine designer, the field service man and the pilot will be very valuable in working out designs for engine repair stands, valve lifters, piston ring compressors, pullers of various descriptions and the few special wrenches that any good design may require.

General Discussion of the Papers

(The three papers were then opened for discussion by the chairman.)

MR. MEAD (Pratt & Whitney Aircraft Engine Corporation, Hartford, Conn.): I think it is only fair to say that in the well-established transportation companies and likewise in the case of the plane manufacturers, the engine builder now receives cooperation such as he wished he could have received a number of years ago. There is a constant interchange of information, trouble reports coming in from the operator and changes going out to correct the troubles from the manufacturer.

CHAIRMAN WARNER: The appropriate subtitle of that paper would be "The Infinite Importance of Little Things."

It is not merely those who are engine designers who can make valuable contributions to the discussion of these papers. The subject of safety is one that interests the potential consumer of air travel and the non-technical lay viewpoint is often of the utmost importance. Obviously, likewise, the viewpoint of the man who uses the engine, any pilot, is of very great importance.

F. J. D. FULLER (White, Weld & Company, New York City): I am a layman and I feel that perhaps I represent those who believe almost anything they read. We only hear gossip that is rather contradictory and don't know exactly what to believe. I have heard stressed this morning the importance of cooperation between

the engine designer, those who are testing the engines, and also those in charge of maintenance. There is one point I have not heard discussed, but which is important and that is the cooperation between the aircraft engine designer and the airplane designer. The aircraft engine designer will always face the problem of improper use of aircraft engines, and if as a result of improper use failures occur, the aircraft engine manufacturer will be forced to take responsibility whether he wants to or not. I have in mind the use of an engine of lower power than is necessary on certain planes requiring the engine to be driven at excessive r.p.m. resulting in more frequent failures than would otherwise occur.

I have also in mind multi-engine planes. I think the public is under some delusion, perhaps, as to the safety provided by more than one engine. It seems to me that perhaps a multi-engine plane when it once has attained its altitude may be safer because it has a wider choice of landing terrain. As to the increased safety on the take-off or immediately after, I am in great doubt.

CHAIRMAN WARNER: The matter of cooperation between the engine designer and the airplane designer is certainly of the utmost importance. Mr. Fuller suggests, when he speaks of overloading the engine to another matter of importance, the real significance of the term "cruising speed." Cruising speed in some cases seems to be anything that the manufacturer of the airplane likes to make it, but in other instances where it does conform to some kind of standard, it is stated on a more or less fixed per cent of the maximum power output and r.p.m. of the engine, somewhere around 85 per cent of maximum.

There is one man who occupies a very prominent position in the aircraft engine field—who states that to rate engines at 15 per cent less than the maximum normal rated speed, is nonsense. It is perfectly justifiable to push the cruising speed up and it ought to be justifiable to run the engine for long periods of time at a point very close to its so-called rated power and speed. Is 85 per cent a figure that contains any particular virtue or is there any other figure which we can establish to mark the level at which we are justified in expecting an engine to run with commercial economy for long periods?

On the general topic of the power of the airplane manufacturer to ruin the performance of the engine and the reputation of the engine builder. I may say that an eminent engineer in this field has repeatedly expressed to me the conviction that the airplane engine manufacturer ought to take over more responsibility. He ought to design the engine mount, and the exhaust manifold, and even the cowlings of the airplane and give a complete detachable power plant unit with everything pertaining to the power plant included in it so far as possible, and it ought to be bolted under the front of the airplane, naturally with a certain amount of option in form to fit various forms in designs.

LEE D. WARRENDER (Vacuum Oil Company, New York City): Dr. Dickinson spoke of the failure due to cooling and lubrication of about 2 per cent. May I ask if that is in operation or in laboratories?

H. C. DICKINSON (Bureau of Standards, Department of Commerce, Washington, D. C.): This percentage is based on the records of the Department of Commerce on accidents in civilian flying for the first six months of the current year, not in laboratory test, but in service. In laboratory tests, I believe we have had no failures due to lubrication directly. There have been some failures or near failures or some rejections due to failure in cooling, but it should be recognized that those are more or less experimental designs, and where failures have been due to failure in cooling, it has merely been a question of revising the design to make it satisfactory.

W. C. NAYLOR (Stout Engineering & Finance Company, Dearborn, Mich.): May I ask Mr. Lawrence, and Mr. Mead also, what has been their experience on rubber motor mounts or other means of dampening the vibration of radial engines?

CHARLES L. LAWRENCE (Wright Aeronautical Corporation, Paterson, N. J.): I will begin with the question of rubber mounts. I know the National Air Transport Company has taken to mounting all its Liberty engines on a rubber motor mount with a very increased length of time between overhauls so they now run above 200 hours. Curiously enough, one thing they found was that they practically eliminated the difficulty of cracked water jackets which does not seem to have any very close connection with the engine mount. There may be a vibration of a very high period which caused some vibration in the water jackets of the Liberty engine, causing it to crack.

With regard to the vibration of nine cylinder radial engines, I believe Mr. Mead will agree with me that in a great many cases where we hear of such vibration, it is traced to unbalanced propellers, but there is no doubt that the engine equipped with a rotary induction system is a very much smoother running engine than the type having the regular triple carburetor such as we used on the J-5 Whirlwind. When the distribution is improved by the rotary induction, the engine becomes about as smooth as the smoothest motor car, and I think when some of you gentlemen have the opportunity of trying that type of engine, you will find that it is exceedingly smooth.

Somebody asked about cooling of engines on test. There was a question of how much failure was due to cooling and how much failure was due to lubrication. In the past the air cooled engine builder has had a great deal of trouble in developing suitable test stands and dynamometers which would cool the engine, especially in hot weather, due to insufficient air space and the fact that very high power for a blower was needed in order to circulate the air properly. We all underestimated the power necessary with the result that most air cooled engine dynamometers, electric dynamometers, did not have an adequate supply of air. We have always been handicapped and always found when the engines were mounted in ships and flown they cooled much better than in the laboratory.

With regard to the rated horsepower, Secretary Warner said that somebody had spoken to him about the fallacy of running at eight tenths or nine tenths of rated power. Why not run at the rated power all the time? When you run at full power of the engine, say at 1,900, it merely means that 1,900 r.p.m. is the cruising speed. The engine should be able to stand an overload. In other words, the engine could be rated higher if it could stand running at full throttle. If an engine is rated at a certain power and is run at that speed all the time, it merely means you are rating the engine higher. If it will stand it, well and good. The question of rated power is really what the user can find is the satisfactory speed to suit his route.

For instance, the Pitcairn air lines have a very high schedule of speed. They have to run their engines at very nearly full throttle all the time. Some other users who have an easy route do not need to make so much speed. They can use their engine more lightly. Obviously the man who is hard on his engine will have a shorter life between overhauls and may have more engine failures.

MR. MEAD (Pratt & Whitney Engine Company, Hartford, Conn.): Rubber mounting will probably receive a good deal of attention for a reason other than that of the engine itself. In most three-engine ships with an engine mounted on the nose, there is quite a little vibration transmitted back to the body of the ship, whereas the shutting off of the center engine and running the other two eliminates a lot of this vibration. I think passengers are going to insist that in air transportation we do not go backwards in our standards of comfort.

As to surplus power in rating, it seems to me they are pretty well tied together. If the engine is operated at full throttle the rating is raised.

The Lufthansa in Germany operate at about 65 to 70 per cent of their horsepower. The B. M. W. Company talk about engines being 800 horsepower. They

are actually operated at 500 horse-power with 300 in reserve. That is the sort of surplus horse-power we have to have in this country. It is all right to say we can operate the engines at full throttle or rated power, but it does shorten the life, and what we want for three-engine safety in taking off is ample horse-power. We have all been so worried in this country about keeping the cost down that we have put in the smallest power plant that would possibly do the job. With the air cooled engine it takes very little additional weight to give you a very considerable increase in horse-power. And the difference in first cost is not very much. The cost over the life of the engine will be much less on account of the lower depreciation, resulting in a gain in increased safety with at least no increase in cost.

DR. H. C. DICKINSON: Another phase of the question which Secretary Warner mentioned and which Mr. Mead just discussed is the relation between cruising and rated horse-power and safety. The question of rated horse-power is a perfectly arbitrary one. To say that you operate at 85 per cent rated horse-power does not mean anything whatever, because the rating is arbitrary, and I believe it is rather important for us to develop something which can be recognized as fairly approaching a standard rating. It does not make so much difference what the rating is. It may be the maximum horsepower at which the engine can safely be run or it may be 75 per cent of the maximum horsepower or the maximum speed at which the engine may be safely run, but it should be something fairly consistent.

We have the same program, of course, in a rating of almost everything. An electric lamp is fixed on some arbitrary choice as to the relation between hours of operation and cost of the lamp, but it has been worked out to a fairly definite point so that rating a lamp is a fairly definite thing. A more indefinite case is the rating of a truck. A truck of 3 ton capacity is often run customarily with 6 or 7 tons load and will keep on running. There is no definite standard.

In the case of aircraft engines, it seems to me from our point of view, that we ought to develop a basis which can be standardized to a point where you can say that cruising power should be 85 per cent of rated power or 90 per cent, or whatever the case may be.

CAPTAIN R. W. A. BREWER: I would like to know if the Department of Commerce has any rule by which an engine of a certain type may be rated. It seems to me engines now running get type certificates on any kind of a rating. I have heard of engines getting type certificates issued at very much below the maximum available horsepower of the engine.

DR. DICKINSON: To answer Captain Brewer, I may say that the rating is fairly definitely handled by the department, but it depends to a certain extent necessarily, upon the speed at which the maker is willing to have his engine run. That is, if he presents an engine for test and says that he wants it rated at 1,800 revolutions, for instance; that means he is willing to subject that engine to a 50 hour endurance test at 1,800 revolutions and within 5 per cent of the maximum horsepower which the engine will develop at full throttle at that speed.

There have been a number of cases in which engines have been rated at horsepower very much lower than claimed for them, but in all cases the ratings which have been given out by the department are probably within 5 per cent of the horsepower which the engine will develop at full throttle at the rated speed. In some cases the operation of some of the engines has been somewhat irregular and the ratings have been fixed at the power which can be consistently maintained.

CHAIRMAN WARNER: It seems to me that the logical procedure is for the rating to be determined by the confidence the engine designer has in his own engine. There may be several engines of 800 cubic inch displacement. One man may think his engine will develop 300 horsepower. If it can and if it will run indefinitely at that power, the rating should be allowed.

It goes without saying that the slower you can run an engine or other piece of machinery, the less the wear will be. If we take a lamp and lower the voltage

5 per cent below normal, its life will be greatly increased. It is important to realize that the rating is not at the cruising speed and that the rated power of the engine ought to be a power at which it is capable of operating indefinitely.

In England this summer I had the good fortune to cruise around quite a bit in British machines. In one I flew in, there was a brass plate on the instrument board on which the rated speed of the engine was given as 2,100, and it was capable of operating safely, continuously, and indefinitely at that speed. Of course, though, it would have run much longer without overhaul if cut to 1,800. The engine manufacturer must realize that that is what rating means. Perhaps some of the pilots realize already, that if they run the engine full throttle it is not going to blow up. It should mean merely that the wear will be more rapid. There should not be any liability of structural failures at rated power.

MR. REID (National Advisory Committee, Langley Field, Va.): I wish to concur in our chairman's remarks about the manufacturers of engines designing the engine bearers and cowling, and similar parts. While we have had no particular trouble with engine bearers or mountings, I really believe that that is really part of the engine builders' job because there no doubt can be failures due to mounting. I am sure the engine builders should design the cowling. We are in the midst now of some rather elaborate tests on engine cowling and cooling in our propeller research tunnel, with which you are familiar.

One of a series of tests has been made on a cabin type of monoplane model, full scale, using an air cooled engine. We made some tests first without an engine in place and with the nose of the fuselage well stream lined. Then we made a test with the engine mounted, as is often done, with no cowling whatsoever. Of course under those conditions the fuselage and the engine combination had a very large drag. Then we cowed the engine one-third, two-thirds, three-quarters, and then completely cowed the engine; that is to say, from any viewpoint whatsoever except looking directly through the cowl you could see nothing of the engine.

We have had considerable difficulty with the cooling even with the one-third and two-thirds cowling and we were in a splendid position to know what the cooling was because we had some 60 odd thermo-couples distributed around the engine cylinders. Of course, we knew where the hot spots were, where to make changes in cowling in order to obtain proper cooling. However, the airplane builder or the man who is cowling the engine is not going to be in such an advantageous position. He is not going to have a great many thermo-couples around his engine to find out what his cooling is. Therefore, he is going to build a cowling which cannot be as satisfactory as if the engine builder were to make the study and cowl the engine himself.

We found that with the two-thirds cowling, which is quite common with the air cooled engine, the percentage of drag, (difference in drag between the stream line fuselage with no engine in place and the uncowed engine) was reduced about 30 per cent, whereas with the completely cowed engine, the difference between the uncowed and no engine condition was reduced about 85 per cent. This shows that the performance of the airplanes can be considerably increased, and it seems that the engine builder is in a very good position to do this work and give the aircraft manufacturers the benefit.

LT. C. R. BROWN (Washington, D. C.): I have some statistics here which should be rather interesting to everyone connected with building and manufacture of aircraft engines. During a period of seven years of navy experience there were 115 deaths, fatalities from aircraft accidents, and of those, in only 18 did the aircraft engine figure. Every one of those also had the personnel element introduced. The pilot in one particular case was doing a stunt in a type of engine known to cut out under those conditions. Not a single case of a fatality from engine failure pure and simple is on record during that period.

DR. DICKINSON: Lt. Brown's remarks throw very great credit on the work done by the Navy and also the Army in securing reliability of aircraft engines. As I noted in my paper the reliability of these engines is very high indeed. I think we should not lose sight of the fact, however, that similar statistics on civilian flying involving the proportion of the new commercial engines and large proportion also of the same military engines, show a considerably larger number of accidents due to engine failures. If we aren't careful with the newer engines representing a larger and larger percentage of the total the engine failures are going to account for an even larger percentage of accidents. From the point of view of testing, that is a thing that is giving us a great deal of concern.

ADJOURNMENT .

Power Plant (Continued)

GENERAL JAMES E. FECHET, Chairman

Chief of the Army Air Corps, War Department, Washington, D. C.

The second session on the Power Plant was called to order at 2:50 p. m., by General James E. Fechet, Chief of the Army Air Corps, chairman.

CHAIRMAN FECHET: The first part of the program with which we are concerned is the "Modern Power Plant From the Point of View of Safety," by Mr. George J. Mead, who graduated from the Massachusetts Institute of Technology in 1915. His aeronautical activities consist in service with the Wright-Martin Aircraft Corporation; the Power Plant Laboratory of the Air Service at Dayton, Ohio; as Chief Engineer of the Wright Aeronautical Corporation, and at present as Vice-President of the Pratt & Whitney Aircraft Corporation.

The Modern Power Plant from the Point of View of Safety

By **GEORGE J. MEAD**

Vice-President, The Pratt & Whitney Aircraft Company, Hartford, Conn.

Infalible. That, in a word, is the requirement of a safe aviation power plant when used in heavier-than-air machines. With no other prime mover is the penalty for failure apt to be so severe, and yet the very character of flying requires the weight per horsepower to be a very small fraction of that which is permissible and customary with the others. It used to be thought, and still is by many, that because of their light weight, aviation engines would never be reliable.

The problem, therefore, has been to make the light power plant more reliable than its heavy transportation contemporaries. How well this has been accomplished, may be gathered from the fact that modern power plants, weighing a pound and a half to a pound and three-quarters per horsepower, have run without accident 50,000 to 60,000 miles between overhauls. This is equivalent to some 500 hours of flying. The air cooled type of engine has been of great assistance in meeting the demands of commercial aviation. The elimination of the water cooling system has done away with one of the most prevalent causes of trouble that was encountered with the engines of several years ago. The weight saving, too, has its effect on the safety of the plane from the passenger's standpoint, since it may be put into a greater reserve power. As air cooling has become the accepted standard, I will not attempt to cover the safety situation in regard to water cooled engines.

A powerplant that is 100 per cent safe will continue to propel the plane under all normal flying conditions as long as its supply of fuel and oil is maintained. It will not itself catch fire nor ignite the plane either on the ground or in flight, and it operates without excessive vibration. From this it will be seen that defective design, material, fabrication, installation or operating care may all cause the power plant to stop. The record of safety achieved by the modern power plant is due to the efforts of its manufacturer, its operators and the Government. To fully appreciate the part each has had in this development a general review of their activities will be undertaken. These remarks represent the more or less

composite practices of the few experienced and well established engine builders and plane operators.

The Manufacturer

The manufacturer's work and interest starts with the design, and it might be added, never ends until the engines are all scrapped. Design is a matter of experience in an industry as young and revolutionary as ours. There are very few standards or precedents such as older engineering professions have, to check by. Under these circumstances, the safety of a power plant may be measured to a large extent by the experience of the designer, and the "know how" of the shop. The engineer must first determine the type of power plant to be built. This involves the question of the number and disposition of the cylinders and the proper displacement for the required speed and fuel to be used.

Much of the future success of a design depends upon the amount of displacement provided. If too little, the engine must work harder than necessary, both when taking the plane off and in cruising. A good design involves basic rigidity in the engine structure, and minute attention to the gradual change in section in the various parts. Localized stress cannot be permitted. Serious consideration must be given the matter of vibration when choosing a type. Poor mechanical balance, inherently bad distribution or firing orders cannot be tolerated. Vibration may cause engine failures, but more probably mounting a piping breakage due to crystallization. Provision for ample heat transfer must be made in parts, such as cylinders, pistons, valves and bearings. Hot spots must be avoided, not only on account of causing the parts to become overheated and thus be a fire hazard, but because of limiting the engine's output. Each joint must be made oil tight. This is extremely important as a fire preventive.

It has been found that lubricating oil thrown on hot surfaces of the engine is responsible for most of the fires resulting from a crash. The fuel and oil lines incorporated in the engine must be carefully worked out so that there is no vibration in the piping, and that the joints are properly made and locked. Extreme care must also be used in locking each engine part in some manner so that it cannot become loose or fall off. Ready access to all parts requiring periodic inspection and adjustment is essential. Adequate carburetor control must be provided so that proper mixture may be supplied to the engine under all temperature and barometric conditions.

It is interesting to note that the normal temperature range met in flying over our continent is from -50° F. to $+120^{\circ}$ F. Reliable and waterproof dual ignition is required. A carefully worked out exhaust system is also a necessity. The determination of the proper material and heat treatment for each part is a problem in itself. Uniformity in all material is essential. Here production problems, and the fatigue value of the material must be taken into account, as well as its physical properties. Needless to say, all these factors should come in for detailed consideration in every design. The more carefully they are provided for, the safer the resulting power plant. An experienced manufacturer subjects each new type to a great number of over-load and duration tests of his own before submitting it to a Government type test. It usually takes six months to a year to complete the manufacturer's tests alone, and generally involves the operation of several engines, both on the dynamometers and in flight.

Even after satisfactory experimental engines have been developed, the problem of their duplication has to be solved. This involves quantity procurement of uniformly good materials, tooling up the shop and Inspection Department, and development of the necessary shop "know how." The general public does not realize that our most experienced engineering staffs require nearly three years to develop a new type to the point where the shop is ready to produce it in quantity. It is common practice to incorporate changes in production engines immediately

that they are found necessary, and the change proven. This is very different than is customary in other industries where changes are usually made in new models only. To insure the maximum safety, all users are notified of the change so that they may replace the parts in their own engines which have been improved. To this end, changes are made in such a way that they are applicable in general to all engines of the same type previously built. In this manner continual refinement and improvement are taking place in a design.

Extreme care is used in the manufacturing operations, and these are all checked by the inspection department. In the case of one company, the inspection department reports to the chief engineer instead of the factory manager so that quality, not quantity, is their sole object. Never before has such minute inspection been carried out on such a large scale. The inspection department is responsible for the condition of the material in each part and its dimensional accuracy. All the castings are checked by chemical analysis of the material of each heat, and important castings, for physical properties by means of test pieces attached. In addition to this, they are all given dimensional inspection, particularly for the uniformity of sections and visual inspection for surface imperfections. The steel used for all important parts is analyzed chemically and tested for physical properties. Bar stock is examined by heats for chemical properties and by individual bars for physical properties. The bars of steel for the forgings of the rods and shafts are each chemically tested. The forgings are individually tested for the required physical properties by the use of test pieces which are integrally forged with the part. If the part is small, several are taken at random from each lot and used as test pieces, while all the other forgings in the lot are brinelled.

Extremely careful visual inspection is given each steel part for surface defects, such as seams, cracks and hair lines. To facilitate this work, the parts are etched several times during the process of manufacture and finally given a high polish. All important parts carry numbers all through their manufacture, and retain these in their finished state so that their metallurgical history may be checked back to the raw material. This provides a way to determine the cause of a failure and avoid it in the future. Complete dimensional inspection is provided for and at each stage of the fabrication of the important parts. Before each piece goes to the finished stock room, all its dimensions have been checked by "go" and "no go" gages, micrometers and form gages. A check on this inspection is had by the assembly of the parts. The individual inspection of practically every piece of each engine is a tremendous task, since there are often some 3,000 parts involved.

This all adds considerably to the cost of a power plant, but we feel that the utmost vigilance is absolutely necessary. Each complete engine is run with a propeller load usually at least from eight to ten hours before shipment. Prior to the acceptance test, which is of one hour's duration, each engine is disassembled for inspection. At this time a final check is made of the fits and limits of the running parts. Such a rigid inspection program provides as nearly as possible that every part that reaches the user is perfect from a metallurgical and dimensional standpoint. The matter of inspection has been gone into in detail, as unless one is familiar with the process, it is surprising to find the amount of care exercised and the amount of work involved.

Each type of installation is usually passed on by the engine builder. In this way the builder endeavors to see that a proper mounting is provided and that there is provision for temperature control by means of suitable cowling, correct and substantial piping for the fuel and oil lines, etc., etc. The matter of temperature control of an air cooled engine is extremely important. Not only must some means be provided to regulate the temperature of the lubricating oil, but also of the fuel mixture. It has been shown by the operation of the Transcontinental mail that it is readily possible to have the oil so cold in flight that it will not flow, and that ice may form in the carburetor chokes unless the necessary amount of heat is

provided. The matter of proper installation is of the utmost importance. Records show that many of our present day failures are still due to "plumbing" shortcomings. How often we hear of planes forced down because of fuel line failures or oil line breakage!

The manufacturer usually maintains a service department. This organization covers the country by means of expert service men assigned to various districts. By this means the different installations are checked and immediate assistance made available for any user. The information made available for the designer by this department is invaluable, both as to correcting faults which may appear, as well as improving new models. We have found that most large commercial companies are most helpful in keeping us in constant touch with their operations, especially the Boeing and Western Air Express Companies. This is of the greatest assistance, as their operations are what might be termed a "final" proving ground.

The Operators

The first problem of the user is to determine the amount of power that he will require for each type of airplane. In the case of passenger traffic it is becoming common practice to divide this power into three units. A generous amount of surplus power should be provided. Abroad, Luft-Hansa cruise with 65 to 70 per cent of their full power, so that they have quite a good surplus, while some of our companies have used as much as 85 per cent and even full throttle on their regular runs. The engine installation should be laid out in such a way that the personnel and facilities available along the line can quickly and efficiently take care of it. It is becoming a common practice to send the foremen of the field crews to the plant of the engine manufacturer to become acquainted with each new type which is put in operation on their line. This is the very best way of insuring that the engine receives proper care in service. Practically every well run transportation company has a routine inspection form of power plant items to be checked before each flight. This is a most important procedure from the standpoint of safety. In this manner the necessary routine inspection is not left to chance. Any faulty operation of the power plant is reported by the last pilot, and corrected before the next flight. In this manner the power plant is kept in its most efficient operating condition at all times. No matter how good the engine, it will not run consistently without systematic attention. Besides these inspections, the power plants are completely disassembled every 300 to 500 hours, depending on the service. This is a case of "A stitch in time saves nine," as it is very much safer, as well as cheaper, to discover and correct trouble before it occurs than to remedy it afterwards.

The Government

Several branches of the government are instrumental in checking the reliability of each type of power plant, its various installations, and its operation. Originally the Army and Navy were the only divisions safeguarding the general public. Even this was incidental, and came about because practically all new types of engines were built for either one of the services, and before they were approved, were tested by means of type tests set up by the division. At the present time, passing either the Army or Navy type test is sufficient to obtain a Department of Commerce certificate. Recently the Aeronautics Branch of the Department of Commerce has been established, and all strictly commercial engines must pass its 50-hour type test. This department also passes on plane design, which includes engine installation, and provides for yearly re-inspection.

Suggested Improvements

The occasional failure that still occurs is what we are now anxious to prevent. Naturally, these failures are apt to cause the most serious results in single engined

ships. For this reason multiple-engined ships are the only safe machines for passenger travelling. It is, however, necessary, even in the multi-engined ships, to have ample surplus power so that the ship may continue safely on its way with one power plant inoperative. Analyzing the cause of the failures that occasionally occur even with the modern engine, it seems that they are more or less equally divided between improper design, material fatigue, and defective "plumbing." Very, very few of the failures can be charged to negligence on the part of the inspection departments. How to reduce the number of these failures is our problem. Studying each of the three causes individually, it is possible to make certain suggestions for future improvements.

Design

Most of the design failures are experienced with new models, as might be expected. To overcome this, manufacturers should improve existing power plants wherever possible, and continue them in production until further improvement can only be had by a complete re-design. New engine models brought out solely for the purpose of having new sales talking points should be avoided. This may be all very well in the motor car business, but even with them, an entirely new model is usually in production two or three years before all the "bugs" are eliminated. If an automobile stops no one is hurt, but in aviation it is different. Every change must be proven necessary, and a definite improvement. A really good power plant incorporates the proven suggestions of the engineer, the shop, and operator, collected over a period of years of operation. Regardless of all the testing and care that is taken in manufacture, certain defects show up only in service, so that each really "service perfected" engine type is not to be lightly discarded. An entirely new type or model must go through the same process of refinement covering several years of service operation to be a real improvement over its predecessor. Testing one engine often fails to unearth all of the defects. Several of the engines of an entirely new design should be given a good many hours of real service flying before the type may be considered safe to be released for production.

It is essential that the type tests are sufficiently severe to bring out any latent defects in the design. Unless these tests show up major defects, someone is apt to be injured in a crash before they are discovered. Our commercial flying with modern equipment has been so much more successful than was anticipated, and the engines run so long without the necessity for overhaul that our previous ideas on type tests need revamping. For example, a desirable change might be to make the present Department of Commerce fifty-hour type test one hundred hours at rated power and speed. This does not seem at all too long in view of the performance expected from commercial engines. Running at rated power for this period provides a certain overload which accelerates the wear and fatigue on the parts so that it probably would not be necessary to run three hundred hours as is expected of a commercial engine somewhat throttled. As a matter of fact, the British Air Ministry test is one hundred hours now. In this connection it is interesting to note that the United States Shipping Board require a thirty day continuous test of a new type of Diesel engine.

The wider use of aluminum and magnesium forgings instead of castings is desirable, as it insures greater uniformity of strength. Casting defects are often difficult to detect, such as blow holes, porosity, thin sections, etc.

The Problem of Fatigue

Fatigue is the most difficult problem we have. The principal trouble is that our knowledge is so deficient as regards certain properties of the special alloys that are used, especially the light alloys and valve steels. Constructive aid can be

given us by the metallurgist in providing data on the relative fatigue values of materials, the effect of temperature on these, and also its effect on the elastic limit of the material. From our experience, it seems probable that a good deal of improvement may be made in the properties of our light alloys. Lighter or stronger materials will be of great assistance in improving our strength factors without adding weight. Inspection devices to determine the interior condition of a piece of material, especially steel, would be of great value. Our methods of surface inspection are, practically speaking, perfect, but we do not necessarily know from them whether there is an internal flaw. Fortunately the sections of many parts are comparatively thin so that external inspection is almost sufficient. Nevertheless, we want to eliminate this cause of possible failure entirely.

"Plumbing"

A large proportion of our present forced landings are due to "plumbing" failures. For this reason the plane builder should co-operate to the fullest extent with the engine builder in order that the installation may be made properly in each new type of ship. I am glad to say that this cooperation quite generally exists. It would further be desirable if the Department of Commerce would make an even more careful check of the engine installations in checking and approving each new type of plane. "A chain is no stronger than its weakest link." It is, certainly illogical to perfect both plane and engine and then pay little attention to the combination of the two. This is one part of the plane which has not been improved very much since the days of the Wrights.

The Future

As the industry grows, and because its growth is now extremely rapid, new problems involving safety will confront us. The manufacturer with large unfilled orders may feel the urge to increase his production at the expense of quality. It is not likely that a reputable manufacturer who has been identified with the industry for any great length of time would be guilty of lowering his standard of quality. On the other hand, there are a number of new companies entering the field without experience, and they may unintentionally set up inferior and unsafe standards, which would be a very serious matter.

On account of the rapid growth, we may soon have a shortage of experienced mechanics. The average automobile mechanic without aviation experience is of very little assistance. Good schools for mechanics are most essential. Some of the manufacturers are doing what they can to establish schools at their own plants, but these will not be sufficient to fill the demand.

Universal service is becoming necessary. A country-wide service organization will be essential for every reputable manufacturer. Purchasers will expect this, just as they have in the case of the motor car, and as a matter of fact, it will be the best way in which the manufacturer may safeguard the public. "Genuine" replacement parts will thus be available and intelligent service. The matter of "pirate" parts will be serious, and some way will have to be found to discourage their sale. Since the "pirate" part builder has no particular reputation to sustain, he will not take the care, nor will he have the experience, to make the parts properly.

Those of us who have lived with aviation for some time have learned by experience some facts regarding safety requirements which will bear reiterating. A safe engine is not built to a "price." The builders of small planes have asked for 120 H.P. engines to cost \$1,000. An engine could be built to sell at this price, but in the present small quantities it would either not be a "safe" engine or it would be so heavy per horsepower as to be uninteresting. In aviation, as in everything else, one never gets more than he pays for. Safe aviation power plants involve a great

many expensive operations not required, for instance, in a motor car engine. It is, therefore, not safe to anticipate a proper price based on automobile costs, especially so when the relative quantities involved are considered. Continuous quantity production of a single type will, and is, bringing costs down without sacrificing safety. Of the two, production volume, not design, has the greatest influence on cost.

Another truism is that mere pounds in a power plant are not synonymous with dependability or safety. Commercial engines, in order to have a long life and therefore low rates of depreciation, will weigh something more than a fighting engine. The weight difference need only be slight with proper designing and should be small if the plane in which the engine is used is to carry the maximum pay load. Reverting to our heavy pre-war engines will not make aviation safe. For the most part, these weighed twice as much as the reliable modern power plant. One measure of the efficiency of the commercial plane is weight saved in the plane and engine. In other words, more and more pay load must be more safely carried per horsepower, if we are to progress.

Surplus power is another safety requisite. Underpowered planes are dangerous in high winds or in combating ice-forming moisture on the wings. In avoiding obstacles in a fog, a rapid rate of climb may prevent a crash. This same ability makes it much safer to get out of a small field. This all requires ample power. Fortunately, with an air cooled power plant, surplus power may be provided with the addition of very little weight.

No matter how good a power plant is, and how well it is installed, it will not prove infallible without the proper fuel and oil. Poor fuel is usually used because it is a few cents cheaper a gallon. If the operating costs were analyzed, it would be seen that the fuel cost is approximately 5 per cent of the total cost per mile. The cost of the more frequent overhauls and the new parts, greatly offsets any slight immediate saving. This all affects safety because continued use of low grade fuel ultimately causes piston, spark plug and sometimes valve troubles. In an emergency the modern aircraft engine may be operated on low grade fuel providing it is throttled to prevent knocking. At present "Aviation" gasoline means little or nothing. It depends principally on what part of the country you are in as to how good it is. Straight West Coast fuel is usually good from a knocking standpoint, while East Coast fuel is usually bad, even though they both meet the present Army and Navy specifications. If the East Coast fuel were "doped" satisfactorily so that it equalled the other in anti-knocking properties, the term "Aviation" gasoline would mean something and the resulting uniformity would be a great help towards increasing safety. The chemist could assist us greatly if he would devise some satisfactory means of measuring the anti-knock value of a fuel. We all realize this is a difficult problem, but it needs a satisfactory solution just the same. Lubricating oil of inferior quality or improper viscosity may also cause forced landings due to piston or bearing seizures. Here again the cost of oil is so negligible an item that there is no excuse for running this risk.

The entrance into commercial aviation of the large transportation companies with ample means and experienced executive management has done more, perhaps, to make aviation safe than anything else. Modern equipment is expensive and the individual operator usually could not afford it even though he knew it was much safer and cheaper to operate. In other words, aviation was not showing what it could do. The large operators had the good judgment to use modern equipment exclusively, and it has paid. One of the most valuable things the Guggenheim Fund has done has been to finance a model passenger line and thus show that it was safe to fly with proper equipment. The Western Air Express Company was one of the first to carry passengers on such a large scale in this country. This example and that of the Boeing and N. A. T. Companies, which are now both operating ten and twelve passenger ships, is sufficient to prove to the American business that aviation is here.

Airminded shop personnel is most essential. After all is said and done, our safeguards all depend on the care of the individual, whether he be engineer, mechanic or inspector. If these men fly, even occasionally, they realize the necessity for extreme care. One ride, for example, with the Transcontinental mail will do more towards convincing anyone as to the necessity for extremely efficient inspection than all the talking and regulations.

Commercial aviation has just found its wings, and we are on the threshold of regularly established long distance passenger transportation, thanks to the trail blazing of the Transcontinental mail. Ship and engine types are bound to be influenced by the experience gained in the next few years of commercial operation. Greater safety is going to be the keynote of this development. More accurate design will be possible because of the increased experience of the engines. It is hoped that the chemist and the metallurgist will also add materially to our knowledge, and make available more and more reliable materials to work with. Universal airmindedness will do more to make flying safe than anything else.

Discussion of Mr. Mead's Paper

CHAIRMAN FECHET: Is there any discussion?

CAPTAIN BREWER (of Philadelphia): One of the most important things that we have before us is the question of testing, particularly in view of the fact that so many new makers, are coming on the market, and a good many of them undoubtedly have had no experience, or very little experience as actual designers or manufacturers of aircraft engines. Some of these engines have been taken up as the result of knowledge gained in looking at other people's work, and it is a very different story to criticise other men's mistakes and to put an engine out that doesn't have those mistakes, presumably, but which also embodies very many of the manufacturing tricks to which Mr. Mead referred and which only can be known and understood by people who have had long and extensive experience.

I suggest, in respect to the question of type testing, that it would be very valuable, after a type test has been made, to run the engine to an actual breakdown, for then we would find out some of the weaknesses in the engine which do not develop under ordinary conditions of the type test.

Secondly, I want to endorse strongly Mr. Mead's suggestion that periodic tests of actual production jobs be made, for I think that is extremely important, especially in view of the fact that the type test may be passed by an engine which has been particularly constructed to undergo a type test and nothing else.

Designers of modern commercial engines are always being faced with comparisons with engines designed for military purposes only. I would like to ask Mr. Mead's opinion as to what might be an allowable increase in weight in order to save twenty-five or fifty per cent of the cost of the engine. This is very important to the commercial engine user.

MR. MEAD: None of us have had enough experience to get down to actual figures. The nearest I could come to answering that question would be to venture the opinion that the addition of a quarter of a pound per horsepower or perhaps a half a pound per horsepower would be ample. Our modern military engines are getting down pretty close to a pound and a quarter per horsepower, and our modern commercial engine is somewhat heavier than this. It weighs, depending on the size, between a pound and a half and two pounds per horsepower. We must all appreciate in using this figure that we are required and want to use certain accessories in the small engines that we use in the large engines, and, therefore, the weight per horsepower of the small engine is greater than that of the large engine. On that basis, I should think that a quarter to a half-pound addition for the particular type in mind would be sufficient.

You see, what we meet with is the idea that all you have to do is to put on a quarter of an inch of that or a pound of this or that, and if you keep on doing it you soon would have an engine that very easily weighed four or five pounds per horsepower, and that isn't permissible, as I see it. It is easy for us to take that attitude and just make it heavy. That is easy. But I don't think that is fair to commercial aviation, if we consider all the facts, and we must keep our weight down.

MR. FAYE: How many points did you say there were to inspect in an aircraft engine?

MR. MEAD: It depends on the size, but the average runs about twenty-five hundred to three thousand, including cotter pins and everything else.

J. O. SCHERER (Junkers Corp. of America, New York): May I make a suggestion in connection with the weight of the engine? I think fuel economy and not dollars and cents is the primary consideration. A heavier engine can frequently be built with higher fuel economy than the extremely lightweight engine. The military engine calls for two or three hours of flight, and the lightweight engine is essential. With the commercial machine, I believe that with more pounds in engine weight you get an increase in fuel economy and an increase in fuel economy means longer cruising radius.

MR. MEAD: There are two things to be considered in this connection. The maximum run of the transcontinental air lines, under average weather conditions, is about two and a half or perhaps three hours, and it is then necessary to come down to pick up mail. The same short runs will apply to commercial passenger transportation until our planes are considerably different from what they are now, partly because it is very uncomfortable to sit still in an airplane for a good many hours at a stretch, and partly because it is necessary to pick up and set down passengers at frequent intervals. It does not seem quite as necessary yet to have the long range in a commercial ship that we once thought essential.

You may be hinting at the Diesel engine in your remarks. Diesel engines, of course, are not heavy because of considerations of fuel economy. They are heavy on account of the cycle on which they operate. We have yet to find that the fuel consumption of the Diesel is any better on the average than it is with good gasoline engines, although I will admit that our experience with Diesel engines in this country is small.

MR. SCHERER: I think there is another factor to be considered. The heavier engine is built with a considerably lower r.p.m., giving a higher propeller efficiency. The airplane with the same weight of engine and less power may perform equally well as it will with the fast turning propeller engine with more horsepower.

MR. MEAD: That is again a Diesel argument. It cannot run as fast, so it runs slow. We are having to go up in speed to decrease the weight per horsepower, even though we have to consider safety always. We could arbitrarily slow the engine down to fourteen hundred, but the more advanced way is to try to develop the engines to hold to the present weight, or even less, which can be done by running the speeds up, and yet maintain reliability. In the future we may have a Diesel engine that will compare very favorably in weight with our present engines and that will run perfectly well. I know of a 500-horsepower Diesel engine that was built experimentally in Germany that weighs two and a half pounds per horsepower. That is an engine which has to be seriously considered. But all the early Diesel engines have been too cumbersome and heavy to be considered for aviation purposes. We may next year say that our viewpoint has changed, but at this time the utility of commercial engines does not depend very much on fuel consumption. An extra cost of five per cent in fuel is of little importance. We must also realize that our ideas of speed have changed a great deal. We used to think one hundred miles an hour was all right for a commercial plane, but many of us feel now that it is essential to have higher speed and many manufacturers

are laying down large commercial planes that will cruise at one hundred and twenty-five at the least. It is very likely in the next year that planes will be built that will cruise at nearly one hundred and fifty miles an hour. This will change the problem of propeller efficiency. The faster the speed of the plane, the less need there is of slow propellers.

MR. HENRY REID (Langley Field): I wasn't going to say anything about our work on Diesel engines that the National Advisory Committee did at Langley Field until I heard this brought up.

Theoretically, the Diesel engine has many advantages, and I believe that we will soon see Diesel engines a real competitor of our present-day gasoline engines. It is hard to say how soon that will come, but with our ever increasing speed of attaining knowledge, I think it is coming very soon. Of course, the Diesel engine has some advantages from a safety standpoint. In the first place, it will have no electrical ignition system, with its attendant liability of failure. Furthermore, it will have no carburetor with its liability, under certain conditions, of becoming clogged up with fuel. In addition to that, the Diesel engine burns an oil with a very low flash point, and, of course, in case of crash the danger from fire is very much reduced. In fact, small fires may be easily put out by fuel being dumped under the fire in large quantities.

The Diesel engine is, perhaps, more readily made to operate on the two-stroke cycle, and thereby, by increasing the power per unit weight you can still save in weight of the engine, and in order to have the same strength of engine, you can reduce the weight; or, if you want to increase the safety somewhat or the length of time the engine will operate with a certain amount of overhaul, you can increase its weight to get the requisite strength of the parts.

ADJOURNMENT

Fire Prevention

GENERAL JAMES E. FECHET, Chairman
Chief of the Army Air Corps, War Department, Washington, D. C.

The Session on Fire Prevention was held immediately following, General James Fechet again presiding.

CHAIRMAN FECHET: Fire during flight may be caused by ignition troubles or through the breaking of a gasoline line, the consequent escape of the gasoline and its contact with the hot exhaust pipes or wires causing it to ignite. Fire hazard due to ignition and wiring troubles have been practically eliminated. From the generator to the battery the danger of short circuiting has been largely avoided by placing in the cockpit a control box with circuit breakers. In case these go out of adjustment there is also a master switch which throws off all electrical leads to all parts of the plane excepting to the motor. In addition, the motor leads, or ignition leads, are switched off by independent switches. Independent switches to the radio apparatus, instrument lighting apparatus, landing lights, landing flares and heater apparatus are, of course, a means of cutting off any independent known short circuit which might occur.

Fire may also occur in the magneto in such planes as are equipped with magneto ignition. A fire-proof ventilating hole cap has been devised which diffuses and cools the flame from the vent hole, thus preventing fire outside of the magneto. These caps are applicable to all existing types of magnetos.

Gasoline tanks: These are covered with a heavy rubber fabric envelope of such character that a bullet piercing the tank causes no immediate damage. The rubber fabric closes up the bullet hole and prevents the leakage of gas. This not only prevents fire but conserves the gasoline supply and may allow the pilot to return to his airdrome without a forced landing.

In most military planes there are several types of gasoline tanks, such as the wing, main and auxiliary. In several types of planes provision is also made to carry what is termed a "belly" tank, this to permit an extended cruising radius. In case of trouble during flight the "belly" tanks with their contents can be dropped clear of the plane simply by pulling a lever in the pilot's cockpit. Gasoline being a grave fire hazard in case of a forced landing or in the event a safe landing is doubtful because of a small or strange field, danger of fire may be avoided by pulling another lever which releases all the gasoline supply in the space of a few seconds, the lever opening a large valve in the bottom of the gasoline tank.

Pyrene: In the newer types of planes the motor can be drenched with pyrene simply by pulling a knob in front of the pilot. In case of trouble the pilot rarely has much time to pull a fire extinguisher from its socket and spray the motor. In addition, the air blast practically prevents any beneficial effects through such a method. With the present system the pyrene sprays the entire motor, leaving the pilot and passengers free to control the plane and devote the limited time at their disposal to other matters requiring immediate attention.

We shall now hear the paper prepared by Captain Oliver P. Echols, U. S. Army Air Corps, Wright Field, Dayton, Ohio.

Fire Prevention in Modern Airplanes and Recent Experimentation

By CAPT. O. P. ECHOLS

Chief, Equipment Branch, Material Division, Wright Field, Dayton, Ohio

There are available no statistics on the airplane casualties due to fires during the recent war. Everyone knows that there was a large loss of life due to both fires in the air and fires due to crashes. On the front, the greatest fire hazard was due to bullets in the gas tanks, and as far as can be determined the only real efforts at fire prevention, or the reduction of casualties therefrom, were the covering of the gas tanks with rubber and an attempt by the Germans to use parachutes.

It was not until after the armistice was signed that the large percentage of fatalities due to fire compared to the total number of accidents became apparent, and studies were begun by the Engineering Division of the Army Air Corps as to the causes of fires and the means of preventing them. There were no statistics available, and there was then, as there is now though to a lesser extent, a great deal of difference of opinion as to the causes of airplane fires. There was prevalent an idea that most crash fires were due to ignition, while very few thought that ignition was the primary cause of fires in the air. As I will bring out later, subsequent experiments have proven to our satisfaction that just the reverse is the case.

As early as 1918 it was apparent that the fire hazards in certain types of planes was greater than in others. The DH-4 airplane was considered particularly bad in respect to fires in the air, and the percentage of deaths in crashes was unusually large. It was found that many of the fires in the air were due to back-fires through the carburetor. After this was determined to be the cause, the trouble was easily eliminated by placing a stack over the air-scoop extending well outside of the cowl- ing so that in case of a backfire the fire was not only confined to this stack, but all flame was outside the cowl- ing, and, also, by requiring that carburetors be carefully checked to assure that the air-scoop contained no recesses or plugged openings which would allow gasoline to stand in puddles.

From 1919 to 1924 continuous studies were carried on in connection with fire prevention in aircraft. The most important accomplishment during this period was the development and adoption of the standard parachute, which has resulted in the saving of a large number of lives. A few of the outstanding studies follow:

- (a) Underslung, rubber, crash-proof fuel tanks.
- (b) Main tanks in lower wings.
- (c) Tanks in upper wings.
- (d) Use of air starters in lieu of electric starters.
- (e) Aluminum exhaust manifolds.
- (f) Carbon tetrachloride bombs installed directly behind the engine, so that in case of crash they would break and flood the engine compartment.
- (g) Elimination of pressure fuel system.
- (h) Improvement in oil and gas line installations.

These studies were interesting but proved of little value as in many cases they seriously interfered with the performance of the airplanes, and in other cases the complications involved were too great to justify their use. Further, we still had no definite information as to what caused fires, particularly crash fires. Authority was obtained for the construction of a crash runway for the destruction of obsolete and unserviceable aircraft in an effort to obtain authentic engineering data as to the actual causes of fires in aircraft. This runway was completed in July, 1924, and was approximately 566 feet in length, the first 360 feet of which was a grade of about 5 per cent and the difference in elevation of each end was about 20 feet. At the lower end a reinforced concrete wall 10 feet wide, 3 feet thick, 14 feet above

and 6 feet below the ground was constructed. Shields and bomb shelters were placed in several locations, near the wall, for the protection of photographers and observers. Obsolete and salvaged aircraft were obtained and assembled with gasoline tanks, power plant, landing gear, and other necessary equipment, but minus wings. The airplanes were then placed on the runway and after the engine was sufficiently warm they were released and allowed to crash into the wall; the idea being to simulate the worst conditions of a crash, and slow motion pictures, as well as normal speed pictures, were taken from both sides. These pictures, after development, were studied under a microscope and the origin of the fires located.

Crash Fires

During these tests, which covered a period from July, 1924, to October, 1926, there were 83 airplanes crashed. All of the then available combinations of airplanes, engines, exhaust manifolds, fuel tanks, gasoline systems and ignition systems were used in making these tests. The results obtained on each type and combination of types are available in the Material Division Report on these experiments.

The tests were divided into six series. In the first series, known as Crash Series No. 1, 26 airplanes were crashed and 6 fires resulted. In this series, various types of engines, exhaust manifolds, fuel tanks, gasoline systems, and magnetos and generators were used. The battery, the most accused member of the ignition system, was placed below the airplane on the landing gear axles and was knocked off by striking a stop in the runway 25 feet before the plane crashed. Up until this time we had considered that the battery was a very serious fire hazard in crashes, and in this series of tests wished to determine what fire hazards other than that due to the battery existed in the various combinations. As a result of the Crash Series No. 1, the following data were prepared:

(a) *Fires with respect to kind of gasoline tank:*

Kind of Tank	No. of Crashes	No. of Fires
Leakproof or Crash-proof.....	8	2
Plain	18	4
Total	26	6

The conclusion arrived at from the above was that the value of leakproof or crash-proof tanks in crashes was questionable.

(b) *Fires with respect to ignition systems:*

System	No. of Crashes	No. of Fires
Magneto	14	2
Generator alone.....	2	1
No ignition (battery knocked off just before crash)	10	3
Total	26	6

It seems reasonable to conclude from the above that, in crashes, ignition is not a fire hazard of any great magnitude.

(c) *Fires with respect to gasoline systems:*

System	No. of Crashes	No. of Fires
Air Pressure.....	14	3
Gear or syphon pump.....	10	2
Gravity	2	1
Total	26	6

It will be noted that according to the above data there is no distinguishable difference between the hazards of air pressure, pump feed, or gravity feed gasoline

systems. However, in this case we have refused to place much confidence in our own figures. We feel certain that the air pressure gasoline system was one of the worst offenders in regard to fires and, of course, in time of war a bullet in an air pressure tank is a more serious proposition than one in a tank not under pressure.

(d) *Fires in relation to exhaust systems:*

Kind of System	No. of Crashes	No. of Fires
"Saxophone" manifold.....	5	3
Night Flying manifold.....	1	1
Individual stacks of 12 inches or less.....	8	1
No exhaust stacks.....	12	1
Total	26	6

As a result of this compilation it was believed that some very strong evidences as to the origin of the fires had been obtained. It led to the belief that the exhaust stacks were mainly responsible for crash fires. This was borne out from a study of the moving pictures and notes of the observers. Fairly definite information was available that, of the six fires, four started at the end of the exhaust manifolds, one started at the exhaust port on a plane which had no exhaust stacks, and the origin of the other could not be determined. It will be noted that four out of the five fires whose origin could be determined were started by the exhaust manifolds. The conclusions reached thus far were that in the case of crash fires, ignition is not a hazard of great magnitude, while the exhaust manifold is a serious hazard. Further tests were conducted in order to affirm these conclusions and the following is a summary of the results obtained:

Crash Series No. 2.

In this series individual 12-inch air-cooled aluminum exhaust stacks were compared to other types. Sixteen planes were crashed: 10 with 12-inch air-cooled stacks, 5 with no exhaust stacks and one with the standard steel saxophone manifold. Only one fire resulted, this one from the standard manifold. This was considered ample proof that exhaust manifolds are a great fire hazard and individual, aluminum, air-cooled exhaust stacks are not sufficiently hot to ignite when gasoline is thrown over the engine from bursted tanks.

Crash Series No. 3.

This series was run to determine the efficiency of individual steel stacks. Four planes were crashed, with no fires. On account of the small number of planes involved, this test was considered inconclusive.

Crash Series No. 4.

The same as Crash Series No. 3, except that a different type of engine was used. Fourteen planes were crashed and three fires resulted. Out of the fourteen, four were declared "No Test" as examination of the motion pictures showed that no gasoline reached the exhaust stacks. The conclusion arrived at was that the individual steel stacks are not as great a hazard as the manifold, but are not satisfactory, as all three fires in this series started from the exhaust stacks.

CHAIRMAN FECHET: You have heard this very excellent paper on fire prevention. Is there any question that anyone would like to ask?

MR. BAILEY: I wonder if Captain Echols would say a few words on fire extinguishing systems on airplanes?

CAPTAIN ECHOLS: We use a pressure type fire extinguisher on our planes. The material in the extinguisher is released under pressure and forced into the "V" of the engine. While that is not standard equipment, it is the equipment that we use and recommend.

MR. BAILEY: What is the material in it?

CAPTAIN ECHOLS: It is carbon tetrachloride at this time.

Discussion of Captain Echols' Paper

By J. W. SHOEMAKER

Bureau of Aeronautics, Navy Department, Washington, D. C.

The Bureau of Aeronautics feels that it has been very successful in eliminating fires in naval airplanes. Fires in the air are of negligible occurrence, and fires after a crash are practically unknown.

The following items appear in the specifications for naval airplanes, and have been insisted upon continuously since 1926:

(a) *Structural.*

(1) A flame-tight, fireproof bulkhead or fire shield shall separate the engine compartment from the rest of the fuselage and from the crew and fuel tanks to localize any fire which may occur in the engine compartment.

(2) The fire bulkhead shall be constructed of tinned, galvanized, or terne sheet steel, or shall be built of two sheets of 0.02-inch (minimum) aluminum separated by $\frac{1}{8}$ -inch asbestos sheeting.

(3) The fire bulkhead shall fit closely to the cowling all around the section of the fuselage and shall be pierced with the minimum number of holes practicable. Where structural members, control leads, pipe lines, or other parts must pass through the bulkhead suitable fire-resisting stuffing boxes or bushings shall be provided.

(4) With the exception of the engine bearers, which may be of wood, no wood or other inflammable material shall be used on the engine side of the fire bulkhead. The structure shall consist of metal members and fittings and wires.

(5) The sides of the fuselage for a distance of at least 9 inches behind the fire bulkhead shall be metal covered.

(6) The bottom cowling shall be so designed as to be self-draining, with an opening at the rear edge extending the entire width of the fuselage at the fire wall. The bottom of the fuselage behind this point shall be metal covered for approximately 3 feet.

(7) The cowling around the engine and engine compartment shall be of sheet metal, and shall be easily removable in part or entirely to permit of access to the power plant. It shall be suitably ventilated to prevent accumulation of gases.

(8) The cowling and its fastenings and mountings shall be designed for ruggedness and security, with a view to securing minimum head resistance and maximum protection from the weather for the engine, as well as protection to the crew and structure from oil and fire in the engine compartment.

(9) Care should be exercised in the design of the cowling around the engine to prevent short-circuiting of spark plugs or other interference with the power plant.

(b) *Electrical.*

(1) An approved type of high tension ignition wire terminal must be used.

(2) The junction of the H. T. wires with the spark plugs must be covered with Rajah type rubber nipples.

(3) Ignition circuits shall be secured against excessive vibration and adequately protected against short circuits or grounds caused by chafing.

(4) Ignition circuits shall be installed in such manner as to be protected from spray while taxiing, and from excessive dampness due to rain or fog.

(5) Ignition circuits shall be installed in such manner that they cannot come in contact with fuel or oil from leaking fuel or oil lines or tanks.

(6) All high-tension wiring shall be incased in suitable conduits.

(c) *Engine fuel system.*

(1) In every installation all carburetor air shall be led to the carburetor through an air-intake pipe so designed and installed that in event of backfire through the carburetor, flames shall be led into the open air clear of the fuselage and engine cowling.

(2) Intake pipes shall be flame-proof and shall be so designed and installed as to withstand temperatures and pressures which may occur in the event of a carburetor backfire.

(3) All joints between carburetors and air-intake pipes shall be gasoline tight, with no openings whatever within the engine compartment.

(4) In the design of intake pipes care shall be exercised to avoid pockets which may collect free gasoline. Where such collection of free gasoline is unavoidable, a drain connection shall be provided at the lowest point, and a pipe shall be led therefrom which will drain all gasoline outboard to the open air free of the engine compartment and fuselage.

(d) *Engine exhaust system.*

(1) It shall be so designed that all exhaust gases are carried off in the open air clear of the crew, gasoline tanks, or inflammable parts of the airplane.

(2) Clearance of at least 3 inches shall be provided between the exhaust manifold and wood or fabric parts. The open end of any exhaust pipe shall have a clearance of at least 5 inches in every direction from inflammable parts. The downwind clearance from the open end of any exhaust pipe measured along any direction of normal flight shall be at least 4 feet.

(3) Any exhaust piping not directly exposed to the air outside the cowling shall be cooled by water jacketing or by an air draft induced through a jacket surrounding the exhaust piping.

(e) *Fire extinguishers.*

(1) There shall be one pressure-type extinguisher for each engine.

(2) One hand fire extinguisher shall be provided for each member of the regular airplane crew.

(3) The fixed fire-extinguisher system includes all tanks, pumps, piping, nozzles, gauges, containers, controls, etc., which are used in the installation of the fire-extinguisher medium in the airplane and for its proper distribution in event of fire.

(4) The parts of the fire-extinguisher system shall be so mounted as to reduce the effects of vibration to a minimum.

(5) Piping for the fire-extinguisher system shall be securely supported at frequent intervals. At points where supported and at other points where chafing is likely to occur the piping shall be wrapped with tape or otherwise suitably protected.

(6) Pressure fire extinguishers have been fitted on all naval airplanes for several years.

(f) *Airplane lubricating and fuel systems.*

(1) The oil tank shall be located as near to the oil pump as possible. The bottom of the oil tank shall be above the level of the oil pump.

(The Bureau of Aeronautics is now calling for location of oil tanks forward of the firewall. This aids in oil cooling, and keeps the length of required oil piping a minimum.)

(2) Oil and fuel tanks shall be of approved design and material.

(3) It is considered desirable to reduce the number of openings in the tank to a minimum. Where possible, tank pipe-connections shall be grouped on removable plates provided with suitable gaskets.

(4) Oil tanks shall be designed to withstand a test pressure of 5 pounds per square inch without injury, and with not more than ~~1/8~~-inch distortion for each foot of length, or breadth, or depth of tank. ~~One tank of each new design shall be tested to destruction.~~

The same specification covers fuel tanks, ~~except that the maximum test pressure is 4 pounds per square inch.~~

(The Bureau of Aeronautics is now requiring that one of each fuel and oil tank design of the type to be installed in an airplane ~~withstand a vibration test of 25 hours without failure before the design is accepted.~~)

(5) The location of tank filler openings shall be ~~such as to permit of filling from the outside of the fuselage or engine cowling and without the use of a special type of funnel.~~ Furthermore, it shall be so located ~~that overflowing oil or fuel will not fall upon parts of the engine, electrical wiring, or structure of the airplane which will be damaged, or into inclosed parts of the airplane where an explosive mixture is liable to form.~~

(6) The Bureau of Aeronautics has for about a year required that all oil piping, and all fuel piping between fuel tank and carburetor be of copper.

(7) Insofar as possible, oil piping will be installed in two separate units. One unit shall be supported rigidly on the engine and considered as an integral part of the engine. The other unit shall be supported rigidly by the fuselage and considered as an integral part of the airplane structure. The two units should join at the engine bearers with an approved type of flexible connection.

(8) Piping shall be annealed after bending.

(9) Piping shall be supported at frequent intervals.

(10) Piping where supported, and at places where chafing is likely to occur, shall be protected by tape, or the equivalent, suitably applied.

(11) Piping should be supported near to and on either side of a connection or elbow.

(12) Except as specified above under "Installation" and unless specifically authorized by the Bureau of Aeronautics, solid connections shall be used throughout the lubricating and fuel systems. Where specific approval is given to use other than solid connections, an approved type of flexible connection or hose connection shall be used.

(13) All fuel tanks in the fuselage shall be to the rear of the fire bulkhead.

(14) All piping which from the nature of the design of the fuel system may or does carry fuel into the engine compartment shall be provided behind the fire wall with simple "on" and "off" cocks interconnected in such manner that they may be quickly and positively operated by the same control by the proper member of the crew in case of fire.

A Study of Precautions Against Fire on Board of Airplanes

By J. SABATIER

Engineer-General of the Air Force of France, Paris, France

The fear of fire certainly causes a good many of the great public to keep away from commercial aviation: the violence with which such fires break out, their immediate effects, the difficulty of rendering useful aid,—strike the imagination of those who are, or think they are, exposed to it.

Why does fire menace the airplane more than any other means of transportation? Because airplanes carry considerable quantities of gasoline; because this fuel when

in contact with the surrounding air forms explosive mixtures and on airplanes the chances of leakage and spilling are relatively high.

The Problem of Eliminating Gasoline

The idea which immediately presents itself as a remedy for this dangerous situation is to eliminate the gasoline and to substitute for it a fuel which is less dangerous when in contact with air. Numerous attempts have been made along this line of thought within the last five or six years; they followed two principal courses:

(a) to seek new fuels, less inflammable than gasoline, yet sufficiently allied to it, so that they might be utilized by engines presently used, without requiring profound changes in their construction;

(b) on the other hand, to turn to heavy fuels actually available to industry and to produce special engines capable of using them.

The first method involves not only the finding of a convenient "safe fuel" but also the adaptation of existing engines, notably their carburetors, to its use.

Many hopes have been raised, and several inventors thought they were able to obtain satisfactory products; in general they proposed either coal tar extracts or petroleum derivatives.

The coal derivatives, which were tried in France in recent years, offer good guarantees against fire; a burning match thrown into them, in open air, is extinguished by the liquid. On the other hand they present the following disadvantages:

They require an energetic reheating of the carburetors; and even with such reheating, the engines utilizing them pick up badly and start with difficulty; frequently they must be started with gasoline.

At temperatures below zero centigrade, the products tried become turbid and even disintegrate.

Finally their power yield is much less than what gasoline would give under identical conditions.

A certain reduction in power might be accepted, if necessary, at least for less exacting types of airplanes (tourist and training airplanes for example); but the difficulty of starting and picking up during flight condemn them; this explains why safe fuels derived from oil, which have been tested so far, have not yet been adopted in aviation practice.

Petroleum derivatives, which were experimented with in France, present defects of the same nature, but less accentuated, which leads to hope that they may be more easily remedied. These defects are: the necessity of special strongly reheated carburetors, irregularities of carburation, loss of power (comparatively slight, however). Finally, some of the proposed products oxidize the engine pistons quite intensely.

In short, the researches concerning new fuels, aside from safety, give no satisfactory results as yet. It will take time and renewed efforts to overcome the difficulties encountered; these difficulties are of both engineering and industrial character.

From the point of view of engineering, it will be well to remember that the designers of airplane engines have found, thanks to the development of automobile engines, abundant and precise data on the principal features which they have to give to their carburetors and their accessories.

Thanks to this assistance, they could devote their efforts almost exclusively to the solution of the special problems of the aircraft engine, notably the maintenance of good carburation under all circumstances and at all temperatures and pressures which the airplane may meet with in service. But when it comes to using, in aircraft engines, a new fuel, not gasoline, a fuel which is not used by other industrial engines, the problem is inevitably focussed on carburation.

When only a sensibly constant performance is specified for the engines using the new fuel, and for definite conditions of temperature and pressure, experience has proven that it is possible to find easily a proper adjustment for carburation. But as soon as circumstances vary, and moreover, when all the flight elements influencing carburation come into action, the difficulties increase. It is sufficient, in order to appreciate the situation, to reflect on the efforts which had to be expended to get over a similar stage in the development of the automobile engine.

Independently of this engineering problem, the invention of a new fuel also presents a delicate industrial problem: it is comparatively easy to produce several liters of a substance of a definite nature and composition but it is much more difficult to supply the same substance in large quantities; the industrial processes do not permit the making, under economic conditions, of products of uniform quality and invariably equal to the original specially fabricated product. But uniformity, possibly even more than quality is the essential requirement of fuels intended for use in aviation.

All these considerations explain why the second of the methods indicated above (which at first sight might have seemed more difficult and more expensive) has in practice stimulated more efforts than the preceding one; it consists in resorting to known fuels produced in industrial quantities (kerosene or crude oil, for example), and producing an extra light type of motor capable of utilizing them.

Researches made in most countries for several years demonstrate that such an engine to be of dependable performance, must employ very great compression; that is, to utilize a cycle which is more in a class with a Diesel or semi-Diesel than with the normal explosion cycle. The problem to solve, then, is both of thermodynamic and mechanical character.

The results of the work done along this line of thought, notably in Germany, in England and in France, have not been published,—still there is reason to believe that sufficient progress has been made and that a solution, perhaps incomplete yet acceptable, will soon see the day. It seems in particular that it may be possible to realize engines similar in their general features to existing aviation engines having weights of the order of two kilograms per horsepower, which will embody a solution of the problems of pressure feed, regulation of injection and mixture of fuel introduced in the cylinders.

It will remain to realize a device for speedy starting of the engine, without excessive addition to its weight. Devices of this sort already exist but their weight is prohibitive, for airplanes at any rate.

To sum up, the problem of eliminating gasoline and substituting a less inflammable fuel for it has not been solved yet; but the researches which have been undertaken should be continued, which applies equally to new fuels and to engines making use of thermal cycles which differ from those of existing engines.

Pending their conclusion, the airplane must get along with the illness—gasoline, which cannot yet be avoided. Let us first apply ourselves to a reduction of the dangers inherent to the presence of gasoline on board of airplanes.

Precautions Against Leakage of Gasoline and Back Firing

A combination of two circumstances is necessary for gasoline to catch fire:

The gasoline must be in contact with the surrounding air and evaporate into it. The air thus carburetted must, in its turn, be in contact with an ignited point which causes it to explode.

To reduce the risks of ignition, it is necessary to prevent each one of these causes, taken separately, from occurring; and in case one of them cannot be avoided, its concurrence with the other one must be precluded.

Along these lines, it will be proper to examine first the precautions for normal conditions of flight and then the precautions corresponding to a grave accident such as a violent crash.

In normal flight, mixtures of dangerous carburetted air are produced either by leaks from gasoline tanks or from the piping, or by poorly functioning carburetors.

When the tanks are carefully constructed and sufficiently protected from engine vibrations, there is but little danger of leakage; with reference to them the following precautions are to be taken: their fastenings to the body of the airplane should be strong enough to withstand not only the forces of inertia to which the airplane is subjected when in flight, but also those which may be brought about by violent landing or by upsetting. Their air inlet apertures should be designed with minimum cross section and to prevent all risk of spilling of gasoline in rough weather. The air inlets and the orifices for filling the tanks should lead freely outside of the airplane, so that in case some gasoline is accidentally spilled, as when refilling for example, none of it should enter the hood or the fuselage.

This last mentioned precaution is particularly important in the case of hydroplanes, whose tanks are placed in water tight compartments, as well as for tanks placed in the wings in confined atmosphere.

The specifications for gasoline pipes are, unfortunately, more difficult to satisfy. These pipes and their fittings must be sufficiently flexible to resist the engine expansions and vibrations. Most designers sought to achieve this result by making the pipes of rigid elements connected among themselves by a great number of flexible joints. These joints consist of rubber tubes reinforced with fabric (durit joints) and fastened to the piping by means of special collars.

This practice presents serious disadvantages: the rubber joints, if well set, as they should be to begin with, soon lose their flexibility and tightness; they become loose; the rubber is attacked by the gasoline, becomes hard, or crumbles; the crumbled particles obstruct the piping or the nozzles and are one of the most serious causes of interruption of operation during flight.

In any case, if only to reduce the leakage of gasoline, it would be necessary to avoid a random distribution of joints along the pipes and to reduce their number by all means. It is permissible to think that if the gasoline pipes were planned methodically and with care as is done for example on ships with steam piping, it might be possible to retain only a few flexible joints, indispensable either for disassembling purposes or for resisting the greatest vibrations and expansions.

Such a result would be particularly important in the case of multi-engine airplanes whose gasoline piping is rather extensive and stretches at times almost over the whole width of the wing span.

In spite of a careful design of the piping it will generally not be possible to entirely eliminate flexible joints; it will be necessary, then, to have them remain tight regardless of vibrations and aging.

A competition in design of joints, organized in France, for this purpose by the Committee on Aeronautic Propaganda, has demonstrated the progress which might be realized in that which concerns these important accessories.

The qualities demanded of the competing designs were as follows:

Flexibility and good performance with respect to vibrations—absolute gasoline-tightness.

Resistance to corrosion by gasoline and benzol—fire-proofness—convenience of keeping in stock.

Ease of disassembling and reassembling.

Lightness—moderate cost.

Several of the models presented have on the whole satisfied these requirements; the most interesting of them are of metal and retain as the flexible element a rubber fitting encased in metal to protect it against gasoline and against fire. Their weights and costs are reasonable.

It is particularly desirable that joints similar to these or others having analogous qualities, should take the place of durit joints which are still so much in use, in spite of all of their disadvantages which have been pointed out above.

The air drawn in by the engine, passes through the carburetor, is charged with gasoline vapor and enters the cylinders. On account of poor functioning, due to various causes (jammed valve, irregular feed, etc.), the mixture introduced into the cylinders finds itself in contact with the plug spark, at the instance when the admission valves are still open; it catches fire; the flames which it emits return in part of the carburetor chamber, set fire to the gasoline contained in it and flash out into the atmosphere through the air intakes. These flames threaten, then, to extend the fire even to the body of the airplane.

The best means of avoiding this danger is evidently to prevent the poor functioning of the engine which brings it about. But since complete success in this direction is not attainable, measures should be taken for stopping the flames before they reach the carburetor chamber, and then to render the flames, which nevertheless will have reached the atmosphere through the air intakes, comparatively harmless.

It is easy to obtain this last named result; it is sufficient to have the air inlets open outwards on the exterior of the fuselage or the hood, by means of an air-tight pipe which extends for quite a distance outside, so that the issuing flaming gases shall not encounter any combustible element of the airplane; it is often preferable to have the air inlets opening laterally outwards rather than in the lower part of the engine cradle, in such manner that discharges of gasoline due to accidental leaks, should not be directly in the way of returning gases.

It is absolutely necessary to make the air inlets end freely on the exterior of the fuselage or the hoods. This does not apply only to principal engines but also to the auxiliary ones which may be found on board (starting, electricity and wireless) which one may fail to think of in this connection.

The devices which have been proposed for preventing the flames issuing from the cylinders from reaching the carburetor chamber and the corresponding air inlet are quite varied.

One of them which was recently experimented with in France proposes the breaking up of carburation into two separate operations.

The first operation is made as in an ordinary carburetor; but measures are taken that a mixture issuing from the carburetor should contain a great excess of gasoline. This mixture passes through a relatively long pipe line at the end of which there is found an additional air inlet; this inlet regulates the final dosage of the carburated air, prior to its introduction into the cylinders.

Under these circumstances when the flames will accidentally break out through the admission valve, they will encounter above the additional air inlet, a gas column which had come out of the carburetor. This column being charged with an excess of gasoline, will not support combustion and the flames will become extinguished upon contact with it.

The preceding device is ingenious and quite effective against back firing; it also permits to remove the carburetor chamber from the engine, and thus protect it against accidents which breaking of the crank case or connecting rod generally entails.

On the other hand it is a delicate matter to adjust it precisely on account of gasoline condensation between carburetor and engine which it often gives rise to. Other devices based on entirely different principles were experimented with in France; one of them proposes to arrest the flames by means of an automatic flap valve, which stays open when the air travels from the outside into the cylinders, but shuts when the gas current inverts itself to return from the cylinders outwards; other methods consist in opposing cooling baffles to the flames.

The system of flap valves has not given conclusive results so far, because the conditions they have to satisfy are partly contradictory. These conditions are as follows:

To have very low inertia, to shut at the least return and to open in opposite direction when running normally.

To function at any position of the airplane in flight.

Not to get distorted under shocks and to remain shut and gas tight.

To reserve for the admitted air, a passage of sufficient cross-section so that the engine will not suffer any appreciable loss of power, and that in case of flapping of the valve irregularities of carburation should not occur.

In fact loss in power or the mediocre efficiency which the various models of flap valves experimented with so far have shown, was the reason for their not being more generally used.

The system of cooling baffles seems to be actually preferable to them; it consists in interposing a series of corrugated metal sheets of very large surface in the admission channel between the carburetor and the motor and parallel to the gas current; these sheets offer only slight resistance to the passage of the admitted air, and the loss in power which this entails is practically negligible. When the back fire flames come in contact with them they are cooled abruptly and are extinguished. Several devices of this sort which were recently tested in France have proven very efficient; their use therefore should be particularly recommended.

Precautions Against Sparks

We have seen above that it is necessary to avoid all emission of sparks and presence of heated metal which is liable to cause an explosion of the gasoline vapors which may form on board in spite of the precautions taken. The principal sources of sparks are ignition circuits of engines, wireless apparatus and electric wiring, for the distribution of light or power, with their accessories.

Precautions to be taken concerning these does not present any special difficulties; the principal ones are as follows:

The electric wires should not be placed under the gasoline or oil pipes and have their insulation gradually destroyed by accidental leakage. Terminals of different polarity should be separated and the connections must not get loosened by vibrations; commutators, magnetos and similar apparatus should be encased in metal as far as possible. When fusible circuit breakers are in use, no incandescent metal should be projecting to the exterior. The back surfaces of switchboards should be available for inspection. Wireless apparatus should be removed from the gasoline receptacles and should be protected as much as necessary by metallic gratings.

The ignition wires of the engines require special precautions as much for the reason of their important role as for their proximity to the engines and the gasoline tanks and pipes. It seems that the use of protective ramps, which group all the lighting wires throughout their common length and protect them against shocks, rubbing contact and leakage of gasoline or oil, are particularly interesting to consider. Of course the wire connections on the spark plugs must be of a type which will not unhook or become loose during flight.

Finally if there be storage batteries on board, it is necessary to insure them against the risks of short circuits and the spilling of acids.

The above set of precautions should, under normal conditions, prevent the formation of all dangerous sparking.

Sparks outside of the engine may be produced in spite of these precautions in the case of a severe accident to the airplane which may cause a dislocation of the arrangements and bring together, in contact, the torn strands of live wires of different polarity; such eventuality may occur but very rarely, at any rate it is difficult to foresee measures of a general character which might prevent it.

Exhaust Gas

The danger presented by exhaust gases of the engines, of valves and corresponding channels is much more immediate. It is not only that these gases are very hot

in themselves but they carry along flames, particles of incandescent carbon due to imperfect combustion of gasoline, and occasionally also rust particles due to oxidation of the piping. Flames and sparks appear whenever the regime of the engine is changed abruptly.

The idea which immediately presents itself for the avoidance of these inconveniences is to extend the exhaust pipes attached to the engines by means of expansion chambers wherein the gases will be detained and cooled sufficiently to be extinguished before getting to the exterior. It is also possible to place at the exit of the gases into the atmosphere a tight grillage which will filter the incandescent particles carried by the gases without stopping the gases themselves.

When the expansion chambers are properly arranged they deaden the noise of the engine exhaust and perform then the double role of silencer and fire screen.

To tell the truth the inventors have been more after the development of good silencers, because life on board of an airplane with direct exhaust engines soon becomes impossible. They concern themselves with security against fire only as an accessory reason.

Similarly they cared more about reducing the brilliance of flames issuing from the gasoline than about suppressing them completely. These flames are in effect very annoying in night flying, particularly in making a landing while it is fairly simple to reduce the brilliance of flames so that they do not dazzle the sight, it is much more difficult to achieve their complete suppression, especially when the regime of the engine changes very abruptly. The real test of the efficiency of the design considered against fire depends on this last condition. Particularly when an airplane is upset or a rough landing is made the engine may pass immediately from a regime of high speed to a complete stop, and it is very important then that there should not be any emission of dangerous flames at that time.

The circumstances which have just been analyzed and the difficulty of the problem, explain why the fire screens experimented with so far have not yet given any definite results from the point of view of fire protection; but once the problem is stated, it should be possible to solve it at the expenditure of some efforts and perseverance.

Granting that so little has been realized as to satisfactory fire screens, should their use be imposed in order to increase safety against fire? Several authors have expressed their doubts on this subject.

They called attention to the fact that by extending the exhaust pipes by means of channels or extension chambers, the valves and the adjacent metal plates are prevented from cooling as well and as fast as they would have, had they been in direct contact with the atmosphere. The warming up of the valves, if it be excessive, will bring about many serious defects in the functioning of the engine (wedging of shafts, breaking of the body of the valves, loosening, etc.).

The real danger is not there, but in the case of a faulty landing it becomes apparent.

If the shock of the airplane landing on the ground is sufficient to burst the tank or break a gasoline channel, the fuel flows out and saturates the air with its vapors. These gradually penetrate into the exhaust box, coming into contact with its hot parts; if the temperature of these is sufficiently high to inflame the carburated air, the explosion is immediate.

The experiments made in the United States with obsolete planes which were destroyed by crushing them against obstacles, are symptomatic in this respect; they prove the incendiary role which exhaust valves and insufficiently cooled metal plates may play in the case of landing accidents.

It is not sufficient, then, when experimenting with the fire screen to test whether it stops the super heated gases, it is also necessary to make sure that the *maximum temperature of its internal parts* remains low enough to preclude the explosion of the carburated air which may come in contact with them. This condition is partly

in opposition to the first, but it is essential from the point of view of fire safety in time of a rough landing; it should never be neglected.

It has been recently proposed in the United States to test its application in the following practical form: to run the engine provided with the fire screen which is being tested, in such a manner as to warm up the valves and the adjacent plates to the highest degree possible; then to stop the engine and inject gasoline or oil into the channels of the fire screen; test that no flame flashes out under such conditions. It would be interesting to know if this testing method is actually being used, and what results it has finally yielded. In any case, it has value only if the cooling conditions of the fire screen are like the ones encountered in flying. In fact, gasoline or oil projected upon a hot plate, catch fire spontaneously, when the temperature of this reaches about five hundred degrees centigrade. But it is difficult to affirm, even with regard to valves opening directly into the atmosphere, and which are so well ventilated, that they will never have a temperature of this order of magnitude.

On the other hand, one must not neglect two factors, which independently of the maximum temperature of the exhaust, exercise an important influence on the greater or lesser chance of a fire in case of gasoline leak. They are the speed with which the hottest parts of the fire screen and valves cool off both during flight and when the engine is at rest, and the time it takes the gasoline or oil to come in contact with them. The longer time interval the more of the calories accumulated at the exhaust can actually be dissipated into the atmosphere. It will be seen later what measures may be taken in order to bar as much as possible the path of the gasoline towards the engines; as to measures which concern the rapid cooling of the exhaust after the motor had stopped,—they are too delicate to indicate with precision in a general way and require methodical study in each case; in fact, it may be observed that these measures may vary not only with the type of fire screen but also with the type of engine. Thus, for example, a fire screen arranged within the V formed by the two rows of engine cylinders, may find itself sufficiently cooled while the breeze caused by the running persists, but it may stay hot for a long time after the engine has stopped, because the intense radiation of the organs surrounding it will act directly upon it. The same fire screen arranged on the side will guarantee a much more rapid and superior cooling. Similarly, a fire screen isolated from the exhaust valve chamber by means of a conduit provided with cooling blades, may give higher security than it would if it were directly connected to the engine.

All the above considerations indicate the complexity of the problem of protection against the danger due to engine exhaust. They also demonstrate the vital interest of close study, not only of the fire screen models but also of the special conditions for installing them on board of airplanes.

In conclusion it is possible to say that as long as the conditions of flight remain normal, the presence of a fire screen increases the safety against fire. On the other hand, when a wave of gasoline spreads out on account of a faulty landing, the situation is reversed and the presence of a *poorly constructed* fire screen threatens to greatly increase the danger which it is proposed to eliminate.

It is very desirable that systematic studies be undertaken for a better knowledge of the measures which will permit avoidance of this difficulty, which is one of the most serious encountered in the attempt to improve the security of airplanes.

It is self understood that besides qualities of principle which have been discussed, fire screens should satisfy the following conditions:

- Comparative lightness and low aerodynamic resistance;
- Low absorption of motive power;
- Insulation of their walls from the combustible parts of the airplane;
- Good performance in presence of vibrations, shocks and oxidation by gases at hot temperatures.

Before leaving the problem of exhaust, it will be convenient to add a few words concerning the *heating of carburetors*, which directly belongs here; on powerful engines, it is not unusual that the admission pipes be covered with frost even in calm weather; the phenomenon is particularly dangerous when it happens during flight, since it may entail misfiring, defective picking up and even abrupt stoppage of the engine. Trouble when taking off which is so often tragic in its results, is frequently imputed to this cause. It is generally sought to remedy this inconvenience by heating the carburetor chamber either with engine oil or with exhaust gases.

Warming with oil does not present any disadvantages from the point of view of fire; but it is not always capable of producing high enough temperature to be effective. Particularly when it is a question of taking off in cold weather or of resuming flight after the engine has stopped for some time, the water or oil are themselves cold, and cannot render the service demanded of them at the moment when it is most needed.

In this case, it becomes necessary to warm the carburetor with engine exhaust gases; but this introduces very grave fire hazards, if most minute precautions are not taken to avoid all accidental communication between the heating gases and the gasoline of the carburetor. This communication is not to be feared in normal time, if the installation has been properly designed; but it is not so when a landing shock dislocates the engine and its accessories. Experience shows that the designers do not always sufficiently visualize this possibility and quite often produce installations which are dangerous in this respect.

Two precautions which are comparatively simple to realize are, in the meantime, likely to give the necessary security.

To arrange the bracing of the pipes which will lead the exhaust gases to the carburetor, as a branch of the principal current, and throttle it down enough so that the temperature of the heating gases shall not exceed 200 deg. cent. for example. Under these circumstances, even the breaking of the bracing or an untimely emission of gas, either in the hood or even in the gasoline in the carburetor chamber, will not be dangerous.

In case there is difficulty in materializing the above mentioned arrangements, insert an anti-return device similar to the one whose principle has been indicated above, between the heating pipe and the carburetor casing; complete this precaution by placing the carburetor with its heating pipes in a space in the engine where it could not be damaged or dislocated, in case of landing shock, except after other vital parts, the cylinders for example, have been damaged first.

Precautions in Case of a Rough Landing

All these instructions just analyzed should suffice to suppress all possibility of fire in the air, as long as the engine does not suffer any serious accident and as long as the conditions of flight remain normal. Moreover, experience confirms their efficacy.

But unfortunately these instructions are not sufficient when the engine suffers a major accident, or the airplane lands under unfavorable conditions.

This last case is by far the most dangerous from the point of view of fire; the consequences which it entails produce, by aggravation, the conditions of an engine accident; it is, therefore, preferable to study fires produced by faulty landings.

The process involved in this phenomenon are well known. They can be summed up as follows:

The airplane comes down striking the ground; the shock dislocates the engine and its accessories; the pipe joints begin to leak or become disconnected; the pipes themselves break.

In most serious cases, the tank bursts, the carburetor chamber is battered in or torn out. Finally, the gasoline flows out and brings about the dreaded explosive atmosphere.

If the pilot does not have the time or the thought for cutting the ignition, the engine hits the obstacle while still running; the immediate-stop imposed upon it by the shock of hitting the ground, brings about exhaust flames and returns to the admission. A spark due to ignition circuits or to a broken electric distribution wire or a contact of the gasoline vapors with the hot portions of the exhaust may equally produce it. They are so many causes of ignition of the carbureted air which explodes; a general conflagration results, a conflagration which is so difficult to fight, because it is fed by the vapors that are spread all about.

If the gasoline tanks were not isolated from the focus of conflagration at the beginning of the accident, either by a stop cock or by setting in operation a blow-off device, and still more if the tanks be burst by the shock, they feed the fires and further intensify their violence by pouring out their contents.

The succession of phenomena just analyzed indicates the measures by which their development may be stopped or retarded.

The first and most classical, consists of allowing the pilot to cut the ignition as soon as violent contact with the ground becomes inevitable for him. In general, the cutting device is within the direct reach of the pilot's hand and its installation does not present any difficulties except in the case of multi-engine airplanes.

In this case the pilot should be able, in accordance with his choice and circumstances, to cut the individual ignition of any one of the engines, or to cut by one single operation, the ignition of *all his engines*; the safety which this arrangement will give him, will greatly compensate for the comparative complexity of the electric circuits which it involves.

Certain inventors, impressed by the accidents happening when the pilot does not cut at the right time, have proposed apparatus interrupting the ignition as soon as the airplane gets into trouble, for example, with the loss of speed. But the danger involved in the untimely functioning of such apparatus, has always, and justly so, discouraged their use.

Devices for the avoidance of return to the admission and the exhaust have been discussed above and it is unnecessary to return to them. It will only be remarked that in order to play their role, anti-return apparatus and fire screens should not be destroyed too soon when the engine hits an obstacle; on the contrary, it is of great advantage to place them in a portion of the hood where they may be relatively protected against violent destruction, and where they would be attacked only after the vital parts of the engine. In fact, exhaust boxes, admission inlets and carburetors are often arranged at the extreme front end of the engines, so that they may be the first accessories to be torn out or crushed when the ground is struck; the engine then risks to continue running for a few fractions of a second with the valves exhausting into the air, with the carburetor chamber broken, or with the admission re-entering. Nothing more is necessary to precipitate a conflagration, which might have been avoided, if the massive parts of the engine had been broken first, which would have entailed the stopping of the engine before the emission of dangerous flames had taken place.

It may be further asked if it would not be possible to generalize the preceding precaution and to protect the engine and its accessories against landing shocks in a better manner than has been usual heretofore. There are shock compartments in the bow of ships which destroy and deaden the effect of fouling before the vital parts are injured. Similarly buffer cars are placed at the head and the tail ends of passenger trains. But there is nothing of the kind on airplanes, on the contrary, on apparatus with the engine set on the axis it is the propeller shaft and the engine which are the first ones to take the shock and through them the destruction commences.

Moreover the engine, its crankshaft and its casing form one rigid, integral block, and they perform the role of a veritable hammer driving everything in the rear of itself.

It would seem possible, at least in some cases for example, for reduction gear engines where the distance between the propeller and the casing is greater than in the direct-connected engines, to protect the engine by surrounding its front with an armour of angle iron, strongly attached to the rest of the fuselage. This armour is intended to be destroyed by the shock before the engine itself and its principal accessories are injured in their turn.

Though admitting that this *protective cage* can destroy but a portion of the violent shocks and that it is not sufficient to preclude the dislocation of the engine, yet it will increase the time interval which will separate the stopping of the engine from the destruction of the gasoline piping and the organs of protection against fire. But to gain time in a case like this is of paramount importance.

At any rate this idea of armour deserves to be examined and put in practice, if possible.

Besides the landing shock there is also a rather frequently occurring case in which fire occurs from a return of the flame to the admission, even when the precautions indicated above have been taken; this happens when the breaking of a driving rod of the engine, which is adjacent to the carburetor, brings about the dislocation of the carburetor and the barring of the admission to the cylinders.

If the pilot cuts the gasoline feed pipes, as he should do, the quantity of fuel catching fire will be reduced to the gasoline contained in the carburetor chamber and the adjacent piping; intensity of the fire will not be so great as to preclude extinction if they have the necessary apparatus on board; it will, nevertheless, be wise to avoid risks of this nature by placing the anti-return devices most directly upon the cylinders and to encase the carburetor chambers within the zone where the rods project, in a manner compatible with the other general arrangements of the engine.

The measures for preventing, as much as possible, explosions of carbureted air which occur after a landing shock, have just been examined. It has been shown that it is necessary to increase the time interval which separates the shock from the moment when the gasoline pours out, evaporates and comes in contact with the still hot parts of the engine. Finally, it is evident, that the more the gasoline leaks will be confined, the easier it will be to fight a fire, if it breaks out.

How can these diverse results be obtained? First by reducing to a strict minimum all joints of gasoline and oil piping and by making them by means of metallic couplings. Couplings of a rubber base get loose or tear as a result of shock, and are destroyed by fire. Three reasons, besides the ones which have been given above, for which they should be eliminated.

Piping should also be designed so, that its flexibility may allow it to deflect with the shock without breaking. For this purpose, the fastenings of the pipes should be designed so as to fail before the pipes themselves have been torn out, even more, it will be preferable to use tubing of brass which is a metal less brittle than duralumin, for example.

Finally, the hoods, motor cradles and fuselages should be designed so as to evacuate most directly the discharges of gasoline or oil which they will receive in case of leakage.

Isolation of the Motor Compartment and the Reservoirs

It has been shown, that the motor compartment constitutes a hot chamber where the least incident may precipitate a fire. It is, therefore, necessary to reduce to a strict minimum all the combustible elements which it contains. It is also neces-

sary to isolate it from the rest of the airplane, so that a fire once started may not spread.

Everybody is in agreement as to the indispensability of installing a fireproof partition between the engine and the rest of the airplane: no gasoline or oil tank of appreciable capacity (carburetors expected), should be placed on the engine side of the partition. The principal gasoline and oil tanks, those of gasoline above all, should also be provided with facilities for the immediate isolation of channels crossing the partition and leading to the engine, by means of a sectioning with an instantaneous cut-off to be operated by the pilot; each sectioning should be placed as directly as possible on the tank which it protects.

If it is feared, that a sectioning with a rapid shut-off may not stay perfectly tight, at the expiration of a certain period, it will have to be supplemented with a slow-operation cock; the first will be used by the pilot only in cases of emergency; the second, on the other hand, will be operated under normal conditions of service.

The role of the fire-proof partition is double; it has to prevent the flames, which may originate in the engine compartment, from spreading through the body of the airplane; and it has to, in an opposite sense, prevent gasoline leaks which may appear outside of the motor compartment, from oozing into the latter.

To be able to stop the flames, the partition must be made of metal and have, if possible, a non-conducting lining; this is often made of one or two sheets of metal with asbestos cardboard interposed.

The fireproof partition should not be restricted to the cross section of the fuselage, but should be extended along the sides of this, in the direction of the motor compartment.

In fact, the flames arrested by the transverse partition proper will attempt to make their exit from the compartment along the sides of the fuselage. They will be deflected towards the body of the airplane by the breeze due to the motion of the airplane, if the fire occurs when in flight, or by the normal draft, if the fire takes place after a violent landing. In both cases, it will be difficult to completely prevent flames from flashing out laterally toward the hood, still it is necessary to remove it far enough from the partition if the protection of the body of the airplane is not to become merely illusory.

Similarly, it is also necessary to extend the partition away from the motor compartment. If it is not done, the gasoline poured upon the partition in time of a violent landing will flow by simple gravity, without encountering a single obstacle, towards the center of the fire, which it will reach quickly.

But by extending the fireproof partition in a direction opposite the engine compartment a veritable trough will be formed, from which the gasoline will escape only when filled by the leaking fluid, which will not happen immediately except in the case of a very severe accident to the tank.

The extension of the partition by means of metallic elements toward the engine compartment is generally practiced; but this is not true as to the extension towards the body of the airplane, of which the designers do not think very often, in spite of its importance. Great progress can therefore be realized in this direction.

It is well understood that the passages of conduits and control mechanisms which cross the fireproof partition from the body of the airplane to the engine must be fireproof and gasoline proof.

This specification does not raise any technical difficulty for careful designers, but it is not always followed; for this reason an aviator has recently been badly burned, when flying, by the flames which flashed out from his engine across the interstices and the passages through a poorly constructed fireproof partition.

The above considerations concern the case of an airplane having its engine on the axis of the fuselage and its main gasoline tank in the fuselage, back of the engine.

The specifications will be different in case the engines are placed on the sides, or if the gasoline tanks will be in the wings instead of in the fuselage. But the principles to follow will remain the same.

It has been assumed so far, that the fireproof partition will be intact at the time the fire begins to develop. It will be really efficient then, and the cases of fire during flight which have been stopped or retarded in their destructive effects are numerous.

Unfortunately in the case of a violent landing the fireproof partition is often dislocated and the check which it is to offer is not always assured.

In general, the engine when hitting the ground acts as a hammer upon the partition, which is broken through by it.

Sometimes also the tank whose fastenings fail under the shock of the landing, shatters, by force of inertia, the partition placed before it; if the fastenings do not all fail under the shock, it is the tank itself that becomes distorted and lets its contents flow out.

Finally, when the tank is on the axis of the engine and near the partition which separates them, the engine, after breaking through the partition, proceeds to burst the tank: a dangerous circumstance,—since it at once enables the gasoline to leak out and gives it access to the engine compartment.

A good designer will have no difficulty in producing tanks and fastenings capable of resisting the effects of inertia caused by landing shock, even by a violent one. The use of elastic suspension and of interior bulkheads can also reduce, in considerable proportion, the water-hammer produced by abrupt displacements of the gasoline. It may be advisable then, to figure out, after some systematic experiments, the value of the dynamic stresses which the tanks must withstand without distortion and without appreciable leakage.

Unfortunately, it is not so easy to find a way (at least in the case of airplanes with engine on the axis of the fuselage) of avoiding the hammering of the partition by the engine.

It is only possible to limit its destructive effects either by making use of a protective armour as sketched above, or by removing the engine from the partition (if the plan of the airplane permit this), or, finally, by reinforcing the partition itself.

It will be noticed with reference to the last remark that the fireproof partitions which actually exist in most airplanes, are not generally constructed to offer resistance to shocks, even to feeble ones. They are provided only for the checking of flames or leaks of gasoline. It will be easy then to reinforce them without adding much to their weight, at least in the lower portion back of the engine salient.

Finally, it is necessary to prevent, at all costs, the engine from attacking the reservoir and bursting it, after it had broken through the partition: the measures to be taken for this purpose depend too much upon local arrangements to allow to detail them in advance; they will be confined to the following:

(a) place the gasoline tanks inasmuch as possible at a certain distance from the fireproof partition, so that it might be considerably distorted before the tanks are reached (from 10 to 15 cm. would be desirable);

(b) not to place the tanks exactly on the axis of the engine.

It is generally possible to place them on either side of this axis and thus prevent the salient parts of the engine, which are first to hit the partition, from injuring them immediately after;

(c) to provide an elastic protection for the tanks, so that they might stay tight even after they are distorted or cracked. There are protections of this kind which are quite efficient against perforation by machine gun bullets; they can therefore be applied in this case; these protections, however, absorb gasoline in case of a leak from the tank, a leak which one risks not to realize in time, since the protection conceals the wall and their seams.

In this case the remedy may entail great disadvantages which may lead to its rejection.

In short, the best protection against the destruction of tanks by the engine is to remove them liberally from the engine; from this point of view, the placing of the gasoline tanks in the wings gives great security and must be recommended whenever the arrangement of the airplane permits its realization.

Finally certain authors have indicated that it may be important from the point of view of fire safety to be able to quickly empty or blow-off the gasoline tanks when in flight; the pilot could thus eliminate at his will the greater portion of his fuel and insomuch reduce the violence of the catastrophe. These devices which are logical on military airplanes threatened by incendiary bullets, are generally not obligatory on civilian airplanes; they will give them but little additional security and may give them no security whatever in the most dangerous case, which is a landing on the ground with loss of speed. On the contrary, an ill-timed emptying of the tanks when in flight, with insufficient precautions against the diffusion of the gasoline in the atmosphere, may be very dangerous; similarly, blowing off the tank is as dangerous to the one who blows it off, whose equilibrium it upsets, as for someone on land who might receive it on the head.

Extinguishers

If fire does break out in spite of all these numerous and various precautions which have just been studied, it must be reduced at all costs before it extended so far as to render a catastrophe inevitable.

The sooner the pilot becomes aware of the beginning of a fire, the more efficient his intervention will be.

A gain of several seconds may decide between salvation and destruction.

Extinguishers and fire alarms are intended to satisfy this double requirement.

Extinguishers of the fixed type are the most efficient; in France their use has permitted to extinguish two out of three fires, while in flight, or to retard their progress, to make possible a rescue operation.

They generally make use of a spray of carbon tetrachloride produced by compressed gas.

The vapors thus diffused are toxic in effect; of course it can be arranged that they should not trouble the occupants of the airplane, but it is best, in all respects, not to use them except with full knowledge; moreover it will be necessary to take some precautions against eventual leaks from the tetrachloride tanks. Furthermore, fixed extinguishers should be allowed only in the hands of pilots capable of using them properly. With this reservation, which will be abandoned the day when less toxic extinguishing products will be found, the use of fixed extinguishers must be strongly recommended, particularly on airplanes of public transportation.

The extinguishers should discharge into every engine compartment, in the vicinity of carburetors, which are the most vulnerable parts from the point of view of fire safety; it should be noticed, that the extinguishing vapors will work best if the compartments, which they are to fill, will be least in volume and the poorest ventilated; the use of hoodless engines, the advantages of which from the point of view of cooling and openness to inspection in flight are beyond discussion, raises serious objections in this respect.

It is also to be observed, that if the extinguishers are able to check an incipient fire, they generally attack both its effects and its original cause. As long as the cause persists, the fire which has been extinguished one time may threaten to break out again; such is the case of a fire caused by a jammed admission valve, or by a gasoline leak in the vicinity of the magneto spark plugs; it is necessary, therefore, that the extinguishing liquid at the disposal of an airplane should permit three or four successive extinctions in the course of one flying trip.

In principle, there should be one fixed extinguisher for each engine compartment. On large airplanes, hand extinguishers of one of the common types should be added at the rate of one for each important chamber of the fuselage.

Fixed extinguishers should be set in operation as immediately as possible in case of emergency. The compressed air should be controlled, therefore, by a quick-opening cock; if leaks through the cock are feared, a second slowly operating and tighter cock should be provided, this last one to be closed when on land, and to be always open when flying.

The use of fire alarms may advantageously reduce the time of setting the fixed extinguishers in operation; these apparatus are based on the use of materials which melt or burn out, as soon as the surrounding temperature attains a critical value, and release a signal which attracts the attention of the pilot to the threatening danger. They are simple and inexpensive; they should be preferred to the so-called automatic apparatus in which the alarm itself operates the extinguisher instead of being satisfied with informing the pilot. The automatic apparatus are complicated and delicate in construction; there is always the fear that they may function at the wrong time, or that they will create a panic, or that they will emit gases which may annoy the pilot and his crew.

General Resume and Conclusions

The whole of the study just made evidences the complexity of the problem of preventing and fighting of fires. The technical means on which this fight should be based are many and varied; none should be neglected.

Experience proves that *fires in time of flight* can be most frequently checked or avoided with the precautions presently adopted, which have been analyzed in detail.

Unfortunately this is not equally true of *fires following the crashing of the airplane to the ground*. The shock, by dislocating the apparatus or the frame work, too often interferes with the fire prevention measures not permitting them to have full effect. But, even if these measures result only in retarding the moment in which the fire breaks out and spreads to dangerous proportions, it would still be worth while to accept and develop them.

There is no doubt that great progress can still be made in fire protection after a violent landing. The difficulty encountered in realizing it is partly due to the variety of the required measures, a variety demanding an all-embracing view which many of the inventors, who may be very well informed on this or that detail, do not themselves always possess.

The principal points upon which technical researches should be directed are as follows:

(a) eliminate gasoline and substitute less dangerous fuels for it. This involves difficult and costly researches which cannot be completed in a short period; in spite of their extraordinary importance, they are here mentioned only as a matter of record;

(b) to initiate new studies for the improvement in quality and reduction in quantity of *joints of gasoline and oil piping*;

(c) develop the use of *anti-back-fire apparatus*; a competition which should excite the spirit of emulation of inventors; to encourage the perfectioning of these apparatus; it is of importance above all to attract the attention of the users to the security which these apparatus can give;

(d) proceed with systematic and complete researches for means of suppressing or reducing the projection of flames and of exhaust sparks.

So far it has been sought to produce silencers and fire screens, without caring sufficiently about security against fire, which they should offer. These securities are real when the apparatus is well worked out: they soon change into sources of great danger in the contrary case.

Great technical effort should be devoted to this line of thought. It could be advantageously encouraged by offering a prize for experimental researches in accordance with a program to be determined after the considerations which has been developed above.

(e) proceed with some experiments which will give a better knowledge of the conditions of shock resistance which gasoline tanks must satisfy, and of the protective devices corresponding to them;

(f) in a general way, when a new airplane appears, to proceed with a systematic examination of its arrangements from the point of view of fire in landing, and to oppose strongly those which are objectionable from this special point of view; reservoirs exposed to immediate onslaught by the engine; fireproof partitions, inadequate as to resistance of tightness; tanks placed too closely to the fireproof partition, etc.;

(g) to encourage researches on the use of extinguishing materials less toxic than those now in use.

One more important point has to be indicated. It is not sufficient that airplanes, to be protected against fire, should be provided with well executed installations and efficient apparatus; they must also be *very carefully maintained*. In the airports one may see only too often private airplanes and even airplanes for public transportation, belonging to great companies, with gasoline and oil leaking all over.

These highly combustible materials impregnate especially the engine chamber, the engine and its accessories; they create there an ever-present danger, particularly when there is wood or cloth fabric in proximity.

It is therefore not rare that fire breaks out on airplanes thus neglected, when they are on the ground, with the first back-fire produced by the starting of the engine.

A thorough campaign in favor of *meticulous cleanliness on airplanes* and of a merciless fight against gasoline and oil leaks can have, from this point of view, salutary effects; it may be of greater import than one may at first credit it with.

ADJOURNMENT

**SEVENTEENTH ANNUAL SAFETY CONGRESS
NATIONAL SAFETY COUNCIL**

Airports and Airways

First National Aeronautical Safety Conference

Under Joint Auspices of

***The Daniel Guggenheim Fund for the
Promotion of Aeronautics and the
National Safety Council***

October 4 and 5, 1928

**LT. COL. H. C. PRATT, Chairman
Air Corps, U. S. Army**

The first session of the Division on Airports and Airways at the Seventeenth Annual Safety Congress was called to order at 10:30 o'clock by the chairman, Lt.-Col. H. C. Pratt, Air Corps, U. S. Army.

CHAIRMAN PRATT: It is a great pleasure and honor, gentlemen, to have the opportunity, at Mr. Guggenheim's invitation, to preside over this meeting this morning. I feel that you are unfortunate, however, in not having with you Major Young, of the Department of Commerce, who was to preside and whose place I am taking. Major Young, due to his intimate association with airports and airways could, I am sure, have given you from his own knowledge a great many facts and much assistance in this conference.

We are, however, fortunate in our speakers, and I am sure that the papers they are to present will prove of great interest.

It gives me great pleasure to introduce as the first speaker this morning Mr. Harry H. Blee, Chief of the Airport Section of the Department of Commerce. Mr. Blee has had great experience in the Department of Commerce in work in connection with the subject upon which he is to address you, and I am sure we will find his remarks most interesting and instructive.

Designing Safe and Adequate Airports

By HARRY H. BLEE

Chief of Airport Section, Department of Commerce, Washington, D. C.

The problems of achieving safety in transportation and of providing facilities essential to the realization of the greatest benefits from the development of transportation, are by no means new problems. They have faced man down through the ages,—from the time when he built his first ox-cart, and then found it necessary to widen his footpaths into roads.

Now that aviation has emerged from the experimental stage and is taking its place in the commercial and industrial life of the world, the civilized nations are beginning to avail themselves of this newest means of transportation and to provide the facilities necessary for its safe and successful utilization. As a result, a great network of airlines is spreading out to encompass the four corners of the globe, and progressive cities are realizing that they must provide themselves with suitable airports, if they are to have a place in this far-flung transportation system and reap the profits of the pioneer. We find in the United States, approximately one thousand cities organizing airport committees and studying available sites; and another thousand cities actually engaged in the development of airport facilities.

The airport is to air transportation what harbors and docks, and stations and yards, are to marine and to rail transportation. The design of suitable airports involves many problems analogous to those encountered in designing other transportation terminals. But some of the problems in airport design are unique, because the airport must facilitate and make safe the work of pilots, in effecting for their planes—while rapidly moving in an invisible medium, subject to currents flowing in any direction and varying through a wide range of velocities—the transition from a craft operating in three dimensions, to a surface vehicle operating in two dimensions; and likewise, vice versa.

In as much as practically every phase of airport design has to do directly or indirectly with safety in aviation, the author has endeavored in preparing this paper, briefly to set forth the outstanding problems presenting themselves to airport engineers, and to stress those problems in which the question of safety plays a large part. Although the airship (dirigible) bids fair to become an important factor in the air transportation system of the world, particularly in connection with scheduled transoceanic service, it may be some time before any considerable number of airports will be called upon to provide terminal facilities for this type of craft. Hence, this phase of airport design need not be discussed in this paper.

Selection of Airport Sites

A study of the present and probable future airport requirements of a district should be made before proceeding with the selection of airport sites, in order to obtain, so far as possible, a perspective of the conditions to be met, and in order to formulate a general plan for the development of adequate airport facilities for that district. These facilities may comprise a single airport, a series of airports, or a principal airport with one or more auxiliary ports so located as to insure safety and continuity of operations at times when the principal airport may be fog bound, or otherwise unavailable. It is impossible, of course, to predict the ultimate state of development of commercial aeronautics, and hence, to foretell the future requirements of any particular district; nevertheless, in the light of present-day requirements and with a knowledge of the trend of developments in aviation, an endeavor should be made to anticipate future requirements. A general plan having been formulated, the minimum requisites by which to measure available sites can then be determined.

In determining the suitability of any particular site, or in comparing the relative merits of several sites, there are a number of factors to be taken into consideration, many of which have a direct bearing on the safety of operations at the airport. These factors naturally divide themselves into several more or less distinct groups. One group of factors has to do with the physical aspects of a site; such as, size, shape, effective landing area (see *Figure 1*), possibility of expansion, elevation above sea level, and topography as affecting drainage and general adaptability; nature of soil as affecting drainage, growth of tough sod, and maintenance of landing area; aerial approaches; presence of open fields

Figure 1. Reduction of effective landing area by obstacles.

or other landing areas in vicinity; suitability as determined by present or probable future development of surrounding terrain; and ease with which site can be located from the air.

Another group of factors deals with the prevailing meteorological conditions affecting airport operation. These factors embrace such considerations as the percentage of days on which the ceiling (height of the under surface of the lowest cloud layer) is less than 500 feet; the direction and velocity of prevailing winds, the orientation of the site with respect to these prevailing wind directions, and freedom from the necessity of taking off over densely built-up areas (as determined by prevailing wind directions); freedom from poor visibility due to fog or smoke, or both; freedom from objectionable air currents and eddies; and freedom from snowdrifts.

There are also several factors related to the location of a site; such as, accessibility with respect to the business and other centers of a community (a consideration of which involves, of course, a study of existing and probable future

Figure 2. Sketch from aerial photograph of a proposed site presenting a number of typical problems.

transportation facilities); location from the standpoint of attracting the maximum volume of business; and location with respect to the direction of flow of air traffic.

In addition, there is a group of factors; such as, cost of property; clearing, grading, and leveling; drainage and flood protection, where necessary; preparation of landing surface; installation of light, power, water, sewer, gas, and telephone and telegraph lines; and connection of the site with existing highway and other transportation systems,—all of which may be directly reduced to a cost basis and grouped together to represent the combined cost of acquiring a certain property and of developing it, exclusive of buildings, drives, and equipment, the cost of which items varies but little regardless of the site selected.

The application of some of the foregoing factors may well be illustrated by a brief consideration of a typical example. The conventional sketch presented in *Figure 2* was made from an aerial photograph of a site considered by one of our American cities as a possible location for its municipal airport. This site, which was located northwest of the center of the city, and west and southwest of the principal industrial district, comprised some 520 acres of nearly level agricultural land, with good soil, excellent natural drainage, and entirely free from overflow. The local power company offered to move the pole line extending along the east side of the field and the railroad company consented to place underground the telephone and telegraph lines located on the right-of-way to the north.

After deducting the area rendered ineffective by the hill to the west and the several tall structures in the vicinity, there remained an effective landing area of about 360 acres, which was of sufficiently regular shape to permit the development of an all-way landing area, with effective landing lengths in all directions of at least 4,000 feet, and with the longest dimensions in the directions of the prevailing winds. (See wind rose in *Figure 2*.)

The site offered excellent surface transportation facilities. It was within 15 minutes of the business center of the city by either automobile, motor bus, or street car. Power, light, water, sewer, gas, telephone and telegraph service were at hand. The river bounding the property on the southwest afforded opportunity for the development of satisfactory seaplane facilities; and a bend in the river at this point, together with other landmarks, made it very easy to locate the site from the air. There were plenty of available industrial sites in the neighborhood of the tract; there were also a number of open fields, particularly to the west and northwest, on which emergency landings could be made.

It was found that this site could be bought at a reasonable figure, that the small stream crossing the southern portion of the property could be diverted and carried in an underground pipe line, and that the entire site could be cleared, graded, and put in shape for airport development at comparatively little expense. This site seemed to offer many advantages. But few sites are entirely free from disadvantages.

The normal direction of flow of air traffic for this city was east and southeast; hence, many planes approaching or leaving an airport developed on this site would be compelled to fly across the city.

A study of the meteorological conditions prevailing in the vicinity, showed that this rather low-lying tract along the river was subject to a great deal of fog,—one of the few remaining hazards besetting aviation and one of the worst enemies of scheduled air-transport service. To be more specific, it was found that dense fogs (fogs obscuring objects 1,000 feet away) of at least one hour's duration, occurred over this area twenty-nine days of the year, and that the area was often blanketed with ground mist, while higher areas were entirely clear, or nearly so. Furthermore, with 27 per cent of the wind blowing in over the industrial district to the east and northeast, the site was often shrouded in a dense cloud of smoke.

As 40 per cent of the wind, including the winds of highest velocity, blew from

the west and northwest, the sharp hill at that side of the field was at times instrumental in producing dangerous air currents over the landing area.

The tall isolated structures in the vicinity of the field, together with the hill to the west, constituted serious obstructions to the approaches and were particularly hazardous at times of poor visibility. The gas plant to the west of the field, though well under the 7 to 1 climbing and gliding angle, was a menace to planes taking off or approaching in that direction.

In spite of the advantages offered by this site, it was rejected in favor of one affording opportunity for the development of a much safer and an almost equally accessible airport.

When comparing available airport sites, it is very important that the several factors entering into the selection be carefully balanced and properly weighted in accordance with local conditions and requirements. No fixed set of rules can be expected to govern the selection of an airport site. Every problem is an individual one peculiar to its own locality and must be treated as such. Nevertheless, it will be found helpful, after having made a survey of the airport requirements of the community, to indicate the location and boundaries of the most promising sites on a map showing the various centers of the community, together with existing and probable future highways and transportation systems. A survey should be made of the meteorological conditions prevailing at these sites and each should be studied from on the ground and in the air. In each case, estimates covering the total cost of acquisition and development, exclusive of the cost of buildings and equipment, should be prepared. Complete data covering the several factors governing the suitability of each site should be tabulated and preliminary studies should be made of possible layouts as an aid in determining the suitability of each.

It will also be of assistance to prepare a rating schedule in which the relative suitability of each site is rated on the basis of the weights assigned to the determining factors. That done, a figure representing the cost per unit of suitability may then be determined for each site, by dividing the total cost figure by the figure representing the relative suitability. Each of these three figures is useful in making comparisons. It is important, however, that they be used only as an aid to independent judgment, and not as a substitute for judgment. The selection of airport sites cannot be reduced to a matter of mechanical routine; it necessitates the exercise of sound engineering and business judgment, coupled with a thorough understanding of the aeronautical problems involved.

Planning an Airport

It is important, in the development of an airport, to have a carefully prepared plan, not only covering the more or less immediate construction, but also providing for the ultimate development of the airport. In this way only, can a community be assured that the construction work on its airport will progress most advantageously in meeting the rapidly increasing demands of air commerce. Hence, after selecting a site, the preliminary layout studies should be continued with the idea of working out the best possible arrangement for the development of the site, from the standpoint of safety and efficiency of operation.

The general layout of the landing area, and the location and arrangement of buildings, should be determined first. This should be done only after a careful consideration of such factors as prevailing wind directions and velocities, aerial approaches, existing and probable future transportation facilities, and topography of the site and adjoining terrain. This layout should be so planned as to permit handling a maximum volume of air traffic with a minimum amount of congestion. It is also well, particularly in the case of major

airports that are likely to be called upon to handle a wide variety of activities and a large volume of traffic, to plan the airport so as to permit the ultimate, if not the immediate, segregation of scheduled air transport from aerial service and private flying operations.

After determining this general layout, a comprehensive plan covering the ultimate development of the airport should be prepared, special attention being given to the proper coordination of all activities on the airport, to suitable architectural treatment, and to appropriate landscaping. There are many points to be taken into consideration in preparing this plan. Although some of them are indirectly connected with flying activities, they play an important part in the successful operation of the airport. These include such items as fire protection, service systems (water, light, power, heat, etc.), space for various concessions, railroad sidings and spurs, driveways for vehicular traffic, automobile parking areas and service station, provisions for the safety and comfort of the public.

In planning the airport, the fact should be borne in mind that it is a terminal in what is destined to become one of our great transportation systems and that it merits the same well organized appearance of dignity and permanence as a railroad terminal. Such a port will naturally carry with it an atmosphere of assurance to the traveling public and will tend to bring about a higher standard of operation.

The Landing Area

The landing area should have clear approaches in all directions; should present a firm, smooth, well-drained surface free from all obstructions; and should be approximately level, the mean slope not to exceed two per cent in any direction.

It is highly desirable that the entire landing area be available for landing and taking off at all times and that it be of regular shape and of such proportions as to afford opportunity for the development of an all-way field that will not only permit landing and taking off in all directions, but that will also permit a number of landings and take-offs to be made simultaneously, regardless of the wind direction.

The size of the landing area will depend, of course, upon the type of planes to be operated on the field, the volume of traffic to be handled, and the elevation of the airport above sea level. Where conditions permit, provision should be made for the development of at least a 2,500-foot all-way landing area. It must be borne in mind, however, that areas limited to this size will not necessarily be large enough to take care of the needs of every city. In view of the tendency toward the building of larger and larger transport planes requiring comparatively long runways to insure maximum safety of operation, provision should be made at the major airports, for the ultimate development of runways of 3,500 to 5,000 feet, or more, as conditions may dictate. For fields located at altitudes above sea level, the effective landing lengths and the allowable safe climbing ratio (7 to 1) for sea-level conditions, should be increased according to the percentages given in *Figure 3*, which are in accordance with the requirements of the Airport Rating Regulations of the Department of Commerce. (At altitudes above sea-level, airplanes land and take off at higher speeds and climb at flatter angles than at sea-level).

Where soil conditions are favorable; where drainage, either natural or artificial, is good; and where a tough sod can be maintained on the surface of the landing area, it will often be possible to handle the traffic for some time without the construction of artificial runways, particularly in localities where there is little or no freezing. It may be found necessary, however, to stabilize the soil, before seeding,

by the admixture of several inches of granular material, such as crushed stone. Nevertheless, with increasing traffic and the building of heavier transport planes, the demand for hard-surfaced runways will be imperative in many cases. Furthermore, the traveling public will demand smooth landings and take-offs. From a safety standpoint, the runways will be necessary in order that heavy planes may take the air with the shortest possible run and thus attain a safe altitude before passing over the opposite boundary of the field.

The principles governing the design and construction of runways and taxi-ways, are, for the most part, the same as those governing the design and construction of highways. Hence, it is necessary that the same careful consideration be given to such matters as preparation of sub-grade and shoulders, adequate surface and

Figure 3. Required increase in length of landing area at altitudes above sea level.

subsurface drainage (see Figure 4), and to the necessity of designing the runway to meet the service for which it is intended, without excessive maintenance cost. In designing runways, it may be assumed that the landing load will vary from about three times the weight of the plane, for planes weighing 5,000 pounds, to about twice the weight of the plane, for planes weighing from 20,000 to 30,000 pounds.

Runways may be constructed of gravel, crushed stone, crushed slag, or other granular wear-resisting material, each used with a suitable binder. There are several types of construction; such as, bituminous macadam, bituminous concrete and Portland cement concrete, that are well adapted to airport requirements. It is highly desirable that the widths of runways be at least 100 feet, and, preferably more. The runway surface may be given a crown of from four to six inches per 100 feet of width, where necessary, to facilitate drainage. In order that planes may land and take off across the runways, the edges of the runways must be flush with the adjacent surfaces of the field and should be constructed with shoulders of crushed stone or other granular material.

The construction of double runways permitting simultaneous landings and take-offs, has been suggested as a means of facilitating the handling of traffic. Another suggestion to this end has been the construction of a taxiway around the outside of the landing area.

In order to assist pilots in locating the airport, the landing area should be marked with the conventional 100-foot circle, set flush with the surface, and with suitable boundary markers. (See Figure 5.) If desired, the name of the city may be placed near the circle but should not be placed inside it. The effective landing areas and the aerial approaches of airports should be protected against the encroachment of high buildings, or other structures, by local ordinances. Poles, water towers, and like obstructions in the vicinity, should be painted with alternate horizontal bands of black and chrome yellow, with a chrome yellow band at the top.

Figure 4. Tile drain for sub-draining and handling surface run-off.

Buildings and Related Facilities

The buildings and related facilities for the airport should, of course, be designed to meet the specific requirements incident to airport operations. Special consideration should be given to such matters as, provision of barriers and fences for the protection of the public, and suitable guards for the protection of airport personnel working in the shops and at motor-test stands; lighting, heating, and ventilating systems; exterior painting to give maximum visibility; fire prevention and protection, including fireproof construction, proper provision for operations involving fire-hazard, storage and handling of gasoline and other flammable liquids, and special fire-fighting equipment.

The terminal building, or group of buildings, as the case may be, should provide the same facilities for serving passengers, shippers, and the general public, as are found in other terminals, not necessarily on an extensive scale to begin with, but of at least the same degree of excellence. Such buildings may well include: administration offices, with an operations office so located as to command an unobstructed view of the entire landing area; a meteorological office and bulletin-board; ticket, telegraph, and information office; comfortable waiting-rooms overlooking the landing area; rest-rooms; restaurant; baggage, express, mail, and check room; public telephone booths; and concession stands.

In connection with the terminal building, it is important that provision be made for concrete loading areas—preferably under cover, or at least connected with the terminal building by a covered passage-way—for the convenient handling of passengers and goods; and that guards be installed to protect

Figure 5. Typical boundary light installation with painted cone for day marking.

passengers, when boarding or leaving planes, from coming in contact with whirling propellers.

In designing hangars and shops, the important considerations, in addition to the special considerations above, include: location and area of windows; construction and drainage of floors; provision of suitable concrete aprons; location and protection of fuel-burning appliances; construction and ventilation of paint, varnish, lacquer, and dope rooms; and construction and operation of main doors. Hangars with full-width door openings on either or both sides will be found to add greatly to the ease and convenience of handling planes.

Careful consideration should be given to the provision of suitable facilities for the servicing of planes at convenient points on the airport.

The indications are that sooner or later, many of the airports will be equipped with low-power, two-way, radio-telephone stations for communicating with planes flying in the immediate vicinity. It is highly desirable however, that a visual signal system, suitable for day and night use, be provided for the benefit of planes not equipped with radio, to give the pilots information regarding landing conditions and weather conditions on the airway.

A compass circle, or platform (preferably of the turntable type) located on a portion of the field well away from stray magnetic influences, and constructed with care and accuracy, should be provided to facilitate the work of checking and swinging compasses in planes using the airport.

Night Lighting Equipment

The proper lighting of an airport for night operations has a very important bearing on the subject of safety in aviation. This lighting equipment involves a number of distinctive features and may well be considered under the following headings: (a) the airport beacon, (b) the illuminated wind-direction indicator, (c) boundary lights, (d) obstruction lights, (e) floodlighting of hangars and roof-markings, (f) the ceiling projector, (g) the landing-area floodlighting system.

The requirements for a satisfactory aeronautical beacon light for airports are: adequate candle power, not less than 100,000 for long range visibility, proper distribution of light in the vertical plane to make the beacon visible all around the horizon and to the zenith, or nearly so, for altitudes of from 500 to 2,000 feet; distinctiveness for identification; flashes of not less than one-tenth second duration; luminous period of not less than 10 per cent; and eclipse periods of not more than 10 seconds' duration. Apparatus having characteristics differing from these, but of equivalent effectiveness owing to greater luminous periods and shorter eclipse periods, to greater candle power, or to color effect, will be found satisfactory. In no case however, should the beam candlepower be less than 15,000; nor the luminous period, greater than 60 per cent. For beacons of 30,000 candlepower or less, the luminous period should be at least 35 per cent; beacons of less than 20,000 candlepower should have a distinctive color characteristic.

It is highly desirable that all flashing beacons have a definite Morse code characteristic and that they be operated by flashing mechanisms so designed as not to interfere with radio reception; and also, that beacons having a single light source be provided with automatic lamp-changers for bringing spare lamps into the focal position. A green, flashing, double light source, auxiliary beacon of at least 5,000 candlepower mounted directly above the main beacon, makes an excellent installation; particularly in view of the fact that on our National Airway System, flashing, red, course-lights are used at beacons where no landing fields are located, and flashing, yellow, course-lights are used at beacons where intermediate fields have been established. The uniform use of red, yellow, and green auxiliary beacon lights to indicate landing conditions, would add materially to the safety of night flying.

The wind-direction indicator—either a wind cone or a wind tee—should be illuminated so as to make it visible at night from a distance of at least 1,000 feet in any direction, and located so as to give a true indication of the direction of the wind on the landing area, and be readily visible to aircraft approaching from any direction.

The borders of the landing area should be outlined by a series of boundary

lights, spaced not more than 300 feet apart and served by an underground distribution system. (See Figure 5.) Either white or yellow lights should be used for this purpose, except where the entire field is not available for landing in all directions at all times; in which case, green lights should be placed so as to indicate clearly the ranges of the landing strips or runways; and red lights, installed at points where an approach is particularly hazardous. The lamps used for the boundary lights should be not less than 25 watts for white lights, and not less than 30 watts for yellow, red, and green lights. Diffusing globes or frosted lamps for all white lights are effective in obviating glare.

It is very important that all obstructions, on and in the vicinity of the airport, be marked with red lights of the same brilliancy as the lights used in the boundary circuit. These lights should, in each case, be mounted above the highest point of obstruction or on poles of corresponding height, placed along the side thereof. In marking tall, isolated structures; such as, transmission towers, radio towers, chimneys, etc., four red lights should be used. Two of these should be placed directly above the obstruction; a third, at two-thirds the height; and the fourth, at one-third the height.

The exterior surfaces of one or more of the hangars should be flood-lighted to an average intensity of at least $2\frac{1}{2}$ foot-candles, in order that these buildings may stand out in perspective to assist the pilot in judging his elevation above the field when landing. Roof-markings on the airport may be illuminated either by flood-lighting or by outlining the markings with exposed lamps.

A projector concentrating a narrow beam of light and mounted at a fixed angle of elevation is generally used to determine the height of the ceiling above the airport at night. The value of this apparatus will be greatly augmented, if the light be installed in conjunction with a graduated alidade, in such manner as to permit direct readings of the ceiling height.

There are two general systems in use for floodlighting airport landing areas: the centralized system, which consists of one or more light sources located at or near a single point; and the distributed system, which consists of a number of light sources spaced at more or less equal intervals along the borders of the area. Whichever system is used, it should be so designed as to provide an even distribution of illumination (free from abrupt changes in intensity and free from shadow areas) over the entire usable portion of the landing area. There should be sufficient intensity of illumination to reveal the details of the surface and to make depth perception readily possible from a minimum altitude of 30 feet, in the center of the lighted area. It is highly desirable that the minimum, vertical-plane intensity of illumination for the usable portion of the landing area, be not less than 0.15 foot-candle. The floodlight system should be available for immediate use, through the operation of controls located at a convenient point on the airport, and should be sufficiently elaborate or flexible to permit landing under all conditions of wind direction, and under no necessity of landing directly toward the light source.

It is of utmost importance that the floodlight system be so designed and installed as to eliminate glare and the consequent blinding of pilots. Each unit should be mounted as low as possible—consistent with the contour of the landing area—and project a beam with a small vertical divergence and a sharp cut-off at the top. The top of the beam should be as nearly parallel with, and as close to, the surface of the landing area as is practicable. In case the floodlighting is accomplished from a single light source, it is highly desirable, from a safety point of view, to provide an automatic lamp-changer to bring a new lamp immediately into the focal position in case of lamp failure.

Airports for Seaplanes

The general requirements governing the location and development of airports for seaplanes are similar in many respects to those pertaining to landplane airports. There are, however, a number of fundamental differences. These have to do primarily with the landing area and facilities for handling the planes.

Seaplane airports should be situated on, or directly connected with, a body of water having a minimum depth of not less than 6 feet at any time; calm enough for operations in ordinary weather; free from reefs, shoals, sand-bars, etc.; sufficiently large to permit landing and taking off of seaplanes and flying-boats without hazard; and with approaches permitting an unobstructed climb after taking off. In case the airport is not located directly on the edge of the landing area, it should be connected thereto by a canal, or other stream of water, wide enough to permit taxiing of planes without difficulty, and not more than one-quarter of a mile in length.

The size of the landing area required will depend, of course, upon the operations to be conducted at the port. If possible, this area should be of such size as to afford at least 3,000-foot runs in all directions. However, 4,000- to 5,000-foot runs are to be desired, particularly in major airports.

The equipment and facilities required for seaplane airports, differing from those required for landplane airports, include such items as, mooring facilities; motor boat to act as tender; means for hauling planes out of the water; dollies, cradles, and other apparatus for moving planes between hangars and ramps. In this connection it should be noted that, as a general rule, the overhead clearance necessary in hangars for seaplanes and flying-boats is somewhat greater than that for landplanes.

Night lighting equipment for landplane airports is, for the most part, applicable to the lighting of seaplane airports. Nevertheless, the lighting of seaplane airports should be treated as a separate problem in every case, on account of its possible interference with river, ocean, or harbor traffic.

In Conclusion

Aviation is becoming a vital factor in our business and social life; and before we hardly realize it, swift aerial carriers will be bearing their cargoes to every corner of the land, with a degree of safety and reliability rivaling the best of our surface carriers. The establishment of carefully-designed, well-located airports throughout the country will hasten the development of this new means of transportation and play an important part in bringing about the high standard of safety essential to its complete success.

CHAIRMAN PRATT: I am sure I am expressing the opinion of all in thanking Mr. Blee for his most excellently prepared and well delivered address.

The purpose of this conference is not only to have an opportunity to hear the papers read by certain selected individuals but to offer to those most interested an opportunity to discuss these papers and present their views thereon. Before proceeding to this discussion, it gives me pleasure to read a communication from a gentleman to whom a copy of Mr. Blee's address was presented prior to its delivery.

ARTHUR HALSTED (Associate Electrical Engineer, Bureau of Standards, Department of Commerce, Washington, D. C.): Mr. Blee has dealt with his subject so thoroughly and analyzed it in such good proportion that discussion seems limited to the amplification of details. One point in particular seems to me worthy of em-

phasis. The paper mentions a principal airport with one or more auxiliary ports so located as to insure safety and continuity of operations at times when the principal port may be fog bound.

Many of our cities have found it advantageous to locate their commercial airport on low land, often near a body of water. Such land may be subject to ground mists in the early morning or evening, that may form earlier or persist sometime after higher land, not far away has cleared. The early morning and early evening hours are assuming greater and greater importance in dispatch aviation.

It will be found that well within reach of the city whose airport is on low land, there is a knoll from 300 to 600 feet higher that could serve as an auxiliary field when the lower lands are covered with ground mist. Such an auxiliary field will facilitate scheduled arrivals and departures and other urgent flying.

Large area will not be so necessary to an auxiliary landing field on the crest of high land. The elevation above the surrounding country does in some respects compensate for area for landing and taking off. A good usable area as small as 1800 by 1800 feet with no surrounding obstacles, that can be approached flying low, will serve well for such an auxiliary field. It seems to me probable that the question of a field, auxiliary to the city airport, on the highest nearby land will face some cities soon.

CHAIRMAN PRATT: The main value of this assembly is to give to others such views as you may have. I would be very glad therefore to open the conference to discussion.

To inaugurate this, gentlemen, I am going to call on Lt. Donald Duke, of the Boston Airport. Lieutenant Duke for a long period was in the office of the Chief of Air Corps, associated with the Airway Section, at a time when the Department of Commerce had not as yet taken over the supervision of airports and airways. I think Lieutenant Duke can probably give us a few comments as a result of his experience that may prove interesting.

Discussion of Adequate Airports

By **LT. DONALD DUKE**
Boston Airport, Boston, Mass.

It has been my privilege to grow up with the airport business from the cow pasture landing field days, and it has been my privilege also to visit practically all of the recognized airports throughout the United States; to land on them and more or less inspect them, and to see the changes that have taken place in those airports, in the construction of buildings, to keep up with the advancing stage of commercial aviation.

I particularly want to stress at this time the comments of Mr. Blee on modernizing our airport. In the August issue of *Air Travel News* I had an article on that subject, and it goes into detail. Perhaps some of you would like to refer back to it. It has certain sketches and photographs are therein reproduced.

It is my contention that we have reached the point now in commercial aviation where we have got to give the people who support the airports, that is, the commercial operator, a better break for his money, comparable to the first-class store in our larger cities. If Marshall Field, in Chicago, didn't provide more conveniences for their customers, provide rest rooms and comfort rooms and libraries, and so forth, all of the conveniences that people may expect, they wouldn't be in business very long. Neither can the airport operator of today

expect to put up an old, rickety shed for a hangar, have no office facilities, and have those other things absent that modern people expect today.

The commercial airport of today may be compared to a business street in that the airport is the business street and the hangars are the stores along that street. In the course of a business block we will have several rival competitors for the business along that street, and the same way with the airport. Each operator there is competing with the man in the hangar next to him. Therefore the more facilities and the more conveniences he provides for the people who come to that airport, the better pleased they will be and the more patronage he will get and the more money he will make.

I venture to say that more than 60 per cent of the hangars in the United States are obsolete now. You can't get a modern large passenger plane in but very few hangars in the country. All hangars should have an overhead clearance of at least twenty feet. Most of them are around eight and nine or twelve, and less than that.

Our hangars should be modernized as well as the other buildings on the airport, and they should be situated in a different manner. If you go to the average commercial airport today, in the first place, as you approach the airport, you usually pass a dump heap or a sewage disposal plant or a gas plant or a swamp or something else. There are not enough highways to get to the airport. Every airport, as we know from Lindbergh's visit, should have ample highway facilities for traffic both in and out, so that traffic can be routed one way and not use the same street for two-way traffic.

Every airport should have a very substantial fence to keep the people away from the planes and to keep people off of the airport who do not belong there. There are very few airports in the United States that have control over the throngs of people that visit those airports when a prominent flyer comes in, and for that reason most mothers and fathers are afraid to let their children go out there, and they are the very people that are going to support aviation in the next few years. These youngsters are all curious and interested and eager to get near an airplane, and they should not be deprived of that privilege which is inherent and natural with them. They are the people we are looking to in the next ten years to buy commercial planes and to support airport traffic.

I think hangars should be turned around. I think the front of the hangar should face the flying field and not the side of it, as it does now. Turn the hangar around. Put your office in the front of the hangar. Up above the office, in the second story, put a roof garden with an awning over it so that people can come out there in the summer time; those people who are flying with you as an operator and are going to buy one of your planes should be given the privilege of having a place to rest and to see what is going on without getting their eyes full of dirt and clay and cinders.

Fix it up like a little roof garden on top. Put a loud speaker there, have somebody announce who is coming in and who is going out. People are interested in those things. Refreshments could be served there. Also in connection with this hangar there should be a little classroom to teach pupils the fundamentals of the ground school course.

I am speaking now of the average commercial operator who is trying to make a living on a commercial airport. He also may be running an air mail line, but all of these activities are related to the commercial operator's bread and butter.

On back of the rear of this office comes the hangar, with doors down both sides. It doesn't have to be a cantilever hangar, because those cantilever hangars are very expensive in construction, but have folding doors so that the plane can go in one side of the hangar, under its own power.

This thing of having four or five men lift up the tail of an airplane and put it on a dolly and then wiggle it into a hangar, perhaps moving half a dozen

planes and bumping propellers and wing tips is passé. The planes have plenty of power, our larger planes, to pull them into a hangar, just the same as our automobiles drive into a garage. We don't stop our automobile out in front of our garage and push it in. Neither should we stop our planes out on the dead line and push them in the hangar on a dolly or pull them in with a tractor.

The next morning when you are ready to start your activities, your plane goes out the other side of the hangar. On both sides of that hangar are concrete aprons 50 or 100 feet wide. That is where the plane should do its warming up. That is where all the tinkering should be done, so that there is no dirt and very little noise. Then your plane, when it is ready to start activities for the day, either on local hops or student work or on distant cross-country flights, pulls up to the front of the hangar, which is the office, takes in its load, goes out on the field and takes off without bothering anybody or without inconveniencing anybody.

That gives you protection over the people that are entering that plane. They are shielded and protected from the propellers because they stop right at your office door.

Every airport, as Mr. Blee has said, should have a central administrative control building because an airport manager is just like the captain on the bridge of a battleship; he must have every activity within reach. When things happen on an airport they happen quickly. He must be able to get his weather man right here, his radio man there, his fire marshal, his guard. They must all be within immediate call. That is the system used at Croydon and Tempelhof, and it is working out very well.

Also in that office, as Mr. Blee has said, we must have facilities provided for storage of baggage, ticket sales, contracting for flights, a customs office and immigration office, because most of our larger airports must necessarily become ports of entry. Foreign planes might not want to stop at one airport and enter, so they will come to the next one. Provision must be made for that.

Going farther with my thought on modernizing our airports, the tendency in the United States now for municipal airports is to build the airport itself and light it, but not put up hangars for somebody else to use. I don't think any city should spend money to erect hangars on a municipal airport. I think that system is wrong, and I think we have outgrown it.

We are planning that now at Boston. The city has taken over the Boston Airport and is going to make it one of the best, probably the outstanding airport in the United States and possibly in the world. It is going to be modernized. The city is going to build the airport and light it and provide highways and all facilities that visiting personnel may expect, all the comforts will be provided for them. But the hangars will be erected by the people who are coming in there to enter that business. It is up to them to put up their establishment, but the city will specify a type of hangar to which their design must conform. Boston will have an airport with its hangars uniform in construction. They will have brick fronts just like an office building downtown. In front of the hangar will be a little plot of grass, flower beds, hedged around, because the airplane doesn't come out of the front of the hangar; it comes out of the side. The airport is going to be beautified, and I think that if you will watch the construction of the Boston airport, you will find that this will be the turning point in airport construction in the United States. I think we are going to give the rest of the country something to shoot at up there in Boston, and it is going to be very interesting.

There are one or two points in Mr. Blee's statement that I would like to discuss, and that is the use of multicolored lights for night lighting or for boundary lights. I have been doing quite a little night flying lately, and I find

no trouble at all in following the lighted airways. But just the minute you come into a city like Chicago or New York or Boston, there is a great sense of confusion by all of the glimmering and the billboard lights blinking at you and maybe a half dozen beacons in one town; all these beacons flashing from all over town don't mean anything except that somebody is getting advertising out of it. But it is confusing the pilot when he sees a beacon here and one up there and one over there, and he doesn't know which beacon is which. There should be one main beacon on the airport. That is where the pilot wants to get and all these other lights are just so much confusion.

As far as boundary lights are concerned, there too you have confusion by having two or more colors. I contend the proper colored globe for boundary lights depends on the surrounding lights in that city. As I have said before, there are no two airports alike, and no two operated alike. We must analyze local conditions, diagnose the case, and provide the equipment that will best meet the need. So that if you have your airport close into town like it is in Boston, which is just adjacent to the business district, and all these lights flashing everywhere, we should have a distinctive boundary light, preferably chrome yellow or something distinctive, so that it cannot possibly be confused with a park which also has white boundary lights around it.

Then if you want to use another colored light, use a green light to show the pilot where his best approach is, depending on the wind. The pilot then spirals around his boundary lights until he sees the green light burning, and he comes in over the green light which has been turned on by the man in the control tower. Every runway or every angle of approach has a green light around the periphery of your boundary lights which the man in the control tower can turn on, but there will only be one green light burning; and I believe that is the best solution to boundary lights in landing at night, together with the other equipment which has been referred to.

There is one more point that I want to take time to discuss here, and that is of general interest to everybody and is more or less propaganda or more or less offsetting propaganda.

Occasionally you see articles in the papers stating that big airports are no longer needed somebody is building a helicopter or an autogyro or something else so that you can land in the back yard. It has caused many erroneous impressions to go throughout the country that large airports are no longer needed, which is not the case. Airports should become larger, and those cities today which are figuring on airports should provide not only the land for their present needs but land for expansion rather than buying a back yard and expecting to make an airport out of it for the planes that are not yet proven practical.

I think the paper by Mr. Blee is a very wonderful piece of work and will do a lot of good if circulated throughout the country.

CHAIRMAN PRATT: This subject naturally divides itself into the selection of airports from a safety point of view, which I wish to stress, and their preparation for operation after their selection.

We have with us Colonel Stedman Hanks, who is connected with an organization that has done considerable work in the selection of airports. He has made a trip recently which should give him much information, and I am going to ask him if he will be kind enough to give us a few minutes, bringing out the result of his experience in this connection.

COL. STEDMAN HANKS (President, American Airports Corporation): I really feel quite honored to speak to such a distinguished group of men. It is quite unexpected.

Of the few things I was able to learn abroad, two stand out in my mind above all others. I shall mention those very briefly.

I do want first, though, to publicly state what a great help the Department of Commerce was to me when I went abroad. Through the commercial attachés in the various countries, they were able to collect a lot of information and were of invaluable assistance. I also got a great deal of help from the War Department, and if it wasn't for the military attachés it would have been very difficult to see all that I did see. Also Mr. Guggenheim very kindly suggested that I might call on some of their representatives. They are the highest type of men in Europe and are in touch with all phases of development in aviation, not only airports.

Mr. Blee in his paper has shown extremely good judgment. He has not confused the issue. I think when we talk about airports we are apt to be too definite. We are apt to lay down the law and say this is so, and this cannot be done. This whole game is so new, no matter how much experience one may have, it is growing so fast, that I was impressed particularly abroad with the mere fact that the Italians didn't know very much of what the Germans were doing or the Germans were going so fast that they felt it wasn't necessary to see what the French were doing and the Dutch were doing, and the same with the British. They were all interested in knowing what the other nations were doing but they weren't exchanging their ideas. So I feel in this matter of designing airports, of building airports, it is just now a very, very early stage. I think very few of us know where we are going, and in Mr. Blee's paper he has produced so many different phases without being too definite. And the point I want to make is this, that we must get the people's confidence. We all want to talk the same language. We don't want to confuse the issue so that engineers will say, "Well, why does one person do this and why does the other person say this cannot be done?"

Without question, abroad the outstanding phases of airport development are these—first, the hangars over there are large. They are making larger and bigger hangars, and many of the officials there told me that all hangars built today will be amply large to take care of all the airplanes or the increasing size of airplanes. That point was of course brought out by Mr. Duke in his very able remarks just a few minutes ago.

Secondly, the hangars and the laying out of airports abroad go over a far greater area in that taxiing is required to a far greater extent than we want to taxi an airplane in this country. I think such a situation as you find abroad is perfectly logical because if you remember the airport and the air transportation company are very largely controlled by the same group of officials, so that the air transportation company can't go to the airport manager and say that he does not want to taxi halfway around the field or want to taxi around behind the control tower because it is bad for his airplane.

Abroad, the air transportation companies and airport corporations are working hand in hand, so that the primal thought there is the thought of the comfort of the passengers, the best way to impress the public, and to make the airport a part of the community.

I hope that point is clear because I think it is very important, and I think it will continue to be more important in this country because the air transportation companies are always going to try to look after their own interests, which they should rightly do, and they should have every possible help, but the airport manager is looking out for the interests of his community.

In conclusion, I would like to say, if my opinion is of any use in connection with sea-planes, that the development of the flying boat or the sea-plane abroad is perfectly appalling. I feel that it is a phase of aviation which we must give much more consideration to.

CHAIRMAN PRATT: Gentlemen, we have another paper to hear later which

deals with more of the safety of operation of airports. If, however, after these remarks there are other gentlemen who would be good enough to give us their opinions, I should be very glad indeed if they would take this opportunity to do so.

There are one or two points in Mr. Blee's paper which I remarked and which I would like to comment upon very briefly. I think the matter of the influence of future design on airports will have to be given consideration, as Mr. Blee brought out, to a very great extent. We can compare it with the development of the railroads. An airport which is satisfactory now may not be so a few years hence. However, we have to establish these airports based on what we have at present and what we know at present. The difficulty is a railroad station which is not large enough or properly situated at present can be very much more readily moved than an airport which is incorrectly chosen in the first place.

I think all those interested in the organization of new airports should bend every effort to secure proper assistance from the neighboring communities. It is comparatively easy to mark and lay out your own airports. It is exceedingly difficult in many instances to get the neighboring communities to assist you in marking and lighting which would be of benefit to the operators from your airport, particularly if it costs them money.

I think there is sometimes considerable advantage in holding back on the development of airports. I am afraid in many instances airports are being placed where they eventually will be of no value to the development of real commercial aviation. Of course we have to distinguish between airports for operating organizations and little airports that are erected for schools and individual operation. But I think those of you who are called in in consultation in this connection, it is a fair thing to do if somebody is desirous of establishing an airport and you can see no value for it, to tell him so even though at that time he may not appreciate it.

Our next paper, gentlemen, deals with the other phase, the operating, and it gives me great pleasure to present to you Major John Berry, the manager of the Cleveland Airport, of Cleveland, Ohio, who will address you.

MAJOR JOHN BERRY: This paper is not presented to you as authoritative. It is simply my reaction, after fifty-seven thousand ship movements through the Cleveland Airport. The things suggested as needed aren't yet installed in the Cleveland Airport. We haven't the best airport in the world. We have a busy port. We are still in the process of construction and will be for quite some time, and if you will bear with me, I will read this to you.

Airport Operation from a Safety Point of View

By MAJOR JOHN BERRY
Manager Cleveland Airport, Cleveland, Ohio

The phenomenal growth of commercial aviation and the diversified types of service, coupled with the countless student flying activities, presents today an operating problem for the airport executive to weigh carefully. Despite the care and thought given to the preparation of laws for navigation, and particularly to those that apply to airport flying, by the Aeronautics Division of the Department of Commerce, casualties continue to multiply in a greater ratio.

The great diversification in types of fields has necessarily superinduced many rules for the governing of local conditions. Flying traffic regulation is covered in its activity by the air commerce regulations, yet lack of standardization in airport construction gives leeway to the individual flier.

Take-offs and landings shall be made upwind, when practicable. The basic principles of airport design should make it possible for the elimination of the

word practical. Airports built with run-ways when sufficient area is available for the construction of the all-way field are inviting casualties.

On the terminal ports today, with ships landing and taking off every few minutes, it is essential that a control station with unobstructed visibility be the point from which all departures are controlled. The inability of the pilot, in certain types of cabin planes, to see the air from all angles has frequently led him to take off just ahead of a ship landing and thus jeopardized the lives of the passengers in both planes.

The law giving the incoming ship the right of way automatically safeguards the entire traffic if control is exercised from a tower and signals used designating the area that is to take the air. The advancement of the art of navigation, as practiced by the pilots of the New York-Cleveland leg of the N. A. T. service, namely, that of flying blind and solely dependent upon instruments, makes it extremely necessary that precautions be taken to protect the incoming flier, not only from collision but also from over-shooting his landing area.

A four way field with the perimeter outlined with boundary lights gives a sense of security to a pilot in bad weather if the entire area inside the lights is safe for a landing. This is particularly true in winter, when snow covers run-ways and the losing of the run-way means nosing up, with resultant damage to ship and delay to ship's cargo.

A far greater source of worry than all the flying activities is the absolute lack of precaution taken by the average spectator on an airport. Whether it is because of his interest in things strange and unfamiliar or whether he is merely exercising his inalienable rights as an American citizen, it seems impossible to impress the thought of caution and the necessity for care into the sightseer at an airport.

The whirling propeller seems to be a natural attraction and the average spectator is drawn into danger by a lack of knowledge of this hazard. Naturally you ask, why not a fence? Primarily our first reaction is that a fence high enough for the purpose will automatically become a hazard.

The average port today is municipally owned and dependent for some years to come upon the taxpayer for the money with which to operate. A complete exclusion from the port means a lack of support when funds are needed for further development and added necessities. The enclosed area at Tempelhofer Field seems from the airport manager's point of view an ideal set up, yet with eight to ten companies competing for the traffic and the removal of the few from the center of operations we would at once encounter the cry of favoritism and also encounter stubborn resistance from the public.

Sufficient mounted police patrolling along a dead line have proven quite satisfactory as far as the sightseer is concerned, but once the sightseer buys a ticket and becomes a prospective passenger it is impossible to hold him on the line. He is in the hands of the operator, who with limited personnel and the ever present necessity of selling another prospect seems to feel only a negative responsibility.

On single motored biplanes the wing acts as a guard for the passenger entering and leaving, but the ever present hazard of the starboard motor on tri-motored monoplanes constitutes what is probably the greatest hazard to the user of air travel. A rope fastened to the fuselage prior to the loading or unloading of passengers would in a simple, inexpensive manner reduce this hazard to a minimum.

In the life of every airport certain construction work is necessary. This in itself is a hazard and must be so marked that the pilot unfamiliar with the port may know at a glance that the area is closed and unfit for service. The painting of tractors, trenchers and graders with the standard black and chrome tector striping of the Department of Commerce sets out clearly these obstacles, and the complete surrounding of the area with a series of flags similarly marked and spaced about 20 feet apart guarantees protection during the daylight hours.

It is exceedingly desirable and should be the practice of airport executives to see that all obstructions are removed before dark, but if the area itself is unsafe red electric lights, not lanterns, should replace the flags at the same spacing. The insisting of the Aeronautics Division upon fire extinguishers in every ship has been an education for most operators. When a mechanic wheels a ship on the line it should be an inviolable rule that two hand fire extinguishers be mounted in a carrier and accompany him and be available for immediate use in case of back fire.

Every hangar should have spaced about the walls extinguishers that are ready for emergencies. These should be inspected at least once a week and care should be taken to see that they are immediately refilled after having been used. The hand extinguisher should be supplemented by a forty or fifty gallon tank of the foam type, for further protection. The field itself must have an efficient fire department that is motorized and equipped with chemicals, pumps, hose and first aid equipment. In addition to this equipment it is the duty of the airport executive to supervise general conditions and, when carelessness and neglect are noticeable, to exercise his authority and eliminate the cause of both.

The duties and responsibilities of the airport manager are so many and of such wide variance that to attempt to cover the entire field would tax a super-man. The supervision of flying is a minor incident in the day's work. The fact that the average pilot is a man of sound brain and approximate physical perfection guarantees to the manager strict compliance with the air code. This, of course, applies only to the experienced pilot. Student flying and the period after solo requires more attention.

Printed rules mean little; constant contact by the airport manager with the courses of instruction given by the various schools will educate the student in what is required of him on the particular port, both as to the hours of flying and the priority of flight and the necessity to conform himself strictly to straight flying.

The care of the layman is, as I have previously stated, a paramount worry. At Cleveland a week-end average crowd is about 75,000 people. There are about twenty to twenty-four ships in the air from daylight to dark. Each delay in loading and unloading lessens the day's receipts. The reputation of the port rests with the manager and it is his duty to insure safety to spectator and passenger alike.

The constant supervision of equipment and close contact with the aircraft inspector is necessary in order that no ship not inspected and licensed may leave the ground. The service rendered to transients is bound to react on the reputation of the port. Strange pilots must be accorded every courtesy possible and the quality of the gas and oil must be unquestionable.

Mechanics that are not licensed are frequently the cause of forced landings, due entirely to their lack of experience, and it should be an inviolable rule that at least one member of each servicing crew be an experienced man and licensed by the Department of Commerce.

The information as to routes, weather, available fields belongs primarily to the manager's duties. This information or lack of it is a determining factor in the progress of the port.

Where aids to navigation are provided by the Government, it little behooves any field manager to remain in ignorance of all conditions that pertain to flying within a two-hundred-mile radius.

Finally, the base of all his work—the bedrock from which he builds—it is the prime duty of every airport manager to know every hour in the day the exact condition of the entire flying area. During fair weather and foul the air traffic depends entirely for its very existence upon the airport. If a port is good it must be watched and maintained daily to keep it good. If it is ever to be good, only a thorough knowledge of its faults and a concentration of work on those faults will

make it better. No port stays in shape no matter how well built unless it receives daily attention.

This close inspection should not be delegated to other than trained men, for upon this more than any one factor does the port prosper or fall into disuse and for the resultant reputation so fluctuates the efforts of the airport and the airport manager.

CHAIRMAN PRATT: Major Berry's remarks are certainly full of meat, and I am sure those of you who are interested in the operation of the airports will benefit exceedingly therefrom.

I remember that during the war we had the opposite extremes in the control of flying from the airdromes in the army. I recall one field from which no plane was allowed to take off until that plane's number was flashed. I recall another field where aircraft were allowed to take off in any direction and at any time they preferred, the basis of the latter being the idea that a pilot must be at all times wide awake and alert, that if he were taught flying under any other conditions he would soon become a flyer of a character where his operations would be mechanical and controlled by outside sources.

The happy medium is, I believe, what we are after. In the case of the Cleveland Airport, it seems to me, from Major Beery's remarks, that they are endeavoring to reach that happy medium by controlling to a certain extent, but at the same time not limiting, the initiative of the pilots.

My heart goes out to him with reference to the crowds. I happen at the present time to be at Mitchel Field, and every time anyone says that an aviator is coming across the Atlantic I think a large part of New York thinks he is going to land at Mitchel, and they all come out there.

So far, the only means that has been at the disposal of the authorities at Mitchel Field to handle these crowds are policemen and guards. However, we are erecting a fence along the border of the field, and I believe that the combination is the proper solution. Gentlemen, I am very glad now to open this paper for discussion, and I am sure there are some present who have some comments upon it.

Mr. Shaw, this is a little out of your line, but I am sure you have had sufficient experience to enlighten us a little.

B. RUSSELL SHAW (B. Russell Shaw Co., St. Louis): I am going to disagree with you for just a moment in that it is not out of my line because I don't think that it is out of anybody's line who is in the airport business. I think that our experience in the operation of air lines has convinced us that the things that the major has just said are of paramount importance; at least those were the important things that it was my pleasure to learn during my affiliation with the National Aeronautic Association and the air races that we ran insofar as the control of air traffic and spectators is concerned; also in the operation of air lines for the Ford Motor Company and Stout Air Service.

I am thoroughly convinced that we need airports with runways. I am not differing from Major Berry in the slightest degree. If hard-surfaced runways are not provided, then theoretical or fictitious runways must be marked with a view to absolutely controlling the operations from the airport and the landings to it. If we are to allow airplanes to take off and land promiscuously, we are inviting dangers, and therefore some definite system of runways should be established, whether they are physical things or not, at least they should be designated so that incoming pilots and pilots taking off may know where they are supposed to land and where they are supposed to take off.

As for the accommodation of the public and the use of fences, I think that is also of great importance. One thing that I would like to stress and which I think

we are getting off on the wrong foot on, is that we are calling the majority of landing fields airports.

I believe there are three distinct phases. One is the landing field, the other an airport, and the next an air terminal. At a flying field we will perhaps have several individual operators, the equipment will not be so elaborate, and perhaps the field will not be night lighted. At the airport, we will have night-lighting facilities, hangars, and shops, and perhaps air mail operators from it, even air line operators. At the air terminal, we will have, in addition to this, proper terminal facilities for taking care of passengers on our large air lines and the servicing of our big ships.

We have in air transportation what we are pleased to call the highest class of transportation. We are charging more for it, we are catering to the best of the traveling public. Yet at the average air terminal or airport in the United States, our passengers are being taken out to board the planes in bad weather, under borrowed umbrellas and slickers, and the ladies are walking out perhaps in slush or at least in the rain to get on board one of our modern \$50,000 or better ships.

We must provide terminal facilities that are at least equal to rail facilities in so far as the traveling public is concerned. If we are going to charge for this service and we hold out to the public the fact that it is the highest class of transportation, then that same public has a right to demand similar conveniences as are accorded our rail passengers.

We are planning on several of the airports we now have under construction air terminal facilities, by which planes may take on and discharge passengers under cover. The first of these will be erected at Tulsa, Okla., and the next at Philadelphia. We believe that this will mark a decided advance in the handling of our passengers.

Major Berry's statement concerning the upkeep on an airport is absolutely right. The field surface is of the greatest importance, and it does require constant attention. I know that in the operation of Stout Air Service Lines, I used to put equipment off of the airport every afternoon after our regular lines had stopped operation in order to bring that field up to perfect condition for the next day's flying, and I think all of our airports should do that.

As to runways and what they are to be constructed of, we don't know. We have a lot of ideas, and we are trying to learn. Concrete runways have been installed at Ford Airport, combinations of this and macadam are being placed on the other field, and they are bringing up certain conditions that we must think about. One is the drainage along the side of the runways which I think can be very easily met, and the other is the surface and its reaction to the tire making contact with it.

One difficulty that has been brought out with a hardsurfaced runway such as concrete is overcoming the inertia of one of these large wheels, preventing the tires from being shredded as they make contact at 60 miles an hour or thereabouts. That can be very easily overcome. All we need to do is to turn the wheel before we land, and if our wheels are in motion, then we can land on that kind of a surface without any damage to the tire. That can be accomplished by putting small rubber fins or modifications of the cup on the sides of the tire. You say, they fill up with mud. That is all right. They turn the wheel just the same.

There is a thought we should give some attention to because an airplane, after all, is nothing but another vehicle, a ground vehicle of similar weight, until that weight is being taken on to wings, and until that time it should be moved around over a surface sufficiently hard to accommodate it without rutting, even under conditions of rain and when frost is coming out of the ground. The answer seems to be hard surface.

Whether hard surface will extend over the entire area, that is, from one side

to the other throughout the length of the runway is something that we don't know yet. We think we are learning. Our taxi strips certainly must be of hard surface.

The lighting equipment that is now available I believe is to a great extent a makeshift. I believe that through the future design of airports within the next few years and the possible application of hard surface runways, we will see an entire change in our method of illuminating the port.

I make the statement that at present we are all wrong on the method of illuminating and that within the next four or five years we will see a decided change. I made that statement at the Detroit Aero Show before some of the representatives of the various lighting companies, and I am happy to say they agreed with it.

We have been illuminating railroad yards with certain types of flood lights. When we attempt to illuminate an airport, therefore, we attempt to use that flood light in the airport with certain modifications. It is true enough there have been certain units that have been developed particularly for this type of lighting, but after all is said and done, they all use the same system, and I think that system will be greatly changed, not necessarily with the sod field, but certainly as we learn more about and instal hard-surfaced runs.

CHAIRMAN PRATT: I was asked to present this thought to you, that there may be an advantage in the provision of mats, which we may call safety mats, which can be placed upon the ground and so marked that visitors will not walk on them and thus be kept away from propellers or from dangerous areas on a flying field.

Is Mr. Cooper here? I wonder if Mr. Ray Cooper would favor us with some remarks as to his experiences in Detroit.

RAY COOPER (Board of Commerce, Detroit, Mich.): I would prefer not to say anything about the recent experiences in Detroit. There is some prospect of an airport in the immediate future, as Mr. Shaw will tell you, but it is not the airport that either Mr. Shaw or many of the rest of us thought was the preferable one.

We are probably in the kindergarten class at the present time. We hope to get out of it some of these days before long, but our airport situation, with the exception of the privately owned airport belonging to the Ford organization, is rather a deplorable one.

I did listen with a great deal of pleasure to Major Berry's paper, and I am anxious to compliment him both on his paper and on the excellent manner in which his airport is operated. Having been on a number of them recently, I am very friendly to the service that we can get there.

I had another experience in a city not quite as big as Cleveland but a very prominent city in the United States within the last week in which we found a total of 32 gallons of gas on the entire port, and probably 100 ships out on the line.

I hope that within the coming year we will be able to say something about airports in Detroit that will be interesting.

CHAIRMAN PRATT: Is there anybody now who would be kind enough to submit any further remarks in connection with this subject.

P. T. COOLECAN (Asst. Deputy Postmaster General, Ottawa, Canada): I am sorry I didn't hear the last paper, but I was very much interested in the safety of airports and the matter of hard-surfaced landing. I wonder if the last speaker or the one before the last would give me some idea of whether he has had any experience on that. We of course in certain parts of our country lack a good many of the conditions which you have here, so far as climate is concerned. I am thinking now of the eastern end of Canada on the north shore of the St. Lawrence. You possibly may remember the Bremen affair. The assistance that went to the Bremen and reached it as rapidly as it did, was due to the experience that one of the Canadian companies had had in flying the mail on the north shore

of the St. Lawrence under conditions that were extreme, to say the least—snow storms, low temperatures, taking off from the ice and landing on water, and so on. Airport design and airport safety under such conditions as I have mentioned call for considerations in design somewhat out of the line which we were discussing here this morning.

Personally, I have never had any experience with any airport except what you have here in the United States. We in Canada have not yet developed to the extent that you have, either airport design or the management of the flying, although we are well on our way, and it is just as well to start right.

I was wondering if I could get any idea here as to how to work for safety in airports under winter conditions. Hard-surfaced runways are not possible in the country that I have mentioned for a considerable time of the year, say the first four months of the year, January to April.

I represent the Canadian Post Office Department. We ran the mail to Magdalene Islands. Magdalene Islands never had a mail during the winter before last year. We ran seven trips. We had to take off on the ice and land on the water, covering about seventy-five miles of sea. Naturally, expensive airports could hardly be put up except by the government in a place like the Magdalene Islands; neither could expensive airports be established in such places as we take off.

R. A. RIDDELL (Standard Oil Co., New Orleans): I would like to inquire what the consensus of opinion is regarding safe fueling and safe handling of fuel for the planes in the larger ports, or what the general practice is. We are just getting into it down there.

Cooperation on the Part of the Oil Companies

COL. STEDMAN HANKS (President, American Airports Corporation): We felt very strongly, in connection with fueling of gas in airports, that the different oil companies should give that a great deal of thought and that we should cooperate with the oil companies. That can be handled in many different ways. It depends on whether it is municipally owned or privately owned. If it is municipally owned, it is a question of legislation, just how that oil concession can best be given. If it is privately owned, you can go jointly with the oil company, or the oil company can pay you for the concession.

It seems in an airport where a great deal of fueling is necessary, it is much better to have all your fueling placed under ground with proper outlets away from your hangars at the end of your concrete apron.

There are two ways of doing that. One is by having your gasoline tanks come on your motor trucks and make an arrangement with the gasoline company as you need the oil, or to have the gasoline company put in a large tank in the beginning.

I think in this country probably it is better, while these airports are just going through their early stages of development, to use the gasoline company with the gasoline oil tanks, as I don't think that we have yet determined which is the best place at which to put the outlet on the field. I think we must go into this matter of underground piping rather slowly on account of the expense, and I think that very shortly, with the movability of the plane and the control of the airports through the airport manager, you will be able to save a great deal of wear and tear on the plane.

I am afraid I am very conservative on some of these matters, because I think the matters are so important that it is a question really of cooperating with the oil company.

R. A. RIDDELL (Standard Oil Co., New Orleans): My idea was to get any information that was possible. We have just completed the installation of an under-

ground storage and fueling system at Pine Bluff, Arkansas, and of course we were interested to know whether we were headed on the right line or whether there may be some development brought up that might lead to radical change from the way we are doing it.

COL. STEDMAN HANKS: I am sure your work will be of great interest to our people, and it is just that kind of work that makes it possible to improve.

ADJOURNMENT

Airports and Airways (Continued)

DR. W. F. DURAND, Chairman

Professor Emeritus of Mechanical Engineering, Leland Stanford University, California

The second session was called to order at two-fifteen o'clock by the chairman, Dr. W. F. Durand, Professor Emeritus of Mechanical Engineering, Leland Stanford University, California.

CHAIRMAN DURAND: I want to say first that I appreciate very much the pleasure and honor of presiding at this meeting. If there is any one feature of the development of aviation which has especially impressed me, as the years have gone by—and I have been watching it for a good many years—it is the advancing importance in significance of the work on the ground.

It isn't alone sufficient that we should be able to design a plane and build a plane and fly a plane; but we have to have a whole program of operation and investment on the ground, in order that this plane may be made commercially significant. There must be an airport from which a plane may rise and another one in which it may safely descend and there must be lighted airways and all that sort of thing.

As we know, in many types of operation, the investment and the expense on the ground may well be more than in the air. All of that only emphasizes the particular significance of the work that goes on on the ground, taking in the whole domain of engineering in its general sense—civil, mechanical, electrical,—and involving large expenditures of money and of vital importance in order that the plane may serve its significance in fitting in as a factor in commercial use.

This afternoon session is simply a continuation of a similar session this forenoon, and the first paper is by Harold Pitcairn, President of the Pitcairn Aviation, Inc., Philadelphia.

Unfortunately Mr. Pitcairn is not able to be with us this afternoon, and his paper will be read by Mr. W. L. Le Page, who is associated, I believe, with him.

Airway Selection from a Safety Point of View

By HAROLD F. PITCAIRN

President, Pitcairn Aviation, Inc., Philadelphia, Pa.

Safety is the watchword of commercial air transportation. Without a reasonable degree of safety, air transportation would have no future, were it even to have a present. In organizing for air transport operation, therefore, this most important factor calls for a broad consideration in its relation to the many other problems involved.

In view of the subject assigned to me I think it important to point out that the demand for air transportation is the reason for establishing an airway. It is the demand which is the primary consideration in the selection of any particular route, for where the demand exists, there the airway will lie. From the standpoint of selection only, therefore, safety becomes a secondary consideration which must be secured wherever and however possible, and usually has little influence upon the choice of an airway. We

ourselves, for instance, had very little choice in the selection of the route for the New York-Atlanta airway. There existed a demand for air mail service between New York and Atlanta, touching at Philadelphia, Washington, Richmond, Greensboro and Spartanburg, and our only choice lay in undertaking the job or not.

Therefore, in this discussion I am going to take the liberty of treating the subject of airway selection in a broader manner than the title would seem to permit, for a strict adherence to the title allotted to me would involve wholly theoretical considerations many of which would instantly break down in the light of practical application.

In the initial survey of an air route, it is a good plan to fly over the route thoroughly and take many oblique photographs. In the preliminary survey of our route we followed this practice, and the photographs that we secured threw very definite light on some of the problems of this route. The pictures demonstrated unmistakably for instance the necessity for a greater number of intermediate landing fields along the southern stretches of the route, where the characteristic terracing of all unwooded land makes it virtually impossible for a pilot to locate a suitable field in which to land in case of need. Without this preliminary survey, it is improbable that we would have realized this need until actual operations were under way.

Although there is little opportunity for selection of an airway from a safety point of view, there is opportunity in the choice of Equipment, Personnel and Policies. Too much emphasis cannot be laid upon the importance of proper selection as applied to meeting the problems coming under these three heads.

The Equipment

The selection of equipment involves choice of aircraft based upon certain required characteristics, and their maintenance on the ground. The outstanding elements in the choosing of aircraft from a safety point of view are stability, sturdiness of construction, speed and cruising range.

The problems involved in blind flying present one of the greatest handicaps to safety in the operation of an airway, and it must be remembered that in night flying sometimes a pilot is caught by a sudden change in the weather and is compelled to fly blind although this was not his intention when he left the ground. For this reason, it is vital to select aircraft with good flying characteristics. Rather recently, it has become generally recognized that almost all pilots lose their sense of balance after flying blind for an extended period. It is obvious that a pilot who has lost his sense of balance while flying blind will be very greatly assisted in maintaining direction and proper flying attitude by means of his instruments, if his machine is inherently stable. At least one instance has come to my attention where the pilot regained control of the machine by actually releasing the controls until the machine assumed level flight.

Regardless of the steps taken to insure safety, it should be recognized that accidents will occur occasionally, particularly in the operation of a night mail line in territory frequented by low clouds and fog, under present operating conditions. Therefore careful consideration should be given to the protection of the pilot in case of crash.

In this connection we had occasion recently to see the importance of sturdiness in the construction of our aircraft. John Kytte, one of the pilots on the Southern division of our line, has twice flown into a mountain side, owing to abnormal weather conditions. In both cases his speed was in excess of 100 miles per hour when he hit the mountain, since in neither case did he have any warning that he was going to hit. His escape with minor

injuries in both cases can be explained only by good luck plus a pilots' cockpit capable of withstanding tremendous shocks.

Of course, good flying equipment without provision for its maintenance when not in the air would be a one-sided proposition. Consequently, we attach very great importance to the equipment which we maintain at our stations for the over-haul of aircraft, engines, instruments and parachutes. In the interests of safety and reliability an airplane operating on a regular air line requires a thorough inspection every day or after each complete trip. Movement of ships must, therefore, be so arranged that they will be at points where provision and equipment exist for such inspection at stated intervals.

Under the general heading of equipment I also desire to stress the importance of ground communication. For a successful and safe operation, it is imperative that before taking off the pilot be fully informed of weather conditions prevailing along the route over which he is to fly as well as conditions at his destination and even beyond. Because of the rapidity with which the weather changes it is also important that he be constantly informed by wireless during flight of any changes which may occur.

Our safety and reliability are seriously handicapped at the present time because there can be no direct communication between the pilot and the ground personnel, and it is earnestly hoped that the experiments now being conducted along these lines by the Department of Commerce will shortly be sufficiently perfected to be of practical value.

Speed also has its bearing on safety, for the faster a machine flies the less it is affected by adverse winds which results in less flying at nearly full throttle, and this reduces probable engine failure. Also bad weather areas between stations are crossed more quickly, which is particularly important on a line like ours where the weather changes so rapidly that frequently when the pilot arrives at his next destination the weather is very different from what it was when he left the ground. Cruising range is also of great importance because when caught blind, a long cruising range will give opportunity to fly around until a hole is found in the weather before running out of gas.

The Personnel

Another opportunity for selection is personnel. Of probably more importance than the selection of equipment, the selection of personnel can spell success or failure. Setting aside at this time the undoubted and obvious need for a progressive executive staff, the selection of the operations personnel is of vital importance. Every one knows that only pilots of proved experience are eligible for carrying the U. S. mail, or passengers. But I want to emphasize the importance of something more than experience among flying personnel. I have in mind that somewhat intangible yet very apparent factor in life called "character." Certainly in the flying business, character, sharp wit, and resourcefulness play a leading role. A pilot may have a vast knowledge of technical flying but lack that force of character which pulls him through some gruelling experience. Also a pilot's decision whether or not to go through, should not be influenced by what he thinks the other pilots will think if he does not get through. This quality almost always is lacking in young pilots, but it is always to be fostered, and only a man of strong character can attain it.

Perhaps a recent experience of one of our men will illustrate my point of the value of sharp wit. It was a dark but clear night when Ambrose Banks was flying on his regular schedule south from Hadley Field at an altitude of about 2,000 feet. He was directly on the airway and had nothing to do but keep a normal watch as he flew serenely along his course. Suddenly ahead of him what appeared to be an enormous gray monster loomed up of such

proportions and shape as to completely baffle his senses as to what the nature of this obstacle might be. His reaction, however, lagged not for an instant as he quickly pulled the stick far back and zoomed high over this nebulous mass which passed out of sight as quickly as it had come.

Being genuinely baffled and wishing to prove to himself that he was not not merely the victim of a hallucination, and that this obstacle was something more than a mere cloud bank, the pilot circled back, carefully retracing his path. A few moments later the powerful headlights of his plane revealed in the darkness the enormous bulk of the U. S. Airship Los Angeles. Quick wit saved what might have been a disaster.

Nor is this phase of the personnel problem confined solely to pilots. The choice of the ground personnel is equally important in its relation to the entire problem. Again, experience is of necessity a prime requisite, but a deep sense of confidence must be created and maintained between those responsible for the flying and those having to handle the maintenance and overhaul of the ships. Furthermore, the public usually comes in closer contact with the ground staff and a high grade of personnel will aid materially in instilling confidence in the organization on the part of the public.

Policies Another Field

And now I want to refer briefly to the matter of policies, which is a most fruitful field for selection, and one in which there is ample room for success or failure.

The only basis upon which an air transport organization can be built is one of service. Service must, therefore, be the basic policy to be followed and all activities of the organization must be brought into harmony with this fundamental. Without the unqualified determination to provide a service in every sense of the word, the air transport organization is courting failure.

However, no organization can live entirely by itself. Far less, an air transport organization at this stage. The cooperation of other organizations, governmental, civic and commercial, is essential and must be sought, and when secured, cherished, for it is a much prized possession. No air transport operator can build up a sound air transport business without help direct or indirect from the Department of Commerce, the Post Office Department and local post offices and civic groups. This help and cooperation must be earned by sincere effort and thoughtful consideration of all concerned in the interests of air commerce.

In conclusion, let me sum up two basic points that I want to leave with you in connection with this subject. One is that since the selection of an airway is based almost entirely upon the demand—the problem of the operator is to get all the facts that will work against the safety of that particular route and then find ways and means of overcoming those factors.

The second point is the effect of weather upon the safe operation of regular flying along the eastern seaboard where our route lies. Weather is by far the most severe obstacle we have to overcome from the standpoint of safety, as well as of service.

Part of the solution to this problem lies in constant communication with the pilot by means of wireless, so that he may be supplied at all times with accurate information as to the changing conditions of the weather along his route and at his destination. The equipment and personnel required for this purpose calls for resources greater perhaps than any operator can afford to undertake. The most he can do is to cooperate in every way possible with other agencies that are working towards a solution to this problem.

Without governmental aids that have already been installed, it would be impossible to run a night air line here in the east with any degree of safety or reliability. But there is still much to be done, and it is most gratifying to know that the method of attacking this problem by the government is one that should in time remove most of the hazards that now confront our pilots on every trip they take at night. For no matter how perfect the weather at the take off, the pilot is always likely to encounter fog, low clouds or storm before he reaches his destination—at least on our route.

In addition to the Government's effort to solve this problem, I understand that the Guggenheim Fund for the Promotion of Aeronautics has attacked this problem in a very serious manner. Recently while on the Pacific Coast, I was impressed by two things; one that except for definitely confined areas of ground fog around San Francisco, and a few other spots, flying weather is almost ideal the greater part of the time between San Francisco and Los Angeles.

The other thing that impressed me was that in spite of these conditions the Guggenheim Fund had effected a weather reporting system which must be of great value to the operators of scheduled air routes up and down the Pacific Coast.

I also understand that the Guggenheim Fund is going to undertake a serious study of the problem of blind flying. Therefore, in view of the work they are doing, I hope it will not be out of place for me to make a plea that their energies and attention be directed to the problem of flying in the east, where conditions to my knowledge, are, taken the year round, worse than any other part of the United States. I am convinced that the regularity of our service will always be disappointing to us until the pilot can, with a reasonable degree of safety, take off with the deliberate intention of flying blind most of the way and then land blind if the necessity arises. I believe our line is confronted with greater difficulties in relation to blind flying than any other in the country, and therefore it is my earnest hope that the Guggenheim Fund will attack the problem on our line where the solution is sorely needed.

CHAIRMAN DURAND: The author of the paper referred, among other things, to the lack of dependence which can be placed on those instruments which have been developed in the inside of our heads during an evolutionary period, which goes back, I suppose, to the old "Flying Lizzard." We have various things that tell us when we are right side up and when we are not. But it appears that when we ourselves are subjected to accelerating movement, these indications become wholly unreliable.

Of course, I am not telling you anything new. The fact has been known for some little time. But it is important in connection with blind flying, and perhaps has only recently come to be fully realized.

I want to illustrate this with a little incident which came to my attention a short time ago, in connection with one of the pilots on the Pacific Coast. He ran into some fog or thick flying, and after going on a bit, he realized from the behavior of his instruments that he was in a spin. He knew that he was in a spin, and yet he, as far as the indications or feelings in his head were concerned, felt he was all right.

He knew by looking at the instruments on his board what he ought to do in order to get out of that spin. They gave him some indication. He had a demonstration in an ocular way that he was in a spin. And he knew what he ought to do, but he simply couldn't overcome the inhibition, and he kept on until finally he came out below the clouds, was able to see the ground, get some idea of really what he was doing, and found the earth spinning around under him. Then he

was able to overcome this inhibition and do the correct things, and he was fortunately at a sufficient altitude so he got out of his trouble and things were all right.

That illustrates the significance of this particular condition which renders the instrument we have inside our heads wholly unreliable under conditions of that sort, and impresses upon us the importance of learning to depend on instrumental indications.

Now, gentlemen, this paper is open for discussion. It is a most important and interesting one. Who will ask a question or make some comment that may be of interest?

H. W. HENDRICKS (Travelers Insurance Co., Hartford, Conn.): I was very much interested in the speaker's reference to the necessity for an inspection and perhaps of an overhaul of (I assume) the engine and the craft after a flight. I would naturally assume that the reference to overhaul was not the dismantling of the engine after the flight.

I would like to have the speaker, if he will, indicate to what extent, or rather how complete, perhaps, the inspection should be, or the overhaul, after each flight.

Second, in regard to the complete overhaul, is it the thought of the operators and the owners of the aircraft at the present time that flying a certain number of hours constitutes a limit or period at the end of which a complete overhaul should be made in the interests of safe navigation?

CHAIRMAN DURAND: We might have all the questions and the discussion, and have these various matters answered at the end.

Are there any other questions or comments?

Major Blee, you have had a lot of experience in connection with airports. Can't you ask some question of the author of this paper?

H. H. BLEE (Senior Business Specialist, Aeronautics Division, Department of Commerce, Washington, D. C.): I think the author has gone into that subject very thoroughly and has made it very clear. I know the points he has brought out have been those that have impressed me as being very vital from the standpoint of successful operation of scheduled service over the airlines.

This is a paper to which anyone may profitably refer who may be contemplating entering that field of activity.

LT. DONALD DUKE (U. S. Army, Boston Airport, East Boston, Mass.): There were two pilots killed on the Southern Air Mail Route near Richmond, Va. I wonder if that was attributed to some certain thing, and what would make it safer? This is not a criticism but I would like to bring out any action that was taken to prevent that.

CHAIRMAN DURAND: You might answer those questions now.

W. L. LE PAGE: The gentleman mentioned Mr. Pitcairn's reference to the necessity for overhauling ships and engines at regular periods during operation.

The extent to which an airship—I am speaking, of course, of our own operations entirely—or engine is overhauled after a scheduled flight depends entirely upon the report which the pilot makes at the conclusion of the flight, as to whether or not he feels the ship and engine are in good operating order.

However, the New York-Atlanta line is divided for the purposes of maintenance, into two sections at Richmond. And no airplane flies out of Richmond either north or south without a general, complete overhaul, and by overhaul I mean inspection.

If that airplane as a result of that inspection, or if its engine as a result of that inspection, or as a result of the report of the pilot, is found to be not in the best condition, there are other planes maintained at Richmond for replacing the defective ship. And the schedule and the position of each ship during the operation of the line each night is such that at no time would it be impossible to find a reserve ship convenient to replace a defective one.

The question of the number of hours that we permit an airplane or its engine to fly before a complete overhaul, including dismantling, is a subject on which we feel there is not enough definite information at this time to permit us to run the risk of laying down any definite ruling. We feel that rules, unless they are established because of an unqualified realization of what they mean and their necessity, can be snags in an operation.

At present we are going on the principle of providing more complete overhauls than we believe to be necessary, in order that we can build up an experience which will at a later time permit us to economize, we will say, in overhauls on a definite and certain basis.

Does that answer your question?

MR. HENDRICKS: Yes, it does answer it perhaps as well as it can be answered. I would like, however, if it were possible, to get some general idea as to whether you still think perhaps an overestimate or maximum 500 hours is a proper thing to follow until you have obtained that experience. Perhaps it is impossible to say. I think it, however, has been mentioned, and I was very much interested in some sort of maximum.

MR. LE PAGE: The time that any airline operator, the period that he stipulates between the overhauls of his equipment, particularly his engine, varies with each different operation. What may be all right for our line may be entirely too much or too little for a line operating in the West Coast.

I should say that in our own experience we have found that we have been compelled to overhaul an engine long before it really needed overhauling, because of some major breakage which occurred, either in flight or during testing, and which necessitated the complete dismantling of the engine. That applies only to engines. Airplanes don't suffer from anything like the small ills that aircraft engines do.

In reply to Lt. Duke's question on the fatalities which occurred unfortunately on our line, in May, I can say at this time, in brief, that we learned considerable from those experiences and were able to incorporate definite changes in operating policy and in operating arrangement as a result of lessons learned.

The unfortunate death of Pilot Maurice, who was the first to go, was undoubtedly the result of just what Dr. Durand was talking about after I finished reading Mr. Pitcairn's paper, namely that the pilot lost all sense of what he was doing, of his altitude in flight, and in his endeavor to correct what he thought was an incorrect altitude, each time he overcorrected, and he unfortunately had not got sufficient altitude to right himself and regain mental equilibrium as opposed to the equilibrium of the ship before the ship hit the ground, and he dived into the ground at a very steep angle at top speed. He had only taken off a few minutes before and was still at a low altitude.

We are not in such a fortunate position I would say in regard to the reasons for the accident which resulted in the loss of Pilot Reeve, who apparently attempted to make a perfectly normal, forced landing without visibility. He, too, was flying in dense fog and was the victim of unfortunate circumstances in that his ship ran over the edge of an embankment.

However, both of those accidents brought to our realization very definitely that with the present aids to navigation which exist on our line—and we have as many and as efficient aids as all of the other regular Department of Commerce Airways of the country—that those aids were not yet such that we could fly under all conditions. Our pilot personnel was keyed up to a keen sense of duty, that their job was to deliver the mail.

As a result of those two accidents, we definitely put into force a policy of safety first, and since that time we have trained the air mail, as a result of conditions which our operating personnel realized might very well result in a repetition of the Maurice and Reeve catastrophes.

But as a result of putting this policy into effect, our pilots have been able to fly with a keener and surer sense of safety and of performance of duty, with the result that since that moment when the new policy of operating went into effect, we have been maintaining a higher percentage of completed trips on a progressive basis.

CHAIRMAN DURAND: Is there any further discussion on this paper?

Our second paper is entitled, "Marking of Airways," and will be delivered by Mr. Woody Hockaday, Aeronautics Division, Department of Commerce, Washington, D. C.

MR. HOCKADAY: Mr. Chairman, Ladies and Gentlemen: Before I read the paper I have prepared, I would like to say that my paper as printed by the Fund mentioned the fact that I was with the Department of Commerce. I wish to state that, while I am not directly connected with the Department, I am working in connection with the Department of Commerce and the Army and Navy in trying to bring about a uniform system of air marking.

And I would further state that in this paper, the credit is more due to the committee than to myself personally.

I would also like to take this occasion to compliment Mr. Harry Guggenheim on bringing about this National Convention on Safety in Aviation, which will mean the saving of many thousands of lives in the future years to come.

Marking of the Airway

By WOODY HOCKADAY

Aeronautics Division, Department of Commerce, Washington, D. C.

The subject of air marking divides into two rather distinct parts: first, the methods employed in marking the regularly constituted federal airways designated, equipped and maintained by the government through the Department of Commerce; second, all other airmarking of cities, towns, villages and airports whether on or off the constituted airways apart from the federal markings at airway intermediate fields and beacon sites, a vast field and a factor of tremendous importance to the safety of air navigation. As the marking of airports is being covered in another paper to be presented before this Congress, it is not proposed to treat of this phase of air marking in this paper.

The federal airways which link up terminal municipal airports with a chain of lighted intermediate landing fields approximately every thirty miles and beacon lights every ten miles, have been marked according to a standard practice determined by the Department of Commerce.

Beacon sites and intermediate fields are numbered on the basis of mileage starting from either the south or west terminals and working north or east, as the case may be. With beacons approximately ten miles apart, it is readily possible for a pilot to ascertain his distance from a southern or western terminal by adding a zero to the beacon number; thus beacon number twelve is approximately one hundred and twenty miles from the starting point.

Routes are designated by using the first letters of the names of the terminal cities, with the south or west designation preceding. In this manner A-N Y refers to the Atlanta-New York Airway.

At each beacon site is found a fifty-six foot chrome yellow concrete arrow with the power house for the beacon equipment forming the feather end. The beacon straddles the center part of the arrow which points along the course to the next northerly or easterly beacon. Located on the two sides of the pitched roof is found the route and site designation, on the left the route and on the right the site.

For example, there would be found A-N Y on one side and the figure sixteen on the other, which informs the pilot he is located at site number sixteen on the New York-Atlanta Airway, one hundred and sixty miles north of Atlanta. Both the arrow and roof of the power house are floodlighted for night visibility. In cases where commercial power is available and power houses are not erected at the site in question, the site designations appear on the feather end of the arrow.

The second field of air markings embraces all markings established by private individuals, corporations, civic organizations and others. These agencies have marked some three thousand cities and towns throughout the country with various types of markings, a splendid work but somewhat offset because of the lack of a universal system.

Interest in air marking was brought to a head last spring when the Wichita Chamber of Commerce sponsored an air marking conference awarding suitable prizes for the best designs submitted. Several thousand markings were received and interest in the contest far exceeded the most optimistic predictions.

After the conference it was felt that before definite standards were recommended for national use, the designs be carefully studied and that the most effective be erected and observed under varying service conditions.

It was at this juncture that the Hon. William P. MacCracken, Assistant Secretary of Commerce for Aeronautics, stepped into the breach and made the suggestion that a committee be formed in Washington and charged with the duty of working out a system of air markings, later to publish literature and specifications that, it was hoped, would result in the adoption of their recommendations.

This committee is made up of representatives of the Army Air Corps, the Bureau of Aeronautics of the Navy, the Department of Commerce and myself, as a representative of the original National Airway Marking Association of Wichita.

At the initial meeting of the committee a decision was reached as to the information that air markings should convey. The pilot should be able to ascertain the name of the town, the direction and distance to the nearest airport, the type of airport together with the facilities provided, and true north.

It is also conceivable that it may be found desirable to give information as to distances and directions to other cities. It will be valuable to so mark farm buildings that a pilot who may have become lost can readily orient himself through the medium of some farmer's barn that will give him the distance and direction to a nearby city or town.

The designation of a small town is not as difficult a matter as is the marking of a large city. However, the need for marking the small town seems to be as great, in that they are hard to recognize, whereas a large city is much easier to identify. The smaller town in most cases, provides only a few surfaces that lend themselves readily to air marking and the approaching pilot quickly picks out the outstanding structures and will alter his course to fly over them.

In the case of larger towns and cities such a procedure cannot be followed owing to the number of roofs that are adaptable for use. It has been thought that, owing to the fact that flyers in a majority of instances, follow railroads, markings should be placed along the various railroads leading into town and in the outskirts of the town itself. There are many surfaces in such districts, such as warehouses, factories, elevators and other structures that lend themselves readily to air markings. By adopting such a universal system, pilots and the flying public would know exactly where to go to look for these signs. Such a system would not, of course, preclude the markings of buildings within the city, but such other markings would become a very valuable adjunct.

Numerous studies have established the fact, that chrome yellow, white and dead black are the best colors to be employed in the actual painting of air markings. The white and chrome yellow reflect the light and the dead black provides an

excellent contrasting background. These colors have been decided upon only after experimentation by the Army, Navy, Department of Commerce, and private agencies, and are so well substantiated as the most efficient that we may consider them as definitely approved.

There has been brought up, in reference to the studies being made of air marking, the extent that advertising signs will interfere with regular guidance indicators. It has been felt that industry will quickly take up this new means of putting their products and organizations before the public. In order to counteract any confusion that might arise, it has been deemed advisable to install some sort of insignia that will identify markings as official. Such an emblem, if distinctive, would quickly segregate official markings and advertising matter, and might do much to influence advertisers to incorporate in the markings, information that would be of value to the flying public. If such a course should be followed, an organization properly authorized could pass on all markings and award official emblems to those meeting requirements. The emblem is then installed on the roof and the marking effected is obviously official and true information is guaranteed the flying public.

As to the actual physical make-up of the markings, it is felt that the name of the town or city is of primary importance. Such a marking should be of sufficient size as to be visible from an altitude of between two to five thousand feet under good visibility conditions. Naturally, fog or ground haze will not allow the same degree of legibility, and thus it will be well to make requirements rather severe.

The second most important requisite for an adequate air marker is the direction, distance and type of the nearest airport. A tentative system which has been tested satisfactorily by the Committee in Washington is to erect an arrow pointing in the direction of the airport with the mileage thereto in front of the arrow. At the feather end of the arrow the type of airport available is carried. It has been thought that the Department of Commerce ratings could be incorporated in this marking. Thus, an A 1 A preceding an arrow with the Arabic figure three succeeding would identify the airport in question as an A 1 A rated airport situated three miles from the markings in the direction the arrow points. Suitable symbols could be used to designate Army, Navy, Department of Commerce and Auxiliary fields and unrated airports.

The meridian or north marker should consist of an arrow, broken approximately one-third of the distance from the head by the letter "N." This arrow should have an unusually long shank in order that there should be no confusion between it and the arrow designating the direction to the airport.

There has now been covered the factors which should be incorporated into an adequate air marking. Any additional markings such as distances to neighboring cities or points of interest will naturally vary greatly according to the information that is to be conveyed. However, a rule that if followed in all markings will lead to success, is particularly applicable to these cases. That rule is to, as simply as possible, convey the minimum amount of information necessary in a manner that leaves no doubt as to the meaning. For example, a rural marking endeavoring to show the direction and distance to Pittsburgh, should carry an arrow preceded by the distance with the words either below or above the arrow, "To Pittsburgh."

Any airmarking will become doubly effective if illumination is provided. There are two general methods for lighting such signs, namely by a system of floodlights and reflectors or by outlining the legends with lamps. There are a few isolated instances of night lighting of air markings in the country and lighting engineers are now at work to determine methods and intensities of illumination required to satisfactorily illuminate markings.

The Air Marking Committee is planning to use various lighting systems in conjunction with its markings in Washington and will fly over them and observe them under varying service conditions. Several lighting engineers are working

with the Committee in this problem and it is expected that some definite information and recommendations will be forthcoming when the experimentation is completed.

In order that the committee's findings will be followed, it will be found advisable that aviation organizations appeal to the nation to provide air markings. Undoubtedly the Department of Commerce will write specifications and distribute them as far as possible. It will be impossible, however, for the Department of Commerce to wage as an intensive campaign as could an organization of private individuals functioning without profit where the expenses are met through public subscriptions. Such organizations could prevail upon civil organizations, corporations, private individuals, organizations, and others to mark their various holdings throughout the country. Specifications could be circulated giving definite tables and figures regarding size and spacing of letters, symbols and legends that have been approved, color charts, approved methods of illumination and other factors that would serve to make the actual work of air marking merely a matter of following simple and comprehensive directions.

Large corporations such as railroads, oil companies, mercantile concerns and the like that have warehouses and holdings scattered throughout the nation, might become interested in marking on a national scope. In any event, proper organization and dissemination of air marking propaganda will do much to interest the public in this most important aeronautical development.

With the increase of air travel and the fact that specialized air navigation maps are available for only an exceedingly small portion of the country, it is readily seen that an adequately air marked nation will greatly enhance the value of the airplane as a dependable means of transportation. If adequate airmarking is effected, delays due to becoming lost will be minimized, the circling of towns in search of an airport will become a thing of the past, as will the low flying over railroad stations to ascertain the name of the town.

It is sincerely hoped that a universal system will be adopted in the near future that will do much to make air marking the simple proposition that it should become.

The members of the Committee in Washington are sparing neither time nor effort to bring to a speedy and satisfactory conclusion the studies now being made and would appreciate any constructive criticisms that may be forthcoming from any interested parties.

In closing it is my sincere opinion that the subject of air marking is of prime importance and that ultimately it will take its place as one of the most potent factors in the bringing about of increased safety in air transportation.

CHAIRMAN DURAND: You have heard the paper. Are there any questions or comments? It is an interesting and significant subject.

It seems to me of the greatest importance naturally that a pilot flying along should wish to know just where he is, how long it is to the next point he is likely to meet. The more complete information that can be conveyed to the pilot, the more comfortable he will be, and all these conditions, of course, will be conducive to safety, regularity, reliability, and efficiency of operation. This is simply one of the agencies of conveying information to him.

We are hearing in other sections, of course, with regard to the methods by radio, conveying information to the pilot while flying. But there are various things which can just as well be conveyed by visual means, at least under ordinary conditions, and the author of this paper has discussed these admirably and it seems to be a very complete way.

Some of you, however, must have some comment or question which will serve to bring out some of the points.

MR. LE PAGE: I wonder whether Mr. Hockaday has any opinion to express on the advantages of indirect illumination of markers, or what I might call direct

illumination, namely the actual lighting of the marker by, as you mentioned, the outlining with vacuum tubes or electric bulbs?

In that connection, it occurs to me that at times, when I have looked down, while flying at night, at an illuminated sign, a letter like for instance the letter "N," which would come in your meridian hour, might appear, if it were actually illuminated with electric lights, as though it were a square block of light, whereas if it were a painted letter, illuminated by reflected light to form a beam, the sign would be visible and distinct to a pilot at perhaps a far greater distance or under far more adverse conditions.

That is a question I would like to ask.

Regarding the comment which Mr. Durand, our chairman, made just now, expressing the necessity for visual markers, in spite of our interest and experimental work in the development of radio markers, my own feeling is that that point is extremely important, since we have to look into the future to more than the operating of regular transport lines and to the flight-by-night of air taxis. I mean that there will be, I feel, a great demand for air commerce on special charter, and those ships may not always be equipped with radio. It is perhaps presuming too much to suppose that every airplane that is in the future going to fly at night or in bad weather is going to be equipped with radio, unless it is one of the fleet operating upon regular schedule.

MR. HOCKADAY: The first question you asked—about the lighting—that is something that our committee in Washington hasn't tried out. That is, we haven't tried out the lighting of these markers. We have been trying out the painted system, painting them.

In this connection, the committee is going to do a lot of night flying under various conditions, and we are going to outline, just as I say, or we are going to floodlight some of them and some of them we will outline the legend. For instance, the ends will be outlined with lamps, and then we will floodlight the others. Then we will go up a mile and make a record, starting up say 6,000 feet or such a matter, and coming down. We will make a record of the different altitudes as to what we can make out.

The different members of the committee will do this, and also the Army and Navy flyers. The flyers in the Navy are instructed to make reports on these markings and how they show up, and make records of them at the different altitudes.

There are a lot of different phases to air marking, and it is just something that takes time. We would be glad to have any criticism or any ideas from anyone else, so that we can try them out. In fact, this original contest we had brought out a lot of various ideas, and the committee has studied those various ideas. Some of them were good and some of them weren't any good.

As far as the lighting is concerned, we will soon have that pretty well tested out.

However, we want to keep closely in touch with those interested in the beacon proposition so they will be able to help us and we will be able to help them. We haven't tried out all the experiments in connection with the marking that we expect to in the future.

The committee expects to get out specifications and tell of our findings. Those will possibly be mailed out to the pilots all over the country and to the various aviation magazines and through the press so that the public may have a chance to criticize or approve these different systems.

It is very necessary that that be done, as we will eliminate a lot of trouble they have in highway marking or had years ago, by figuring out a practical system, because if every town was marked with a different kind of system, it would cause the Chamber of Commerce men and the public to spend millions of dollars on

unnecessary marking that instead of being a help would be a hindrance to the flyer.

When the flyer is in the air and gets lost and doesn't know where he is, he can't stop and ask somebody how to go, as he could in an automobile.

LAYMAN ANDREWS (Portland Cement Association, New York City): I would like to ask what dimensions you have in mind for these markers. About how long and how wide should they be?

MR. HOCKADAY: The minimum size we have at Washington is about 30 inches. It is 30 inches wide and about 30 feet long. That is, with the end about two-thirds from the end of the arrow. The arrow we are trying out is a slim shaft; that is, it has a small head and a long shaft without any large feather end at all, just a straight bar with small head to it, and back here a little ways from the head is a great, large end that extends out on each side of this bar so you won't mistake it for any other kind of marker.

After a pilot gets accustomed to that, he will know instantly without scrutinizing the marker that it is a north signal; and we are always trying out various emblems to work in connection with the arrow, so that an aviator from long distance will know it is an airplane sign, and will know where the arrow is situated from the emblem, the direction of the airport. So if he should run short of gasoline or anything should go wrong with his plane, he can almost instantly look out without scrutinizing various signs, and pick out the airplane sign and find his way to a landing.

CHAIRMAN DURAND: Are there any further questions?

If there is nothing further on this paper we will pass to the third and last paper of the afternoon's session, which is a paper on a most interesting subject, "Operation of Aerodrome from Point of View of Safety."

If there is any one place where experience should have been gathered in connection with this subject, it is in Croydon, England. This paper has been prepared by Major L. F. Richard, Croydon Aerodrome, London, England. We are all very sorry that Major Richard is not here. It was too much, perhaps, to expect him to come across to present this paper, but I am sure we would all like to see him and talk to him and have a chance to ask him some questions.

In the absence of Major Richard, Lieutenant Donald Duke has been kind enough to offer to present his paper for him.

Operation of Aerodrome from Safety Point of View

By MAJOR L. F. RICHARD

Croydon Aerodrome, London, England

I consider that it is essential for the control of flying operations to be vested in thoroughly qualified officers, one of whom is on duty during all flying hours, and who is also available immediately at night, even if no flying is anticipated. These officers should be experienced pilots, preferably with experience of air line work, and also qualified aerial navigators. This point is particularly stressed in the interest of safety, as it is felt that only such a man is competent to control aircraft on the ground and direct and assist aircraft while in flight.

I believe that the system of control used at Croydon is more complete than at any other aerodrome, so I propose to describe it in detail.

This control is carried out from a Control Room, 30 feet square and about 50 feet above the ground. In it, while any flying is in progress, are the Duty Officer and two wireless operators, who communicate by Radio Telephony

on 900 meters with machines in flight. A look-out is stationed on the balcony outside.

The Duty Officer is in close touch with the following other services, which are essential to his efficient working:—

Meteorological Office

This office is situated immediately below the Control Room. Weather reports are received hourly from stations on the various routes. These reports are despatched immediately on receipt by pneumatic tube to the Control Room for the information of the Duty Officer and for transmission, as necessary, to the pilots of aircraft in flight. In addition to these reports, special intermediate reports are received when sudden changes in the conditions, which are likely to affect aircraft, occur at any station. These reports are passed without delay to any aircraft likely to be affected. Weather forecasts are also available, and advice as to existing and probable weather conditions along the air routes is given personally to pilots by the Meteorologist i/c. Pilots are encouraged to make the fullest possible use of the Meteorological Office.

Route Traffic Wireless Room

In this room all messages to and from other ground stations are transmitted and received by Radio Telegraphy on 1,400 meters.

Communications Office

In this office all messages intended for transmission to other ground stations are coded and despatched to the Route Traffic Wireless Room by means of pneumatic tube for transmission. Incoming messages are de-coded and passed to the Control Room, also by pneumatic tube.

It is very important that all messages regarding the movements of aircraft be notified to the Duty Officer as early as possible. Cases have occurred when only five minutes have elapsed between the transmission of a message from a Station on the Continent and its actual reception in the Control Room.

Control of Aircraft Departure

When an aircraft is observed by the look-out to be ready to depart from the arrival and departure paved area, he reports the fact to the Duty Officer and if the latter agrees, a disc is displayed on which are the initials of the company concerned. This gives the aircraft permission to taxi out on to the Aerodrome preparatory to taking off. When the look-out observes that the machine is turning into wind preparatory to taking off he reports again to the Duty Officer, and if the latter considers that it is safe for the aircraft to take off a small searchlight is directed on the machine. If this signal is withheld the aircraft must not leave. It has been found at Croydon that an orange screen used with this light gives the best general effect under all conditions of weather.

The Duty Officer must at all times know the position of all aircraft on the various routes from Croydon. These positions are plotted on a special steel map and small magnetic symbols, about an inch long, are used to represent a machine. There is a symbol with the registration markings painted on it for every aircraft which is known ever to fly on the routes. Different colored symbols are used for the various operating companies. The positions are plotted at short intervals by the Duty Officer, using his knowledge of the

cruising speed of the various machines and the force and direction of the wind. This plotting is, of course, checked up by positions given by pilots from their machines by wireless, and by those taken by direction finding apparatus.

During bad weather conditions accurate plotting is very necessary. The Duty Officer will inform pilots of their proximity to other machines and, if necessary, direct them to fly at different heights. He will also give advice, when asked, as to the best direction from which to approach the aerodrome. The Duty Officer should never, except under most exceptional circumstances, direct a machine to land. This question must be left to the pilot's discretion.

To assist pilots in locating the aerodrome in misty weather, the Duty Officer will direct the firing of pyrotechnics. Various types of pyrotechnics have been tried out at Croydon, but it is considered that the best type is one which will give an intense light from the moment of leaving the ground and should go to a height of approximately 1,000 feet, when it should be entirely consumed in order that no residue may fall on the Aerodrome.

When aircraft are approaching the aerodrome in misty weather, the Duty Officer goes out on to the balcony with a Wireless Operator, who can plug in his head set at various points; if the aircraft is observed, the pilot will be told in which direction to fly to reach the aerodrome.

Forced Landing in the English Channel

If a pilot of an aircraft considers that there is any chance of his having to descend in the Channel, he will immediately give the distress call "MAYDAY," when all stations working on 900 meters stop working so that Croydon, in conjunction with another W/T station, can get the position of the aircraft by direction finding apparatus.

A third W/T station near the coast endeavors to get any message which the pilot may send. Immediately a distress call is received by Croydon, the Duty Officer, who has special facilities, telephones to the appropriate coastal wireless station. If the machine has to land in the water this station is instructed to issue immediately the S. O. S. broadcast to all shipping. A tug is always available with steam up at Dover, and can be sent immediately out to the aircraft. The French authorities also have similar arrangements.

Calm Signal

When it is calm (the wind less than 2 m.p.h.) a calm signal consisting of a white disc is displayed on the ground. It is considered that this method to indicate calm is preferable to that of hoisting a ball on a tower, as this is difficult to see from the air unless the machine is very low. When this signal is displayed all machines must land and take off approximately on a certain bearing.

Regulations

The Air Navigation Regulations and local regulations are all framed from the safety point of view. These must be carefully enforced, and any infringement should be immediately reported to the Officer i/c of the Aerodrome. For instance, both in the interests of safety and of the comfort of passengers, climbing turns straight from the ground are definitely prohibited.

The regulations to the effect that all aircraft must make at least one circuit of the aerodrome before landing is a good one and I understand is in force at many other aerodromes.

A very rigid regulation is the one which requires all aircraft when turning in the vicinity of the aerodrome to do so in a left handed direction.

Aerodrome Lighting

At Croydon a Neon lighthouse has been erected, this consists of sixteen 20-foot Neon tubes placed nearly vertically in the form of a square. This light is operated by a switch in the Control Room by relay mechanism. The normal range is about 40 miles.

Surface Lighting

It is considered very advisable that the surface of the aerodrome should be thoroughly illuminated at night.

A special form of floodlight, projecting a flat beam over an arc of 180 degrees, is used at Croydon. It is mounted on a special chassis having caterpillar driving tracks, and, accordingly, can be moved easily to any part of the aerodrome however bad the surface may be. It can also be used as a second location light, as it can be pointed up to an angle of 45 degrees and then rotated by means of a small electric motor. In conditions of poor visibility some pilots have stated that this light can be picked up sooner than the Neon light. Its operations are directed from the Control Room by visual signalling with a powerful lamp.

Obstruction Lights

All buildings and other obstructions on the aerodrome must be clearly defined by means of obstruction lights. These are also controlled directly, in the case of Croydon, from the Control Room.

Boundary Lights

The outline of the safe landing area must be indicated by some form of lights. This is done most effectively at Berlin Aerodrome by means of a very large number of Neon tubes.

Indication of Wind Direction at Night

The direction of the wind must be clearly indicated.

The simplest method is by a revolving illuminated T or arrow. Care should be exercised in locating it so as to obtain a fair reading of the direction of wind on the actual landing area.

It should be frequently examined to ascertain whether it is rotating freely.

At present the Duty Officer at Croydon by means of a simple revolving switch, can put in operation a series of electric lights sunk in the landing area. These appear in the form of two L's back to back. The switch is so operated that the long arm of the L indicates the wind direction and the short arm the end of the run of the machine. If a change in direction of wind occurs, the switch is immediately moved accordingly. This is, of course, a preferable method to having to move flares by hand.

Fire

A fully equipped fire tender should be available immediately in case of fire. As much "Fire Snow" should be carried as possible on this vehicle.

Many cases of fire in aircraft on the ground have been extinguished, but

this has only been possible on account of immediate action being taken before the flames could spread. If a machine once gets thoroughly on fire I do not know of any method which is of the slightest avail.

A complete system of water hydrants should be installed round all buildings and personnel should be instructed carefully in fire drill. A large number of chemical fire extinguishers should be available in the hangars.

A really powerful fire alarm signalling apparatus should be installed, and alarm points connected to it should be easily and quickly available.

Surface of Aerodrome

Any bad part of the surface should receive immediate attention and at least one man can be continuously employed on this work. This is particularly necessary round the arrival and departure area, where tail skids of heavy machines cut the ground very badly. These tracks, if left unattended, are a danger to light aircraft.

Compass Swinging

In order to encourage compass swinging an efficient compass swinging base should be available. Machines should be able to run on to it and be rotated with very little effort so that they can be placed quickly on the various compass points and not have to be manoeuvred laboriously by hand.

CHAIRMAN DURAND: As I said a moment ago, we are very sorry that Major Richard is not here so we may have a chance to ask questions of him. I am sure many of you will be in position to make some comment or give some suggestion out of your own experience in connection with some of these problems.

But before throwing the paper open for general discussion, I will read a short discussion which has been received in written form from Arthur Halsted, Associated Electrical Engineer of the Department of Commerce.

Discussion of "Operation of Airdrome from Safety Point of View"

By ARTHUR HALSTED

Associate Electrical Engineer, Department of Commerce, Washington, D. C.

Major Richard has succeeded remarkably in illuminating in brief scope the outstanding points in the operation of important airdromes from a safety point of view. Because of its bearing on airport custom in the United States it may be well to emphasize what has been referred to as the "calm signal."

It is a decided safety precaution for two or more airplanes, using the airport at about the same time, to land or take-off, all in the same direction. When the wind is blowing this direction is determined by the wind. When no wind is blowing the landing and take-off direction is not so determinate.

There is usually at any landing field, a most convenient and safe direction to land and take-off, all things but wind considered. It would be advantageous to demark this direction as the one to be used in calm. Some three years ago an authoritative committee gave this matter much study and has suggested that the "no wind landing direction" be included in the permanent surface marking at the field. A white circle is generally accepted as the marking for the center of the landing area. A small radial line outside of and near this circle could indicate the "no wind landing" and take-off direction. Accordingly when the

landing direction is not fixed by the wind; landings should be made toward the circle along the radial indicator. This direction is easily remembered if the circle is thought of as representing the front end and wings of an airplane and the radial indicator its fuselage and tail. At the present it is not uncommon to see airplanes landing or taking off in diverging or converging directions even at important airports.

The regulation to the effect that all aircraft must make at least one circuit of the airdrome before landing is mentioned. This rule has been given considerable study and there is not unanimity as to its value for universal application. There is some exposure to hazard involved in keeping an airplane in the air in the vicinity of an airport. If the landing and take-off direction is known, there is much to be said in favor of the airplane approaching the field for a landing without much turning from a considerable distance away. From a practical standpoint the minute or two often unnecessarily consumed in a circuit of the airport will be objectionable to air mail and other despatch commercial flying. It has been thought that possibly some other routine, equally effective from the safety standpoint, could be worked out, that would permit straight approach for a landing when this is possible with safety.

The subject of fire protection at airdromes is very important. The reference to a fire truck charged with "fire snow," that is interpreted to signify carbon dioxide snow, at Croydon, is very interesting. High hopes are entertained for carbon dioxide snow as a fire-extinguishing material. Its effectiveness is not diminished at the coldest weather temperatures, it is suitable for use in confined spaces since it does not generate large volumes of poisonous gases when thrown on a fire, its chilling action is calculated to stop the generation of inflammable vapors from the surfaces of volatile liquids such as gasoline, among other promising advantages. Its comparative value, however, as a material suitable for charging vehicular fire apparatus for airdromes with reference to other fire-extinguishing materials such as the foam materials, cannot be considered to be thoroughly determined as yet, especially if it is possible to protect the vehicle during standby periods from temperatures below 40°F.

LIEUT. DUKE: We have had some trouble in the military service with foamite extinguishers in cold weather. In Boston our foamite extinguishers froze up. They are liable to explode after they have been frozen. That is the only objection I know to foamite. It is very effective in extinguishing flames, especially gasoline fire. It is more effective than anything else we have found. The only disadvantage is the freezing of the extinguisher.

MR. HALSTED: I think the Bureau of Standards has performed a good many tests on fire extinguishers in connection with another activity of the Government, and it might be interesting here to tell you that foam materials have the disadvantage that they are affected by cold weather, when they are not quite down to freezing. That is, when it is even warmer than freezing. The material might be there, but the chemical reaction seems to be very greatly slowed up as the freezing point is reached. So your standby foam material would be very effective if it could be kept in a hangar that is somewhat warm. In that way, by warming in a hangar, you are protecting it from temperatures below, say, 40 degrees Fahrenheit.

CHAIRMAN DURAND: Are there any further comments? So far the comments have run to the matter of fire extinguishers. Can't we have something else?

Of course, we haven't anything in this country approximate to Croydon. We are making some small approach in various parts of the country toward passenger-carrying and toward the development of those conditions which the author of this paper writes about.

I don't know whether there is anyone here who has had personal experience of that sort. If there is, I wish he would rise and tell us something about it.

MR. LE PAGE: Is there anyone here from Buffalo Airport or from Oakland Airport?

CHAIRMAN DURAND: Not to my knowledge. I was looking about to see if by any chance I could see anyone from my own state of California, where we are, perhaps, doing as much of that kind of flying as anywhere at this time.

Major Blee, has your experience taken you into anything which is parallel to the matters discussed in that paper?

MAJOR H. H. BLEE (Department of Commerce, Washington): I can't help but be impressed with the very practical points that the author has brought out. All the points he mentioned have a very direct and material bearing upon the safety of operation of airports. If one attempted to go through and reiterate or stress the important points it would really necessitate a rereading of the paper. I can only say, "Amen," to what has been said already.

MR. LE PAGE: In thinking over, just during the past two or three minutes, the import of Major Richard's paper and what it indicates as the future trend in the operation of our major air terminals, it occurs to me that considerable thought will have to be given as to how we are to secure ordinary material necessary for safety in the operation of minor airports where any such equipment as Major Richard outlines in his paper as being in use at Croydon would be entirely out of the question.

Just how one is to secure a degree of safety in the regular daily arrivals and departures from an airport, which is not a major terminal, on an air route over which there is considerable traffic, just how we should acquire that necessary safety, is something which to my mind has not been touched upon as yet and which must undoubtedly be given consideration in the very immediate future.

Allowing one's thoughts to become somewhat imaginative, I recall that I recently read of experiments being made with an automatic form of traffic signal for our highways. By way of adding perhaps a little imaginative thought in a lighter vein in this discussion, it seems to me that there is just a vague possibility that some form of automatic signal operation which might come into effect in the operation, through perhaps the impulses of the ignition on an airplane engine or as a result of sound impulse set out in the air by the airplane propeller, or a number of other possibilities, that perhaps that is a future means of acquiring some form of orderliness in the operation of the many flying fields which are extremely busy and yet which do not have any such equipment as Major Richard has outlined as being in force at Croydon.

B. RUSSELL SHAW (B. Russell Shaw, Inc., St. Louis, Mo.): I would like to bring out the fact that in connection with these large airports and terminals, we are endeavoring to lay out now a system of traffic control by which planes can be given signals for landing and taking off, first in the indication to the incoming pilot by means of submerged lights at the end of the proper runways, and these interconnected with suitable stop and go signals, placed at the same ends of that particular runway referred to so that any plane taxiing for position for takeoff would automatically get the stop signal until the planes going in had landed, and their landing would indicate the flashing on of this indicator at the end of the runway.

As soon as that is cut off, the stop signal that has been holding up the pilot from taking off automatically turns to "Go," and he is able to clear.

Other planes in the air, not seeing any visual means of indicating the proper runway for them to land on, would remain in the air until that plane had cleared.

We have worked out a rather elaborate system which probably would not be installed except on the very largest and busiest air terminals.

DR. DUKE: On the general subject of airports, there are two points I want to bring up. One is, I think something should be done by the Federal Government

or by other agencies to prevent the naming of a landing field, an airport. In other words, a mere landing field should not be dignified by the title of airport.

I know of four or five cases now in the United States where there are dangerous landing fields, what I would call an emergency or intermediate landing field, and all those places have been called airports and classified extensively as airports. Yet there are hazards there which have not been removed and the people who promoted those airports were ignorant as to what an airport should be.

Another thing is that throughout the United States attempts have been made to establish good first-class airports, and there have arisen political actions to the extent that instead of having one good airport, properly located, properly organized, where they could control air traffic and control the maintenance and inspection of aircraft under overhead, they have through their difference of opinion established three or four small landing fields, none of which is suitable or safe.

In my opinion, an airport can only be rated in one way. It is either a safe airport or an unsafe airport, and it should not be dignified by the title of airport unless it is safe, regardless of the rating it gets.

Therefore, the rating of an airport should be either safe or unsafe, because the flying public has a right to expect safety in air travel just the same as they have when they go up in an elevator or ride in a railroad train, bus, or street car. They are not assured of that safety now, and measures should be stressed to bring that about.

MR. SHAW: I would like to back up what Lieutenant Duke just said, because in going around over the country I run into the same problems.

CHAIRMAN DURAND: We might very well at this point throw open the further discussion on the subject generally. It is all one subject, so far as the afternoon is concerned, considered under three particular heads. Are there any further comments or suggestions regarding the general subject of airports?

MR. HALSTED: I might make a comment on that line. One of the troubles in getting what Mr. Duke is advocating has been a great amount of heterogeneous expert advice. Everybody is not unanimous in their opinion as to what constitutes safe airports, and it seems to me that it would assist greatly in getting what Mr. Duke has just mentioned as so desirable, if some organization—it might be the Department of Commerce or the Guggenheim Fund, or the Aeronautical Chamber of Commerce—could give authority as to what constitutes a safe airport by working out a system on co-operative lines and have some general understanding.

The Department of Commerce is doing that now, but I think it probably would be better carried out if the leadership were vested in the industry rather than in an agency, with authority to enforce regulations.

If there are some authoritative, general criteria of what a safe airport is, I feel that many of the cities now contemplating the design of airports would be very much benefited.

CHAIRMAN DURAND: Is there anything further?

In the opening session, I spoke of the significance of the work on the ground. In bringing the session to a close, I just want to say a word with regard to the broader significance of our participation in this general Safety Conference, our participation as an aeronautical unit.

In speaking with one of the head officers of the National Safety Council this afternoon, he told me we were starting in on this present occasion with our four-ring circus—Shall I call it?—going on for a couple of days with a larger membership than the entire Safety Council started in with some few years ago. And all of that is a most impressive indication of the extent to which the aeronautic field has arrived in the estimation of the public at large and of those who are connected with it as an important and significant factor in our present-day civilization.

Most of us remember 25 years ago, when the conquest of air was first achieved,

and as I have watched the developments of the airplane, it seems to me it has been marked out by three very clearly identified divisions or phases.

For the first eight or ten years it was largely a toy or a matter of demonstration. So far as practical use was concerned, there was none, of course. It had some significance as an agency whereby the attendance at the county fair could perhaps be stimulated, and that was about all.

A certain degree of interest was developed by the discovery of the possible stunts which could be performed by an airman in the air.

But that sort of thing characterized the development during the first few years. Then along came 1914, and the years following, when the entire effort was concentrated on the development of aircraft as an agency of war, without any particular reference to its significance as a factor in commercial air transports.

Then, since the war, of course, as we all know, the study has been concentrated on development along the line of commercial application as well as, of course, the application in warfare, and the degree to which this has arrived is, of course, well known to you all. I don't need to dilate on that point.

But it is very interesting and significant that we are here in 1928, twenty-five years after the first demonstration of the possibility of flight in heavier-than-air machines, as a full-fledged unit in this great conference of the National Safety Council, and as I said just a moment ago, with a larger membership in our division than the entire Council comprised at its start a few years ago.

All that is certainly very gratifying and very significant, but it also indicates a very great responsibility which rests on our shoulders. It is for us to work out the great problems of the advancement of the application of aircraft as a really dependable factor in the advance of our civilization. And it has been stressed so often this afternoon, not only in this session, but I am sure in other sessions as well, that the primary condition for such advancement is further improvement of these elements which contribute toward safety.

I don't need again to dilate on that, because that is the reason we are all here. And if we can make use of all of these conditions which modern science and engineering are holding out for our service, we may well hope that in the course of a few years we may bring the conditions which affect safety in air transport to a condition comparable with those which now prevail in other lines.

ADJOURNMENT

**SEVENTEENTH ANNUAL SAFETY CONGRESS
NATIONAL SAFETY COUNCIL**

Aids to Navigation

First National Aeronautical Safety Conference

Under Joint Auspices of

***The Daniel Guggenheim Fund for the
Promotion of Aeronautics and the
National Safety Council***

October 4 and 5, 1928

DR. J. C. HUNSAKER, Chairman

**Assistant to the Vice-President, Bell Telephone Laboratories,
New York City**

The first session dealing with Aids to Navigation at the Seventeenth Annual Safety Congress, was called to order at ten-fifteen o'clock by the chairman, Dr. J. C. Hunsaker, Assistant Vice-President, Bell Telephone Laboratories, New York City.

CHAIRMAN HUNSAKER: Gentlemen, I have been honored by an invitation to sit at the grand table as Chairman. I have no more to say than that we will listen to two papers bearing on Aids to Navigation, the first by Captain C. F. Hingsburg. That includes the lighting features involved in the safety of flight. The title of Captain Hingsburg's paper is, "Aeronautical Lighting as an Aid to Safety."

I think we are fortunate in having that whole subject reviewed by a man of Captain Hingsburg's experience, as he has worked more than fifteen years with the lighthouse service of the United States, through all the problems and griefs they have encountered, and has brought that experience over into the development of our airways. He is the Chief of Airways. Captain Hingsburg is well known to us and it is foolish of me to make any further introductory remarks. Captain Hingsburg, will you let us have your paper?

Aeronautical Lighting As An Aid To Safety

By F. C. HINGSBURG

Chief Engineer, Airways Division, U. S. Department of Commerce

Night flying is essential for successful air transportation operations in the United States, as the basic source of revenue is the transportation of air mail and express. The Civil Airways are established under present policies to serve the requirements of the air mail routes and schedules. The economics of present air transportation require the gathering of mail at the close of the business day and transporting it to remote destinations for early delivery

on the next or successive business day. *Figure 1* shows the routes established on which night flying takes place.

Airway lights have been installed on more than 7,500 miles of airways and 4,000 additional miles are being lighted during the fiscal year ending June 30, 1929. The present program includes the completion of the transcontinental lighting system from Salt Lake City to San Francisco. Upon the completion of the lighting a double mail schedule will be established. Mail collected at the close of the business day on the Pacific Coast will be delivered on the Atlantic Seaboard in the first mail delivery on the second day after posting, the mail having traveled two nights and one day on its journey from coast to coast. Close connections with feeder routes will make this service available

Figure No. 1. The American Airways.

to sixty-nine million people through 109 air mail stops at commercial centers. This fast transportation system will be an important factor in the exchange of ideas, enlargement of the scope of business activity, and in the creation of a better understanding of our national problems.

Night Flying Requirements

Night flying, although it has been carried on successfully by air transport companies, is more hazardous than day flying. This is due to poor visibility, imperfect observation of weather conditions by the pilot and difficulty with which the extent and severity of storms may be determined, and the prevalence and rapid formation of fog and change of weather conditions at night. To reduce these hazards, the Air Commerce Act authorized the establishment of airways equipped with air navigation facilities. The airways are selected

to follow the route offering the best flying conditions between the designated airports and are provided with intermediate landing fields approximately 30 miles apart to provide safe landing places under conditions of stress of weather or mechanical troubles.

Figure No. 2. Proposed boundary cone and light for airports.

One company flying 1,500,000 miles had 420 forced landings due to adverse weather and 55 due to mechanical and other difficulties. A forced landing due to impossible flying weather was made for every 1,350 miles of flight and a

forced landing due to mechanical or other reasons for every 27,000 miles of flight.

The air navigation facilities consist of route markers and landing field markers for day flying, an airway lighting system for night flying, a weather reporting and forecast system under the Weather Bureau, a communications system for the exchange of weather and other information over the airway, radio direction for the guidance of airplanes over the lighted airway and radio telephone communications to aircraft in flight. A high percentage of night flying efficiency coupled with safety will require the combined use of all these facilities, properly coordinated.

Airport Lighting

The establishment, maintenance and operation of airports and terminal fields are the responsibilities of the municipality or commercial operator, in accordance with the Air Commerce Act, but the Department of Commerce is charged with the duty of fostering and sponsoring air commerce and rating such facilities. The Airport Construction Bulletin and Airport Rating Regulations, issued by the Department of Commerce, set forth the requirements for safe airports. The rating of an airport certifies its adequacy and proper maintenance. The lighting required at an airport under the rating regulations consists of an airport beacon, to locate and identify the airport at long range, a boundary lighting system to outline the landing areas, red obstruction lights, green range lights on the safe approaches, a lighted wind indicator to show the direction and velocity of the wind, floodlighted hangars and buildings for perspective marking, a floodlight system illuminating the landing area to the proper brilliancy without glare, a ceiling light and height indicator. The lighting system prescribed in the airport rating regulations is adequate and meets the requirements for safe night landings under ordinary conditions. Safe landing under conditions of fog is not yet an assured accomplishment. Fog penetrating lights have often been mentioned but are not yet available.

The use of colored lights as an indication of landing conditions is recommended. The use of red course lights at airway beacons where there is no lighted landing field and yellow lights at intermediate landing fields has already been initiated. The use of a flashing green code light as an auxiliary airport beacon completes a rational system of indicating available landing places by colored lights. The code characteristic serves to identify the airport. It is also suggested that boundary cone markers three feet in diameter, three feet high, painted in alternate bands of chrome yellow and white, separated by a narrow black band, be used in connection with the boundary lighting system and floodlighted to show perspective. The proposed arrangement is shown in *Figure 2*.

Considerable research work remains to be done before landing at airports under conditions of fog will be practicable and safe. Fog dispersion appears to be a solution if a practical method is devised. In this connection the immense volume of fog drifting across a landing field in a very short period of time must be considered. Blind landing by aid of leader cables, or radio direction and instrument landing may have possibilities using inherently stable airplanes, but there always will be a hazard in connection with such landings. It is questioned whether fog piercing lights will be available within the near future. Until the fog problem is solved it is the plan and purpose of the Department of Commerce to aid airplanes in flight by a system of weather reports and radio telephone communications to aircraft.

Before departing, the pilot will be advised of weather conditions at his destination and, if impossible landing conditions exist, alternate landing fields

may be chosen for the destination, or the trip delayed. After departure the pilot will be periodically advised as to landing conditions and weather conditions by radio telephone and, if landing at the chosen destination appears hazardous, the pilot will be advised regarding alternate landing fields at which a safe landing can be made. Pertinent information, such as ceiling heights, barometric pressure, elevation of the landing field, arrangements made

Figure No. 5. Standard airways beacon on Atlanta-New York airway.

for transportation of mail, express and passengers, and orders from the transport company, will be given to the pilot en route.

Airway Lighting

The establishment of a lighting system for clear weather visibility is comparatively simple. Under such conditions the patterns of city lights and stray lights are beacons of the first magnitude, but under adverse weather conditions the stray lights lose their characteristics and become confusing, competitive lights. The airway lighting system should be designed for poor visibility flying. The beacon light should have an optical design that utilizes

the greatest percentage of light flux from the light source, concentrating the light into a high intensity beam of candlepower in excess of competitive or stray lights, and project the beam into the sectors most useful to the pilot. The light should have a distinctive characteristic so as to be recognized instantly among the stray lights as a light of aeronautical character and should have individuality so as to be recognized as a landmark of known geographic location. The durations of flashes should be sufficiently great to develop the maximum luminous value on the retina of the eye and the luminous period and frequency of flashes should be proper to fix the location on the horizon. The lights should be spaced as close as availability of funds permits.

Figure No. 6. Twenty-four inch revolving beacon and course light characteristics for identifying mileage numbers of beacons.

The determination of the proper light intensity, power input, and spacing of lights is a complicated economic and scientific problem. One of the factors involved is the penetration of lights through the atmosphere under varying degrees of poor visibility. Figure 3 is an interesting study of comparison of light penetration on the several coasts and corresponds to 90 per cent visibility under ideal conditions of relative darkness. A thirty-five mile light on the East Indian Archipelago is reduced to a six mile light in Dover Straits. It is interesting to note how the curves coincide for short ranges and the relatively low candlepowers required for two mile visibility. Reduced to the needs of air transportation having a flying efficiency of 96 to 98 per cent, much higher candlepowers would be required to meet the conditions under which air navigation takes place and the competition of stray lights of high candlepower in thickly populated regions. This was demonstrated by the inadequacy of the three mile spacing of low candlepowered acetylene lights installed by the

Figure No. 7. Details of twenty-four inch revolving beacon with zenith lights.

Post Office Department. The 200 m/m unit with one foot burner developed about 120 candlepower. Aeronautical lights should have candlepowers in excess of 1,000 but the close spacing was correct in principle. An interesting chart of equation of ranges is shown in *Figure 4*, and is reproduced from the Hydrographic Review. This chart is useful in comparing candlepowers and relative ranges for equivalent flying efficiency under identical conditions.

Based on the results of economic studies it was determined that the best average results were obtained by using a 24 inch revolving beacon of two million candlepower with identifying course lights spaced ten miles apart along the airway as shown in *Figure 5*. The lights are mounted on a skeleton tower, as shown in *Figure 6*. Commercial power is used where available, but

Figure No. 8. Detail of eighteen inch light with doublet lens and spread light mirror.

otherwise duplicate gasoline driven generating plants of 2 KW capacity furnish the current.

Ten lights of this character are established to each block of one hundred miles and code numbers are flashed on the course light projectors giving the mileage location along the airway. Red course lights are used at beacons where no landing fields are located; yellow course lights are used at beacons on intermediate landing fields. The lights are elevated to show the greatest candlepower to the pilot when he is flying above the adjacent beacon at a height of 500 to 1,500 feet.

The latest design of 24 inch revolving beacon is shown in *Figure 7*. The light from a 1,000 watt, 110 volt, T-20, airway lamp is concentrated by a parabolic mirror into a beam of two million candlepower having a 4 degree beam spread. The front cover glass has prisms on the inside surface which deflect some of the light upward from 0 to 25 degrees, so that the pilot will not miss the beam by flying too far above it as he approaches over the airway. A half drum lens is mounted as a saddle on the drum, gathering the light, otherwise lost, into a fan shaped beam of light showing from horizon to horizon perpen-

dicular to the axis of the main beam. As the beacon rotates, secondary flashes of 12,000 candlepower are shown two and half seconds before and after the principal flash and are decidedly advantageous at close range, especially in thick weather.

Figure No. 9. Electric code beacon.

Figure No. 10. Wiring diagram of twenty-four inch revolving beacon, course lights, wind cone, and landing field.

A course light of entirely new design using doublet lenses and horizontal spread light mirror is shown in Figure 8. The lamp used in this unit is a 500 watt, G 40, 110 volt monoplane filament lamp of 800 hours life, and develops 165,000 candlepower with 15 degree beam spread.

Another new addition to the list of optical apparatus of the Airways Division is a flashing code beacon shown in *Figure 9*. The lantern is a 300 m/m double unit with two light sources using 200 watt, P S 30, ring filament lamp of 1,000 hours life, both lamps burning simultaneously. The flashing code beacon is used for marking major obstructions along airways, and also for intermediate airway lights, where power is available, and for marking intermediate landing fields located off the airway, in a valley or obstructed from view of adjacent beacons, in which case an airway beacon is located on high ground and has yellow course lights to show the availability of the landing field.

Intermediate landing fields are marked by an airway beacon with yellow course lights and the landing area is outlined by boundary cones and lights spaced approximately 300 feet apart. Red obstruction lights are mounted on all obstructions. Green range lights in the boundary system mark the best approaches and runways. The wiring diagram of a typical field lighting system is shown in *Figure 10*. An internally lighted wind cone is mounted on the beacon tower. Ceiling lights are installed at intermediate landing fields at which weather reporting stations are located. The ceiling light is a 14 inch projector and is shown in *Figure 11*. The light is projected at an angle of 63 degrees—26 minutes above the horizon and the height of the ceiling is measured by a ceiling height indicator shown in *Figure 12*.

Airway Lights for Isolated Localities

The maintenance of airway lights through isolated and sparsely inhabited sections presents a serious problem. To meet this situation an improved acetylene route beacon was developed by the Airways Division. It combines the highest development of railroad signal practice with marine range lighting system and is applied to airway lighting in a new and unique manner. Two lanterns are used, one being mounted above the other. The top lantern is an azimuth and off course light, having a separate flasher, piping and gas supply, showing 40 flashes per minute of 180 candlepower. The lower light is a course light of 15 degree beam spread and 5,000 candlepower flashing 20 times per minute. The lower light is shown in *Figure 13* and is a double ended range light lantern having 18 inch bull's-eye lenses with 10 inch doublet lenses. This acetylene apparatus offers the greatest degree of reliability with its dual lanterns, each with separate mechanism and gas supply, and its automatic features enable its installation in isolated localities for operation without attendance for periods of six months or more. These lights will be spaced three miles apart. They bring within the realm of possibility, close spacing of lights of adequate candlepower, luminous period, and distinctive aeronautical character at a cost of installation and maintenance comparable to electric lights at ten mile spacing.

Where a revolving beacon of two million candlepower is picked up by a pilot at thirty miles, the acetylene range light of 5,000 candlepower will be visible thirteen miles. Under conditions of fair visibility when a revolving beacon is seen ten miles, the acetylene range light is visible five miles. On a thick night when the pilot advances five miles beyond a revolving beacon, before he picks up another revolving beacon five miles ahead of him, the acetylene range beacons will be visible from light to light at three miles spacing.

Airways are laid out over the safest low level routes providing weather landing fields 30 miles apart, preferably following habitation, roads, communications and power, and reconciled to the installation of lighting and radio aids. A high percentage of completed trips on schedule time is essential for the success of air transportation and the combined use of lights and

radio direction is essential to meet this requirement. For safety the radio marked airway must coincide with the lighted airway, the pilots making use of all facilities and traveling the same routes in bad weather as on clear nights. When lights are not visible one to another, radio direction takes the pilot over the airway, enabling him to catch a glimpse of lights and fields at close range

Figure No. 11. Ceiling light.

and this combination of blind-contact flying will increase the flying efficiency with the greatest degree of safety. On the Transcontinental Airway 15 radio range beacons are required to mark the lighted airway from coast to coast. The radio range beacons will be erected at the center of straight courses and radio mark 50 to 150 miles of airways in opposite directions.

Once established and checked the radio marked course will be permanently

fixed so that the edge of the radio range will cut on definite landmarks and never be shifted. This requirement will develop the greatest confidence in blind flying by the pilots. At the change of course and at intersections of airways, great confusion would result due to interference of the overlapping signals if all beacon signals are transmitted on one wave length, and to meet the situation about six channels separated by a frequency of 5 K.C. are required. Each beacon should also be identified by its individual characteristic. This winter will see nine radio-beacons in operation on the Transcontinental, marking lighted airway courses. Five individual characteristics suitable for the interlock equisignal range beacon will be used for identifying the beacons.

Figure No. 12. Ceiling light indicator for measuring ceiling lights.

Visual indication appears to have great possibilities when developed to meet operating conditions involving a number of radio-beacon installations with overlapping ranges. Radio direction is the subject of a paper by another author and is introduced here to show its inter-relationship to lighted airways from an operating point of view.

Maintenance of Lighted Airways

Careful consideration has been given in the design and construction of structures and equipment to reliability of service for the safety of air navigation. Lamp exchangers are used to guard against lamp failure and duplicate engine generators are installed where power is not available. Electrical work is placed in waterproof conduits according to the National Underwriters Rules and underground cable is lead incased and armoured with underground connections made in waterproof boxes filled with insulating compound. Apparatus

is rugged in construction and efficient in operation. Airway mechanics are assigned to about 200 miles of airways and thoroughly inspect and overhaul all apparatus at least once a month. A fleet of 40 trucks, some of which are shown in *Figure 14*, are used for transportation and carry spare parts for all apparatus so that immediate replacement of any defective apparatus may be

Figure No. 13. Acetylene airways course light of 5000 C. P. and 15° beam spread.

made. The general supervision of airways is under the direction of District Lighthouse Superintendents and Airway Engineers assigned to these offices supervise the maintenance work. (The lighted airways receive the same attention and the same policies and practices are followed as in administering the great work of the Lighthouse Service.

Cooperation With Air Transport Companies

Close cooperation exists between the Air Transport Companies and airways personnel. Arrangements have been made on all lighted airways for daily pilot reports covering the operation of lights. Airways mechanics communicate each morning with Air Transport representatives for pilots' reports and defects reported by pilots are given immediate attention. Local notices to Air Transport Companies and to the aeronautical public are issued covering all changes in aids to navigation and these changes are published in the *Domestic Air News*.

Certification of Safe Airways and Landing Fields

Steps have recently been taken to equip an airplane for the quarterly inspection of all airways and landing fields, for the purpose of certifying to the aeronautical public the adequacy and safety of air navigation facilities. The crew will consist of a pilot, radio engineer and airway mechanic and the airplane will be equipped with radio transmitter, receiving equipment and testing instruments. The pilots will be experienced in night flying and expert on airways and landing field requirements. The radio engineer will check up on the communications service and radio direction as well as communications to aircraft. The airway mechanic will check up on the proper focus, elevation and proper operation of lights and equipment. By landing in each field, by day and by night, and checking up on the service rendered by each airway mechanic and radio communications station, a thoroughly efficient organization will be assured and safe airways maintained.

Private Aeronautical Lights

Privately established aeronautical lights are certified as to their adequacy by the Department of Commerce under the Air Commerce Act. The airways lights established by the Department and the majority of airport lights are revolving beacons and this type of light has been developed and characterized as an aeronautical light. Lights established on an airway are given characteristics similar to airway lights, revolving 6 R.P.M. and elevated about 1 degree above the horizon. Rotating beacons that are not located on an airway revolve 2 R.P.M. and are elevated 15 degrees or more. Private advertising lights that serve a useful aeronautical purpose must establish a landmark from which a departure can be taken to reach a landing field or must mark a landing field. Unfortunately great demands are made for the establishment of revolving beacons for purely advertising purposes that do not serve the best interests of the pilot. Most of these lights are not certified or authorized. The establishment of a great number of advertising lights of aeronautical character leads to confusion and destroys the value of true aids.

- Before authorizing and certifying private aeronautical lights, the local aeronautical interests and air transportation companies should be requested to submit their reports and recommendations as to the purpose served by its establishment. Proper attention to these matters will prevent the establishment and certification of improper lights. The Air Commerce Act authorizes

the discontinuance of any false light or signal at such place or in such manner that it is likely to be mistaken for a true light, and private lights that prove a menace should be reported by pilots so that steps may be taken under the law for their discontinuance, after proper investigation.

Lights for Marking Major Obstructions

Under agreements made between the War Department and the Department of Commerce, aeronautical lights and markings are required on transmission lines and other structures built across navigable waters of the United States. The towers of transmission lines are required to be painted alternate bands of chrome yellow and white separated by narrow black bands and the towers marked with red obstruction lights. The electric code lantern with 200 watt lamps and red globes is suitable for tower obstruction lights. Marking the span across navigable waters is required but presents several difficulties in

Figure No. 14. Airways trucks equipped with tools and spare parts for servicing air navigation facilities.

connection with proper maintenance. The indirect marking of the span by high intensity projected light beams from the tops of the towers along the span is suggested, using 14 inch ceiling light units with 250 watt low voltage lamps for spotlight service.

It is suggested that the Federal Radio Commission be prevailed upon to require the painting of all radio towers to increase visibility and the lighting of them, by use of 100 watt red lamps in waterproof glass globes at the top and at points one-third and two-thirds from the tops of towers, the lights being visible from any angle of approach. All radio stations operate on licenses issued under the authority of the Federal Radio Commission. If necessary, proper legislation should be passed to assure safeguarding airplanes in flight from the hazards of radio towers. The marking of high lines at intersections with an airway is needed to safeguard airplanes in flight and this requirement is taken into consideration in laying out the airway lighting system. It would facilitate lighting if neon high voltage lamps of 10,000 hours life were available for installation on high tension lines, using lamps built for the voltage carried by the high line. The intersection of the airway with the high line could then be marked for the full width of the intersection and would facilitate and cheapen the maintenance of a more adequate lighting system.

The marking by owners, of obstructions not in the navigable air space, is not required according to present policies. However, bridges, transmission lines or other obstructions, spanning rivers used during bad weather as airway routes, must be marked.

CHAIRMAN HUNSAKER: I think most of us are aware that night flying is going on all over the country, and with a fair degree of safety, certainly a commercial degree. It is especially interesting to me now to learn how it is done. It has been done by reason of lights of many kinds, organized, integrated, worked as a system. It has taken a good many years to arrive at this place. As I recall it, night flying really began during the war and there were no license lights involved at all. If they were bombing somebody you sneaked in and hoped to get back. After the war it was proposed that we fly the mail at night. People threw up their hands and said, "It can't be done. They will never find their way."

The question was put up to the National Advisory Committee of air lights. This committee said that it could be done. Professor Durand, of Leland Stanford University, a member of the committee at that time, might perhaps tell us why the committee had the courage to recommend this thing to the government. I am sure they didn't have much evidence.

PROFESSOR DURAND: I wish I could tell you just why it was or how it was that we believed this thing could be done. We had no tangible evidence; it never had been done; but we had the courage of our convictions. We saw clearly that if transmission of mail across the country was going to be of real commercial value, it simply had to be done. There would be no significance, whatever, in flying mail by day and putting it on the railroad train by night, and again going on by day. That might do, possibly, for the beginning of passenger transport service, but if the transport of important correspondence was going to be of real value it had to be a continuous flight without any interruption by way of railroad transportation.

We knew there were certain elements which might serve toward the solution of this problem. Just how they were going to be combined we didn't know. We knew we had the electric light and projectors. We knew there were possible aids through the use of radio energy and we had faith that in some way or another the problem could be solved. It is by faith of this sort that many of our great achievements in engineering, of course, have been accomplished. We may not see the exact method, may not know the exact details of the solution, but we can see certain elements in the picture and believe certain people can be found who will be able to put those elements together in a practical way.

That was about all the foundation we had, but certainly the achievement which has been sketched or developed in the paper you have just heard, the splendid results which have been realized in recent years, have, I think, abundantly justified the measure of faith we had at that time.

CHAIRMAN HUNSAKER: We have a little time before proceeding with the next paper, and whereas I am sure Captain Hingsburg will be very glad to answer any questions anyone may ask about matters he didn't have time to go into, I hope nobody will ask that kind of a question. I would rather have something controversial. Does anybody disagree with anything, and if so, why? Is there some factor we might have called to our attention?

S. W. HICKS (Lakehurst, N. J.): There is one thing that came up a short while ago in discussion between the Navy Department and a commercial concern, that wasn't covered by the paper. That is—what are the rules on the lighted way? The Los Angeles was proceeding down the lighted airway on the righthand side of the course, and a plane in the middle of the night almost hit it. That thing is under discussion now. The plane was going in the opposite direction at 100 miles an hour. The Los Angeles was coming at 50 miles an hour. They were

coming head on at the rate of 150 miles an hour. The plane finally saw the ship in time. Naturally the big ship couldn't manoeuvre in a few seconds. The plane side stepped, stuck one wing down, and got out of the way. That started the discussion of who, what and where, and the question should be raised as to what are the rules of the road on the lighted way.

CHAIRMAN HUNSAKER: Is it a question so much of whose turn is first and why as between sailing vessels and steamships, or a question of what kind of lights are they carrying, and can they see each other at a great enough distance to avoid collision. Both ships had lights, but could not see as far as they thought they could with the short time element. Then should the southbound travel be on one side and the northbound on the other? I think that is more pertinent because when you are on the water your rate of speed is so much lower that you have a great deal more time.

CAPTAIN HINGSBURG: The air commerce regulations set forth the rules of the road under the air traffic rules. The points brought up by you are covered by regulation. Any violations of those regulations when they do occur should be sent to the Department and have the proper investigation, and the proper penalties will be made.

For flying at night, airplanes are supposed to carry navigational lights—green, red and white lights—and a flying light along the airway. The air way is three miles wide for the purpose of interpreting the application of the air commerce regulations and the air traffic rules. The right of way is provided for by the regulations and reference to the regulations you will find set out as established by the Department.

W. PARKER BERRY (Somerset, N. J.): I would like to ask if there is any known or theoretical apparatus manufactured, or that can be manufactured that is practical, which will be actuated upon by a radio wave of very short wave length and which will give the pilot a definite light or signal in his cockpit if his aerial is directional on his plane and centered on a certain directional beam of radio waves? If he turns off his course, he will receive another from another town. Is there any apparatus made by being actuated on a very sensible relay which will light a light or give him a visual notice of which town he is heading toward?

CHAIRMAN HUNSAKER: I could say, from my knowledge of sense relation, they can be made so they will be actuated by radio signals. The trouble is, static and other signals will actuate them, too. You have to have a combination of correct impulses like the combination of a safe.

MR. PERRY: You know wave lengths run down to way below x-rays. A short wave length is anywhere from a millimeter up to a yard. There are very few wave lengths so short, I believe. Is that true?

CHAIRMAN HUNSAKER: I don't believe so. The shorter they get, the worse they get, according to my experience. Your suggestion was bearing on the problem of collision, I take it, meaning to avoid collision by an indication of someone coming who can't be seen by lights.

MR. PERRY: Not necessarily, although it would hold to that somewhat. Supposing you had the ideal type of visible or invisible lighting from a town. Is there an apparatus made which will be actuated by this visual or visible light: which will give a telltale signal to the pilot?

CHAIRMAN HUNSAKER: I think it is a good question. Let's save it. We have just a minute or two more and we had better go on to the next paper. Is there anyone else who can make a contribution on the matter of safety as affected by air way or airplane lighting?

When the lighting began, it seemed to be very essential to night flying. When it began we had night flying, but had lighting, and some of our pessimistic pilots said, "These lights are fine. I love to see them stretch out mile after mile. On a

very bright, starry night when I can see them I don't need them. I know my way. When the clouds are low I can't see any lights and they aren't any good."

The answer to that is to be found in Dr. Dellinger's work in giving indications of direction under conditions of visibility when the lights fail. I would like to introduce Dr. Dellinger who will give us a paper on "Directional Radio as an Aid to Safe Flying." Dr. Dellinger, as you know, is in charge of the radio section of the Bureau of Standards which is developing these directional beacons, signal type beacons for our airways. It is a new conception, entirely original, I believe in this country, and gives great promise of affording an additional element of safety.

Directional Radio as an Aid to Safe Flying

By DR. J. H. DELLINGER

Chief Engineer, Federal Radio Commission, Washington, D. C.

Among the several developments now in progress to make flying safe, none is more urgently needed than the navigational aid supplied by radio. I would go so far as to say that without it genuine air passenger service is impossible. I may be considered a heretic for the implied assertion that we have no air passenger service at present. However, real service is not available until the air traveler can count on a scheduled service as regular as the railway trains, independent of weather or other contingencies.

This is no imaginative ideal. On December 13 last I was scheduled to give a talk in Chicago. I dislike to use up the twenty hours necessary to reach there from Washington on the train. Instead of leaving Washington the preceding afternoon, I could, theoretically, have taken the trip by airplane in less than six hours on the day I was to be in Chicago. What happened? Since I had to be sure of being in Chicago at the appointed time I went on the train. If I had planned to go by airplane I would not have kept the appointment on the 13, as a dense fog settled down during the night of the 12 and there was not an airplane in the air in north-eastern United States on the 13.

Take another instance. On July 11 last year I called on Air Commodore Blandy, in charge of radio in the British Air Ministry, who arranged for me to see the start of an experimental flight at Croydon the next day. This flight was to be from Croydon to Brussels. Commodore Blandy also had business in Brussels in the evening of the same day. While he would have liked to be a witness to the experimental work abroad the airplane, he went by boat instead because his appointment in Brussels was important. His judgment, so it happened, was confirmed, for a fog prevented the airplane's flight.

The nullification of the most essential feature of the air passenger travel as a serious service arises entirely from the hazards of weather. As we shall doubtless learn from the accounts of progress now being given in the various phases of safety in aviation, all other limitations are in a fair way to be overcome. Airways and airports are being provided in abundance, aircraft of adequate strength and stability are more and more available, every provision of comfort and convenience is offered the air traveler, and yet air traffic can still be halted when low visibility prevents the pilot from seeing his landmarks or lights on the ground.

It is impossible to exaggerate the solitude and helplessness of an airplane flying in dense fog. Deprived of all landmarks, under incessant strain at the controls to maintain equilibrium and direction, the aviator must frankly abandon dependence upon his senses and navigate according to the information conveyed by his instruments. It is contrary to all human instinct to throw overboard the testimony of the senses and stake life itself on a mute instrument dial. Not every pilot can

do it, and unquestionably the oceans hide the sad remains of more than one hero whose only mistake was failure to learn "instrument flying" before he essayed the great adventure.

By means of the familiar instruments such as the altimeter, turn indicator, and compass, a pilot can continue flying in fog, but it is only by radio means that he can be certain to keep on a given course and find his landing field when the ground

Radio beacon tower. First radio beacon installation on the transcontinental airway, installed by Bureau of Standards at Bellefonte, Pa.

is invisible. Accurate as a compass may be, it can not tell the pilot how much he is drifting sidewise due to cross winds, nor what actual progress he is making forward because of the unknown effects of head or tail winds. Unless radio aids are used, fog always brings the hazard of getting off the desired course into unfamiliar or dangerous areas, and also makes even the possibility of a landing unknown.

By radio means, however, particularly by the use of the radio beacon system which is being established on the airways of the United States, the pilot can, regardless of fog, keep accurately on his course, know the points he is flying over,

and proceed unerringly to the landing field. This, I believe, largely destroys the menace of fog. When this system is fully established there is every reason to believe that the last great obstacle to safe flying will have been conquered, scheduled flights will be dependable, and passenger flying can be considered established as a serious service.

Directional Radio Off the Airways

Before describing the radio beacon system I would like to indicate briefly the possibilities of navigation by radio on other than the established airways. The beacon system will mark out the airway routes but will give no aid to the flyer

Transmitting apparatus in the radio beacon house.

on an independent course. There are several ways in which radio can be adapted to this navigational need.

One is the system used in Europe: radio direction-finding stations are maintained by the Governments at various airports, and each airplane carries both a transmitting and a receiving set. Upon request by radio from an airplane, two or more of the direction-finding stations determine the direction of travel of radio waves from the airplane; combining their determinations they calculate the airplane's position and send this information by radio to the airplane.

A second means of radio navigation for the independent flyer is the use of a radio direction finder on the airplane. By steering a course in the indicated direction of a radio station on the ground, the airplane can be certain of reaching that point, the accuracy of the indicated direction increasing as the objective is approached. Direction finders are used extensively as a navigational instrument

on marine vessels and on lighter-than-air craft. On airplanes their use is difficult. It is considerably more difficult to protect them from error and disturbances caused by the engine ignition and other sources aboard an airplane. They have been used successfully to some extent, and their use will doubtless increase; they do however, require expert handling. This method of navigation has the inherent limitation that it does not prevent wind-drift from shifting the airplane off its course; the method does eventually bring the airplane to its destination, although by a circuitous route if there is a side wind.

A third method of furnishing navigational aid to the independent flyer is the rotating radio beacon. This is a radio transmitting station, located at an airport, which has a rotating directive antenna. This causes a sort of beam of radio waves

Experimental airplane of the Bureau of Standards equipped with vertical pole antenna and visual indicator.

to sweep constantly around. A special signal indicates when the beam sweeps through the north. A pilot listening for this beacon's signal with his receiving set can determine his direction by the time elapsing between the north signal and the instant when the beam is heard with maximum (or minimum) intensity. The elapsed time is determined by means of a stop-watch, which can be calibrated to read direction.

The Airway Radio Beacon

The radio beacon system for the United States airways has been designated to operate with the minimum of apparatus and attention on the airplane. The objective in its development was to place a simple visual indicator on the airplane instrument board to tell the pilot whether he is on the course or how far off, which should operate without any effort or attention by the pilot. This has been successfully accomplished, and navigation over the official air routes thus has the advantage of a superior means of radio navigation not available to the independent flyer off those routes. The three methods of radio navigation for the independent flyer described in the foregoing require the pilot to listen with headphones through the

roar of noises on the airplane. Also, each of them requires other apparatus besides a radio receiving set; thus in the first method the airplane must carry a radio transmitting set, in the second a direction finder, and in the third a special type of stop-watch.

While the radio beacon system for the airways attained practical development only this year, its origin goes back to 1920. At the request of the War Department, the Bureau of Standards undertook to develop a directive radio system for airplane navigation. A method was devised in which radio waves were transmitted alternately from two directive antennas placed at an angle with each other.

Airplane instrument board showing beacon visual indicator.

Equality of signal intensity from the two antennas along a certain line or zone determined a course which an airplane could follow. The system was tried out successfully in Washington and in Dayton, Ohio. In succeeding years the Army engineers at Dayton developed the system further.

When the Aeronautics Branch was formed in the Department of Commerce in 1926, it determined that radio aids would be necessary on the civil airways, and assigned their development to the Bureau of Standards. As part of this work, the Bureau undertook to perfect the radio beacon, particularly by developing a visual indicator so that a pilot would have a direct indication, on his instrument board, of his location.

The required radio equipment on the airplanes is reduced to a short pole antenna and a simple receiving set weighing a few pounds, plus the indicator on the instrument board which tells the pilot whether he is on the course or how far off. All

of the expensive and powerful apparatus necessary for the system is on the ground, maintained by the Government.

The radio beacons operate in the frequency band 285 to 315 kilocycles. Airway radio telephone stations are to communicate with airplanes in flight, in the band 315 to 350 kilocycles. These are allocated to air service by the 1927 International Radio Convention. For the present the beacons are adjusted to the frequency of 290 kilocycles, and the telephone stations to 333 kilocycles.

Visual reed indicator in shock mounting for installation on instrument board.

The directive radio beacon is a special kind of radio station, usually located at an airport, just off the landing field. Instead of having a single antenna like an ordinary radio station, it has two loop antennas at an angle with each other. Each of these emits a set of waves which is directive, i. e., it is stronger in one direction than others. When an airplane flies along the line exactly equidistant from the two beams of radio waves, it receives signals of equal intensity from the two. If the airplane gets off this line it receives a stronger signal from one than the other.

The current in the two antennas is of exactly the same frequency, but is modulated at a different low frequency in each. I. e., the current in one antenna has a tone of 65 cycles impressed on it, and the current in the other antenna has a tone of 85 cycles impressed on it.

The indicator connected to the receiving set on the airplane shows when the signals from the two beams are received with equal intensity, by means of two vibrating reeds which are tuned to the different modulating frequencies used on the two antennas at the directive radio beacon station. When the beacon signal is received the two reeds vibrate. The tips of these reeds are white in a dark background so that when vibrating they appear as a vertical white line. The reed on the pilot's right is tuned to a frequency of 65 cycles and the one on the left to 85 cycles. It is only necessary for the pilot to watch the two white lines produced by the vibrating reeds. If they are equal in length, he is on his correct course. If the one on his right becomes longer than the other, the airplane has drifted

Interior of visual indicator showing the two metal reeds and electromagnets.

off the course to the right (into the region where there is more of the 65 cycles). If he drifts off the course to the left, the white line on the left becomes longer. Thus if the pilot leaves the regular course either accidentally or to avoid a stormy area, the radio beacon will show him the way back.

The whole receiving system comprises a small indicator unit on the instrument board weighing one pound, a receiving set weighing less than 15 pounds, and a 15-pound battery. The same receiving set can be used to receive radiotelephone messages, by plugging in a pair of headphones. The receiving system is very little affected by interference, including static, other radio stations, and airplane ignition interference, which has hitherto been the bar to satisfactory use of radio on airplanes.

The beacon stations will probably be placed at airports in general averaging about 200 miles apart. The Airways Division of the Department of Commerce

Aeronautics Branch has begun a program of installing them on the various airways. The directive beacons, with a straight airway between them, will be supplemented by small marker beacons at intervals (perhaps 20 miles) along the route. These are simply very low-power radio transmitting stations serving as mile-posts. A characteristic signal from a marker beacon will show on the visual indicator aboard the airplanes what point is being flown over.

Thus the radio beacon system guides the airplane along the airway regardless of fog, informs the pilot of the distance passed over, and brings him to the landing field. There are two other services which directional radio can eventually perform,

Marker beacon. A low power transmitter developed by the Bureau of Standards for use at emergency fields to mark fixed points along an airway.

to complete the conquest over fog, the providing of a field localizer and a landing altimeter, i. e., to mark out clearly the landing area and to indicate distances above ground in the act of landing. While it is not yet certain whether radio or other methods will be the best means to provide these two services, the need of a field localizer is already partially met. When the pilot arrives at the radio beacon station and flies over it, there is a sudden deflection of his indicator which enables him to ascertain the location of the radio station within 100 feet. This is accomplished by virtue of the peculiar properties of the vertical pole antenna on the airplane, and is of material assistance when landing during poor visibility.

The increasing role of directional radio in safe flying has already been foreshadowed. The successful flight of Art Goebel and Lieutenant Davis from California to Hawaii in 1927 was made with the aid of the radio beacon of the aural type. A long flight over sea, terminating in a relatively small objective like the

Hawaiian Islands, is extremely hazardous if undertaken without radio aid. Navigation by compass is subject to the indeterminate effects of wind drift, and the airplane's path may easily be shifted entirely away from the objective. Any practical scheme for transoceanic air service would seem to require directional radio aid. It would be imperative for a system such as that involving a number of seadrones anchored at intervals across the ocean. Navigation on such a system without directional radio could not be considered; there is no other known means of being sure to arrive at the next airdrone.

Exploration by air is another instance where directional radio must be used. An exploring party takes unnecessary risks if it neglects directional radio aids to reach its objective or to find the way back to its base. This is recognized by Commander Byrd who is taking direction finding equipment along on the airplanes which he will use in exploring the Antarctic Continent.

The principal saving of life and saving of time through directional radio, however, will doubtless come on the regular commercial airways. The radio beacon system developed for the airways is now being subjected to the test of routine operation. As an instance of what has been accomplished in trial flights, I may cite a recent experience. On a day of low visibility, a pilot unfamiliar with the route took the air in Philadelphia for Washington. With no maps or instructions as to landmarks, he was told to proceed to Washington and land at the College Park field solely in accordance with the guidance given by the beacon indicator on his instrument board. He not only flew in a straight line to Washington, but when over College Park field, which he had never seen before, the special deflection of the indicator told him he was at his journey's end, whereupon he landed.

As the radio aids have been slow in coming, compared with the advances in airplane design, engine reliability, and airway development, there has been a constantly increasing percentage of aviation accidents due to the hazards of weather. Directional radio seems the answer to those hazards, and there is ground for hope that not only this percentage of accidents but the whole number of accidents will become vanishingly small when the present possibilities of directional radio are realized in practice.

(At this point lantern slides showing the pictures on the accompanying pages and many others were introduced.)

CHAIRMAN HUNSAKER: I think our section is fortunate in having two authoritative papers on most important developments in the art that are making commercial flying safe enough to be commercial. This radio beacon service that Dr. Dellinger has outlined, I think, is 100 per cent American. He mentioned, in passing, the European system (I think largely British) in which the direction finding equipment is on the ground. The man in the air has to have a transmitter and receiver to find out where he is. I looked into that myself once and found it has elements of risk and confusion that are not in the American plan. In the European system, as used at Croyden, it so happens that people starting from the Continent time their flights to arrive before dark, so between five and six on a foggy afternoon, there was a Belgian, a Dutchman, a German, two Frenchmen and several Englishmen, all coming in and unable to find Croyden, asking in various versions of the English language where they were, all on the same wave lengths. The thing didn't work. They had to pick out one fellow and say, "Now you talk for a minute." The others would break in and were told to lay off until they got through. They had to cruise around and waste time until the positions had been given one at a time. The longer they waited, the worse they got lost.

The American system, I think, is a broadcasting system. Broadcasting is an American idea, anyway, and is in a way an indirect subsidy to civil aviation, because all the apparatus along the airways is provided by the Government of

the United States. A flyer has to provide only the receiving equipment. The service of the radio beacon will serve any number of airplanes on the route. There is no question of precedence. I think that is a feature that has great elements for future explanation. The system of the man in the air asking people on the ground where he is, is all right when two or three are in the air, but it is no good with 40 or 50 coming in.

I notice that we have a radio pioneer in our audience. I don't know whether he has worked on radio beacons. He may have some comments as to where we are going. I would like to call on Dr. Alexanderson.

DR. ALEXANDERSON: I am getting intensely interested, and have been spending a lot of time in the air just recently. I feel that it is an intensely practical subject, this navigation. The ideas we have gotten in discussion today will have to serve as a guide as to what we may be able to do in adapting radio to these purposes.

The question was asked here as to what should be done to avoid collisions. A skipper at sea blows his fog horn when he is in danger of collision. Couldn't we perhaps have the equivalent of a fog horn by radio on each ship, a loud speaker to give out a kind of noise that is easily audible, where a wave would be sent out not selective and directive, but be picked up with any kind of receiving set? Whether that is a practical suggestion or not, I don't know; but I think we have to think along those lines and get our suggestions from the aviators.

CHAIRMAN HUNSAKER: I think there is something being done to avoid collision at sea, isn't there? I heard some discussion recently of some device for warning ships when approaching each other by radio means.

CAPTAIN C. F. HINGSBURG (Chief of Airways Division, Department of Commerce, Washington, D. C.): Yes there is. It is proposed to place a small radio beacon on board ships using the direction finders placed aboard the ships to determine the direction of ships. They are low powered and in that way will give warnings at greater distances than now practicable with the audible signals.

CHAIRMAN HUNSAKER: I suppose we are really considering means of navigation. We began with lights, how they can help the man navigate and find his way. We have spoken of how radio helps find the way when lights are not available. No one has mentioned the lights that are placed by the good God in the sky, the old-fashioned, celestial navigation. Have we a seagoing navigator here? What is the state when we go over the ocean. We are not going to have all these lights spread out.

LT.-COM. Z. W. WICKS (Lakehurst, N. J.): I was looking over the program last night before I started here from Lakehurst. As I read it over, I noticed this lack of celestial navigation as one of the subjects. That is a very moot question, and many people who haven't been to sea consider navigation as avigation, and there isn't any such hope as the stars and moon and sun being any good to you. That has been very severely handicapped the same as radio and lights and everything else.

It has been a question studied by a few for many years. I don't feel like saying much about this subject because I am not one of those who have been doing the work, but I have been associated for several years with Commander Pierce, at Lakehurst, and for the last five years he has been working on navigation, not only for the airplane and airship, but also to make it easier for sea-going men. He has two phases to the subject. One, of course, is taking the altitude of the object. The other is the solution of the position after you know your altitude. The solution he has divided into two parts, one by means of tables, the other by mechanical solution. His scheme as worked out is the camera. In other words, he takes a picture of the sun or moon on a filament which at the same time takes a picture of a bubble which is in the camera section, and a picture of the watch so he has the time right on the film.

In order to get away from acceleration errors he can take anywhere from five to ten sights on the same film, the average of the times, the average of the bubble error, the average of the altitude is obtained by measuring the distance above the base line and taking in conjunction the angle of the lens which is printed on the film.

Several years ago one of these cameras was made by the Bureau of Standards and the advisability of it proved. Just recently the Eastman Kodak Company took up the matter of development of a real proposition and pushed one through in time to give it to Dick Byrd to take South with him. That will not only give him a knowledge so he can calculate his position, but will enable him to bring back proof that he got where he said he was. There isn't any question. The altitude is there on the film, and he can bring it back. The watch time is right there. The only thing we can say he gypped us on is the direction to his watch. If his pictures don't show he was there, he didn't get there.

That is an expensive proposition that was developed there, and it is not suitable for the stars as yet, although the Eastman Kodak people are working on it and hope to be able to take a picture of the stars, as well. As a cheaper means of getting the same thing and making it usable for any kind of celestial object including the stars, they have taken a standard camera. On the front they have mounted a board ahead of the lens which carries the watch and a pendulum instead of the bubble. There is a telescope to look at the moon, sun, stars, whatever you want to take the altitude of. When you have that object on your crosswire, you snap your button and take a picture. That gives you everything on the assumption that your celestial object is on the crosswire and on the base line so you have a picture of your object. That instrument will come out very shortly as a commercial proposition and will undersell the ordinary sextant.

The advantage for the sea-going man is that you need no horizon. It has its artificial horizon. For aircraft, where it is hard to use the natural horizon, it is good where the horizon is obscured. It is also good not only over the sea, but also over the land when you can't see anything under you, providing the fog is so you can see over the top of it. If you get over the top of the fog, you can find out where you are just as well. In that it has its assistance in flying over low clouds or fog even over land.

The second phase of it was a question of developing a quick means of solving the celestial triangle to determine your position from altitude. It is worked out by switching the astronomical triangle around, turning it up-side-down. Pierce has worked out a set of tables which, after a couple of hours of practice, anybody can work out a line of position from, including the bearing, in 30 seconds. It requires only two entries on a table and two additions.

QUESTION: How long does it take to have your picture developed?

MR. WICKS: On taking the picture, you take your sights in about ten seconds, take five or ten of them just as fast as you can snap the trigger, and it takes a minute to develop the film. So you can get your position, or line of position, in two to three minutes after you take hold of your sextant.

That question of the tables is one that he has spent many years on and he has developed several sets of them. He wouldn't put anything out until he had what he considered the best to be obtained. He is now in Washington arranging with the hydrographic office to have the tables printed, and other special tables for aviators. For that reason he couldn't be here today. He should be talking to you about it; however, I will give you a line on what he is doing.

His third proposition is to solve the position by means of mechanical apparatus which requires no books, whatever, for a solution of the star, not even a nautical almanac. All he needs is time and the instrument to find his position. When he uses the sun or moon he has to have his nautical almanac in order to get his declination.

The question of time has been overcome to a large extent because we now have watches which will keep sidereal time and local apparent time. Those watches are set at Greenwich sidereal time and Greenwich apparent time. Before you start your flight, you take your picture, read your time and hour angle direct in the watch, with no fooling around with finding the time which has always been the bugbear of the navigator. As I told the Commander, the only thing I had against him was that he didn't do it 20 years ago to make it easier for seafaring men.

CHAIRMAN HUNSAKER: Thank you for completing our records.

To go back to our radio beacon service, that is the interesting and new thing that is going all over our airways. It makes a very important contribution. The question as to whether the general scheme and type are satisfactory, I think, has been answered by the work done today. There is one question I would like to throw out. Perhaps some of you have an idea. That is the new radio device which obtains measurement or effect by comparing amplitudes. The question is, what will be the effect of fading; if the fading takes place to a degree on both modulations, there may be no effect; but if the fading is at all selective would it not cause a shift of the equal symbol zone to one side and the other?

DR. J. H. DELLINGER (Bureau of Standards, Department of Commerce, Washington, D. C.): We discovered that just a year ago and made some study of it. In the mountainous area, the Bellefonte sector between Cleveland and New York, such fading will affect the accuracy of the directive beacon at instances of 50 miles and up at times at night. So the beacon system will have to be used with caution at night particularly in mountainous areas. We have made some trials in other areas where the topography is more ordinary, and get very little of that effect.

Furthermore, the effects mentioned, caused by fading in distances which were concerned, that is distances less than 150 miles, are essentially caused by interference between the radio wave along the ground and that which goes up to high levels in the atmosphere, and is reflected down by changed conditions in the upper atmosphere; so that the fading is an interference phenomena between the ground wave and sky wave, and is only evidenced differentially between the two beams when you are dealing with an antenna somewhat directional, and thus receive differentially the ground wave and sky wave. We have made only a few tests but we have some evidence now that by the use of this vertical antenna, which does not receive very much of this wave which is reflected down, does not receive much vertical, only horizontal components, and it is practically ineffective. So it seems as though this vertical antenna has largely solved the question of possible errors due to fading. I can't say positively that this has been done, but there is every evidence so far that it is true.

That is one of the main reasons, in fact, why we proceeded to the use of this short vertical antenna. The shorter the antenna, the less intensity it receives, so you are sacrificing something when you use so short an antenna and have to compensate by increased amplification which brings in more intensely additional services. You have to do a better job of shielding your apparatus, but a little expenditure for electrical shielding seems well worth while if it does relieve us from possible directive errors.

COLONEL H. E. HARTLEY (New York): I would like to inquire if there is any impairment of the range of this very wonderful visual signalling?

CHAIRMAN HUNSAKER: Where the range is as great visually as aurally?

COLONEL HARTLEY: Yes, from the ear phones. I can recall cases where pilots have absolutely thrown down ear phones in disgust and almost stopped the progress of any radio advance on the plane. I certainly think it is wonderful to have this visual signalling to the pilot instead of through the phone. I am

wondering if we are not giving away something, perhaps the range, or we have to resort to too much shielding.

DR. J. H. DELLINGER (Bureau of Standards, Department of Commerce, Washington, D. C.): You have to provide some shielding. As far as the range is concerned the use of the visual indicator is a gain over the aural system because it discriminates better against interference. You have not only your electrical tuning and receiving set, but also mechanical tuning in the vibrating reed. Therefore, it does not respond as much to atmospheric and other disturbances and any lack of sensitivity you can compensate. The receiving set is supposed to do that. The distance range you get depends entirely on the ratio of the effect of disturbances of the receiving set and the desired signal. This discriminates better against disturbances and therefore the distance ranges are better than the aural system.

This particular means of visual indication was the result of quite a long series of experiments. A good many other types have been tried out. Perhaps this isn't the best answer, but it is by far the best of any we tried out.

MR. RHEA (General Electric Co., Schenectady, N. Y.): Have you automatic amplitude control on these reeds?

DR. DELLINGER: As the pilot proceeds along when the deflection gets too large because of getting closer and closer to the object, he turns it down, brings it down to a convenient amplitude. It looks as though it is quite possible to develop automatic amplitude.

MR. RHEA: May I ask what is being done to bring the pilot down after he has found the airport?

DR. DELLINGER: Well my reply would be, not much. There are a lot of possible schemes. I don't think it is worth while to go into that, Mr. Chairman. It will make a fine subject for somebody to give a paper on two or three years from now.

CHAIRMAN HUNSAKER: It has nothing to do with safety yet.

DR. DELLINGER: There are a number of things being developed that are more or less hopeful, but none has given much service yet and it would be a long story and hardly worth while.

W. PARKER PERRY (Somerset, N. J.): Is there any way of propagating radio waves in one direction other than with one wire or loop aerial?

CHAIRMAN HUNSAKER: You can have an array of wires such as a Marconi system. You know, all waves are supposed to be reflectable from a polished metal surface. Working on that principle, if that is true, then a reflector with the aerial focused in the reflector would logically send out a beam somewhat similar to a searchlight of invisible waves. Is that true?

DR. DELLINGER: I will just say in a general way more directive antennas can be used than the one we are using here, and it may well be that an improvement will be using a more directive antenna, and reflectors, as you say, can be used effectively in directing radio-waves. I don't know yet whether it will be worth while or not.

CHAIRMAN HUNSAKER: Isn't the reflector matter limited to short waves because of the physical dimensions?

DR. DELLINGER: It is harder and harder the longer the wave.

JOHN B. KOHLER (Chicago, Ill.): In the discussion of the fixed radio beacon with direction finder on the plane, the discussion was entirely along the line of a single beacon. Has anything been done in using a combination of numerous beacons spaced at widely different points to get different bearings on a series of different fixes?

CHAIRMAN HUNSAKER: We were shown a map where there were 15 or 20 airports with beacons at them.

MR. KOHLER: I have in mind a fixed beacon, not a series, along the route so a

pilot with his direction finder on the plane can get a series of definite fixes along the route through the combination.

CHAIRMAN HUNSAKER: That is more marine navigation.

MR. KOHLER: Yes, marine navigation.

DR. DELLINGER: You can do it analagously, the way a ship does. When discussing direction finders, it is a very expert job to use it. It is less sensitive than a receiving set. You have disturbances affecting sensitivity and direction and it is very difficult to use under practical conditions. I do believe they are going to be used, but on account of the difficulty, I don't know.

DR. LANGMUIR: A question about the distance markers. Is that affected by the third vibrating reed and the indications obtained when that rises to maximum and falls?

The Idea Behind the Marker Beacons

DR. DELLINGER: The idea of the marker beacons is this: (It isn't the only way it can be done; it is one way.) The pilot flies along, keeps on his course by observing the two white lines remaining equally as to length. If he gets off to the side one gets longer and he comes back. There is a third reed near by, tuned to another frequency characteristic of marker beacons. Normally it doesn't vibrate. We have every 20 miles this little low power transmitting set. When it gets within perhaps five or three miles, whatever is found most convenient for the pilot's use (say five miles) he begins to see this little white spot widen out. It is beginning to vibrate. It rises up to full amplitude when it is exactly over the point when the signal is being sent and falls off; so for a period of five or ten minutes he is getting gradually increasing and decreasing indications that he is flying over such-and-such a point. Probably that won't be just a constant deflection, but will be rising up and back again in accordance with the characteristic dot and dash arrangement. Whether that will be before him for one minute or ten minutes, it remains to be determined what will be the most useful.

PROFESSOR W. F. DURAND (Leland Stanford University, California): How much energy are you putting into those radio beacons at the present time?

DR. DELLINGER: The directive beacons are being run on one kilowatt. The marker beacons at 5 watts.

CHAIRMAN HUNSAKER: I suppose there is theoretically another form of beacon we haven't mentioned that would be equivalent to a lighthouse. That is, one which would give a distinguishable signal for various degrees of azimuth. That wouldn't be a beam signal at all. Have you considered that type of beacon?

DR. DELLINGER: I take it, that it would have to be a beam signal, otherwise you couldn't distinguish azimuth.

CHAIRMAN HUNSAKER: Perhaps a multiplicity of beams, a whole star-shaped array from every five or ten degrees you get a signal, so an airman then flying along would get the signal of a character which would tell him the line of bearing.

DR. DELLINGER: I should imagine the transmitting outfit would have to be rather complicated for that. Of course, the same thing is accomplished by the rotating beacon.

CAPTAIN C. F. HINGSBURG (Chief of Airways, Department of Commerce, Washington, D. C.): The system you speak of, I believe, has been in operation in England.

CHAIRMAN HUNSAKER: The rotating beacon?

CAPTAIN HINGSBURG: No, the one having distinguishable beams rotating with changed characteristics on each point.

CHAIRMAN HUNSAKER: That is a rotating beam, isn't it?

CAPTAIN HINGSBURG: But a change of characteristic as it goes around the compass.

CHAIRMAN HUNSAKER: Yes, I understand they have experimented with that.
COLONEL H. E. HARTLEY (New York): What would be the total weight, roughly, of the receiving apparatus necessary to operate one of these beams?
DR. DELLINGER: Twenty pounds, including the batteries and everything.
COLONEL HARTLEY: That is very remarkable.

ADJOURNMENT

Aids to Navigation

(Continued)

REAR ADMIRAL W. A. MOFFETT, Chairman
Chief of Bureau of Aeronautics, Navy Department, Washington, D. C.

The second session was called to order at two-fifteen o'clock by the Chairman, Rear Admiral W. A. Moffett.

CHAIRMAN MOFFETT: I feel particularly fortunate in my duty as Chairman to be able to introduce two officers of the Service—one of them formerly of the service and one in the service at the present time—both very distinguished. One I have had the closest personal relations with for a great many years and I am glad to see him now directly connected with aviation.

The two papers we have to read, I am sure, will do a great deal of good when published. We will listen to what is said with much interest, and will first have the pleasure of hearing Dr. J. C. Hunsaker who needs no further introduction.

Communications as an Aid to Safe Flying

By J. C. HUNSAKER, D. Sc.

Assistant to Vice-President, Bell Telephone Laboratories, New York City

Is flying safe? Is it safe enough? The answers to these questions are yes and no, with reservations depending upon what sort of flying is meant. So far as concerns aircraft and engines, we must agree that flying, under favorable conditions, has now demonstrated a commercial degree of safety and reliability. We also must agree that under unfavorable conditions flying has been amply demonstrated to be not only unsafe but highly dangerous. The safety of flying, then is conditioned upon circumstances. The relation between an aircraft in flight and the circumstances which govern its safety is largely dependent on communication services.

To fix our ideas, I have somewhat arbitrarily classified flying in what follows but have left out of account acrobatic and exhibition flying, flight instruction of students, naval and military formation flying and maneuvers. Such flying will always be inherently dangerous but under proper regulation need not endanger the public.

Short Flights

Flights of less than one hour's duration in the vicinity of a landing field (sight seeing trips) are usually the public's first introduction to the delights of flying. Such flights are unscheduled and performed in daylight and in fair weather. A flight begun under weather and visibility conditions evident at the start can be completed before dangerous weather develops, due to the fortunate tendency of our weather to persist or to change slowly. There is no need for radio communication between the airplane and the ground, and it should be sufficient for the landing field to be in possession of the Weather Bureau's morning weather report and general forecast. If the nearest airport issues a short range forecast of local weather, this can be obtained by telephone, and used to determine whether flights should be repeated. A commercial telephone connection is all that is needed.

Short cross country flights and taxi trips of less than two hours duration

require knowledge of weather and visibility conditions at the terminal field. This information can be obtained at the start by a commercial long distance telephone call and it is unlikely that the weather will change greatly during the flight.

Similarly, scheduled flights of less than two hours' duration along an airway may depend upon commercial telephone service to avoid unpleasant surprises due to bad weather. Such point to point communication service between landing fields is an essential of all flying that leaves the vicinity of the home port.

Long Flights

Scheduled flights of more than two hours' duration along an airway, especially at night, and long cross country flights are relatively unsafe unless adequate communication services are provided. A ground organization is required which will collect by wire at frequent intervals weather data from points along and to the side of the airway and which will, from this data and the general weather map, prepare short range forecasts of local weather. This special forecast of flying weather is supplied the pilot when he leaves and a revised version should be transmitted to him by radio enroute. When approaching his destination the pilot should obtain by radio from the terminal airport the actual visibility and landing conditions there, and he may consult as to the relative safety of attempting a landing or proceeding to some other landing field.

There is, therefore, required to safeguard long flights from the dangers of bad flying weather, a comprehensive ground organization to collect weather data over a wide area and a radio service to transmit the results of such collection to planes in flight.

This is no place to discuss the growing ability of modern aircraft to survive in bad weather. Every improvement merely increases the number of days per year that flying is possible. There will always remain, however, especially in the winter months, a discouraging number of days and nights when flying is unsafe.

Scheduled flying becomes commercially impractical in the face of uncertainty. Safety is, of course, obtained by cancelling scheduled flights, but operations cannot be suspended indefinitely. More exact knowledge of weather would enable disturbances, fog, etc., to be localized and flights to be got through in safety avoiding the really dangerous times and places.

Short Range Forecasts

Meteorological science is able to forecast weather phenomena with a high degree of precision provided data describing present and past weather can be collected from a sufficient number of places. The collection of data is a problem of the communication art.

A full scale meteorological experiment is now being conducted in California in cooperation with the Weather Bureau by the Guggenheim Fund for the Promotion of Aeronautics and the Pacific Telephone and Telegraph Company, one of the Associated Companies of the Bell System. About forty observers are now reporting weather by telephone to the Los Angeles and Oakland airports five times a day. The collected reports are exchanged and airplanes starting over the airway are provided with a forecast of the weather they may expect to meet enroute and upon arrival. On the basis of these forecasts, it is hoped that the pilots may be able to avoid bad weather by choosing an alternative route or by selecting the terminal field where weather conditions are more propitious. Both Los Angeles and the San Francisco Bay region have several airports and there are two routes between them, one up the valley via Bakersfield, and the other the more direct line to the west.

In the East, weather data from observers in New Jersey and Pennsylvania is also being collected at frequent intervals by the meteorologist at Hadley Field employing a somewhat similar method of sequence operation of the long distance telephone lines.

Point-to-Point Service

In addition to the problem of collecting weather data, there is the closely related matter of distributing local weather reports and forecasts between airports. This is a point-to-point service and may be accomplished by a special radio telegraph network, by commercial telegraph or long distance telephone, or by a private or leased wire service, either telephone or telegraph. Local conditions, rates and volume of traffic determine which type of service should be provided.

Besides its use for weather messages, there is need for point-to-point communication between landing fields along an airway to follow the progress of an airplane and its passengers and cargo. Such a despatching service is somewhat analagous to that of a railway and is a necessity if connections with trains and other aircraft are to be met.

The present airways are laid out with intermediate landing fields spaced at short intervals upon which planes may land when forced down by weather or mechanical trouble. Such landings are infrequent and will presumably become increasingly rare. However, when a forced landing does take place, instant communication with the nearest airport becomes a very urgent matter, involving the passengers, the mail and the air transport company. Telephones are now provided at these intermediate fields by the Department of Commerce and kept available for such emergency use. The same telephones can be used, in addition, for the routine collection of weather data.

Communication between terminal landing fields or airports on certain airways is now handled by radio telegraph and on others by long distance telephone. Neither system is ideal. Radio telegraph is slow and is often unreliable in times of bad static when weather messages become urgent. It also takes up radio channels needed for communication with planes. Moreover, a telegraph operator must be constantly listening throughout the 24 hours even though messages come infrequently. Commercial wire telephone service while generally fast and reliable gives no written record of the messages passed. Long distance telephone service does not economically repeat messages at other and distant airports which may be interested. For example, the weather at Cleveland is of interest both to New York and Chicago Air Ports. Likewise the time of departure of the New York air mail from Chicago is of interest to all terminal fields enroute.

An ideal system which is instantaneous and reliable, repeats messages at all airports, is free from interference, takes up no radio channels, and furnishes a permanent record of all messages at all airports, is the telephone typewriter or printer service developed for the use of business houses with branches scattered over the country.

To apply the telephone typewriter to an airway requires the installation of keyboard transmitting and tape printing apparatus at terminal fields and their interconnection by a private wire circuit. Then anyone familiar with a typewriter may type a message which will appear on the tape fed automatically from the apparatus at every other connected point. No one is required to be in attendance to receive the messages which are typed automatically under the control of the sending station. The receiving operators are thus free to attend to telephone calls from intermediate fields, operate radio telephone service to airplanes, radio beacons, lights, or to carry on whatever duties may be assigned them. Telephone typewriter equipment has been installed between Oakland and Los Angeles with drops at Fresno and Bakersfield.

Radio Service

An aviator leaving an airport should be given information of the weather along the airway ahead of him and a forecast of the nature of probable changes during the time of his flight. If general weather conditions are settled, or if his flight is a short one, such a forecast is entirely adequate. However, for long flights and at times of uncertain and threatening weather, it is important to keep the pilot advised by radio during the flight of the weather conditions he may expect. In particular, visibility and landing conditions at the airport where he expects to land and storm warnings are required.

Weather and landing advice can be broadcast from each airport along the airway. Provision of radio transmitters at airports and receiving sets in the planes will make possible a simple one-way system of communication and will permit any number of planes in the air to be advised without confusion. European practice, however, has not developed a broadcasting service along this line but has evolved a two-way system in which the pilot of the airplane talks with the nearest airport. Such a system has obvious advantages where it is desired by an air transport company to control rather than advise its planes. The obvious disadvantage lies in the fact that, on one radio channel, the airport can converse with but one airplane at a time.

This two-way system has the great merit of permitting the pilot to discuss the weather outlook with the airport meteorologist, to consider alternative landing places in view of his remaining fuel supply, direction of wind, etc., to decide on a change in landing place and to make necessary arrangements there to care for his passengers and mail.

It seems reasonable to predict that operators of air transport fleets will want two-way communication with their planes in flight, while taxi services and private owners without ground organization along the airway will be content with a public one-way or broadcasting service.

Whether one-way or two-way communication is desired, it appears that, for plane to ground use, radio telephony, as distinguished from telegraphy, will be essential. Radio telegraphy requires the individual attention of a special radio operator on board the plane for sending and receiving. While very large multi-engined passenger planes will certainly carry a relief pilot in flight, it is doubtful whether good commercial pilots can be made into good telegraphers and vice versa. Telegraphy has the advantage of longer range with the same transmitter power and can be read through a higher level of interfering signals and acoustic noise on board. For long distance over-sea flights and for expeditionary purposes the radio telegraph has, without doubt, preponderating advantages from a power-distance point of view, aside from the convenience of communicating with surface vessels enroute. For regular service on established airways, however, the telephone is undoubtedly superior.

Goniometry

The perfection of facilities for communicating weather and landing information to planes in flight, which will enable them to operate with safety under relatively unfavorable meteorological conditions, will greatly stimulate the demand for improved aids to navigation. It seems to be established that flying under conditions of poor visibility, when landmarks are totally obscured and beacon lights are useless, requires some form of radio goniometry if the pilot is to find his way through. A number of systems have been proposed for this purpose. The London-Paris airway is equipped with radio direction finding equipment on the ground by means of which the position of planes can be determined on request. The disadvantages of this arrangement lie mainly in its relative slowness and its lack of

traffic capacity. The radio beacon of the type being developed by the Bureau of Standards, giving an equi-signal zone which can be observed by the plane, is free from these objections but is subject to the disadvantage that it indicates a straightline course which cannot always coincide with the airway and further it is of little value if detours to avoid storm centers and foggy areas are required. Another system, a recent development of the British Royal Air Force, employs a rotating loop transmitter at the ground stations. The plane obtains its bearing with respect to the transmitter by means of an ordinary receiving set and special stop watch. This system is relatively slow but permits the pilot to navigate as he would if one or more beacon lights were visible. All of these various methods of goniometry have special advantages and disadvantages, and occupy more or less of the valuable and restricted ether space. The evolution of the system which is most satisfactory will be a matter of time and will require close cooperation on the part of all factors in the industry.

Future Development

It seems evident that commercial aviation in this country requires and should have for the regularity and safety of its flying operations as, indeed, for its commercial survival, a wire service on the ground, a radio beacon service and a radio telephone service. The wire service can be obtained from the existing communication companies and needs no discussion here.

It remains to consider whether a radio beacon service and a radio telephone service at all the airports over the country can be made practicable without jamming one another. The frequency bands available are rapidly being occupied and the definite space reserved for the airways is likely to prove very inadequate at an early date. As our airports become equipped with modern radio apparatus, we may expect serious interference, which can only be eliminated by the assignment by Federal authority of communication channels additional to those now reserved.

While radio communication appears to be essential to the safety of the public when flying on long distance commercial routes, today American aircraft are not provided with radio. The provision of a proper radio service will take time and can only follow the ground organization. Evidently the installation of radio apparatus in airplanes cannot be insisted until the airports are equipped to broadcast weather information which has been collected by wire and digested by competent meteorologists.

Legislation to require radio apparatus in certain airplanes will no doubt parallel similar legislation for shipping, but any consideration of such legislation would be futile at this time. We must first have public airway wire and radio services. This part of the problem is analogous to that of the Lighthouse Service of the United States and, within the limit of funds appropriated by Congress, a practical solution is being approached.

Though not yet required, it can be predicted that at busy airports there will soon arise a need for radio means to control precedence in the take off and landing of airplanes. This virtually amounts to traffic control and can be accomplished by low power two-way radio telephone. Planes wishing to land will announce themselves and remain aloft until landing at a designated part of the field is directed by the airport manager in the control tower.

Transoceanic Flying

The foregoing discussion has all been based upon present conditions and tendencies of commercial aviation within the continental limits of the United States. Transoceanic flying has not yet been exploited commercially. A number of air-

planes and seaplanes have attempted to cross the Atlantic, with varying degrees of success. There have been three attempts by rigid airships, all of which were successful. Of the airplane attempts many have never been heard from again. The successful contenders have waited for weather, have left at times considered by them to be as favorable as might be expected, yet practically all have reported bad weather encountered and arrived with little fuel. The area covered is so large and the time of flight so long that it seems unlikely that a forecast given at the start can hold good until arrival.

Frequent reports of ocean weather could, of course, be transmitted by radio to an airplane in flight, but a report of bad weather ahead is of no help to an airplane with only a few precious gallons of fuel remaining to reach land. The North Atlantic is so wide that bad flying weather may be assumed to exist somewhere on the course at practically all times.

To fly the Atlantic safely and regularly appears to require such a margin of fuel or flight radius that localized bad weather may be avoided by alteration of course. Otherwise one gambles with weather. Existing cable facilities can be organized to collect weather data from the shores and islands of the North Atlantic from the West Indies to Labrador and from the Azores to Iceland. Existing radio services can collect weather data from the ships at sea. From such collected data a weather disturbance can be located and tracked. Frequent reports and forecasts transmitted by radio telegraph would give the commander of a Transatlantic airship the data from which to draw his own weather map and on it to select his course with confidence that he is avoiding trouble.

It can be argued with some force that, by means of adequate communication, a Transatlantic airship can be made safer than a house on shore. With a margin of endurance of a day or two beyond that required for the direct crossing, and with modern communication facilities giving the airship a thousand eyes scattered over the sea, a severe weather disturbance can always be avoided. No amount of surplus endurance nor radio warnings will save the house on shore from a twister. Being fixed, the house gambles with the weather, but fortunately its chance of survival for many years is good merely because the track of a tornado is narrow.

An airplane at sea has a very slight margin of endurance and is in an unfortunate situation. It must hold its course in order to conserve fuel. Either the weather on the course is good or it is not. Fog, sleet and gales have been, without doubt, responsible for the deaths of many aspirants for Transatlantic laurels. Definite knowledge of the meteorological situation can, if the effort be made, be supplied by modern communication agencies, but the weather itself cannot be altered. Safety is, therefore, to be secured by choosing a course to avoid trouble. To do this one must have adequate communications combined with a large margin of flight endurance.

CHAIRMAN MOFFETT: I was told when I was asked to act as Chairman here that they were very anxious to have discussion following the papers, and some one remarked if the paper was read with no discussion and no further light, we might as well let them print them for us and send them to us so we could read them at home. I hope in the time we have allowed that those present will discuss what has been said by Dr. Hunsaker and criticize or offer further suggestions you may have to make.

LIEUT. A. F. HEGENBERGER (U. S. Army Air Corps, Wright Field, Dayton, Ohio): I would like to ask him if he knows of any agency now trying to organize the broadcast service so that they will broadcast the weather?

DR. HUNSAKER: The gentleman on your left is equipping our airways very rapidly to broadcast the weather right across the transcontinental airway.

CAPTAIN C. F. HINGSBURG (Chief of Airways Division, Department of Commerce, Washington, D. C.): We have listened with a great deal of interest to the discussion presented by Dr. Hunsaker on communications of various kinds. That is a problem which we are confronted with right now. The Department is getting delivery on twelve 2,000 watt broadcast sets and nine radio beacons which will be installed before the end of this year. It is our responsibility to determine the plan on which these facilities will be operated.

Radio direction and radio communications are interrelated, owing to the fact that frequencies must be assigned to the various types of facilities and weather, for that is what we are embodying to the pilot and is also connected with the same problem. In order that the plans of the Department may be more fully discussed and in order that we may get some of the benefits from the discussion which will ensue, I have prepared a paper covering the discussion of weather information and communications to aircraft which I would like to read if I may.

CHAIRMAN MOFFETT: Certainly.

Discussion of Weather and Communications From an Airways Maintenance Point of View

By F. C. HINGSBURG

Chief Engineer, Airways Division, Department of Commerce,
Washington, D. C.

Weather is one of the uncontrollable factors that seriously affects the reliability and safety of air transportation and, therefore, influences the air navigation facilities that must be provided on airways. Candlepower and spacing of lights, as well as location of intermediate landing fields, are determined in conjunction with the study of weather conditions encountered on an airway route. An adequate weather service and communications system, in addition to aids to navigation along the airway is essential for the full development of a dependable and safe air transportation system. The establishment of safety aids essential for this purpose has been authorized by the Air Commerce Act of 1926.

Airway facilities may be classified into two groups: first, the facilities designed to make flying feasible and safe under conditions of poor visibility and thick weather and second, the safety aids that are required to bring airplanes safely to a well-lighted and equipped landing field when hazardous weather conditions are encountered.

Radio Direction for Thick Weather Flying

The aids to navigation established on an airway should make it possible for airplanes to maintain a high degree of flying efficiency. The airway routes are laid out to follow the best flying country and equipped with a lighting system of closely spaced lights that permits flying in moderately clear weather. Radio-range beacons are essential to guide airplanes over the lighted route when the lights are not visible one from another. Radio-range beacons for the guidance of airplanes flying the Transcontinental route are now being installed. Two radio-range beacons are in operation experimentally and six additional stations are under construction. By the close of 1928, radio-range will mark the lighted airway between Hadley Field and North Platte. The radio-range beacons are being installed at the middle points of straight stretches of lighted airways and the range signals extend in both directions along the course.

The stations will be located at Hadley Field, Bellefonte, Cleveland, Goshen, Sterling, Des Moines, York and Gothenburg, marking a continuous route by a

series of straight courses. The radio-ranges will intersect at Ringtown, Clarion, Toledo, Lansing, Cicero, Grinnell, Ft. Crook, Kearney and North Platte, at which points marker beacons will be installed to mark the turning points in the airway courses. Each Radio-range will have a definite characteristic so as to identify the course flown, and will take the airplane over the lighted airway, giving the pilot full advantage of lights, landing fields and landmarks, which may be visible at close range.

Typical characteristics of radio-range signals are as follows:

- (a) Dash Dot
Dot Dash
- (b) Dash Dot Dot
Dot Dot Dash
- (c) Dash Dash
Dot Dot
- (d) Dash Dash Dash
Dot Dot Dot
- (e) Dash Dot Dash
Dot Dash Dot

The radio-ranges are never shifted and can be operated continuously, thereby serving any number of airplanes flying the route in either direction at any time. The greatest service would be rendered and absolute confidence in instrument flying developed when the pilot appreciates that the radio-ranges mark definite unvarying courses over the safe lighted airway and radio-range signals intersect on fixed landmarks. Instrument flying over airways must develop as a necessity to maintain a high percentage of flying efficiency and can be accomplished with safety, but blind landing at airports and terminal fields is not yet an assured accomplishment. Airport terminals along the route may be marked by a system of radio marker beacons or leader cables to bring the airplanes directly above to the landing field, but it is very evident that reliable radio communications to aircraft is required to advise the pilot as to landing conditions at terminal airports. Should landing at the terminal become hazardous due to fog or thick weather, the pilot may be advised regarding landing conditions at alternate fields and the airplane brought down safely elsewhere. There would be no justification in flying blind by instruments over an airway unless a safe landing is certain at the completion of a trip.

Present Weather and Communications System

Under the Air Commerce Act of 1926, the Weather Bureau is the responsible agency for collecting and disseminating weather information. The Airways Division operates in connection with the Weather Bureau in disseminating weather information along airways. The Weather Bureau maintains personnel at the principal airports to analyze and interpret weather reports. The Airways Division now maintains twenty-eight radio stations for the exchange of weather information and dispatch of airplanes; this service being supplemented by telephone and teletype communications. The present system of weather information is the expansion of the system initiated by the Post Office Department, which has served for more than 10,000,000 miles of flight, and has established a fine record of performance. Nevertheless, the system cannot be considered altogether satisfactory. The pilot receives the weather information and forecasts before taking-off and concerns himself with weather conditions he may encounter three or four hours hence at points 300 or 400 miles distant, whereas, the bulk of his information turns "stale" and unreliable thirty minutes after taking-off, due to rapidly changing weather conditions. An adequate weather communications system should convey to the pilot enroute the changes in weather and landing con-

ditions, giving him reliable information as of the moment. It is, therefore, considered that radio communications to aircraft is the solution of the weather problem.

Radio Telephone Communications

Great progress has been made during the past year in the development of radio communications to aircraft. On the Transcontinental Airway, two stations have been in operation experimentally for several months, and twelve additional radio telephone transmitters are being installed at Cleveland, Bryan, Chicago, Omaha, North Platte, Cheyenne, Rock Springs, Salt Lake City, Elko, Reno and Oakland. By the close of 1928, these radio stations will have been completed and a new system of control of airways operation will be initiated. The radio telephone transmitters are of 2,000 watt capacity, broadcasting voice on 900 meters, with a reliable range of 125 miles. Apparatus for fifteen additional stations is on order for delivery seven months hence, and the additional stations will be established along other routes on which night flying takes place. In addition to the foregoing, a radio-beacon and communication station is now being established at Key West for the Pan American Air Mail Service.

New System of Weather Communications

An entire new system of weather communications service is under consideration to develop the greatest utility from the new radio telephone facilities now available, and it is proposed to introduce this system on the Transcontinental Airway, using the stations now under construction. This system promises the degree of safety required by air transportation on a basis that permits unlimited traffic. Timely and accurate weather and landing conditions will be made available to any airplane, airport, landing field, or individual, that cares to tune in. The information will be broadcast on hourly schedules. Any airplane equipped with a radio receiver similar to the apparatus installed for the reception of radio-range signals will receive weather information at any point within the sector.

The Transcontinental route will be divided into six sectors, with control centers at Salt Lake City, Omaha and Cleveland. The Weather Bureau, as well as the air transport companies, have their principal offices at these points. Two weather sectors will be controlled from each control center. The six weather sectors are San Francisco-Salt Lake sector, and Salt Lake-Cheyenne sector, which are controlled from Salt Lake City; Cheyenne-Omaha sector and Omaha-Chicago sector, which are controlled from Omaha; Chicago-Cleveland sector and Cleveland-Newark sector, which are controlled from Cleveland. Each sector will have three radio communications stations, located about 200 miles apart and which will be connected by leased telephone lines for chain broadcasting so as to cover all points within the sector.

The weather service, forming the basis of this new system, is founded on the regular weather reports gathered by the Weather Bureau throughout the United States each morning and evening, supplemented by a secondary net of weather reports gathered at intervals of three hours from critical points in the vicinity of the airway route and further supplemented by hourly reports of weather and landing field conditions from intermediate landing fields located sixty miles apart along the airway. The weather reports are gathered at the control centers and weather information and landing conditions along the routes are broadcast once each hour.

In order that the proposed system may be more clearly described, let us consider the service rendered to an airplane leaving Hadley Field, at 9:35 P. M. for Chicago, with a mail stop at Cleveland and due to arrive at Chicago at 5:35 A. M. The control point for the two sectors involved is located at Cleveland.

Radio stations with telephone transmitters for voice communications to the pilot on the Cleveland-Newark sector are located at Cleveland, Bellefonte and Hadley Field, and are connected with leased wire telephone for chain broadcasting. The sector between Cleveland and Chicago is likewise controlled from Cleveland.

A radio operator is in charge of each radio station along the airway and an additional operator at Cleveland is in charge of the leased wire telephone and microphone lines which are controlled from Cleveland. Two-way voice amplifiers are connected along the telephone line, and the circuits are properly balanced by the telephone company for the service to be rendered. Telephone loops are connected to the leased wire telephone at the principal intermediate landing fields located approximately sixty miles apart. On the Cleveland-New York sector, these points are located at Northampton, Park Place, Numidia, Bellefonte, Snowshoe, Clarion and Mercer. The weather reporters located at the intermediate fields and critical points along the airway telephone weather data on sequence schedules to the Cleveland operator, starting at fifteen minutes before each hour. The reports are taken over the telephone and typed in triplicate on prepared forms, one copy goes to the operations manager of the air transport company, and one copy to the Weather Bureau representative, who analyzes the data and interprets the conditions. The Weather Bureau prepares a fifty word statement covering their interpretation of weather conditions based on the primary and secondary nets together with the data gathered along the airway. The Weather Bureau keeps track of the movement of storm centers and, from the weather data collected hourly along the airway, determines the time when storm centers will move across airway routes. On the even hour, the Cleveland operator broadcasts the sector weather and landing data followed by the Weather Bureau statement, and in addition, such orders as may be necessary from the operations manager to the airplane pilot in flight.

At fifteen minutes after the hour, the Cleveland operator gathers weather data over the Chicago-Cleveland sector from intermediate landing fields and reporting stations located at Chicago, Lansing, Lakeville, Bryan, Toledo, Vickery and Sandusky, and delivers copies to the operations manager and Weather Bureau representatives. At thirty minutes after the hour, the Cleveland operator broadcasts over the Cleveland-Bryan-Chicago chain of stations followed by the Weather Bureau statement and air transport company orders.
