CHAIRMAN HASSE: We are mighty happy to have so representative a gathering as we have here today. While we are known as the baby section of the National Safety Council, nevertheless, those of us who gathered in Detroit at the time the Food Section was organized, more or less feel today that we are going to be, eventually, one of the leading Sections. Every year we have increased our membership just a little bit, which means that in the end we are going to have practically every food industry in the United States in our Section, and that is what we are aiming for.

As the first subject on our program this afternoon, I am going to ask the chairman of our Statistical Committee, Mr. Prouty, to read his report to you.

Report of the Statistical Committee

By RALPH E. PROUTY

Chairman

The duties of the Statistical Committee are described in a pamphlet prepared by the National Safety Council and may be summarized as follows:

1. To assist the headquarters staff in securing from the section members accident data to be used in compiling the annual accident experience.
2. To prepare an accident cause classification chart, have it reviewed and finally approved by the members of the section for local use.

The chairman of the statistical committee last year reported at the Chicago Congress the submission of accident data by 63 establishments representing 20,928 employees for the calendar year 1926. It is pleasing to report that 121 establishments reported for 1927 and this is an increase of 92 per cent. This is indeed gratifying as the dependability of statistics increases as the statistics increase in volume.

While no attempt will be made to give a detailed comparison of the 1926 to 1927 record it is interesting to note that the frequency rate for the section is 16 per cent lower for 1927 than for 1926 and the average severity rate 3 per cent lower in 1927 than in 1926. Sixty-three per cent of the establishments reporting had lower frequency rate for 1927 than 1926 and 79 per cent had lower severity rates.

From what has been said it is easy to see that the duty of assisting the headquarters staff in securing accident records was not a difficult one. The section members cooperated in a whole-hearted way and it is the belief that each succeeding year will find a larger percentage of the members submitting their records for cooperation in the annual compilation.

Shortly after the Chicago Congress, the Statistical Committee, which was composed of the Chairman, Jerome J. Lyons, John F. Jelke Co., Chicago, Illinois, Charles Prahl, Gridley Dairy Company, Milwaukee, Wisconsin; Frank Smoke, Kellogg Company, Battle Creek, Michigan, and C. J. Strobel, Wagner-Taylor Company, Philadelphia, Pennsylvania, began work on accident cause classification. A tentative classification was prepared by the chairman, sent to each member for

Accident Cause Classification

5

[illegible]

the criticisms and suggestions for improvements, and finally considered complete.

By referring to the cause classification it will be noted that No. 4 is "Power Driven Machinery." It was the thought of the committee that it might be well to prepare a separate machinery accident cause classification on which accidents could be charged to specific machines. Correspondence soon showed that the number of machines used in the food industry was so large that such a special classification would be impracticable. The committee, therefore, presents for your consideration and possible adoption for sectional use a cause classification embodying 20 separate items.

CHAIRMAN HASSE: Now we will go on with the program. You are at liberty to speak as you please. What we want to hear now, is about the best stunt which has been used by the members in their plants during the past year in putting over their accident prevention campaign. Who is going to be the first one to get up and tell us what they did? We are all in this game of accident prevention, looking for further information.

Our Best Safety Stunt During the Past Year

By W. GATES

Peter's Chocolate Company, Fulton, N. Y.

It is common experience that a good record on Industrial Safety can be obtained only through a well organized, general program, which is carefully carried out in all details over quite a period of time.

It is only when a background of such a program exists that special features or stunts are effective. Therefore, in discussing special features, we should bear in mind that they are accessories to the main program.

The mechanical features of safety, such as guards and safety appliances are in general well covered and in the majority of plants are not a cause for worry. The large part of the safety problem is that of making each employee see it as a personal problem.

It is along this line that our special features have been of the greatest help to the general program. Of these, the following have given the best results.

Infections.—In all cases of infections which arise from failure to get first-aid promptly—and this causes nearly all the infection cases—the employee is interviewed by the manager or personnel manager. He is questioned regarding the case and the matter of infections is explained to him. His promise is secured, not only to report promptly to First-Aid in the future, but to urge his fellow workers to do the same. A second case of neglect results in dismissal. This method although in operation a little over a year has produced good results.

Machine Accidents.—Following two rather serious accidents arising from employees injuring their hands by inserting them into moving machinery, a general notice was sent to each employee that anyone putting their hands into moving machinery if detected would be discharged whether they were injured or not. Any employees so injured have been discharged. The inflexibility of this rule is well known and has had a good effect.

Individual Records.—A record is kept of lost time accidents to each employee. A tendency to accidents, as shown by the records, results in a personal talk by the manager on safety and an explanation that employees who do not work safely are a source of expense to the company and are not as valuable as those who do. If improvement is not shown, the employee is dismissed.

First-Aid Records.—A similar record as to individuals is kept on minor accidents which involve only first-aid treatment. These are analyzed for cause and if they

indicate carelessness or inattention, the man is marked for general observation as to his value as a workman. Publicity cannot be given to this record nor can the man be confronted by it, since this would soon have the effect of causing employees to keep away from First-Aid and more serious trouble would ensue. However, there are some indications that an abnormal number of First Aid cases is often tied up with lost time or major accidents and that the employee who has a large number of small accidents is likely to have a major one sooner or later.

In most cases investigation develops the fact that such an employee is not the best type and there are usually other objections to his work. His failure to take the general safety program seriously is often coupled with a failure to carry out instructions on his work faithfully or to take his work seriously. It therefore follows that the First Aid cases in the main give an indication of a poor worker in other respects.

Where the investigation shows that the employee's work is good, the foreman is instructed to pay particular attention to the employee and to see that he improves. The foreman usually knows when the employee goes to First Aid but at any rate he gets a notice of the visit. By watching the recurrence of minor accidents he can make a point of each one. Failure to improve leads the foreman to warn the employee and usually the man becomes a safe workman, in most cases without the necessity of a definite warning from the management.

These four special features in combination with the general program have undoubtedly produced results. We should not wish to give them undue importance in comparison with other special efforts. However, they are fundamental and since they are always in application their effects are constant and not temporary. In these respects they may be more valuable than other types of special safety work.

W. B. COSTER (American Sugar Refining Company, Brooklyn, N. Y.): I want to apologize to the Chair. I really should have brought up this question while Mr. Prouty was discussing his Statistical report. I wonder how many of us here in our statistical work or in our classification or nomenclature of "Lost Time Accidents," go on the same basis. I mean this: In our plant we have a safety committee. We are striving, the same as everybody here, to reduce our lost time accidents, and we have as a definition for lost time accidents, where the injured loses time other than is necessary to obtain first aid. For instance, if an employee is injured at three o'clock in the afternoon and goes to the first aid station, and the doctor passes on the accident and deems it wise that the employee go home, and the man goes home and is away from one to three hours on that day, we classify that as a lost time accident.

Now we entered a contest here some time ago conducted by the Merchants' Association, and we didn't make a very good showing; and I was wondering if the reason we didn't make a very good showing in that contest was because possibly all of the firms who entered that contest didn't do so on the same basis. Was it understood just what a lost time accident is?

So I would like to ask you if it is permissible to poll this room to find out if the majority of us here classify as a lost time accident one where the employee does not report the next day or shift, or if it is figured as such when he loses time on the day on which he is injured?

A: A. CLARKE (Secretary-Treasurer, General Baking Co., New York City): I was on the Merchants' Association Committee, and we went a little further than your classification on lost time accidents. We classified as a lost time accident an accident where a man was injured and went for medical treatment and didn't report back the next day for the same duty. Now a man may be injured and report back for partial duty or some other duty, but unless he reports back for the same duty we figured it as a lost time accident.

W. B. COSTER (American Sugar Refining Co., Brooklyn): In other words, if he loses time only on the day on which he is injured, it is not classified as a lost time accident?

MR. CLARKE: That is the understanding.

MR. COSTER: I wonder how many in this room go by that definition.

C. C. CLEMENTS (Sheffield Farms Co., New York City): I want to add to what Mr. Clarke said in regard to the contest held by the Merchants' Association. We were entered in that contest and were under the impression that if a man returned to work the next day on the same job, it was not to be classified as a lost time accident.

MR. CLARKE: You are right; I didn't mean to convey the impression that it was.

ALEXANDER DIENST (National Sugar Refining Co., Edgewater, New Jersey): We happen to be entered in a contest in the State of New Jersey, and the lost time accidents there are so classified when there is time lost other than on the day of the accident. That is their definition.

CHAIRMAN HASSE: I believe the understanding, so far as the National Safety Council is concerned, is that if a man is injured today and returns tomorrow on his regular job, it is not considered a lost time accident.

Well, who is next? Who has another problem or has something to add?

T. M. LIPPINCOTT (Liberty Mutual Ins. Co., Erie, Pa.): Up in Erie I have a bakery. Some of you people might be interested in it. I have been trying a little stunt and there is a lot of fun connected with it and it has brought results. This bakery was having a lot of accidents. There was a pretty jolly sort of a foreman. I happened to know them all from about 12 years' contact with them, and one of the managers had a toy elephant which stood about three feet high. They named him the White Elephant. And the idea of the contest is that this elephant is the booby prize. The department having the most injuries, not necessarily lost time injuries, but calls to the doctor, for the month, wins the elephant. Now when a department wins the elephant for a month, the foreman of that department comes to the department where they now have the elephant and gets on the elephant and these fellows push the elephant over to the other department. This is usually done at noon hour. And the outcome has been that this company has not only reduced its accidents, but has gone three months without a lost time accident.

CHAIRMAN HASSE: That is what we like to hear. Someone else has a good stunt in his system; who is it?

FRANK T. COLEMAN (Continental Bakeries, New York City): I got a pretty good idea from Bob Clair, who is chairman of the Taxicab and Fleet Owners Section. In one of his news letters he set out a scheme that had been tried in the west, and we have adopted it in some of our bakeries. It is to divide the men into two or three teams and have each man put a nickel a day in a glass jar in the office. At the end of a five weeks' period the team having the least accidents took everything that was in that kitty, plus what the company put in, either a quarter or a third. The only trouble we had was in getting those nickels out of them. If we made it 30 cents a week it sounded like too much, but a nickel a day wasn't so bad. In the plants where we tried it, it went over very well—it was the best safety stunt we had seen this year. But I think the Taxicab and Fleet Owners Section worked that quite considerably through their membership.

CHAIRMAN HASSE: Has anyone else a stunt? Perhaps Mr. Clarke has some sort of a stunt that he would like to tell us about. I understand his company has a very good record.

A. A. CLARKE (General Baking Co., New York City): Well, this is unexpected, Mr. Chairman. I came here to listen. It is quite unfair, I think, in discussing

a contest procedure, or planning a contest, to just say that this is work. I think first that all plants should be put on a similar basis of comparison to make sure that a plan, if expounded to you, would work out satisfactorily.

We have been using numerous ways of promoting safety. We are trying to think of most novel ways. We don't want any so-called straight line track systems. What we do in one plant we don't do in another, and I think sections of the country are different in every way. This year we have used so-called inter-plant contests. The biggest thought we have given to safety this year has been along the personnel program. That is not so much a contest as it is to foster safety from the very inception of an employee's service, to see that the employee has a good foundation; to instill safety as our company believes in safety, right from the beginning. We do all the things that I have heard about. We analyze our accidents. We classify our accidents by employees, by vehicles, by horses, by whatever ways and means necessary to find out the source of trouble. And then when we find out what the source of trouble is we begin some kind of a contest which is practical to the section of the country where the trouble is arising.

At the present time we have 47 plants, and we have these plants divided into groups. Our lowest group consists of about seven plants. We compete each plant against another. We have a banner that we give at the end of every 30 days to the plant in that group that goes through with a perfect score. Last month we had 26 of our plants go perfect through the preceding month without any accident.

CHAIRMAN HASSE: I am sure someone else here has a good stunt we would all like to hear about.

Well, I dislike very much to bring in my own connection. However, we have a man with us today from our Edgewater plant which has operated since March 5th of this year without a lost time accident. Just how that man has accomplished this good record I am not going to tell you, but I am going to leave it up to the man himself. Mr. Schraediger of our Edgewater Plant!

F. SCHRAEDIGER (Corn Products Refining Co., Edgewater, N. J.): As far as the Food Section is concerned I think, from what we had for dinner, it is going to be a success. So Mr. Hasse said to me, "Bill, I am going to have you tell the boys how you did it."

Now Edgewater plant has been an awful problem, as Mr. Hasse well knows, because he once had the same job I have now. It has taken a good many years to put this thing over. Our plant went through six months without a lost time accident. In October, 1924, the Edgewater plant made a record; it went through one month without a lost time accident. That was considered a wonderful achievement. Then, in 1925 we had one accident each month. In fact we had 13 that year. In '26 we had 14, and in '27 two departments went six months without a lost time accident, and one of those departments was the can plant, which was considered wonderful. It was nothing new to see somebody coming from the can plant with a finger cut off, here and there, regularly. And you have an idea what the can plant is with the hazard of the stamping machines. But that has been done away with. This can plant has gone one year and nine months without a single lost time accident. Also the filling department has gone a year and nine months. Furthermore, the entire plant went six months and we have only had three lost time accidents so far this year.

Mr. Hasse wants to know what particular stunts were used. That is something I can't tell you. There were no particular stunts, just the regular fundamental principles of putting up bill posters and having safety committees, and the likes of that. There was one thing that I did; that was to have plenty of patience and perseverance, and a little diplomacy, and above all, personal contact with the men.

Now the first thing to do, according to my way of thinking, is to get hold of your foremen. In a plant like ours some of them have been there 23 years—try to talk safety to them. They resent that, and say, "You can't come here and tell me how to run this department." Tell him you don't want to run the department but want to run the safety end of it. Win him over. You can do it. Of course you have got to have a lot of patience. Some of them won't like that idea at all; but finally I have won them over. Then you want to get him to feel his responsibility; get him to immediately take care of the existing hazards in his department and get rid of them. But you must have the backing of the executives; otherwise you are handicapped. Show them how to work safely, how to build scaffolds, set ladders properly, and teach them how to use tools in a safe manner. That is personal work. This is especially important on a new job, or with newly hired help. Get after them.

Of course, in order to do this it is well that the safety inspector have a good mechanical knowledge and experience. Every safety man hasn't got that, but if you haven't, try to get someone for your assistant who has. Pick one of the men with mechanical ability and experience to do it for you if you can't do it yourself. I naturally have had mechanical experience; I have been a mechanic all the way through the building trades lines. So I could tell them what they ought to do and what they ought not to do. I soon noticed the effect of my personal contact with the workers in this manner. I observed that after a while working safely became a habit with them. I used to take each department separately. Take the pipe-fitters; if they were doing a new installation of pipes I would go over and watch them. If they weren't putting the ladder right, or had no shoes on it, it was up to me to see that the shoes were on. So I finally made them get ladders with shoes on, or have the shoes put on, and showed them how to set a ladder, and if they had a ladder too long or too big, made them get a shorter ladder. I would probably spend several hours in that department, and that is the way it worked out.

But then there is the labor turnover. New men need constant watching. After I got through with one department I followed the other departments. However, I attribute a good measure of this success to your chairman, Mr. Hasse, for his persistency. When he is after a thing he gets it. I am sure he is well known to you gentlemen for his persistency because he has made the Food Section such a success, or at least helped to do it. As you know, he is at the head of our safety department, and if an accident occurred at our plant he would persistently keep in touch with me until he was satisfied that the hazardous condition was changed and a similar accident would be impossible.

So the only thing that I can say of my particular stunt is personal contact with the men and show them how to do it.

CHAIRMAN HASSE: In connection with what Mr. Schraediger has said I might mention that we have, for the past three years, been offering to the plant making the best record throughout the year a safety trophy. This, we find, has added a good deal of pep to the boys around the plant. The first year we ran our contest our plant in Pekin, Illinois, won the trophy; and in 1927 the Argo plant won it. Incidentally, Argo plant also made a reduction of 50 per cent in lost time accidents compared with their 1926 record. Now I believe there is somebody else here who has something to say.

H. E. WHEELER, JR. (Henry Heide, Inc., New York City): I wanted to sit still, but I brought three of our superintendents along and one of them has been consistently poking me in the back to talk.

You might be interested in knowing that we went eight months without a lost time accident. We only have 700 employees, but have over 900 machines. The candy industry is now a machine industry largely, compared with what it was in former years. I was glad to hear your safety man say that they didn't use

any particular stunts. We don't use any either. We have entered all the worthwhile contests conducted among manufacturers. Two years ago we went into the Associated Industries contest. We went 11 of the 13 weeks without an accident. Last year we won in our division in the Associated Industries in New York State. We just made a 100 per cent record in the Commercial Vehicle contest in New York City. So far, in another campaign we haven't had any accidents, and in the Merchants' Association contest we had 350,000 working hours without an accident and then we had a minor one.

We do all the things we are supposed to do according to insurance standards. We have two safety rallies a year, and our foremen's organization devotes one of their monthly meetings a year to safety, with an outside speaker or motion pictures. We get out our plant safety notices and keep bulletins posted, and we everlastingly keep at it. In the first place the company is sold on safety. Our general manager has spoken at our safety rallies. We had a crew of men who spent a year and a half doing nothing but revising our guards to bring them up to present standards. All of these things we try to do as a consistent program. There are no special stunts at all.

We have in our organization a club called the Horseshoe Club, consisting of men and women who have been in our employ at least 25 years. And three or four years ago we had a very enjoyable event, and the son of the man who was most concerned in that event is with us today, and I think he would like to say a word regarding his father. Mr. Grebenstein!

EDWARD GREBENSTEIN (Henry Heide, Inc., New York City): This is just a little bulletin I want to read. It is one of the bulletins issued from time to time by Brother Wheeler.

Fifty years' service without an accident. Mr. Charles H. Grebenstein on October 21, 1922, celebrated the Fiftieth Anniversary of his association with Mr. Henry Heide, founder of the firm of Henry Heide, Inc. Few men attain the distinction of a business golden jubilee, and yet Mr. Grebenstein, in addition to having reached that goal, has not had a single Lost Time Accident during his career with this firm. Truly a remarkable record, and we should all try for such a record.

THOMAS STROBHAR (Wagner-Taylor Company, Philadelphia, Pa.): I have a message to give to you. We have recently had two particular losses that come to mind in connection with cold storage warehouses. The warehouse was being rebuilt or improved and a new cold storage section added. The plans and specifications that were drawn up by the architect and were argued with the owners and the engineers perhaps did not take into consideration at the time of those conferences the safety engineer, or someone who might have had some hand in them. The concrete walls first had to be prepared to receive the cork. They had a coating of paralin (I believe it is) material that looks like tar or pitch. It was heated in portable kettles, because the specifications provided that this material must be heated within 20 feet of the place of application. The workmen came on the job the first thing in the morning in order to get busy in putting on the cork. The cork and material had been piled on each floor, 7 or 8 or 10 feet high, and running nearly the length of each of the floors. Some of it had already been put on, and it was possibly piled as near the elevator openings as they could get it.

These pitch kettles are heated by oil burners which you have to put under some sort of pressure. Well, that workman won't tell us just what happened, but evidently the kettle either boiled over or was knocked over, and got on fire and spread rapidly to the cork. It set all the cork piles on fire and the cork on the walls and on the floor and the ceiling was burning fast, and there was plenty of smoke. Two of the men, I believe, are still in the hospital, and six

of the pipe fitters, are still wondering what it is all about. They were caught in the smoke and penned in the building.

Now it seems to me that in arranging for the application of cork insulation on a cold storage warehouse, more than ordinary precaution should be taken with regard to how you stand up one of those kettles or where you place it. Don't put it so it is going to upset easily. There certainly should be someone provided to supervise it. There certainly should be provided some extraordinary precautions with regard to extinguishing fire if it should occur. All of the workmen in the building should be told the different ways out.

I cite that particular case because of the losses in connection therewith, not only the fire damage, which is to the extent of \$30,000 or more, but the poor men who were injured.

I have another case that may be interesting to those in the Food Section. It was the removal with a varnish remover of the paint or varnish from the ceilings. The whole area of the room was arranged with a scaffolding, which gave about six feet headroom. The flooring of the scaffold was sealed tight so as to preserve the machinery and equipment underneath from this dripping material. The only access to this whole area was through a very small opening near one of the windows, a recess in the window with a ladder where these fellows climbed on this scaffold to work. Well, they daubed the ceiling and the whole covering of the scaffolding was pretty well saturated with the benzol varnish remover. They found that after putting up the scaffolding they didn't have sufficient light for anybody working to see by, so they had to bring in some portable lights, cluster lights, and various other kinds. They had the lights fastened, I presume, on a nail that the nearest workman happened to drive in, and another workman stumbled over the cord or wire, and down came the cluster, a spark lit the benzol soaked scaffolding and the thing began to burn and burn fast. Now, then, to see those babies scampering out. They had extinguishers, they had Foamite, but there wasn't a man who would stand up there and use it. That place was burning and burning hot. Most of them got out with just burns. They couldn't get out of this opening fast enough and tried to break their way through somewhere else, and they were burned and cut.

Now that is a hazard that seems to me could have been prevented. There should have been more means of access to that scaffolding. There should have been ways so that the fire could have been fought by people below with different extinguishing apparatus. That is something that hadn't been considered.

CHAIRMAN HASSE: The afternoon is still early and everybody seems to be very attentive. Who else wants to tell of some stunt?

H. S. TUTHILL (Vice President, Sheffield Farms Company, New York City): I think this is a good time for me to tell you a little bit about our experiences in the Sheffield Farms Company.

I was in charge of the claim department work of that company for about nine years, and our accidents were increasing all the time, faster than the growth of our business. And a year ago the first of last July I had the good fortune to get with us Mr. Clements, the gentleman here who has charge of our safety work. During that period, for one year, we have reduced our accidents 13 per cent. Our business is a hazardous business. We have about 3,000 wagons on the street; we have about 800 automobile trucks, and so forth. But the thought that occurs to me is that the biggest part of safety work is getting 100 per cent cooperation of your employees. If you don't have that you will not make the success, you won't get the results. And we have sold safety work, I am proud to say, to our employees, I think, 100 per cent, just as though it comes from them. It is a work that we have got to keep after all the time. If we don't, things get slack and carelessness develops again and accidents will increase.

But one thing that Mr. Clements introduced in our company was to equip several wagons with posters denoting safety—and our employees, every one of them, are crazy to drive those wagons. Not only is it a great advertising proposition, but we also get letters from the public commending us on that work.

CHAIRMAN HASSE: Thank you, Mr. Tuthill. I believe this has been published in the last issue of the *National Safety News*.

Has anyone else anything he would like to tell us?

V. D. SUTTON (Postum Co., Inc., Battle Creek, Mich.): I always like to see ladies present wherever food is involved. In our plant one of the problems has been a safety rule book. I am not referring to this in a boastful way—it might better be apologetic—but as I sat down here I was introduced to a gentleman who said he had recently read my attempt at a story—I don't know that he put it just that way—in the *National Safety News*, about the safety calendar. You will notice that one of the last things in that little story was criticism of the plant because they didn't have a safety rule book. That criticism was very personal. Our plant hasn't a safety rule book. For a number of years we have tried to have a safety rule book. I don't know what the opinion is here as to whether we should have a safety rule book. But as was said in one of the sections this morning, a safety rule book in some industries would require a man to take a long vacation to read; and perhaps he might have added, a college course to understand.

I don't know of any industry, unless it is shipbuilding, that involves more variety of hazards than the food industry, and that is the reason we haven't a safety rule book. It would be too long, because we have so many different kinds of hazards; and I wonder if members of the Food Section, representing other industries, have a safety rule book in their plant?

CHAIRMAN HASSE: Has any one of the members present a safety rule book that they could tell Mr. Sutton about? Evidently the rule book seems to be a problem with everybody. Perhaps that is one of the reasons why they haven't any.

Has anyone else anything he would like to bring up?

MEMBER: We are supposed to be in the Metals Section but your subject looked so good we thought we would drop in and listen to what you had to say, and since that my conscience has sort of bothered me to speak.

We reduced our accidents, since January first, 45 per cent, and for our principal safety stunt we divided our employees into three sections. There were three classifications according to their hazards. The first classification was called the "Compensation Class," which included foundry, machine and plate shop. The second was the "Lost Time Accidents"; and the third classification, where the departments weren't very hazardous, was classed as "Any Kind of An Accident," where you bruised your finger, or got a sliver in it, or had it cut off. This contest ran from the first of this year up to date. The prize was that the man most interested in safety from each classification in the winning department would be given a trip to this convention, all expenses paid, and his pay from the time he left the plant until he came back again, which amounted to a considerable amount of money.

I have here a man from the machine shop. Our machine shop ran with just two compensation cases from January first. We have a man from the Lost Time Accident class; they haven't had a lost time accident since the first of January, and we have about 50 men in there. That has never happened before. And then we have a man from our finished stock; they had four accidents since the first of January. We think that is pretty good.

At our gate, where all the employees go out, we have a large signboard about 18 feet long and five feet wide, and there is a flag staff for each department, with a removable flag, and they are divided into the three classifications, and at

each classification they have the number of accidents per hundred men pro-rated. At the end of each month we set these flags according to their standing, or according to the number of accidents they have had the previous month; and the men take considerable interest in it.

Then we have our bulletin board and we have a safety flag, a green and white flag, that comes down for 24 hours every time we have a lost time accident, and a bulletin is placed on the main bulletin board telling where the accident happened,—what department. That is run in connection with our other plant in Evansville. We have an inter-plant contest and also inter-departmental contests.

I think for about six months we ran "Safety Suggestions." Each month we would collect the suggestions from the boxes distributed around the plant, and we gave \$25 in prizes for the best suggestions, distributing that in four prizes, \$10, \$7, \$5, and \$3. And any one man was eligible to all four prizes.

In our steel foundry where we had the most accidents, we put out daily bulletins, just took a piece of wrapping paper from the shipping department, and if we didn't do anything else we would put a safety slogan on there; and every time there was a lost time accident we would put that on the bulletin board along with the night steel foundry and the rest of the plant, so they could compare how they were going. We used to have 10 and 12 lost time accidents a month, and we have reduced it to four.

Then the last, but the best, thing that I found was the personal contact with the men. I interview every new man that is employed, and I go through this so-called rule book with him. We give each man a pair of goggles and we tell him that if he isn't interested in safety that we don't want him, and there is only one man that we have had to reject on that score. He knew too much about safety and we let him go; we thought he would do better some other place. We have strict rules for goggles. They have got to wear them, and if they don't they are given two weeks' lay-off the first time they are caught, and they are fired the second time.

I spend a great deal of my time walking from one department to another and conversing with the men. You might call it "chewing the fat," but it counts a whole lot, and they get to know who you are, and we make a great deal of progress that way.

We also have a safety dinner about once a year, where all the men on the safety committee come and we talk things over. At least once a month we have a meeting in each department, and the foreman is chairman of the meeting, and we talk over the accidents that we have had and get each others' experiences and thoughts.

That is a brief résumé of what we have done in reducing our accidents 45 per cent in our plant, and we are quite proud of it.

CHAIRMAN HASSE: I am mighty glad that you came in. Has anyone else anything to say?

FRANK MORRIS (Liberty Mutual Insurance Co., Boston, Mass.): My experience with this rule book proposition might be a suggestion to Mr. Sutton. About 12 or 13 years ago I was in a plant where we had everything, apparently, except a rule book along safety lines, and we thought that we would get one up. So the duty devolved upon me to compile this rule book. Well, when I started out to write it I found I didn't know much about the rules for the individual departments so I asked the man in charge of each department to write up a set of rules to be incorporated in this book. Incidentally, in going around to see the different men on this proposition, I found that the book would have to be printed in about eight different languages in order to get it across. Then it occurred to me that inasmuch as my job was not preventing the accidents but helping the management supervise the foremen so as to keep their interest up, why did we need a rule book at all? If the foremen knew what the rules should be for their departments,

then my job was to see that they enforced those rules. And so we decided not to have a rule book.

G. A. NOXON (Ralston Purina Co., St. Louis, Mo.): I don't know as these are exactly safety stunts, but I will give you a few of the high lights of the campaign we have carried on this year. We are operating 12 plants. To start out with we organized safety committees in every plant. There is an inspector, as a member of this committee, who makes a complete inspection and report each week of the entire plant, and then once each month three members of the committee make an entire inspection of the plant. A copy of the committee's report comes into the Home Office at St. Louis. That gives us a means, when we go from one plant to another, of checking up and seeing that the work is actually being done as far as safeguarding mechanical hazards, and things of that sort.

Then we designed a Purina Safety Button (just the small button that I am wearing) and a man is entitled to that button after going six months without any sort of an accident. And I can say right now that we have, I should judge, over 50 per cent of our men wearing those buttons. It has been quite a help to us.

Then we held a safety slogan contest. We gave prizes for the best slogans from each plant, and then we posted these slogans on the various bulletin boards and gave credit to the men who produced the slogans. The regular Bulletins issued by the Council were used, of course, at all plants. Then we tried out making home-made bulletins, and we had the men suggest or draw up bulletins that they would like to have us use, and we put these over the time clock, changing them every morning. We found that the home-made bulletins had more drawing power than the ordinary bulletins we got from the Council. We held mass meetings at every plant, not at any special times but whenever we could get a good speaker we would hold a mass meeting. At the St. Louis plant we had eight during the year. We had no trouble in getting good speakers from outside plants to come in. We generally hold those meetings for a few minutes after the noon hour, 15 or 20 minutes, and get the men pepped up. At one of these meetings we had a safety play, a short sketch with a lot of humor in it, showing things that happened in the plant.

We put up score boards at every plant and post records from each of the other plants so that they can know just where they stand. I might say that we are carrying that further this year, and instead of posting the records once a month we are going to post them every week, and we find that that has quite a pulling power. We designed a safety pledge card and we require every new employee to sign this card and turn it over to his foreman, who turns it in to the employment department. That card is kept on record; we do have some use for them. If a man gets hurt we go back to him and show him that he has been explained the safety rules and that those accidents shouldn't happen. We have a safety pin organization that is made up of members who suggest special improvements or actually do some outstanding thing to prevent accidents, and the badge of this safety pin organization is simply a large horse blanket pin. But that goes pretty well in the shop.

Now of these various activities the four outstanding are, first, the safety committees, suggesting the carrying out and removal of hazards; second, the contest for the best safety slogan; third, the home-made safety posters used over the time-clock; and fourth, the safety pin club. The first had to do with removal of actual hazards, and the other three were getting safety over in the minds of the men.

CHAIRMAN HASSE: We have with us today a representative of a well known food manufacturer. They have the reputation for building "Pep" and I believe it would be only fair that we heard from our good friend and secretary, Mr. W. P. Penty, of the Kellogg Company, Battle Creek, Michigan.

W. P. PENTY (Kellogg Co., Battle Creek, Mich.): I was quite interested in some of the stunts which have been going on throughout your plants during the year; also very much interested in getting a fine letter from Brother Wheeler who said he was going to have his three superintendents with him, and when he got up to speak I said, "They sure are here." I appreciate that very much.

But we have, at the Kellogg Company, in Battle Creek, pulled off stunts of all kinds, a good many of which I listened to here today. Getting up slogans was one thing that helped us greatly, and was very instrumental in helping us go 72 days at our plant without a lost time accident. We gave cash prizes for those slogans, but the interest was lost after a while. And we have also used the banner system in our company. We would have a blue banner to go for a month and if there was not a lost time accident we would put up a gold banner, and should we have a lost time accident the gold banner came down and the blue banner went up. And then naturally the employees would want to know all about the accident.

In the last two months we have started a little different plan. We have in the lobby of our factory a large board, on which we have each of our departments noted. The number of employees in each department is listed, and each day that that department has no accidents we put a white chalk mark there; if it is a minor accident, a blue chalk mark, and a lost time accident, a red chalk mark. It is surprising how that has proved interesting to the employees. They gather there each morning after our safety inspector marks it up. And should there be an accident in any department it is very noticeable how the employees laugh at the one that has gotten hurt. It is going to be the means of cutting down a lot of our lost time accidents.

Regarding the rule book, we really have not got a safety rule book, but each new employee is given a card which he in turn turns over to his foreman, and after the foreman has instructed him along the lines of safety in that department, or the machine that he may be working on, the employee then is supposed to sign that card and it is returned to the employment department. As someone said here today, in case he should be hurt and his injury should be of a serious nature and try to say he had never been instructed along the lines of safety, you have a check on him.

Also we have a safety inspector who does that work. Every new employee that comes on now, regardless of what shift it is on, is instructed along the lines of safety as far as possible, and we are having splendid results along that line.

We have a special safety committee composed of five members, of which our assistant superintendent is the chairman, and any accident outside of a minor accident that occurs at our plant is investigated by this committee. We try to lay the blame where the blame belongs, and whatever the history of the accident is, or whoever is to blame for it, we put it on the bulletin in the lobby where it can be read by all employees. That has had a good effect. We also have a general safety meeting once a month in our social hall attended by the heads of all departments, foremen and inspectors. There are usually about 80 at those meetings. We try to have a good speaker, and we always have Travelers Insurance representatives there. They usually make their inspection of the plant at that time, and I can see that their staying right on the job and not letting up has its good effect on safety. I think we did let up for a little while and soon found it didn't pay. You have got to keep eternally at it, and the way you can do that is by educating the employees.

ADJOURNMENT.

October 2, 1928

F. A. HASSE, Chairman
Safety Director, Corn Products Refining Company, Chicago

The Tuesday session of the Food Section at the Seventeenth Annual Safety Congress was called to order at nine-thirty o'clock by the chairman, F. A. Hasse.

CHAIRMAN HASSE: We extend to the members present a hearty welcome. As I stated at our luncheon yesterday, our Section is now going into its third birthday. I believe that the Food Section has progressed considerably, perhaps not to the extent of rendering the service that has been expected by some, but, then, no one will deny that we have accomplished much. We have uppermost in mind one thing and that is building up the service that we can render to our members in accident prevention. To accomplish this, of course, requires the cooperation of all interested members.

The *News Letter*, one of our best mediums of exchanging ideas on safety problems, has probably been more or less neglected. Therefore, I now ask that, in the future, all our members contribute very liberally to the *News Letter* each month.

I want to again call your attention to the Annual Industrial Accident Experience pamphlet which is issued by the National Safety Council. This gives everyone a good view of the accident experience which was established by the Food Section members during the past year. It is worth studying.

Today we can boast of 140 members in our Section. What a wonderful organization we could build, if each of those members would contribute his share toward ways and means of combating our accident problem, thereby helping each other and rendering a service, perhaps, not only to the members of the Food Section but to all interested in the field of accident prevention.

We will now proceed with our regular program. I take great pleasure in introducing Mr. Frank Morris, Assistant Chief Engineer, Liberty Mutual Ins. Co., Boston, Mass.

The Status of the Safety Engineer

By FRANK MORRIS

Assistant Chief Engineer, Liberty Mutual Insurance Company, Boston

At the Chicago Congress a year ago I dropped into one of your Food Section meetings. I confess that I was surprised by your numbers and I left your session with the impression that you were a sincere group, really trying to get somewhere. So I feel that it is indeed a compliment to be asked to address you.

Early this year I was speaking on successive nights in Cleveland and Detroit and I took my first airplane ride between the two cities. I do not presume that none of you have ever gone up in a plane. I know that Frank Coleman was terribly sick crossing the channel and the only reason that he didn't jump out, like Lowenstein, was that he was too weak to open a door. There is really but little hazard to life in a trip of that kind; it is certainly safer than automobiling. The greatest thrill one gets is the feeling of absolute freedom. Up there mundane affairs, like topping your drive, how to see Broadway and get the expense on your swindle sheet—all of these problems fade away like mist before the rising sun and you are for the moment reborn—you are free.

If you want to know how mean and trivial are the worries and cares of your

work-a-day existence just go aloft in a good plane a thousand feet or so and look down on this old world of ours from that vantage point. With your feet off the ground you have that sense of detachment that is necessary in order to properly evaluate the affairs of men whom you can't see but whom you know are thickly congregated in the towns and cities far below. The landscape swims by under you in review, the varied colored fields of a farm resemble a patchwork quilt on a baby's bed and that curling string of baby ribbon weaving along over hills you finally recognize as a concrete highway. You see a sizeable green area with a large building at one end and you guess that it must be a golf course. You suspect that some humans are in that building playing the 19th hole offering all kinds of known alibis and that on the first tee is a group of men arguing vociferously about their handicaps. Ordinary affairs of apparent consequence vanish as being too trivial to consider. You sail along over a town peppered with tiny houses on the outskirts and you give a thought to babies and flowers. Then your eye catches the smoke rising from factories and you imagine the workers at their daily jobs, some watching the clock, trying to do but little, others doing their best to earn an honest day's pay.

Somewhere down there in that big group of brick mill buildings is probably a man who is called "Safety Engineer" and like a shock it occurs to us that if the smoke from one or two of those chimneys failed to rise tomorrow that safety man would probably lose his job. Because our job is of vital interest to most of us I want to talk to you for a moment about that aspect of our profession—so if you please, we'll come back down to earth.

We safety men know from bitter experience that in times of business depression our casualty list is high, but to my mind the fault is ours because we ourselves have not estimated our job correctly, and if we do not value our work correctly of course we cannot blame the management for underestimating our worth to his organization.

Will Rogers has a story that illustrates my point. "I go down to da boat to meet my brudder Sylvest just come from Italic. I seea da boat and bigga da crowd on da dock. I pusha to da front and I yell 'Hallo—Sylvest,' and he holler 'Hallo—Tone,' and wava da hand. Then I heara someone yell 'Man Overboard' and, Christopher Columbo!—I looka round and I see it's me."

There are three or four thousand of us here in New York decorated with Congress badges. The world must be saved from accidents and we are the people who can do it. We are rather proud of ourselves and we like to get together every year to brag about our wonderful accomplishments, but I sometimes wonder if some of us (most of us in fact) aren't overboard and don't realize it. Do you know, I think that most so-called safety engineers, instead of having their feet firmly planted on the solid planks of business, are wallowing around in the waters of emotionalism. We are holding our jobs on a "blood and bones" and "widows and orphans" basis instead of "a reduction in the unit cost of production" basis and that's just why safety men lose their jobs when business slows up.

We call ourselves "safety engineers." Is there anything emotional about any of the other branches of the engineering profession? The civil engineer throws a railroad over a mountain range and brings communities together and people are made happier; the sanitary engineer plans a sewer system for a great city and the people are healthier; the electrical engineer reduces the cost of the kilowatt so that millions benefit; the mechanical engineer develops an internal combustion engine and as a result everybody in town autos out to the country on Sunday and everybody in the country tries to get into town. The work of these engineers results in great benefits to the human race but I doubt very much if the welfare of the race was the motivating instance in any case. An engineer is one who develops the forces in nature to the benefit of mankind. They handle the stored up energy in coal and in water power, they make use of gravity, they deal with

inanimate forces and make them work for people.

Can we not stretch that definition to cover us? Are we not dealing with latent forces in the individual which if brought to the surface and made to work will result in benefit to all mankind? We certainly are. Clearly we are entitled to be classed as engineers. These other engineers know that one horsepower will lift 33,000 pounds 1 foot in 1 minute. The safety engineer on the other hand has to guess that a man may lack horse sense and that in lifting 33 pounds he may drop it on one foot any minute. And why should *safety* engineers then not find an economic basis on which to stand rather than an emotional one? Is there such a thing as an economic excuse for our existence?

Here's a chap up in Racine, Wisconsin, who says "Safety work in our punch press room increased the production of that department 65 per cent and all the other departments are now shooting at that mark." Another man in Walkerville, Ontario, says "Our costs on eye cases alone were reduced from an average of \$1,600 a year for five years to an average of \$80 a year for the last five years." The Buick Motor Car Company shows a saving of \$70,000 a year due to safety work. Let's analyze that. Assume that the safety work costs \$20,000, we still have a credit balance of \$50,000 and that represents, at 6 per cent, some \$833,000 capital investment. Eastman Kodak, annual cost of accidents reduced from \$35,000 to \$3,500. Commonwealth Steel from \$40,000 to \$4,500. International Harvester saves 25 cents on every \$100 of payroll due to safety work. During a 15-year period, for every dollar the American Car and Foundry spent on Safety work they got \$1.70 back. The Norton Company expended in 1922 \$17,456 for accidents; in 1926 this figure had been reduced to \$1,535, less than one-tenth of the former annual cost. Over a 10-year period, for every \$9.70 spent by the Steel Corporation on safety they got \$14.60 back. It is true that probably 40,000 serious injuries and 250,000 minor injuries were averted by them in that period, but why need we, as engineers, drag in the emotional appeal when we are talking about a 50 per cent interest return on the investment? I say this company spent \$9,700,000 in 10 years and got \$14,600,000 back—50 per cent interest on \$9.70 is \$4.85 and add these and you have \$14.55. Safety work isn't wildcat oil or blue sky or gold plated brick—it's a bona fide business investment.

James Stewart & Company contractors right here in New York are today saving \$2.80 on every \$100 of payroll because of their safety work. It is no wonder that Mr. James Stewart is the chairman of a big safety drive among contractors. A small plant making earphones for radios guarded four presses and the net saving is \$1,747 a year. Show me a plant large or small in any kind of business, steel rails or suspenders, locomotives or latch keys, battleships or buttonhooks, automobiles or atomizers, where intelligent well supervised safety work has not paid well in dollars and cents.

Let's talk more about "the reduction in the unit cost of production" and less about "widows and orphans."

We are told by a most reliable authority that 98 per cent of accidents in industry are within the control of supervision. (Even the earliest safety engineers recognized that to be successful we had to have the backing of the management—the Big Boss—as we then called him.) Another report that we can couple up with that is that of the American Research Council who made a study of 13,898 plants for the years 1922-1925 inclusive. That report reveals that the minor accidents appear to be more important from the standpoint of incidental loss than has been realized. Productive time lost in minor cases is three and one-half times that lost in major cases. The loss of production value in the minor cases being three times as great as in the major cases.

Now let's conservatively tie those two reports together and say this: "The production value lost in minor accidents is *twice* that lost in major accidents and proper supervision can control 80 per cent of all industrial accidents." Doesn't

that sound like an engineer talking? Those statements are **matters of record**, they are true, we have the proof Q. E. D. So let's think more in **these terms and less** in terms of blood and bones.

We safety men used to be called crusaders. We weren't even that. We had courage but we lacked a horse. Between you and me we were **simple crepe hangers**. Today, possessing the same old courage and armed with facts **such as I have** outlined, we take our rank along side of those other groups of **engineers who are** conserving our material resources while we are conserving our **human resources**.

But let's keep in mind that we are new in the field and that we are **few in** numbers. True there are thousands of delegates at this Congress but the **men** in industry today giving full time to safety work are numbered by **hundreds only**. Most of us have hybrid jobs made up of first aid, timekeeping, **employment and** so on, and too often in such cases the importance of the safety work is **minimized**. Our safety engineering jobs will be just as big as we make them.

I can't imagine a safety man losing out because he induced the management to supervise and thereby control the accident situation; we will always need safety experts just as we will always need mechanical experts and electrical experts. But who is there who does not want to progress? And what better opportunity to serve do you want than to have chance to reduce the unit cost of production.

I have no quarrel with the altruistic safety man whose sole aim is to prevent human suffering. We have some rare examples of doctors, teachers, and preachers of that sort but most of them are in their chosen professions to make a livelihood. Some of us consider ourselves doctors of the accident disease, others teachers of safety education, others of us feel that we are preachers, or Missionaries, or evangelists, of the safety gospel. All these are but tools in the kit of the genuine safety engineer to be used at his discretion to loosen the particular nut that he is confronted with at the time. Above all let's be engineers.

From my office window I can look down upon the monuments in the famous Boston Public Garden and one of them is inscribed "In gratitude for the relief of human suffering by the inhaling of ether." As safety engineers, we care nothing for monuments to signify that we have prevented human suffering. Our work is on a sound practical statistical basis. We can prove that accidents can be prevented and we can prove moreover that it is good business to prevent them. We talk a lot about lives and limbs saved and we proudly display a chart that shows the decline in accidents but the greatest thrill that you and I really get out of our charts is that it is proof that we are doing well the job we were hired to do and we know full well that if the accident curve continues to go down in all probability our individual wage curve will go up.

Perhaps I have shocked some of you with this rather crass picture of the real status of the safety engineer. But listen—if an oculist prescribes glasses for you and saves you from eventual blindness you don't fall on his neck and kiss him—you pay him \$12, that's his business; if a doctor pulls our child away from death's door we're grateful, of course, but our check on the first of the month looks just the same to him as any other check; if a life guard at the beach rescues some fair maiden from the water we don't decorate him with medals—that's what he is there for. If foolish folks wouldn't venture out too far he wouldn't be earning a living patrolling that particular playground.

So, I say, let's be engineers, let's quit prating about spilled blood and cracked bones, let's think more in terms of, and talk more about, our work reducing the unit cost of production. I am fully aware that reducing the cost of a steel rail that will probably be a part of a roadbed in far Montana, or reducing the cost of a pair of suspenders that may eventually support the pants of a laborer in the oil fields of Texas, or reducing the cost of a loaf of bread to

feed we know not whom, these ideas have no appeal unless we consider our job as a part of the world's work, unless we can see our daily task as a contribution to the welfare of citizens generally.

Our natures prevent us from sustained emotion—we simply cannot live in an ecstasy of constant emotion—and that fundamentally is why so many safety engineers realize that their jobs are insecure.

As the result of your efforts you are preserving men for useful labor and by so doing you are performing a most important duty to society and by society we mean those who constitute the state in the highest sense. But keep in mind also that the engineer who reduces the unit cost of production is also rendering a great service to society. Therefore, we safety engineers may well be doubly proud of our avocation. Let's not be content to be looked upon by management as a necessary evil, or as a sop that capital holds out to labor, or as an experiment in industrial welfare work to be thrown into the discard the moment the first cloud appears on the business horizon. Let's not be content I say, but let's renounce those reputations; let's claim and strive to attain that place that is rightfully ours in the social and economic affairs of men—let's be engineers.

Our heads are in the clouds and that is fine—but let's keep our feet on the ground.

CHAIRMAN HASSE: I believe that Mr. Morris has given us more food for thought. Is there any discussion on Mr. Morris' subject?

The Chair will now take the liberty of appointing the Nominating Committee. This Committee consists of the following:

Mr. Ralph E. Prouty, Chairman, Aetna Life Insurance Company, New York City.

Mr. W. H. Cunningham, Pillsbury Flour Mills, Minneapolis, Minn.

Mr. W. P. Penty, Kellogg Company, Battle Creek, Mich.

I will ask these gentlemen to select the officers for next year and present their report at tomorrow morning's meeting.

WILLIAM P. COSTER (Safety Supervisor, Brooklyn Refinery, American Sugar Refining Company, New York City): Mr. Chairman, is discussion in order?

CHAIRMAN HASSE: Yes.

MR. COSTER: In connection with Mr. Morris' address, some time ago I attended a safety conference in Buffalo, and a gentleman in the same business as Mr. Morris made a very fine address along the same lines. His theme was, "Watch your severity rate and costs, and your job will be a success." I was sitting among four or five fellows who put their heads together, and one fellow said to the other, "See, that is all they worry about; cut down their expenses and let us be killed."

WILL COOPER (Stevens Hotel, Chicago, Ill.): Mr. Chairman, I would like to have some discussion and some views from the members of the Section, leading to the formation and adoption of a uniform accident report plan. I think that this is a very vital thing to accident prevention and correction. There are so many questions that can be asked and so much information that can be gathered with relation to accidents that a great many people only have a very hazy idea of what is necessary. I received through the mail, before I came down here, a sample questionnaire that was made up by the chairman of the Hotel Accidents Committee, and it contains so much material in it that I showed it to Mr. E. J. Stevens. He said a man would have to take a day off to fill that thing out. In our business, we are approaching this thing in the dark. I believe that there is no other hotel member of the National Safety Council, and it has been quite a problem as to just what information we will require and what is really of vital importance. I would like to hear somebody's views on this.

CHAIRMAN HASSE: Is there anyone in the room who could answer Mr. Cooper's question? Mr. Cooper, I believe you are the only hotel man we have here.

MR. COOPER: I do not mean to restrict the discussion to hotels. I do not care whether an accident happens in a hotel or it happens in the subway. There is certain vital information that is necessary in order to classify it and take steps to prevent a repetition of it: the age of the person, whether he was in possession of all his faculties or not, and the kind of an accident it was, and all such things as that. It seems to me that there is a skeleton form that could be drawn up and adopted as a standard by the National Safety Council that would fit all cases with very little change.

CHAIRMAN HASSE: I believe the National Safety Council has on file, Mr. Cooper, some forms of accident reports. I do not know whether you have ever communicated with anyone in the National Safety Council in regard to it, have you?

MR. COOPER: Yes, I have.

CHAIRMAN HASSE: What did they say?

MR. COOPER: Most of them are sample reports submitted by different industries.

CHAIRMAN HASSE: I believe we have a subject here that would be quite interesting and we could, I believe, suggest this subject to the National Safety Council in some way and see if they could not draw it up in a form that would be available. We might also have the Statistical Committee of the Food Section draw up a report which I will suggest to them and submit it to all members for consideration. They could make necessary changes and finally submit one for standard adoption to be used by all members of the Food Section.

MR. COOPER: To make clear what I am trying to get at, you all know the National Safety Council has a standard definition for an accident. It is, "disability that causes a man to lose time from his work on the shift succeeding the one on which he was hurt." That applies in all cases and to all industries. I would like to see the Section pass some resolution to the National Committee that they draw up a standard accident report form which would include the principal facts to be ascertained in all cases.

VERN D. SUTTON (Postum Company, Inc., Battle Creek, Mich.): Mr. Chairman, Mr. Cooper mentioned receiving one of those questionnaires. He is very fortunate. I congratulate him. I have received anywhere from six to twelve of them a year, and I see the need of some standardization. Some questionnaires I received would require me to take some of my classifications and divide them up, a very difficult proposition; others would require me to take my classifications and add them together, because each person sending in an inquiry or each organization is asking for some different sort of classification and division of the information they require and I think the headquarters staff is working on something of that sort—to get a standard form. I do not believe they have yet arrived at it. I think it a mighty good thing for this Section to take up and discuss and see if we can arrive at something nearly a standard at least, and that is a good thing for us to do in our *News Letter*. The *News Letter* is my hobby, as you probably know, and it is the most difficult thing we have attempted in this Section. If we would all contribute our ideas freely in the *News Letter* during the year, we would have a *News Letter* worth while. That is one of the things that we might be discussing in the *News Letter* during the coming year.

R. C. STRATTON (Hartford, Conn., Travelers Insurance Co.): Mr. Chairman, I have been very closely connected with the research problems of A. S. S. E. for a period of three years. The questionnaires that Mr. Cooper has taken up and also Mr. Sutton are special questionnaires developed for the express purpose of evolving special information for research subjects. There has been no attempt in those questionnaires to develop a standard form because we are digging out information for the express purpose of dividing classifications and perhaps adding classifications. That questionnaire is not for a permanent fixture by any means. It is to cover a given period to develop specific information so it can be broken

down and thereby evolve a hazard of specific classification from which a pamphlet or brochure of some sort will be developed and distributed wholesale to any and all Sections of the National Safety Council.

FRANK MORRIS (Assistant Chief Engineer, Liberty Mutual Ins. Co.): Mr. Chairman, I would like to take another minute to answer Mr. Cooper's question. The point I want to get at is this: We are saving money. I see plants saving thousands of dollars and there is some fellow out there in that plant who is responsible for this saving and, in many cases, he does not even know it. Now our job is to find out what we are saving and letting the big boss know that we are responsible for that saving. I have no quarrel with the safety man who is saving humanity; who is out there to keep people from getting hurt. We have preachers and doctors and teachers of that same sort but, mind you, most of them are in their chosen profession to make a livelihood. We can call ourselves teachers of accident prevention, doctors of accident prevention, missionaries, evangelists, or whatever you will of the safety gospel, but, at the bottom of it all, we are out there in that plant as a part of the organization because we can save the company money. I worked my head off for one year preventing accidents and my sole thought was keeping men from getting hurt. Do you know that a year had gone by before it occurred to me to ask the treasurer one day if our savings had been material; and what do you suppose he told me? That our cost for accidents during the year just past was more than \$50,000 less than the previous year.

Now that gave me this slant that I am trying to present to you this morning. There is a money saving. My friend Coster says we must be careful of what we say in the presence of certain groups. That is very true. We must remember that our kit bag is full of tools and we have got to pick out the particular tool for the particular nut that we are confronted with at the particular time. As safety engineers let us keep in mind that we do have an economic basis on which to stand and we can convince the management of that, and then, as I said, when the first clouds appear on the business horizon, we will not be the first ones to go out of the gate.

CHAIRMAN HASSE: The meeting is open for any type of discussion. Has anyone else something to say?

WILLIAM P. COSTER (American Sugar Refining Co.): Mr. Chairman, I hope that I am not monopolizing this discussion but everyone in the Food Section has problems which are more or less related. I wonder if there are any here who have the problem of having employees report promptly for medical treatment for the purpose of keeping down infection? That, to my mind, is rather a bothersome proposition in the food line and we have all been through it, and, as one of the gentlemen said yesterday in analyzing accident reports, they get after the fellow who makes frequent trips to the medical department. If we are fighting to have employees report promptly for treatment in order to guard against infection, it is unjust to get after the fellow who makes frequent trips to the medical department, because, at one end you are undoing what you are trying to do at the other end. I would like to hear some experiences from those who have had the problem and who use some measures, not expensive and not elaborate, which helped them or in which they were able to succeed in overcoming the proposition of getting the men to the medical department promptly but not too often.

WILL COOPER (Hotel Stevens, Chicago, Ill.): Mr. Coster brings up a subject that I think is a very serious one. When the gentleman from the Ralston Mills was talking at the luncheon yesterday about a badge or some kind of award for accident prevention or for accident immunity, I was tempted to make some remarks. I think that it is a very bad thing to offer any reward of any kind or any insignia for anybody to wear for not having any accident reports against him. If you do that, you are encouraging the employees to cover up minor

scratches and injuries and not go to the medical department and get them treated. There is a decided tendency on the part of employees to avoid the red tape and the trouble and the humiliation of having to go to the foreman and get excused and go up to the medical department and have a cut bandaged or have it iodized or whatever you call it. I have not been up there myself yet—I have been very fortunate. But I do think that it is bad policy to give out buttons or badges of any kind to employees who have never had occasion to go up to the medical department.

C. A. NOXON (Ralston Purina Company, St. Louis, Mo.): Mr. Chairman, of course we like to defend the things we believe in. I think it is possible to consider a middle ground here. I suppose a good many of you heard me speak yesterday of the badge that we give for six months' service without an accident. Now, on the other hand, if a man gets hurt in our plant and does not report to the first aid department, that man is subject to a lay-off and, after about the second time, he is subject to discharge. I think that is the other side of giving them an award for going through a certain period without an accident. I would like to hear a little more discussion on this as I think we have got on to a thing here that a good many men would be interested in.

WILL COOPER (Stevens Hotel, Chicago, Ill.): I would like to say in answer that it does not save you any money to lay a man off for not reporting a case, after he has developed a case of blood-poisoning in his arm, and you have had to give him extra medical treatment and he has made a claim for compensation. I can cite two instances at the Stevens Hotel—one was the chamber maid. A guest had spilled something on the floor and the maid took a cleaner and in rubbing it, she skinned the ends of her fingers. She did not pay any attention to it and did not report it and in about a week her whole hand had swelled up and I forget how many days she lost. Under the Illinois Compensation Act, we do not have to pay anybody who is off less than eight days, but it is the policy of the house to be very lenient in those cases and anybody who is off on account of an injury suffered in the service receives full time right along.

Another case was that of a man who scraped the back of his hand on the wire in the fan housing in the engine room and he paid no attention to it, and we almost had to take that man's arm off. He was off about six weeks. His whole arm was swelled up and he had it in a sling. The doctor had to make three or four incisions in it. Now, if either of those people, according to the teaching of the medical department, had gone up for immediate treatment, we would not have had that expense. Would it have saved us that expense if we had laid that man or that maid off? It would not.

CHAIRMAN HASSE: I am afraid that we will have to discontinue this discussion because it will be necessary for our next speaker to leave us as soon as he possibly can on account of other engagements. I now take pleasure in introducing David L. Lindquist, Chief Engineer, Otis Elevator Co., New York City.

Elevators—Their Care and Safety

By DAVID L. LINDQUIST

Chief Engineer, Otis Elevator Company, New York City

The total number of passenger and freight power elevators in operation in the United States is at present 165,000. Of this total number a little more than 50 per cent are freight elevators. It has been estimated that all elevators will make in a year 20,000,000,000 passenger trips, equivalent to carrying the same number of passengers. In comparison with this figure, it may be mentioned that the total number of revenue passengers carried by all the railroads combined in this country

annually, is only 830,000,000. The Borough of Manhattan has about 30,000 more elevators than the other four boroughs. While the elevator accidents are comparatively few in number, as compared with the number of passengers carried, due to the fact that elevators seem to be one of the safest means of mechanical transportation, if not the very safest, nevertheless, the number of accidents that occur every year is more than sufficient reason to give this matter serious consideration. This matter is all the more important because most of the accidents that occur are what may be classified as "preventable" accidents.

A very careful analysis of all of the elevator accidents on record has been made for the last four years, and not only have the various kinds of injuries been classified, but the primary cause has been determined in the large majority of cases. The accidents have been tabulated in relation to types of elevator machinery, method of operation, door and gate equipment, etc.

While statistics are the order of the day, and while these detailed statistics are very interesting, it would take entirely too much time to give anything but the "high spots" of this investigation.

There are over one hundred fatal accidents per year that can be directly or indirectly attributed to elevators. Out of the total number of accidents, the large majority are accidents that occur in connection with shaft openings, and out of those more than 50 per cent were fatal. Only about 5 per cent of the fatal accidents are due to failure of the elevator equipment furnished by the elevator manufacturers. Practically all of the failures of equipment are caused by antiquated equipment, as well as poor maintenance, and the old electric drum type elevator seems to be the worst offender, particularly in connection with hand rope control.

Perhaps it may be permissible to give just a few statistical figures of a typical year:

Number of elevators of all makes and types in the United States, October 1, 1928, 163,000; of which passenger elevators constituted 45 per cent and freight elevators 55 per cent.

Average accidents of all classes reported in the United States per year, 271, resulting in 111 killed and 208 injured, or a total of 319 persons affected. Of this number those caused by unguarded openings, improper shaft and platform guards and carelessness were 148, resulting in 84 killed and 64 injured:

Those occurring in connection with derangement of elevator equipment were 88, of which 5 were killed and 83 injured.

Of this 83 injured, 25 were merely cases of hysteria, etc., where no actual injury resulted, the balance were chiefly due to mechanics working in shaftways and to unknown causes.

The parting of ropes in connection with drum type elevators has been the cause of most of the accidents, due to failure of the elevator hoisting equipment.

It is a generally known fact that the introduction of the traction type elevator has eliminated accidents due to parting of the hoisting ropes, as up to the present time there is not a single case on record where a set of hoisting ropes has parted in actual service, and there is no doubt that the traction type elevator is inherently the safest elevator and that its introduction has done more to increase the safety of the hoisting apparatus than anything else.

Marked improvements in interlock and hatchway construction have been worked out, but when it comes to safeguarding the hatchway openings, as well as the elevator car openings, there seems to be great difficulty in getting the known safeguards adopted, in spite of 10 per cent reduction in insurance rates.

For example, hatchway door interlocks which prevent the opening of the hatchway door unless the car is at that landing and also prevent the car from leaving that particular floor until the hatchway door has been closed and locked, are not always used. In many cases the interlocks are furnished, but as they always reduce

the volume of service of an elevator, particularly in connection with manual control, they are often deliberately rendered inoperative. The same condition exists in connection with car gate contacts on passenger elevators, as well as door contacts on freight elevators, which prevents the movement of the car in case the car gate or hatchway door is open.

To a considerable extent this serious condition is due to the lack of laws or regulations compelling building owners to provide interlocks and gate and door contacts, and, in some instances, due to lack of proper enforcement of existing laws and regulations. In certain sections of this country it is true that there are no laws or regulations whatever governing the installation and operation of elevators, except the safeguards demanded by the insurance carriers. In some cases, even the insurance carriers seem to be a little lax in demanding proper safeguards, as in the city of Chicago, for example, passenger elevators are permitted to be operated without interlocks or gate contacts, and, as a matter of fact, even without gates.

Principally due to the manufacturers' and fire underwriters' endeavors, grille cars and grille elevator fronts have been replaced by entirely enclosed cars and enclosed hatchways. Only quite recently has the dangerous collapsing gate been, in a few installations, replaced by the roll type gate, and only in certain high class buildings, employing full automatic control, flush cab doors replace gates of any type.

As power operation of hatchway doors, as well as car gates, is becoming more common, the car gates are becoming increasingly dangerous and their replacement by doors becomes all the more important. Unfortunately, cab doors without any vision grilles are not practicable to other than installations employing full automatic control.

It is obvious that flush hatchway construction in front of the cab opening would practically eliminate the shearing or squeezing hazard existing between the hatchway and the car platform, but up to the present time no serious attempt has been made in this direction, in spite of the fact that almost 50 per cent of the accidents occur at the entrance of the elevator is due to persons getting jammed between the car platform and some part of the hatchway opposite the car opening.

The present hazards of elevator transportation are to a large extent due to entire lack of any laws governing the installation and operation of elevators in certain sections of this country and insufficient and antiquated laws in other sections, as well as the fact that when new regulations are put into effect, it seems almost impossible to make them retroactive. This means that when new regulations are put into effect, the installations made prior thereto are permitted to continue to operate under hazardous conditions, as referred to before.

Several years ago the American Society of Mechanical Engineers realized the necessity for a National Safety Code for elevators and appointed a committee for the purpose of formulating such a code. This work was later continued by a Sectional Committee of the American Engineering Standards Committee and a Safety Code was formulated and issued by this committee. The sponsors for this code were the Bureau of Standards, the American Institute of Architects and the American Society of Mechanical Engineers. This Code was intended as a guide to law-making bodies and while some states and municipalities adopted its provisions in the form of laws, many states and municipalities have no laws or regulations, and those who have seem to prefer their own antiquated regulations rather than to adopt a more up-to-date code. It almost seems the principal reasons for not adopting the National Safety Code were of a commercial nature, as there was apparently a fear that the adoption of this code would increase the cost of elevators.

There is hardly any doubt but what the adoption of the National Safety Code for elevators would materially reduce the hazards of elevator transportation and

it is reasonable to expect that the additional cost for better safety guards would substantially, if not entirely, be offset by reduced cost of standardizations. At the present time standardization of elevator equipment is impossible, as existing rules or regulations differ widely.

The National Safety Code has further the advantage that there is a standing committee of interpretations and recommendations as well as another standing committee for the purpose of making revisions to keep the Code up-to-date as nearly as possible. The Sectional Committee of the A. E. S. C., as well as the standing committees, are made up of men most familiar with the requirements as well as the present status of the elevator art. It may also be mentioned that the Sectional Committee is carrying on a great deal of fundamental research and investigation of elevator apparatus. Most of this work is done at the Bureau of Standards in Washington, but is also being done in the field.

While in certain sections of the country there seems to be a tendency toward a slight increase in the number of accidents per year, such increase is not so much due to a large increase in number of elevators from year to year, although the number of new elevators is many times the number of abandoned or replaced elevators, but is principally due to the fact that the existing old elevators are becoming older and in poorer condition generally.

It may be stated in justice to the elevator manufacturers that the improvements made in elevator operation and increased safety in passenger transportation are mostly due to the efforts of the elevator manufacturers themselves, and particularly those that have real financial responsibility, as well as a definite feeling of moral obligation.

The foregoing statements are not made in the spirit of criticism, but for the purpose of bringing out some of the salient facts before this Safety Congress, with the hope of bringing about, if possible, more effective cooperation between the parties concerned and interested, in order to eliminate the majority of preventable accidents, thereby making Vertical Transportation by elevators even safer than at present.

The gearless traction elevator eliminating gears was not only a great step forward in improving and simplifying the machinery, particularly for high speed elevators, but it was also a marked improvement in the direction of safety.

The automatic leveling device which makes the car stop level with the landing and maintains that level irrespective of the stretching of hoisting ropes, either when loading or unloading, was not only a great convenience, but was also an improved safety feature, as it eliminated the tripping hazard and it permitted the use of full interlocks without materially reducing the quantity of service of the elevator, eliminating the tendency to deliberately render interlocks inoperative.

There has been a steady tendency toward more and more automatic operation of elevator apparatus, thereby eliminating dependence upon the operator to provide proper and safe operation. The development of full automatic control for high speed elevators is not only economically sound, but it is, without question, in the direction of increased safety.

Experience has shown the necessity of providing better protection at the door openings than has previously been the practice in connection with automatic elevators used particularly for modern apartment houses, and decided changes in hatchway construction to insure better protection have lately been inaugurated.

Marked improvements in automatic car safety devices have lately been made. At the present time safeties are available of the gradual stopping type that are able to apply the full retarding force on the face of the guide rails almost at the instant excessive speed is reached; whereas the old safety device of the sliding type did not apply the retarding force before the car had descended from six to ten feet after the tripping speed of the safety governor was reached.

At the present time safety devices are available which will stop the elevator car smoothly and gradually in practically the same distance, independent of the load on the car. With the new device, in no case will the retardation need to exceed gravity, whereas with the older type, if the retardation with full load in the car was as low as gravity, which, however, was seldom the case, the retardation with only the operator in the car would frequently exceed two and one-half times gravity.

CHAIRMAN HASSE: Gentlemen, the meeting is now open for discussion. Have you any questions to ask Mr. Lindquist?

J. J. SHERIDAN (Supervising Engineer, Royal & Eagle Indemnity Insurance Companies): Have you any data showing what kind of material cables were made of—that is, those that were broken in accidents?

MR. LINDQUIST: Yes, we can in practically every case tell the material used. In many cases, it was so-called iron cables, but, frequently, steel cables were used. It does not matter whether you use iron cables or steel cables. They simply have to part when there is an accident. The ropes are directly attached to the winding drum and that continues to move or wind—something has got to break, and, as the cable fastenings or cables used are usually the weakest part of the machinery, they snap. If you put more cables on or stronger steel cables, some other part of the machinery would break and you would have an accident just the same. As a matter of fact, there is a distinct safeguard in having the cables part in those cases, because, if they did not, you might so strain your car, due to excessive pull of the cables before something gave way, that the car safety device would be put out of business. Therefore, it is my opinion that it is a distinct advantage to have the cables the weakest link, and, as a matter of fact, looking at it from a material viewpoint, the cables are the cheapest and quickest to replace.

MR. SHERIDAN: Would you consider the fully automatic elevator safer than the hand-controlled elevator, Mr. Lindquist?

MR. LINDQUIST: It all depends upon what type of automatic elevators you refer to. If you refer to some of the older type push-button elevators in apartment houses, etc,—

MR. SHERIDAN: Suppose we restrict our discussion to the modern elevators, installed within the last three or four years.

MR. LINDQUIST: The modern type that is turned out is much safer than any of the former types of elevators employed or operated.

MR. SHERIDAN: Have you any statistics showing what safety devices were lacking, so that they would not function properly?

MR. LINDQUIST: Yes, we have.

MR. SHERIDAN: Available?

MR. LINDQUIST: Yes, but I think it would be very embarrassing to most of the elevator manufacturers to inform the public fully on this subject.

MR. COOPER: I understood Mr. Lindquist to say that he believes that there are more casualties through the application of safety devices than otherwise—through their acting than through their failing to act. I would like him to explain that statement. If that is true, why not leave off the safety devices? What particular safety devices did he mean?

MR. LINDQUIST: I referred to car safety devices, in making that statement. I think it is true.

MR. WILL COOPER: The automatic stop?

MR. LINDQUIST: Yes, more people have been injured by the application of car safety devices than lives saved by those devices. Those safety devices used in the past have been of such a nature that, particularly with a light load in the car, retardation effect has been altogether too strong. In other words, the re-

tardation has affected the passengers so that they simply could not withstand it; the safety device may go on from some real cause or may frequently be applied inadvertently, without any reason for it whatsoever. We have had a number of accidents where people were injured due to application of safety devices; they have not been killed, but they have injured backs, sprained ankles, broken bones, etc.

GEO. G. MEAYNS (Standard Accident Insurance Co. of Detroit, Mich.): What solution would you give to the traction light elevator, Otis gear drive, with the compensation and other cables, V groove, 23 passengers, single wrap, of course, I am referring to. There was approximately 29 got on, six more than 23. The elevator first stopped at the fourth floor, approximately 18 inches to two feet above it. The operator reversed his lever, not gently but in the manner that they do today. They went down and she did not stop when he put it on level again but kept on sliding—that is, the cables slid through the sheaves. It did not gain speed enough to throw the car safety. Had it been up higher, say at the 22nd floor, they might have gained momentum at the 15th floor, but, being at the 4th floor, they did not gain momentum enough to throw the car safety in until they were down between the first floor and the bumper. There they gained enough momentum to apply safety and to prevent the car from landing on the bumper springs. We know the car was overloaded. In this particular case, they all claimed they were injured, more or less; one fellow had varicose veins; he said he was badly injured; another fellow had a game arm, but there was no one particularly injured. This type of accident has happened so frequently on this particular type of elevator; is there no way of preventing that? Of course, a single wrap is not as good as a double wrap. I feel that the manufacturers of elevators should do something, even though no serious accident has happened—something should be done regarding the single wrap type of machine.

MR. LINDQUIST: The condition just pointed out is not an unusual one at all, and I do not see any way of stopping overloading, except by demanding proper rating of elevators in proportion to the car size, because, after all, the size of the car, if a passenger elevator, determines its loading. As long as we have the old rule (in some cases still in effect) that loading of an elevator should be figured at 75 pounds per square foot of the car area, we will have overloads and very serious overloads; because it is quite possible to obtain the loading of 150 pounds per square foot by selecting your passengers, and 110 and 120 pounds per square foot is not uncommon in large elevators. As the size of the car goes down, the loading per square foot also goes down, but, in no case, is 75 pounds per square foot sufficient rating.

WILLIAM F. SCHAEDEGER (Safety Inspector, Edgewater Plant, Corn Products Refining Co.): What causes an elevator to slide? Is it the fact that the cables did not grip into the grooves of the sheaves? They tell me they are making a change in the groove; that when the cable slides they have a round, circular groove; and are changing it into a V so that the cable would grip better, and this thing could not happen.

CHAIRMAN HASSE: Mr. Lindquist is going to explain that. He will draw us a sketch of it on the blackboard.

MR. LINDQUIST: Gentlemen, there are two distinct types of traction machines. I think the best classification probably is to say that one has double wrap and the other single wrap. There are various forms of single wrap and I want to call attention to that a little later. In the double wrap traction machine, the hoisting cable starts from the car, runs over the driving sheave once, then over and back again over the driving sheave. In the single wrap traction machines, the hoisting cable passes only once over the traction sheave. Now the double traction machine has a circular or half-circular groove. In other words, if a cable with six strands rests in a groove, of course, the next cable comes here (indicating.) These cables

rest in a half-circular groove, and, in order to get sufficient traction to operate it within the full capacity of the loads, it is necessary to wrap the hoisting cables around the driving sheave twice.

Now, what do we do with the single wrap? Well, the V groove was mentioned. In order to get additional traction, it was a question of pinching the rope. A V groove was made; the cable was put in, and that gave sufficient pinching effect so that the traction obtained was the same as that obtained in this case with the double wrap. The trouble, however, was that wear always occurred with this type of driving. It did not matter with the double wrap how the groove went down, because we still had the same contact in the rope and the traction did not change. With the same amount of traction there was the same amount of wear. But with the single wrap traction machine, you see, as the cable wears into the sheave, after a while the cable eventually reaches the position where you have just the same effect as the single circular groove; so that, with the V groove, if you start with sufficient traction, you know that eventually you may wind up with traction only equivalent to a single groove. In other words, less than half. Now that was a serious defect in the single wrap traction machine, and, of course, in order to make these elevators safe, some way had to be found by which the wear would not affect the traction of the single wrap machine.

Therefore, we resorted to a different construction. (I will draw it on a little larger scale so as to show you what was done.) This is the cable that lies in a half-circular groove. With a single wrap we could not get enough traction because it rests too nicely in the bottom and does not get enough pinching effect. Therefore, we cut down the under cut in the groove. This changes the construction of the sheave. We started with a certain pinching effect, due to the fact that the bottom of the groove was cut away, and, as the cable wore down, we maintained the same pinching effect. Of course, it is true that if you let wear occur long enough, you will eventually land at the bottom, but that is what is expected. Now, the machine that Mr. Schaediger referred to probably had a V groove of this type or was one of the older machines. It might not necessarily have been of this type, because with such an overload there was an extra force of gravity.

GEO. G. MEAYNS (Standard Accident Insurance Co. of Detroit, Mich, New York City): Is there the same possibility of slipping through the double wrap?

MR. LINDQUIST: Even a double wrap can slip, if there is sufficient difference in load between the car's normal capacity and the actual number of passengers in the car, but, in ordinary practice, I do not know of a single case where we have, with the double groove, reached a condition of slipping. That would mean an overload in the car of at least double the full rated load, and, in some cases, considerably over that before slipping would occur. The double wrap is mostly used for high speed elevators. You have to have such a surplus traction in order to accelerate the elevator and make it go fast, so that any slipping—continued slipping—due to overloading is hardly possible, unless you have the car full of cast iron or something like that, but not with passengers.

C. M. FINCH (Superintendent of Inspection, Mass. Bonding and Insurance Co., Boston, Mass.): For the last four or five years, I understand that cables are built of iron outside and steel inside for strength. I would like to ask if you recommend that cable and what has been your experience with it.

MR. LINDQUIST: The sealed cable consists of wire strands. We start with six small wires on the inside and six of same size on the outside, and then you put a wire on the outside of that, the outside wire of somewhat different thickness, but finally making up nineteen wires. The single wrap, however, is different. To start with, you have a large wire and you put in a number of smaller wires, and then the large wires outside of the small wires; in most cases, there are nine wires in a strand. But in a sealed cable, you have a certain number of wires on the

outside, equal in diameter, and much larger than in the regular way and every wire here has two underlying wires. This construction is called the "sealed construction," and has proven to be quite advantageous. The obvious reason for this is that the outside wires are larger in diameter and can stand a good deal more wear before they get down to about the center, because, after the wires are worn down to the center, they inevitably break, so that the sealed construction now is getting more and more universal in use. Attempts have been made to make the outside wire of somewhat softer material with less resistance and to make the inner wires of steel and consequently have greater strength.

While there may be some advantage in having a great surplus of strength in elevator cables, it is very much of a question whether this is of real advantage, because, after all, with old traction machines, at least with the prevailing type of past years, the cables were never subjected to forces coming anywhere nearly up to the latest equipment or even approaching it; as a matter of fact, they could not. Under ordinary operating conditions, therefore, a great surplus of added strength is of so very little advantage and it may under certain conditions be a distinct disadvantage. In traction machines, the wear of the outside wires determines the life of the cable and, when the outside wires are worn down considerably, there is usually plenty of strength left in the cable, even after it is worn to the point where it looks bad on the outside; because with high speed traction machines particularly, the safety seldom is under fourteen and frequently exceeds twenty, so that the cables are anywhere from fourteen to twenty times greater than the maximum loads imposed upon them under normal conditions. There may therefore be a distinct disadvantage in having too-strong cables. I pointed out before in relation to safety devices in connection with the drum type, the drum over the car may eventually become wound up or hoisted up against the overhead structure, the machine keeps on winding because the operator has not cut the power; something must give way because you have the power in the D. C. motor at least ten times greater than normal at its extreme maximum, plus the momentum of the motor and the momentum of the machinery; and, therefore, you have a terrific force to control, even if you had twenty times as many safety wires. Something has to go, and therefore I said I prefer to have the cables go or the cable fastenings, rather than the car frame or the top pieces. You have the drum machinery over you, and if the car hits the overhead, something has to go, and if the car safety is not there to prevent its falling all the way down to the bottom, then it is a serious thing.

JOHN FULLER (Aetna Ins. Co., New York City): Mr. Lindquist, will you tell us something about "Tru-Lay" cables?

MR. LINDQUIST: I rather hesitate to enter into a discussion or make any statements, particularly as there is just now such an advertising campaign going on in favor of "Tru-Lay" cables. Under those conditions, perhaps, you may think that I am on one side or the other of this advertising movement.

DAVID J. GITTO (Aetna Life Ins. Co., New York City): With a car rating 2,500 pounds capacity, how many pounds above that will it go before the slipping takes place?

MR. LINDQUIST: Well, there is no definite figure that can be given; because that may vary anywhere from 3,500 to 4,500 pounds, depending upon various conditions. But it is almost criminal to not rate the elevator's capacity in relation to the size of the platform, as the size of the platform determines the load and that should determine the capacity of the elevator. If you have an elevator platform that can only take 2,500 pounds, there is no possibility of overloading with passengers; but if you have an elevator car platform that may be rated for 2,000 pounds and can take 4,000 pounds, then, of course, you may exceed the load at which slipping occurs. This is something that elevator manufacturers have been fighting for a long time and so far we have been unable to put it through, except in a few

cases. Most cars are comparatively large because they have to be or to make room for a stretcher, as in hospital cars. There are in existence today several that are rated at fifty pounds per square foot for hospital cars. Now you can realize that, if you put in equipment to take care of fifty pounds per square foot and let in 120 pounds, something is apt to go wrong.

R. W. MACADAMS (Engineer, Columbia Casualty Co., Boston, Mass.): Getting back to the straight V type groove on the single traction wrap, and that combination semi-circular design and the V groove at the bottom of it, you stressed the fact that the objection to the straight V groove is the ultimate loss of the traction of the cable and, therefore, you preferred the other type. Is there any other objection to that V type with regard to the life of the cable?

MR. LINDQUIST: Yes, there is a decided difference in the cable life with a V groove and the under-cut circular groove. It is quite obvious that, when you start out with a new V groove, with perfectly straight sides, you just have points of contact between your two sides and the cable; therefore, you have very high pressure. In many cases, the pressure is sufficiently high to crush the material of the sheave which is usually cast iron. The first wearing process (if I may call it such) of a plain V groove is not wearing but a crushing down of the same material. The pressure is so high because the cable does not touch over the whole length or contact only on certain spots and that pressure is sufficient to crush the material of the sheave.

It is rather interesting to know that that crushing process may continue down to the point where insufficient traction occurs and still the crushing keeps on. After a while you have a regular shell worn or, rather, crushed down in your V groove. Then you have not only got this condition but you have the whole lot of wires behind that also making contact and you have apparently a convex surface.

The result is that the surface pressure at those points of contact may frequently be higher than the surface pressure of the few wires in contact with the smooth surface. Therefore, we have had the experience in a number of cases with V groove machines, where the crushing effect continued until they were almost down to the bottom of the V and did not stop. The indication of that was simply that the groove did not polish up but merely kept on crushing down. The instant you get wear, then you find that the surface polishes up. That is wear, otherwise, it is crushing and the surface remains dull. With a microscope you can readily see those mountain tops just like a mountain landscape. If you start with a smooth round groove, after a while you get a shell and you have these wires in contact with a concave surface, a smooth surface to start with. Therefore, this shape causes a pressure on the cables with very slow wear, but the V groove wore down to a point where the V remains the same, as the undercut would not stand the pressure at all.

HENRY J. POTTER (Supt. Eng. and Insp. Dept., Hartford Accident and Indemnity Co.): In reference to the automatic elevator as used in apartment houses, manufacturers have made quite some changes in the last few years to eliminate the inoperation of the car due to the operator or the tenant not closing the car gate. Some have taken care of that by the floating platform and other arrangements. I would like to ask if the elevator manufacturer considers the safe operation of that car. We have had cases in the city here, both fatal and non-fatal, where children have been caught between the shaftway door and the car gate. Does the manufacturer look into that part of it in designing the equipment or is it a case of the architect, in designing the building leaving that door in the wrong position?

MR. LINDQUIST: The movable platform and those other devices are employed for the sake of convenience generally. An automatic elevator in an apartment house, for example, is inoperative unless the hatchway door and the car gate are closed. It cannot move because the car gate is provided with contact and, if that contact is not closed, due to the fact that the gate is opened, the elevator cannot

move: If any of the hatchway doors are open, the car cannot move.

Now, here is what happens. Somebody takes the car from the ground floor, for example, gets into it, closes the gate—the hatchway door usually closes itself. He presses the button, goes to whatever floor he wants to go, gets out of the car and forgets or does not care to close the car gate. Sometimes he may do it deliberately for the purpose of insuring that the elevator is going to be at his floor when he comes back again, and that, of course, is quite an inconvenience to all the rest of the persons that want to use the elevator. Therefore, the movable platform was introduced for the purpose of permitting the car to operate or to be operated with the car gate open providing nobody is in the car, because the car gate is for the purpose of protecting the passengers in the car. It is very important to the people in the car that the gate be closed, particularly on account of the accidents that I have referred to. Practically 50 per cent of the accidents in elevator operation are caused by squeezing in between the car and the platform. With nobody in the car, it does not matter. Therefore, the movable platform was put in so that, if somebody was in the car and the platform was depressed, operation could not be obtained, without closing the car gate. With nobody in the car, you could operate the elevator whether the car gate was closed or not, providing, of course, that the hatchway doors were closed.

Now, there are other devices, such as the self-closing gate, for the purpose of insuring operation of the elevator whether the passenger closes the gate or not. In other words, the gate closes itself. They have to hold it open until they get the hatchway door open, and, when they get out, both car gate and hatchway door close themselves. The self-closing gate is, however, not so convenient. It requires a good deal more effort and, in many cases, the movable platform seems to be preferred. It offers, besides, certain other operating advantages, but, whether you employ one or the other, the accidents that you refer to do happen; for instance, the accidents that happened up in the Bronx. None of the seven fatal accidents that occurred in the Bronx within the last year and a half would have been prevented by any means that the elevator manufacturers could provide.

In other words, it was not the fault of the self-closing gate. It was not the fault of the movable platform; it was the fault of the building construction and arrangement of hatchway doors. The landing door in every case of these accidents that I mention was sufficiently far set back from the landing sill edge that it was possible for a child to stand between the door and the gate with both door and gate closed. Sometimes this space was comparatively small, so that a child had difficulty in getting in between and slightly pushed out the car gate, in which case, the motion of the car pushed him up against the door and he was killed. The hatchway construction itself and the door for the hatchway is ordinarily no part of the elevator equipment or is not included in the elevator contract, and the elevator manufacturer has no jurisdiction about the hatchway doors. He may make suggestions and all that, but it is merely inconvenient to put the doors in certain positions and out at the edge and very frequently we have as much as fourteen or fifteen inches between the car gate and the landing door. Unfortunately, the existing building laws in New York are not sufficiently definite to make it possible for the District Attorney to prosecute these cases.

Now, what should be done, of course, is obvious. Put the hatchway door right out flush with the hatch and make the whole hatchway perfectly flush. Have your car platform come close and then you have practically eliminated all squeezing. You may have some squeezing you may get your finger between, but you could not get your foot down, and while children may get their fingers in between—that is possible, but, then, it would not be so very serious. They may lose a finger. You might have to go to quite some effort in order to get into it.

Now the manufacturers are prepared to furnish doors that can be set flush with the hatchway and I strongly recommend a perfectly flush hatchway construction

Now, on existing information, we have put metal back of the door to practically build out the door to the hatchway line and that suggestion may be adopted by you but I am not so certain of that, either. The building out of the door, of course, is a rather crude way of providing safety, because, when this swing door opens, you reduce the door opening space by the amount that you build out the door, but it would at least provide safety and make this type of elevator practically safe, as far as children are concerned. If you use solid doors instead of gates, they could not even get out to put their hands in. I recommend doors instead of gates.

J. F. HENNESSY (State Insurance Fund, New York City): The first thing that I would ask Mr. Lindquist would be this: What would he suggest from his own experience as a manufacturer that the food products manufacturer, whether he is a tenant or has a building of his own, should do in the interval between elevator inspections to prevent accidents?

MR. LINDQUIST: I really do not know how to answer that question because how to properly take care of elevators and maintain them is quite a long story. You have got to consider every different kind of equipment. One thing that can be said is that you ought to start with good equipment to begin with. Start with equipment as nearly fool-proof as money can provide. I believe, however, that the insurance carriers could probably do more than they have done in the past in order to help the manufacturers in demanding safer and better equipment. I appreciate that the insurance carriers did a wonderful thing when they gave 10 per cent reduction in premium for fully approved interlocks. I think, however, that the time has come when the insurance carriers could go further than they have done so far and the manufacturers certainly would appreciate any action along those lines by the insurance carriers.

GEO. G. MEAYNS (Standard Accident Ins. Co. of Detroit, Mich., New York City): The automatic elevator has been installed to a great extent in apartment houses. The old time automatic elevator has changed considerably. In regarding the fatal accidents that have happened, it has not been to my knowledge the fault of the manufacturers; it has been due to faulty construction, poor layout, and not looking to conditions, but I do believe that the manufacturer should have pointed out to the architect wherein that certain danger existed, because it has given, as I may say, a black-eye to the manufacturer of this particular type of elevator. Regarding the floating platform, it has its good and bad points. The good points you have drawn here, but, between the floating platform and the hatchway door, there is a space of two to three inches; standing space on the landing is six inches, which makes eight to nine inches for a child to stand there very readily. That is where all of the accidents today have occurred—from a child being able to stand there. A grown person has not been injured on this particular type of machine.

Now, to overcome that, they have put on the doors a bevel piece to eliminate that six inch space, so that no one can stand there. The Otis Elevator Company today eliminated the frame in front. The two and three-quarter inches has been eliminated now entirely. The floating platform hazard has been eliminated, and that condition has been so far corrected that I believe, with the installation of the bevel piece on the swinging door, these elevators are perfectly safe.

It would be well to note that all of these accidents have happened where they have swinging doors. There has not been one where there was a sliding door, because they can be built so close that it eliminates that danger; in fact, the entire equipment of the interlock can be better placed with the sliding door than with swinging door. It is where you have the swinging door that you get the condition that one is liable or can stand on the saddle. Today some manufacturers are installing gates that are self-closing. They also have their good points and bad points, but I believe that it would be well for the elevator manufacturer to see to it that there is nothing done in the construction of the shaftway doors that would

be a detriment to the name of their elevator. It is only a matter of time when these elevators will be installed in all mercantile and commercial buildings. We are talking about saving money; there is a saving element here. So it is up to the manufacturer of the elevator to see that the conditions are such that the danger regarding the shaftway doors which is the principal cause will be eliminated.

WILL COOPER (Stevens Hotel, Chicago, Ill.): This discussion is resolving itself into a technical discussion of the construction of elevators which is way over the heads of most of the people here. We started talking about accidents in industrial plants. I think it is the sense of Mr. Lindquist's paper and the remarks that he has made that this is largely a matter of supervision. I used to be mechanical assistant to the general superintendent of Motive Power on the Chicago Railroad, and I heard a roadmaster say that no side track was ever long enough. I think I came to the conclusion myself that no engine tender ever held enough water; and I think that Mr. Lindquist would probably say that no elevator was ever built that could not be overloaded. He hit the nail on the head when he was talking about the drum type—that, if the cables do not give, something else has to give. That is one of the mechanical rules—there is an irresistible force that comes in contact with an immovable object. As long as you have elevators and you allow the operators or people that use them to overload them, you are going to have accidents. It is one of the plainest cases of accident for lack of supervision that I know of.

ADJOURNMENT

October 3, 1928**F. A. HASSE, Chairman**
Safety Director, Corn Products Refining Company, Chicago

The Wednesday session was called to order at nine-thirty o'clock by the Chairman, F. A. Hasse.

CHAIRMAN HASSE: As you read from time to time, there are various industries throughout this country which experience serious dust explosions. We have with us this morning a man who has devoted a good deal of time and study to the hazard of dust explosion. In addition, he is also going to show us some of this dust in the act of exploding. I take great pleasure in introducing to you Mr. Hylton R. Brown, Associate Engineer, Bureau of Chemistry, Dept. of Agriculture, Washington, D. C.

Fighting Dust Explosions

By HYLTON R. BROWN

Associate Engineer, Chemical Engineering Division, Bureau of Chemistry and Soils, United States Department of Agriculture, Washington, D. C.

It is no longer necessary to open a paper or a discussion on dust explosions with a definition of the subject, because the terrific blasts which have occurred in recent years in many industrial plants have left no doubt in the minds of owners and operators of such plants concerning the explosibility of dust in suspension in air. The publicity given such explosions in newspapers, magazines, and trade journals has also served to impress upon all those connected with the operation of dusty industries the fact that they have a serious hazard with which to contend. The need for self-protection gives impetus to organization, and accordingly the representatives of various industries have banded together in a spirit of cooperation in order to obtain or exchange ideas which will enable them to combat successfully this menace in their plants.

For years cleanliness has been the watchword in the battle against dust explosions, and the elimination of the dust cloud is still the most effective weapon at our command. In many cases it is possible to prevent explosions by controlling the dust, and much progress has been made in reducing losses by installing dust collectors, pneumatic cleaning apparatus, and dust tight equipment. The elimination of sources of ignition can also be accomplished in some cases and, this method of explosion prevention has proved of value.

There are, however, a number of places in the modern industrial plant where the dust cloud cannot be eliminated, and it is difficult, if not impossible, to prevent the presence of sources of ignition. In such places as grinding machinery, mixing and conveying equipment, and spray driers, the dust cloud consists of the product being manufactured or handled, and its collection or removal cannot be considered as a possible means of eliminating the explosion hazard. Heat, friction, and the possibility of metallic or static sparks being produced during the operations render them particularly hazardous. Dust explosions in such places must be fought, and in this hand to hand encounter unless we have sufficient power and strength to withstand the attack or employ strategy to defeat the enemy our plants will be destroyed.

If you choose to depend on your power and strength then you must indeed pro-

tect yourself with strong walls. It is of course impractical to attempt to confine an explosion within walls. In one sugar dust explosion it was estimated that a brick wall 30 feet thick would have been necessary to resist the pressure produced. In a grain elevator explosion a group of concrete storage tanks filled with grain and estimated to weigh 300,000 tons was lifted from the foundation. It is possible, however, to choose a well defended position and ward off an attack by building walls sufficiently strong to divert an explosion or limit the enemy's power by dividing his forces into a number of small detachments. Our purposes are best served by supplementing power with strategy. Draw your maps and plan your defense in advance, and then when the attack occurs let the enemy assist in his own defeat.

Just as general attempts to split up the enemy's forces, so should a hazardous process be segregated and split up into small units. If it is necessary to have the unit located within the plant proper then it should be separated from other parts by strong walls with a light outside wall, roof, large window area or automatic sash equipment arranged to permit the venting of an explosion before dangerously high pressures are developed. The wall separating this unit from your plant then becomes your fortress, and all openings through that wall must be carefully guarded. A screw conveyor with several flights removed to form a choke can be used to carry material to or from the machinery in which the hazard exists, and a revolving paddle wheel or damper can be used to seal effectively any spout openings through your wall of defense.

All the above-suggested measures have been adopted and found effective in fighting dust explosions, but at best they are measures of protection only. They do not rout the enemy but serve only to reduce or scatter the losses.

But now a more effective weapon has been developed and we can render our plants absolutely immune to attack. Dust explosion losses are prevented because no dust explosion can occur. It is now possible to take the offensive instead of being always on the defensive, because inert gas has come to our aid and with it we can render the enemy's ammunition useless for any attack on our plant. It has been found that of the requisites of a dust explosion, namely, dust in suspension in air and a source of ignition, it is the oxygen of the air which serves to support combustion.

By introducing an inert gas like carbon dioxide or nitrogen until the percentage of oxygen is reduced below that necessary to support combustion it is impossible for an explosion to occur or a flame to propagate. There is, however, a restriction on the use of this method of fighting dust explosions. It is impractical to consider flooding an entire building or even a room with inert gas. Workmen would be unable to breathe in such an atmosphere of low oxygen content. Inert gas, however, lends itself readily to use in inclosed units and is particularly well adapted to use in grinding equipment. It is with this phase of the subject that investigators have been dealing recently, and as a result of experimental work and factory tests the value of inert gas as a preventive of dust explosions has now been so well demonstrated that its use should be seriously considered wherever an explosion hazard exists which cannot be controlled through the elimination of the dust cloud or the source of ignition.

When planning the installation of an inert gas system the first consideration is of course a source of supply from which sufficient inert gas can be obtained. Where a steam power plant is operated in connection with a mill or factory, designing and installing inert gas equipment for explosion protection is comparatively simple. Where no power plant is located within a reasonable distance of the mill, gas producing equipment can be installed. In either case there are seven factors which should be determined before attempting to design a satisfactory system:

- (1) Quantity of air which normally enters the machine or equipment,
- (2) reduction of oxygen necessary to prevent explosions of the material being handled,
- (3)

percentage of oxygen, if any, in the gas used to create the inert atmosphere, (4) quantity of gas required, (5) availability of the required quantity of gas, (6) type of gas conditioning equipment, if necessary, and (7) the type of gas distributing system best adapted to the plant.

By giving careful consideration to these important points and planning the protective system accordingly it is possible to eliminate from the most hazardous points in industrial plants all danger of dust explosions and win through strategy a victory which we have been unable to accomplish with the weapons previously at our command. The Chemical Engineering Division of the Bureau of Chemistry and Soils will render all assistance possible in your fight against dust explosions and will be pleased to send on request available publications on dust explosions. Anyone interested in the use of inert gas, the newly developed method of explosion prevention, should write for "Technical Bulletin No. 74—The Value of Inert Gas as a Preventive of Dust Explosions in Grinding Equipment."

WILL COOPER (Stevens Hotel, Chicago, Ill.): You spoke about the explosibility of aluminum dust. I have heard about that. I have tried to get some information on it as to why an inflammable material like that would explode.

MR. BROWN: There are three metals the dust of which we consider explosive—aluminum, magnesium, and zinc. Aluminum and magnesium have already proven their explosibility in their use as flashlight powder and photograph flashes. The explosion of so-called metal dust is just a little different from grain dust. In the so-called carbonaceous dusts, the explosibility is probably partly due to a generation of gas. When heat is applied, a reaction takes place in this dust which we believe produces a gas and renders them, we will say, quickly explosive. They are quick on the trigger. They explode much more readily than the grain dust or the wood dust. Grain dusts are fairly slow. In other words, in a large tunnel, you can start a dust ignition at one end and see it progress through the tunnel. Men working in plants where explosions occur have time to throw up their hands and protect their faces; it comes in rolls of flame from one room to another.

But, with aluminum dust, we have a quick explosion produced which gives us a loud report and we account for that, as I say, by feeling that a gas is produced. We are not sure on that point. Investigation is under way. There is another feature that enters in there—the application of water to an aluminum fire renders it far more explosive than it was before. We have to smother our aluminum fires. In carbonaceous dusts, the explosion is simply a burning of material. Aluminum dusts and metal dusts are somewhat out of our regular line; we have been directing our efforts primarily toward grain dust and cereal dust explosions. Being in the Agricultural Department, the feeling has been that we should direct our efforts first toward the agricultural industries. We have had several aluminum explosions recently. I have some aluminum dust with me today. I can probably give you a demonstration here which will give you a chance to compare it with some of the cereal dust.

CHAIRMAN HASSE: Mr. Brown, here are a few samples that we will ask you to test first. *(Mr. Hasse indicated certain jars.)*

MR. BROWN: The cereal we have here is cornstarch. We will see what results we get with this first. We have some aluminum powder here. We will attempt to give a demonstration with the aluminum following the starch.

I might explain the construction of this little elevator to any of you who have not witnessed the demonstration before. In the front part of the elevator we have the workhouse—in other words, the combustion chamber, open from top to bottom. The storage tanks contain an ignition coil—small sheet metal tanks which we fill with air under light pressure sufficient to throw the dust into suspension. A pipe-line leads from this tank into the house and is directed down into the center of a cup. The dust sample (a spoonful in size), is placed in

the cup. When the trigger is thrown back, the air valve is opened, the air rushes in, throws the dust into suspension and the dust is supposed to be ignited by an electric spark. We have an electric connection here in the wall. The explosion is vented through the weakest point in the apparatus, the paper covering on the roof. This is an example of what can be accomplished in the protection of your plant by putting on a weak roof, large window area, or a light curtain wall. This releases the pressure and prevents destruction or damage to the other part of the structure. *(Cornstarch dust exploded.)*

Here is a sample of aluminum powder which we will use in comparison with the starch dust demonstrated. This is our test with aluminum powder used to show the comparison between it and the dust on which we have a little more information. *(Aluminum powder exploded.)*

W. P. PENTRY (Foreman, Kellogg Company, Battle Creek, Mich.): Mr. Brown, what kind of dust was that just used in this last demonstration?

MR. BROWN: That was aluminum powder. Now here we have some Kellogg company dust which we will try next.

MR. PENTRY: I would have brought more of a sample but that was all I could find in our plant.

MR. BROWN: I have my doubts about this Kellogg company dust exploding. It is a dust which conglomerates readily or forms small balls and lumps, and, in this small unit, we have to obtain a fairly uniform dust suspension. In other words, we have to have the particles separated. To demonstrate this dust we should have a screen or sieve that we could use to form the dust cloud a little more readily. We will make an effort to explode it and see what luck we have. *(Kellogg powder exploded.)*

MR. PENTRY: Mr. Brown, here is some hickory wood dust that a firm in Jacksonville sent me to have tested.

MR. BROWN: We will attempt a demonstration, if any of you are interested in wood dust. It is outside of the food industry line. *(Dust did not explode because paper used as roof covering had become torn and allowed the air to escape.)* That shows the advantage of having a small window opening or damper which will release the pressure and prevent any serious damage from dust explosion. *(Wood dust exploded on the second attempt, new roof being used.)* That was hickory wood dust.

We have here a sample of wood dust from the Hercules Powder Company. That sounds bad, doesn't it? At least, the man says it is wood dust. *(Wood dust exploded.)* We have another sample here of corn sugar, 2 per cent cereal through Meade Mill.

CHAIRMAN HASSE: I will ask that, if any of the members have any questions to ask, they hold these questions until after the demonstration has been concluded, please. *(Corn sugar exploded.)*

MR. BROWN: In this last demonstration, we used a smaller amount than usual. I considered the dust explosive and, rather than take any chance with the apparatus, we cut the amount down to about half. We have a sample here from the Postum Cereal Company. It is a material which floats to the top of the corn elevators; gathered from conduit box and eye-beams.

VERN D. SUTTON (Postum Cereal Company, Battle Creek, Mich.): It might be of interest to explain that I did not scoop this dust up out of a bin. I went around the plant, looking for dust; and with a paint brush, I swept this up from the conduit box and eye-beam in the top of the corn receiving tanks. That is where the shell corn is received; it has not been ground but, in the first process, it goes through a cleaner and also through the elevators, and this dust is up at the top of the elevator. The rattling of the corn has dislodged an accumulation of dust from each kernel and that has floated up to the very top of the elevator,—an elevator very much like the one you are using in this demonstration—so that,

if we should have a vibration that would jar that loose and a spark of ignition, we would get the kind of an explosion you will get there now. It is a test of our safety as well as the explosibility of the dust. *(Dust exploded.)*

MR. BROWN: Our test is somewhat limited here. I see quite an array of samples. If we do not get to your particular product, I will ask you to send a sample to Washington where we can make a complete test and give you a report. We have a sample of dust here which someone tells me is explosive, but we will demonstrate it and see. It is pyroxylin of lacquer, another dust outside the field of food industries, but I hope it will serve to demonstrate the purpose. It is in powdered form; it is the dried powdered dressing from the lacquer sprays; seems to be a mixture of all colors apparently. *(Dust exploded.)* In this last demonstration, we used less than half of what one of these cups holds.

MR. SUTTON: Mr. Brown, how much does that cup hold—about a teaspoonful?

MR. BROWN: Possibly a little more, if heaped up. We have a sample here of flour from the Minute Tapioca Co.

MR. SUTTON: This is not wheat flour, but tapioca flour, isn't it?

MR. BROWN: Yes. *(Dust did not explode because the paper roof became torn, as in a previous demonstration.)*

H. P. WARREN (Prod. Mgr., Minute Tapioca Co., Inc., Orange, Mass.): Mr. Brown, would you say that this dust is not very explosive?

MR. BROWN: No, there was a leakage in the paper. Our ring has broken and the wire is cutting the paper when we clamp it on. The hole in the paper releases the pressure before it is built up sufficiently to break through. Possibly it is less explosive, but any leakage in the enclosure which will permit the pressure to be vented will prevent the report. *(Several attempts were made with the tapioca dust, but it did not explode.)* Let us try a sample of wheat flour. *(Several attempts were made with the wheat flour, but they were unsuccessful on account of the paper tearing each time.)*

CHAIRMAN HASSE: I am sorry, but we will have to discontinue the demonstration. The ring for paper roof is broken and keeps tearing the paper. Mr. Brown is now going to give a demonstration that will only take a minute to give you an idea as to just how a dust explosion will travel.

MR. BROWN: This is to indicate the way a flame will propagate through a dust cloud. I have a small cloud of dust in a piece of cloth. By shaking the cloth, I will sift through enough dust to be ignited by a match. *(Sifted cloud, ignited by match, traveled a short distance across the floor and then exploded.)* I am sorry we did not get around to all these samples. If you did not get in on this demonstration, and will be good enough to send a sample to Washington, we will make our test there and give you a written report on it.

CHAIRMAN HASSE: We have about eight minutes for discussion. Have you any questions that you would like to ask?

THOMAS STROBBER (Vice Pres., Wagner-Taylor Co., Philadelphia, Pa.): Mr. Brown, what is the chemical form of inert gas?

MR. BROWN: Inert Gas is simply ordinary air in which a portion of the oxygen has been replaced with an inert gas such as carbon dioxide or nitrogen. In other words, ordinary air being made up of approximately 21 per cent oxygen and 37 per cent nitrogen, changed by the addition of additional nitrogen or carbon dioxide to a form where it contains approximately 10 to 12 per cent oxygen, 10 or 11 per cent H_2O , and the balance in nitrogen. There are a few rare gases, of course, present in air. The oxygen is necessary to allow combustion of the carbonaceous materials. If that oxygen is limited, the combustion is prevented.

CHAIRMAN HASSE: Are there any other questions? If not, we will proceed to our next subject on the program which will be presented by Mr. James H. Baker, Vice-Pres., Franklin Baker Co., Hoboken, N. J. I take pleasure in presenting Mr. Baker.

Safety Contests of the Food Products Group of the Merchants Association of New York

By JAMES H. BAKER

Vice-Pres., Franklin Baker Company, Hoboken, N. J.

The Merchants Association of New York had long felt the pressing need of some influence to reduce compensable accidents, the cost of which, including loss of time, loss of production, machine shut down, etc., was amounting to huge sums. So a year ago they inaugurated an accident prevention campaign among their industrial members in Metropolitan New York.

A General Committee of experienced men was appointed and they formulated a program, splitting the various industries into groups, among which was the Food Products Manufacturers, and it is on the accident prevention campaign of this particular group that I have prepared my report.

Committees were appointed for each individual group and a contest planned under the supervision of the General Committee. The winner of the contest was to receive an appropriate trophy, with other trophies to be given to those winning second and third place. The Merchants Association agreed also to give a certificate of award to all companies having perfect records.

The Food Products accident prevention contest was arranged to run for a period of four months—Feb. 1 to May 31 of this year.

The plan of reporting accidents was made as simple as possible for it was soon quite apparent that few of the industrial organizations in New York had given serious thought to a safety program. They did not keep data on accidents nor seem to understand the purport of this work, feeling that it was too much trouble.

It was therefore only after considerable effort that sufficient members were interested to become participants but we finally secured 53 entries, all of whom remained in the contest until the end.

Reports were sent in weekly by the different contestants giving the total man hours of operation and the number of lost time accidents. Severity of accidents was not taken into consideration; only the frequency and a lost time accident was deemed one in which the employee could not pursue his regular work on the day following the accident.

This method, of course, did not give a true picture of the safety condition in any particular plant but we felt it was the best that could be accomplished in the first contest and the chief idea after all was to stimulate interest in safety work.

The first few reports showed quite a few companies with perfect records; that is, no lost time accidents. But many reports were late in arrival and we did not seem to be securing enough interest and cooperation to obtain any real lasting benefit in accident prevention.

So the committee arranged for the services of a safety engineer to visit the various plants; to give safety talks with motion pictures; and stir up interest.

We further provided posters pertaining to the contest and after another month's progress the contact man had the following report to make.

Report of Contact Man

The following is a résumé of 29 visits to contestants, analyzing in percentages the following points:

- (1) 100 per cent in favor of the plan of the contest.
- (2) 25 per cent entered the contest passively—felt no particular benefit would accrue—entered as a courtesy.
- (3) 75 per cent feel that the benefit to be gained is worth-while.
- (4) 100 per cent favorable to, and pleased with a contact man.

- (5) 90 per cent favorable toward suggestions and recommendations of contact man. Other 10 per cent feel that their present safety organization is handling matters ably, and needs no such assistance. Merely want contest statistics.
- (6) 40 per cent asked what program and publicity the association was presenting. Had received inadequate literature, and had received no reports
- (7) 90 per cent could use safety-posters and safety letter bulletins, 10 per cent had no use for poster service or payroll inserts.
- (8) Only 5 per cent in favor of rallies.
- (9) 50 per cent in favor of foremen's safety meetings to be attacked through contact man.
- (10) 50 per cent of having informal contact with department heads, foremen, etc.

This showed rather conclusively that we were on the right track and that it was essential to have this personal contact with the various organizations if we were to gain worthwhile results and stimulate sufficient interest so that each organization would really give serious thought to the safety program.

Previous to this contest I am inclined to think that the utmost in safety work carried on in about 90 per cent of the plants was that amount sufficient to obtain the insurance credits for so-called safety or inspection committee, first aid equipment and physical condition of the plant.

When the contest was about half completed we sent out questionnaires to each of the contestants, receiving only 20 replies, which in itself is a further indication of lack of interest. The replies were interesting although in some cases contradictory.

Analysis of Questionnaire Sent to Contest Participants

Number of questionnaires mailed.....	53
Number of replies.....	20

The questions asked and the replies of contributing companies are as follows:

1. Has the participation of your company in The Merchants' Association Accident Prevention Contest assisted you in reducing accidents and costs?

Yes	10
No	5
Uncertain	2
Gave no answer	3
2. Do you think that such contests are valuable and worthy of continuance?

Yes	17
No	1
Questionable	1
Gave no answer	1
3. Has the work of our contact service man been of value to you? In what way?

Yes	7
No	3
Gave no answer	4
Had no calls from contact man	6

One company stated that the personal contact was far more effective than writing and entirely responsible for their entering the contest.

Helping its newly appointed Safety Director to meet others interested in Safety work, was the expression of another company.

"Presenting a well worth while cause to us" was the statement of a third company.

Several other companies, while not availing themselves of the contact man's services, firmly believed in it and stated that they received a similar service from their insurance companies or from their own Safety organizations.

4. Which of our contact man's services have you found to be the most valuable? (Plant Inspection, Talks to Employees, Safety Suggestions, etc.)

Safety Suggestions	4
Tips on Posters	2
Safety Talks	2
Plant Inspection and Personal Contact	1
Information on Conditions in Kindred Industries	1
Gave no answer	10

5. Do you think that this contact service should be continued and extended to other contest groups? If not, why?

Yes	17
No	1
Gave no answer	2

Two companies answering "Yes" stated that service should be extended to other groups unless similar service was supplied by insurance companies.

6. Please state below any suggestions or criticisms that may be of value to the committee in charge of The Merchants' Association Accident Prevention Movement.

7. Have you a man on your pay roll who is officially charged with the responsibility for safety?

Yes	11
No	7
Gave no answer	2

8. Approximately what proportion of his time does he spend on safety?

Full time	2
Fifty per cent of time	2
Thirty-three and one-third per cent of time	1
Ten per cent of time	1
Five per cent of time	1
Portion of time—not definitely stated	4
Gave no answer	9

9. Have you an organized Safety Committee?

Yes	11
No	7
Gave no answer	2

Final results of the contest were gratifying in that 18 out of 53 companies had perfect records. The winning banner was presented to D. Auerbach & Sons who had the greatest total man hours work, this being some 550,000 with no lost time accidents. The 18th on the list had a total man hours worked of 4,304 but likewise had 100 per cent record, in that there were no lost time accidents. Certificates of award were presented to each of these organizations.

There were some six other companies who had very commendable records, as for example one organization with 561,000 total man hours work and only one lost time accident. To these companies the Merchants Association presented letters of citation.

The summary of all contestants showed some 17 million man hours worked with 314 lost time accidents or 54,000 man hours of work per accident. This gives a frequency of 18.44 accidents per million man hours.

Careful records were kept showing the causes of accidents and it is interesting to note that 27 per cent of the accidents, occurred in the handling of materials. The next most serious hazard was stumbling or slipping which caused 17½ per cent of the accidents and following this was falling objects totaling 11½ per cent.

Accidents from machine hazards were something less than 10 per cent which

would indicate that the majority of the plants were well provided with the necessary safeguarding equipment.

Most of the accidents were therefore largely due to failure of the human element; were in most instances preventable, and unquestionably a big reduction in the total number of accidents could be accomplished by a carefully planned program of safety.

We will, without doubt, start another contest among The Food Products Manufacturers in the very near future. I think in this contest we should take into consideration the severity of accidents as well as the frequency, and if we are to make the contest a real success we must have more posters, more safety letter bulletins, more frequent reports and closer personal contact with each and every contestant. These plans have already been discussed.

According to reports of our contact man, rallies among our contestants were not particularly popular, presumably because they interfere with production but most companies were favorably disposed toward foremen safety meetings; to safety posters and to suggestions and recommendations for the betterment of their safety organization.

I might add that there was real interest displayed at the meeting in June when the awards were given and we had a large gathering present, so we feel very hopeful that in the next contest we can arouse greater interest and have a larger number of entries.

THOMAS STROHBAR (V. Pres., Wagner-Taylor Co., Phila., Pa.): I am interested in the view point of trade associations to which the members must belong. I would like to know what percentage of the members of the Merchants' Association who were in this contest are members of the National Safety Council.

MR. BAKER: No, I do not know that. That could be readily obtained but I doubt if there are so very many in New York because in New York City there is no local safety council.

MR. STROHBAR: There is a New York Safety Council.

CHAIRMAN HASSE: Not in New York City.

MR. BAKER: We have one in Hoboken—a rather active one, too. But that is not in the Metropolitan District.

MR. STROHBAR: The view point that I think the Food Section of the National Safety Council would be particularly interested in is having more of the members of the Merchants' Association who participated in the contest become affiliated with our campaign; and, therefore, if that is going to be a benefit to the Food Section, perhaps, it would be well to encourage other organizations to take up similar campaigns such as you have had.

CHAIRMAN HASSE: Are there any further questions? If not, we will proceed to the third subject on the program, which is the election of officers. I will ask Mr. Prouty, Chairman of the Nominating Committee, to kindly submit their selection.

Report of Nominating Committee

RALPH E. PROUTY (Aetna Life Insurance Company, New York City): Mr. Chairman, Ladies and Gentlemen, the Nominating Committee presents for the consideration of the Section the following nominations for the ensuing year:

Chairman: Alex. Dienst, National Sugar Ref. Co., Long Island City, N. Y.

Vice Chairman: Wm. P. Penty, Kellogg Co., Battle Creek, Mich.

Secretary & News Editor: Gerald L. Gore, Casualty Reciprocal Exch., Kansas City, Missouri.

Chairman Poster, Lantern Slide and Safety Kinks Committee: H. P. Warren, Minute Tapioca Company, Orange, Mass.

Chairman Membership Committee: J. A. Powers, Pillsbury Flour Mills, Minneapolis, Minn.

Chairman Program Committee: Thomas S. Strobhar, Wagner-Taylor Company, Philadelphia, Pa.

Chairman Engineering Committee: Ralph E. Prouty, Aetna Life Insurance Co., New York City.

Chairman Statistical Committee: Will Cooper, Stevens Hotel, Chicago, Ill.

Executive Committee: Officers, and

Vern D. Sutton, Postum Company, Inc., Battle Creek, Mich.

A. C. Lewis, Detroit Creamery Co., Detroit, Mich.

F. A. Hasse, Corn Products Corp., Chicago, Ill.

G. A. Noxon, Ralston Purina Co., St. Louis, Mo.

Signed: Ralph E. Prouty, W. H. Cunningham, Wm. P. Penty.

CHAIRMAN HASSE: We have heard the report of the Nominating Committee. What is your pleasure?

(Motion to accept nominees made, seconded and unanimously carried.)

CHAIRMAN HASSE: We will now throw the meeting open for any discussion that you many care to have. Perhaps we cut the dust explosion discussion a little short this morning, and, if any member has any further questions to ask, we still have Mr. Brown in our midst and I know that he will be more than pleased to answer any questions.

A. E. WINDLE (Plant Engr., Wilbur-Suchard Chocolate Co.): Mr. Chairman, I would like to know how Mr. Brown rates the explosibility of cocoa in more or less confined places, compared with other things.

HYLTON R. BROWN (Associate Engr., Washington, D. C.): I would say that cocoa is about one of our average dusts, giving between 10 and 10½ pounds pressure per square inch when tested under what we call our uniform testing conditions—that is, a given quantity of the dust in a given quantity of air compared with our standard Pittsburgh Coal dust. All samples are sifted and a given quantity is exploded in a given quantity of air in order to obtain uniform results. Cocoa is classed as an average explosive dust.

MR. WINDLE: Mr. Brown, how do you rate pulverized can sugar?

MR. BROWN: Cane sugar is somewhat more explosive, giving us around 12 pounds per square inch compared with the standard coal dust sample which we have regulated so that we obtain 10 pounds per square inch pressure for coal. The pressure is between 12 and 12½ for sugar dust. That will depend somewhat on the moisture content; the condition of the sample, in other words.

WILLIAM GATES (Peters Chocolate Co., Fulton, N. Y.): Does the butter fat in the cocoa make any difference in the explosibility?

MR. BROWN: Yes, I believe it does with the cocoa dust.

MR. GATES: In the different makes of cocoa there is a different percentage of butter fat. Does that make a difference?

MR. BROWN: All samples vary somewhat according to their composition, just as in sugar dust and some of the starch dust.

G. A. NOXON (Ralston Purina Co., St. Louis, Mo.): I notice that Mr. Brown spoke of the use of inert gas to prevent explosions but he did not say anything about the use of magnetic separators to take out the metal which really causes the spark. I am particularly interested in what is best type of magnetic separator to use. In our business we use numerous types but, naturally, some of them are going to be more efficient than others.

MR. BROWN: Of course, we cannot single out any particular make of magnetic separator and advertise any one company's product over another. We simply recommend efficient magnetic separators in order to remove any metal which may enter grinding machinery. I am afraid that I could not go into any details in answering that question. There are several different types of separators on the market. All of them are comparatively effective but you still have the chance of stones or non-magnetic foreign material entering the mill with the feed, so that

it is not 100 per cent protection. Some companies prefer to use both the magnetic and non-magnetic separators and obtain somewhat better results in that way. Inert gas is 100 per cent protection. By removing all foreign materials that you can and using inert gas, if a spark is produced, you still have non-combustible atmosphere which gives you the protection desired.

VERN D. SUTTON (Postum Co., Battle Creek, Mich.): Some of these explosions that might be attributed to metal in the product are sometimes caused by stones striking the metal of your rollers. Of course, you cannot separate the metal from your rollers, and stones will sometimes get in and magnetic separators will not remedy that condition. Of course, static electricity caused by broken electric lights and many other forms of ignition are present or prevalent. Can you tell us what percentage of the serious explosions that have occurred in our industry might be attributed to the possible presence of metal in the materials?

MR. BROWN: Our records for a twenty-year period show that in feed grinding plants alone there were thirty principal explosions, and the fact that eighteen of these thirty explosions originated in the grinding equipment gives us some idea of the percentage due to foreign material entering with the feed, as practically all explosions originating in the grinding machinery are due to metallic sparks or, as you say, the stones or foreign material in it striking the metallic plates. I would say eighteen out of the thirty.

MR. SUTTON: Of course, there is no knowledge as to what percentage of those explosions were caused by metal and what were caused by stones?

MR. BROWN: No.

MR. SUTTON: My personal experience is that a greater number were from stones than from metal.

MR. BROWN: I felt that way about it, too. We have no figures which would indicate any definite percentage.

FRANK MORRIS (Asst. Chief Engr., Liberty Mutual Ins. Co., Boston, Mass.): I want to tell the Section about our experience with motion picture equipment.

We started making motion pictures about twelve years ago and we had some very interesting experiences.

It might interest you to know that the accidents that are staged in motion pictures like the kind that we have produced are not, of course, real accidents. For instance, we show a man who loses a leg under a locomotive. Of course, we have to find a man with a wooden leg and get him to lie down and let the locomotive run over him. When the locomotive hits the man, however, the man simply stands up in front of the locomotive and the locomotive backs up and he falls down. Then the film is reversed and, as you see it, the locomotive comes the other way and hits him and knocks him down. We used, of course, the old 35 millimeter film. We had a lot of difficulty until the safety stock came on the market, then we were able to show the film anywhere. We have had films catch on fire.

There is something basically logical about the motion picture where you can take it out to a plant and get a picture of the present safety conditions. Then you can take a film that applies to that particular industry, whether it is that particular plant or not, and by sticking in a title or two and the pictures of the manager of the plant and the president of the safety committee, you can make it practically a film for that particular shop. Now there is no trick to taking a picture with a 16 millimeter camera; all you have to do is load the thing, aim it, press a button and shoot. You cannot imagine how much you can get on half a dozen feet of this millimeter film. I have forgotten the proportion, but I would say that six feet of this narrow film is equal to probably twice as much of the standard size. The making of titles to go with the pictures is a very simple matter. There is a board with celluloid letters comparable to the kind you see in restaurants announcing the meal for that day, and you just merely have to

make up the title, put it on that board with your little celluloid letters and go ahead and shoot. Just a foot or so will give you all the film you need for a single plant.

In going into a plant, of course, you have to experiment to find out the proper lighting and in order to get the right effects. You can pick up hazardous situations, careless practices, and, as I said, pictures of the safety committee and of the safety inspector on the job; of the bulletin board that is itself good or bad; and piece them together and, with the proper title, you can make the most interesting film for the employees in that plant. Our idea is to present a picture here today that was taken at the Congress, simply to prove the adaptability and the usability of this machine. It is not expensive. I cannot give you the figures on the cost but it is very small compared with the old style machine.

CHAIRMAN HASSE: We will now proceed with our fourth subject on the program. I take pleasure in introducing to you Mr. Robert Clair, Chairman of the Taxicab & Fleet Owners' Section, National Safety Council.

Amateur Motion Picture Equipment as an Aid in Accident Prevention

By ROBERT CLAIR

Highway Safety Engineer, Liberty Mutual Insurance Co., Boston, Mass.

No one can deny the widespread appeal or the educational advantages of which the motion picture is capable. The professional "Movies" have become one of our great national institutions.

As average citizens, there are very few thrills which can be compared with those experienced in seeing ourselves in the movies for the first time. We bring bundles of snapshots back from our vacations with us and are able to obtain a great deal of pleasure in looking them over frequently to review and renew the good times of which they are a record. But if you have not heard, perhaps in your own parlor at home, the literal screams of delight which are uttered by your neighbors, your friends, or members of your family, upon witnessing the projection of an amateur film which you have taken of them, you have not as yet realized the undeniable enthusiasm which pictures in motion can arouse. *There is magic in motion.*

The last two years have witnessed a most remarkable growth in the development of amateur equipment for the taking of motion pictures. A number of well known photographic concerns have perfected so-called "hand cameras" to a point where their operation is practically foolproof and the expense surprisingly low. I say "foolproof" because even I have had some fairly good results along this line! This means that you and I, as ordinary laymen, have had placed in our hands perhaps the most effective safety medium which has ever come to us. Without any particularly intensive training, without any professional instructions, and with no other specialized education, other than the reading of a few brief pamphlets and the observance of a demonstration or two, we may become producers of effective accident prevention motion pictures. Best of all, these pictures can present what is perhaps our most intimate and direct appeal to the individuals which make up the groups on which we are working.

The 16 millimeter sized safety, or non-inflammable, film has become standardized for use in practically all the latest amateur cameras and projection equipment. At any location where there is an electric socket handy we are ready for safe projection within five minutes.

Let me tell you of what is perhaps the most surprising stunt yet performed by this comparatively new amateur moving picture equipment:

Last summer a group of amateur community players in Rochester, N. Y., produced a comedy film drama in three reels, on this 16-millimeter stock. The interesting facts concerning this production are as follows:

The scenario was written and produced and directed by amateurs. It was photographed in three weeks at times convenient to the cast. No make-up was applied. No sets were built. No tripod was used. No properties were rented. No artificial light was employed. All shots were taken with a hand-held amateur movie camera. Exclusive of the cost of the film, the total production expense was \$1.35.

The title of this unique picture is "Fly Low Jack and the Game."

To view this picture is to wonder that so many professional-like thrills and that so much good fun could be filmed with the aid of such modest material and at such a surprising low cost.

I am not on the payroll of any photographic concern nor is my purpose to sell you or to endorse any of the different types of equipment on the market. My purpose is to tell you what we have learned from a year of experience with this amateur moving picture camera and projector.

We have found in them a new adaptation of a comparatively old medium which possesses peculiar effectiveness for the spreading of our safety messages. We are enthusiastic over the experiments which we have made and yet more so about the future possibilities. It is hoped that these remarks may lead you to result-bringing experiments of your own along similar lines.

We can now make our own moving pictures which are, in reality, nothing more or less than animated bulletins. We can exemplify safe practices and immediately thereafter illustrate unsafe operations with their consequences.

Due to the low cost of amateur picture production, our material can be kept fresh, up to date and abreast of the latest hazards. We can afford to change our programs often. Thus we become rid of the annoyance of depending on out-of-date professional film material. If we cannot borrow, buy or rent a special safety movie to fit our needs (and these are usually tragically scarce) we can now solve our own program by making one ourselves.

Through the binding effect of our titles, we are able to offer progressive thought by which we see an accident through all its stages—its cause, the actual manner of happening, and its effect. Through our continuity we may weave otherwise segregated events into a story unit. This arms us with those human interest factors which are always so effective.

Perhaps best of all, we can localize our subject matter both as to setting, situation and characters. I am sure we have all heard a bulletin criticised by the expression, "That's a good bulletin but it doesn't apply to our plant. Our machine is built differently." With our own camera, we can depict our own machines in our own plant, operated by our own workers.

Just in passing, consider the interest value of a home-made "industrial news reel" for our rally purposes. There are many interesting things which take place in our plant almost every week which are worth recording. For instance, here are some of the things which could go into the making of such a local picture of current events:

1. Foreman Jones is pictured being congratulated by fellow employees upon the arrival of Jones, Jr.
2. A new packing machine has been installed in one of the departments. The superintendent of the plant is shown inspecting it. In this, some of the machine's interesting safety or mechanical features may be shown.
3. Three or four new employees are pictured with their foreman, who is explaining to them the safe way to perform their new duties.

4. The plant manager congratulates Foreman Brown on having the best departmental accident record for the month.
5. Employee White is shown having a piece of steel removed from his eye by the plant doctor. White agrees that he will wear his goggles the next time!

The statement is almost unnecessary that a few shots, such as the above, would certainly put an added "kick" into any safety rally program. I have not been extremely thorough in listing the possibilities of the local "industrial news reel." With very little thought you can develop this into a most important part of any safety program which you may be developing.

Should a number of you become interested enough to work out and "shoot" some accident prevention picture stories in your own plants, there is at once the interesting possibility of exchanging these reels among ourselves. You are in closely related industries—much of your machinery is similar—many of your hazards are common. Perhaps such interchanged films would not be as effective among your workers as those taken by yourself in your own plant because of the absence of "local color" interest, but at least the appeal of the animated bulletin would be present.

With an f 1.9 lens equipment, surprising results may be obtained with these hand cameras in very cloudy days or even during a rainstorm. With a lens of such high speed, an apparently weak diffusion of daylight will give clear and accurate pictures.

For the taking of interior scenes, even in the darkest corners of your plants, very efficient portable artificial lighting units are obtainable. Most of these are light weight, compact and easily transported by hand.

It is a very easy matter to make your own titles for the pictures which you take. No changes in the regular camera lens equipment is necessary. This complete lettering equipment for titling may be obtained, with detailed directions, at any large photographic shop.

You might be interested to know a few facts concerning the developing arrangements for these 16-millimeter films. The film may be obtained in rolls of either 50 or 100 feet. The initial price of these reels includes the developing cost. As soon as the reel of film has been exposed, you return it to your photographic shop and it is sent away for development. The finished film will be returned to you usually within two or three days. The time necessary for development all depends upon how far you are away from one of the developing stations.

The developing of this film is what is known as the "reversal" process. This means, instead of receiving a negative film, that a positive is returned to you. This positive film is the actual film which was exposed in the camera. Instead of appearing as negative, it has been "reversed." Should you want another copy of it, such may be obtained for a given cost. In addition to this regular "reversal" film, which comes back to you as a positive, there is also a "negative" film on the market. We believe that this film is priced at about one-half again as much as the regular "reversal" film. The reason for this is that when this film has been developed and returned to you, you receive both a negative film and one positive copy. This gives you a permanent negative record for your file, which at any time may be copied positively at the standard price rate.

Hand camera motion picture films in natural colors are now realities. I have filmed a test reel of this new process and assure you that it gives remarkably life-like effects and is rich in possibilities. Bright sunlight, a special filter which is inserted in front of the regular camera lens, and a specially prepared roll of film are the only three requirements for the taking of these pictures in natural colors.

I came down here to the Congress last Sunday with no definite idea as to what I would have to show you.

In order that we might show you something in the nature of a home-made news reel, we got busy and shot a reel of film in and around New York on Monday, October 1, which was the first day of this Congress. This film we have prepared especially for this session of the Food Section. It has not yet been shown publicly. We have reason to believe that this is a real "scoop." You will be the judges as to whether or not it proves interesting.

I shall be glad to answer any questions which you may wish to ask after the showing of the pictures.

(Following the address, Mr. Clair showed a moving picture illustrating his subject.)

CHAIRMAN HASSE: Are there any questions that anyone would like to ask?

VERN D. SUTTON (Postum Co., Battle Creek, Mich.): Mr. Clair, you referred, I believe, to the use of the motion picture camera in preparing posters. What is the advantage of the motion picture camera over an ordinary camera in getting poster pictures?

MR. CLAIR: Perhaps I was not clear. My thought there, was, not that the motion picture camera picture itself be used in taking pictures for bulletins; I tried to bring out the point by telling you that pictures in motion from which you can make an animated bulletin present a much better appeal than merely looking at a snapshot.

MR. SUTTON: I think, however, that there is an advantage in using a motion picture camera in taking poster pictures. If you have tried to do that work very extensively, you will find that, when you want to take a hazard, especially if you are going to pose people in that picture, when you have developed your picture, you find the people have lost their pose. Sometimes, I have to try three or four times. If you take a motion picture of a person going through this hazardous operation, you can select one of them for your poster.

MR. CLAIR: That is a very fine thought. Only there is a limitation. Of course, you realize that these pictures are very small and you are more or less restricted as to enlarging them. I can't tell you off-hand the maximum size. Perhaps you might be able to get it up to about 2 x 4 inches, but I doubt very much whether you would be able to get a bigger picture on this size stock.

MR. SUTTON: Mr. Clair, if you should happen to get a real sharp picture, it could be enlarged to sufficient size; if your large picture were made up to 4 x 5, even if your picture were not as perfect as it might otherwise be, I think the boys in the plant would not criticize the picture so much, and still it would portray the hazards. I think there would be a decided advantage in using a motion picture camera.

EDWARD H. FARNAN (Standard Acc. Ins. Co. of Detroit): You cannot get a good enlargements from the 16 millimeter film. I tried to get it up to 3 x 4 inches but they are very poor.

MR. CLAIR: That was my impression. I thought that, if you could get it up to 2 x 4 inches you would have gotten to the limit in size.

C. M. FINCH (Supt. of Inspection, Mass. Bonding and Ind. Co., Boston, Mass.): I think, perhaps, that Mr. Clair has in mind a short film that depicts a man falling down an elevator shaftway. I think a great many of the members here have seen this bulletin; it shows the different stages from where the man falls, all the way down, showing him turn over and over and over, till he reaches the bottom.

MR. CLAIR: You mean just a strip of film?

MR. FINCH: Yes.

ADJOURNMENT

October 4, 1928

F. A. HASSE, Chairman
Safety Director, Corn Products Refining Company, Chicago

The Thursday session of the Food Section was called at nine-forty o'clock by the chairman, F. A. Hasse.

CHAIRMAN HASSE: Our first subject this morning will be covered by Dr. Louis I. Harris, Consultant, National Dairy Products Corporation, New York City. Dr. Harris was also formerly Commissioner of Health of the City of New York, where I understand he made quite a reputation. It gives me great pleasure to introduce to you Dr. Harris.

The Value of Physical Examinations

By DR. LOUIS I. HARRIS

Consultant, National Dairy Products Corporation, New York City

The value of medical examination should require no labored explanation at this stage of our scientific and general educational development. For fourteen years it has been my privilege to watch rather closely the development of industrial medical service, and I am disturbed by the fact that in a country that is so tremendously given over to the promotion of efficiency methods and to the development of machinery which has come to play a dominant role in industrial life, that the human machine has not been conserved adequately.

Possibly this is because it has been felt that it can be replaced, practically speaking, with least difficulty. I have seen industrial organizations lavish no end of care and no end of solicitude on machinery, and, on the other hand, I have seen the workers scrapped for want of adequate protection from accident and health hazards associated with industry. Waving questions of an ethical or humanitarian aspect, I will regard the worker only as an industrial asset.

I recognize the splendid industrial hygiene work done by many, such as the General Electric Works, the Metropolitan Life Insurance Co., the Endicott-Johnson Company, and others. But aside from a relatively small number who are interested in conserving life and health of workers, there has been little progress in medical examination service in industry and the associated activities.

Medical examination is to be considered from two points of view; first, in relation to the benefit it offers to the individual; and, second, to the benefit that accrues to the industry.

May I first speak, parenthetically, of a subject that I cannot discuss at proper length, namely, the sale of a Life Extension Service. I don't know how many of you have read this month's *American Mercury*, in which Dr. Logan Clendenning writes on "Health Audits" and speaks, without mincing words, about the Life Extension activities. If you haven't read it, let me commend it to you as a very sane article, which, while I do not wholly agree with it, scores most excellent points about this miracle which, like Ponce de Leon's fountain of youth, is held out to a great many who read the glamorous promises of the Life Extension Institute as a means to the prolongation of life.

Dr. Raymond Pearl has stated that human beings are very much like clocks that are wound up, through inherited characteristics and qualities, to run for greater or shorter periods. Some are forty-year clocks, some seventy and some perhaps

eighty or ninety, to a doddering old age with second childhood as a feature that marks the running down of the clock.

The Life Extension ballyhoo is unfortunate in that it gives the impression that what you have to do to live long enough is to be medically examined. But scientifically it is utterly inaccurate. A man of forty or forty-and-more, or a woman—and women are by no means immune—if they have high blood pressure, are not going to be benefited in many cases which doctors designate as essential hypertension, or, putting it in plain language, unexplainable high blood pressure, by examination. Advice may be helpful to avoid certain dangers, but it will not, in the majority of instances, be serviceable otherwise; and if advice is given tactlessly and in a routine fashion, it may create a most unfortunate state of mind.

This is not meant to minimize the importance of medical examination and preventive service if aimed to eliminate environmental hazards to health in industry so far as concerns captains of industry as well as the hewers of wood and the drawers of water; those who man the commanding positions or the humble servitors in the industrial organization.

Medical examinations are most useful among pre-school age children; that is, in the group who are under five years of age. In the older age groups, and in industry in particular, they are of value to discover disease tendencies, or diseases that are established, in order to prevent further progress, or to eliminate the industrial factors that may be causing damage to health. There are frequent conditions that one cannot do a thing for at the age of forty; and so I say advisedly that we have to change the system of medical examinations, if they are to do the individual good, by inaugurating such medical examinations as early as possible. A vast fortune is being expended in school medical examinations, many of which are made too late. Children who already have rheumatic affections that have damaged the heart, are a reproach to those of us who are responsible for their protection.

In industry you are particularly concerned with two great features—the feature of safety to those who are working in industry, that is, medical examinations to guard the health of the public who consume food products. So much safety work has been done, that everyone knows that you cannot admit into a plant an epileptic who is likely to have an attack of epilepsy, where just a moment's unconsciousness or loss of control may do untold damage to life or to production.

A worker suffering from heart disease, or with a blood pressure of 200 or 220 or more cannot safely be entrusted with some vital and responsible job upon which the lives and safety of others may depend. This is not to say that persons with heart disease cannot be employed with mutual benefit in industry. The individual who is color blind, and who ought to be able to distinguish colors—the engineer, for example—cannot be permitted to control the throttle. A great many drivers who are now given licenses to drive cars do so without being able to discern colors. The observance of color signals may be most important from the standpoint of personal and public safety.

Parenthetically, may I say, that there are a host of men and women who drive cars, some of them having a mental age of six years, though they shave and have the outward appearance of maturity. These are morons who have no sense of responsibility. There are drivers who have nervous diseases that should disqualify them. There are those who have high blood pressure who are permitted to sit at the wheel of cars that are potential man-killers. There are drug-addicts whose sense of responsibility and intellectual faculties are dulled by frequent use of the needle, and then there are a goodly number of people who are deaf.

Continuing this parenthesis, I should like to urge that there should be an utterly different system of licensing those who drive—whether they be taxi drivers or owners or chauffeurs who drive pleasure cars or other vehicles. I should like to see a medical examination as a requirement to make sure that those who apply for a driver's license are not suffering from such diseases that are recognizable by

medical examination which would disqualify them. I have known instances where men have driven cars who have suffered from this new disease that we are now learning about, a disease that obliterates the arteries of the legs or arms—thrombo-angiitis obliterans—cutting off or shutting up blood vessel canals, which frequently cause amputations to be performed. An annual medical examination would here prove a valuable thing. As to those that are arrested for violations of traffic laws where there is any element of negligence involved, it ought to be required that such persons submit to a mental and medical test, carried out by psychiatrists, to determine whether it is safe to permit such offenders to drive cars.

To return to my main theme, medical examinations are of value to prevent the huge labor turn-over that occurs, particularly in hazardous occupations. I have found that when you provide medical examination, and watch for signs that point to industrial hazards, removing workers who are exposed to lead poisoning for example to another department of work upon the signs of blood disturbances such as anemia, and not waiting for the occurrence of marked and unmistakable trouble, labor turn-over is diminished. Employees come to know and appreciate when they are watched over with medical solicitude and foresight. But, above all, medical examinations throw light upon factory conditions that menace health and safety.

Doctors in industry who merely treat bruises and injuries and have neither the social vision or professional interest to ask "Why do I get so many injuries or cases of sickness to care for?" are narrow and lacking in real value to industry. When girls employed in a factory suffer from persistent headaches in certain departments of a shoe factory, for example, it should arouse medical curiosity whether there is an excess of benzene or naphtha to which they may be exposed.

I am offering random examples and I trust that you will bear with me because I have not had the time to prepare, nor the time to present a well-rounded and full statement of this subject. The doctor in industry, I hope to make it clear, should not only serve to prevent accidents, and to save losses through compensation suits, but he or she should also aid to discover the precise places in the factory where damage to life and limb as well as to health threatens; and it seems to me he ought to be able to sell the idea of prevention with greater persuasiveness than that of patching up injuries. They must bring industrial managers to recognize such service as an absolutely essential thing that pays dividends. If a doctor cannot show that he has saved a company many times more than they pay him, it indicates a serious lack of efficiency, that he is a "bandagist" chiefly. As a doctor you must know how to treat patients intelligently in industry, but you must do far more, you must have a clear idea as to the processes of industry as they relate to safety and health.

I come to medical examinations as they relate to establishments. There is a double relation, so far as food is concerned. If you manufacture food you have a peculiar relation to the public. One cannot tolerate in the food industry a food handler who may have had typhoid fever or who is suffering from a communicable disease. Those who serve company cafeterias or restaurants must be free from communicable disease. In this age of democracy even your captains of industry and company managers may be exposed to disease if the man or woman who serves food has a septic sore throat, tuberculosis, is a typhoid carrier or otherwise infected. But the danger of employing diseased food handlers as it relates to the general public is of greatest importance.

You may remember that in Lee, Massachusetts, a few months ago there was a septic sore throat epidemic that caused about 700 to come down with the disease and about 36 died. We do not know how many more whose cases did not come to public notice were affected and who were carriers of the germs of this disease. We do not know how many were left with damage to the heart.

When I speak of medical examinations I don't mean a casual routine consisting of the hurried use of the stethoscope which makes such a tremendous impression

upon the laity. I also plead for the greatest regard for sanitation in the manufacture of the food-stuff.

A medical examination once a year is a mere entering wedge, an indication that people have come to recognize that medical examinations are necessary. The week or month after a man is examined he may acquire, syphilis, gonorrhea, or show signs of tuberculosis with a positive sputum. It means, that if industry is going to protect itself, there should be something akin to military routine, namely, frequent and thorough examinations. I mean to indicate to you that industry has a great opportunity to promote public confidence by a sincere and thorough system of medical service that adequately protects the public.

The soda fountain is now the source of food supply to millions throughout the country. What sanitary sins are committed at practically all the soda fountains? Most are infested with flies, food is exposed to dust, counters are sloppy, salivated spoons, glasses soiled with saliva are swished around in a little tub of water that is luke-warm instead of being 180°, or 212°F. preferably. Reform of soda fountain practices are urgently needed in most places.

The food industry must realize its obligations to the public, and it must provide medical examination of those engaged in food-handling, whether it be the soda fountain, the restaurant or the bread counter. They must provide for thorough and frequent examinations so that the public may be protected and that industry may be saved from being discredited by attacks that are justified when it is negligent.

There are comparatively few establishments that have shown any great interest in guarding the health of workers. If these lessons are taken to heart, I make bold to say that if you have a Congress ten years hence you may celebrate the fact that a doctor is of the greatest value to industry, that he is not a "bandagist," that he will help tremendously to conserve man power and promote sound business through the protection of the public health.

CHAIRMAN HASSE: I am sure that we have all enjoyed this splendid address by Dr. Harris. I think we have been indeed fortunate that we were able to hear a man of his type present this subject to us. I am sure a number of you have a question in your mind about physical examination, and in talking to Dr. Harris before our meeting started he assured me that he was ready to answer all those hard-boiled honest-to-God safety men. So, if you have any question that you want to ask Dr. Harris, I know he will be more than pleased to answer your question.

MR. COLEMAN (Continental Bakeries, Inc., New York): I would like to ask the doctor—in a company where we employ one hundred, is it advisable to recommend an examination where we have to take a chance on doctors we do not know? Would they not recommend such things as tonsils, etc? Do us more harm than good?

DR. HARRIS: The examination of food handlers has been made a very difficult thing by the fact that private physicians have frequently been allowed to make the examination of the food handler and have given the opinion that the food handler is free from disease. Being interested in bakeries, I take it that you are interested that the public should not suffer from any person who is affected with a communicable disease. A private doctor may be in an embarrassing position. The food handler represents a family whose good-will he desires to retain; therefore he is between the devil and the deep sea, for if he helps the company by saying that a food handler is suffering from tuberculosis, and recommends his exclusion, he loses a patient. If the food handler suffers from scabies (the itch), or something that is ever more dangerous (let us say syphilis in an active stage) and I want to warn you that there are several people who have suffered from syphilis who are free from active infection and should be allowed to work in industry—if you leave that to the private physician he is embarrassed, and in a sense restrained from

divulging such facts to you. So I think that companies that depend upon private physicians are handicapped.

They ought to engage those who are on the company's payroll. Such physicians must be imbued by a public health ideal. They must not be told by managers, "I have had a hard time getting these men in my employ and I don't want you to tell me that six out of the ten I have engaged are not fit for work." They should be free to express the truth, and the truth only. They ought to make frequent inspection, instead of one examination a year. I know of one ice cream company that has a daily morning inspection and the men and women line up. If any man or woman comes to work with black fingernails or unshaven or signs of dirt or carelessness as to person, they are not allowed to go to work; they are sent off for the day. They can't work in that place unless they are really clean.

MR. COLEMAN: Just another one, doctor, if you please. Our bakeries being so widely scattered, if we try to get a doctor to handle them we would just scratch the surface, otherwise the expense would be tremendous.

DR. HARRIS: A part-time employment overcomes that difficulty. If I wanted to do that I would go to the local Health Society—you have a Tuberculosis Society in most cities. Give me a panel of twelve doctors. Let me interview them. I would say in effect—"Doctor, we wish to engage you. We have only twenty people. We would like you to give us periodic help. We want you to come in once a week, and to instruct somebody what to do in an emergency." You wouldn't expect him to make a diagnostician of that person—you can't make a layman a diagnostician—but you can go far. You cut your cloth according to pattern. Where you have hundreds of workers you can indulge yourself and get a man who gives you a half-day every day, or two hours every day, and then you could have a nurse.

H. P. WARREN (Manager, Production Department, Minute Tapioca Co., Inc., Orange, Mass.): I was interested in Mr. Coleman's suggestion. You take your part-time doctor to come up to the factory and he may give you examinations, but he holds recourse to the town just the same. All the people in the small town, he knows them all; they are his patients. So, in a sense, even though he is in your industry he is working in the town, and the arguments that you say about the local doctor apply, and you can't have a doctor for \$5,000 in a factory for fifty employees, and if you have that doctor come in and teach someone in your employ you have limits. Your district nurse does not want to be the doctor and you are still dependent upon the local doctor; you might just as well build up your own organization in your factory. I think you must build up the spirit in your organization and think that you have done the best you can.

DR. HARRIS: I should hate to be a doctor in a small town, dependent upon a community of 5,000 people. I would find myself in a very embarrassing position, and yet I would be willing to say that if I were engaged to do this for an organization, I would value them as a steady, all-year clientele, but in any case, I would not hesitate in my choice between the steady client and the small client. Your nurse can assume a very large burden. Of course, you are badly handicapped there and you are not going to achieve wonders. I agree with you entirely, but I was not speaking of the very small place.

W. H. COOPER, (Stevens Hotel, Chicago, Illinois): I would suggest as a way out, that we could profit by the methods of the life insurance companies—where the head office employs a medical director and he doesn't say anything to the person he examines as to what he finds. In that way, he is completely out of the picture.

DR. HARRIS: May I say that is being done by the foremost industries that have scattered branches? That very idea is a very sound one, but I didn't dare mention it until you submitted it.

MR. ASHBUR (Liberty Mutual Insurance Co., Boston, Mass.): May I ask the

doctor as to periodic examinations of employees, whether it would be possible for a doctor to develop from a man's physical condition or appearance at the time, whether it would be possible to discover a man who is unfitted to do hard, laborious work that would in time cause back-strain, etc., and cause a great deal of concern as well as lost time to the employee?

DR. HARRIS: If the examination is conducted with thoroughness and intelligence, it should to a large degree lead to that. However, if I am a doctor in an industry and remain in my office and just get the victim to come to me and never leave my office to see the plant, I never would accomplish what you say. As a matter of medical backing-up, I would say, "Out of this department I get such and such cases." If you study your back-sprain conditions you will find that same conditions cause that defect. But that is why I advocated before that medical service must be coupled with a knowledge of what goes on in the plant. If the doctor is not examining the plant conditions and sort of checking up the patients with the plant from which they come and the department that they work in, then he is not going to be producing anything of real substantial value to the organization. Does that answer your question?

MR. ASHBUR: Yes and no. Would you be able to discover that from the examination of the man's condition?

DR. HARRIS: The applicant for work, you mean?

MR. ASHBUR: An applicant or a man who is performing that same duty three hundred and sixty-five days a year or so. Would it be possible to discover at the time of your examination whether the man would be possible to continue that work?

DR. HARRIS: I think so. There is no such thing in medicine as holding out a universal promise, but a large number of cases could be discovered.

CHAIRMAN HASSE: If there be no further discussion, I wish to extend to Doctor Harris a vote of thanks.

V. D. SUTTON (Postum Cereal Co., Battle Creek, Mich.): I suggest that we have a minute to rest after each speaker, and that those who are not interested in the next speaker leave the room now rather than when the next speaker is talking.

CHAIRMAN HASSE: Our next subject on the program this morning is one that I believe concerns every man in industry. This subject will be presented to us by Mr. A. L. Brower, Vice-President and Director of Insurance, Bakeries Service Corporation, New York City. I take pleasure in introducing Mr. Brower.

Plant Cleanliness as an Aid to Safety

By A. L. BROWER

Vice-President and Director of Insurance, Bakeries Service Corporation,
New York City

The topic on which I have been asked to speak is rather limited in its scope and I find has been pretty well covered in addresses made before some of the previous meetings of your organization. I am, therefore, going to confine myself more particularly to certain angles of plant cleanliness as an aid to safety which, while they may be rather radical, are the results of my own experience.

Cleanliness is natural to the more civilized races and with most of us is a matter of habit. We take pride in keeping our persons, our homes, our factories and our business places clean. For about fifteen years my duties as special agent for different fire insurance companies necessitated my making thousands of inspections of manufacturing plants of various kinds. My experience proved to me that, generally speaking, the condition of the entrance hall and the office of the manager or superintendent who had charge of the plant I was about to inspect, was indicative of the degree of cleanliness I would find in the plant itself.

While there were some exceptions of course, I found in the majority of cases that a slovenly entrance hall and office indicated a slovenly plant. In addition it was impressed very strongly upon me that the man who did not keep his plant clean was very seldom interested in safeguarding his property against fire and other hazards.

Every man knows how to keep a plant clean. It does not require special instructions or education, except in rare instances, as does the guarding of various machines, etc. If the manager or superintendent of a plant does not do the things that he knows how to do, he is a poor subject to educate to do the things about which he knows very little, if anything. It would seem to me, therefore, that before we can hope to interest a man in safety work about which he knows comparatively little, we must first arouse his pride and interest in cleanliness with which he is familiar. In other words, it is my humble opinion that cleanliness is the greatest aid to safety because it is the nucleus about which other safety habits must be built.

Speaking strictly to my subject, I believe that plant cleanliness as an aid to safety can be divided roughly into three topics: first, fire; second, injuries to employees and others; and third, foreign substances in manufactured products.

Fire

My experience doing inspection work and in connection with my present position has clearly demonstrated to me the importance of cleanliness from a fire prevention standpoint. Loose paper and rubbish in corners and out-of-the-way places, scattered paper, crates, barrels, etc., to be used for starting furnaces and ovens, oily waste thrown in piles of rubbish, ashes carelessly piled against wooden partitions and walls, and similar conditions, have caused many fires to my knowledge although I have been told thousands of times that there was no danger from them.

There is no doubt in my mind that in plants which are not kept clean you will find a great many more fire hazards which are not properly taken care of than you will in the plants which are. Uncleanliness, I can safely say, is a prolific source of fires.

Injuries to Employees and Others

All of you who have occasion to visit or inspect plants of various kinds have undoubtedly had the same experience that I have had in falling or stumbling over debris, broken boxes and barrels and slipping on pieces of pipe or other round objects, grease, dough or other materials dropped on stairs and floors. I might state one instance in this connection which nearly cost me my life. I was inspecting a plant in Syracuse, N. Y., with my agent who fortunately was familiar with it. In advance of him I stepped from a fairly lighted room on the third floor into a dark passageway. Thinking that it ran straight ahead I stepped forward, tripped on a piece of broken box and had it not been for my agent who grabbed me would have fallen and plunged head-first down an unguarded elevator shaft.

I appreciate that the piece of broken box did not indicate of itself that the plant was unclean but my inspection showed that it was. If persons walking through a plant are likely to stumble or fall or slip, there are many more chances that employees hurrying about their work or carrying burdens which prevent their seeing the floor will do so, and experience has proven this to be the fact. There is no doubt that uncleanliness is the cause of many accidents.

Foreign Substances in Manufactured Products

All food manufacturers are faced today with a serious problem in the claims resulting from the alleged finding of foreign substances in their products. The prompt and oftentimes too generous settlement of these claims in the past in order to avoid the undesirable publicity which might be given them if suit were brought and the cases tried, has increased the number as well as the amounts of these claims very materially in certain sections of the country. They have reached the stage where every food manufacturer realizes that a firm stand must be taken and every legitimate claim which cannot be settled for an amount in keeping with its worth, and all fraudulent and doubtful cases must be fought, settlements delayed as long as possible and the resulting suits tried if necessary to cause the claimants just as much trouble and expense as is possible and make their net returns so low that it will discourage further claims by them or similar ones by others.

While there are many fraudulent claims there are also enough legitimate ones to make us realize the danger of serious injury from glass, nails, tacks, etc., in food products, to say nothing of the very undesirable publicity which may result therefrom and from the finding of bugs and other vermin, pieces of string, wood and metal, and other foreign substances. It is important that every precaution be taken to eliminate the possible sources by means of which foreign substances are liable to get into food products. Of these sources I believe that uncleanness is the greatest offender.

A few instances should be all that are necessary to prove that statement. If milk and other bottles are allowed to accumulate in the various process rooms, sooner or later one of them will be broken either as a result of horse play among the employees or from some other cause with the possibility always present of the glass getting into a batch of the food product in process of manufacture. If packages are opened in the stock or ingredient room and nails, pieces of string and wood are just thrown on the floor or allowed to accumulate on shelves or the barrels or boxes next to the containers which have been opened, it is only a question of how often some of this debris will find its way into the raw material and eventually into the finished product. Certainly you will agree with me that scrupulous cleanliness is absolutely necessary to keep a food manufacturing plant free from bugs and other vermin. In the elimination of the dangers from this source I do not hesitate to put the need of cleanliness first as you will find that where a plant is not kept clean the other conditions which should be guarded against for the elimination of foreign substances are not taken care of.

All employees of the right type appreciate a clean, light place in which to work. Everybody agrees that a clean plant improves the morale of the men who work in it. You all undoubtedly have had the same experience that I have had of starting to enter some plant which was so clean that subconsciously you looked around for something on which to wipe your feet. Surely a clean plant is an inspiration to the employees to help keep it that way, and a fertile field in which to sow the seeds of other safety habits.

Perhaps I am over-estimating the value of plant cleanliness as an aid to safety but I am frank to say that I do not believe I am, and that to procure the proper interest and cooperation of the manager or superintendent of any plant in safety it would be well to determine whether he kept his plant clean and if not, to first arouse his pride and interest in cleanliness before attempting to educate him in other safety work.

CHAIRMAN HASSE: You have all heard the paper presented by Mr. Brower, and I am sure that it is going to give us a little discussion. Has anyone any questions that they would like to ask regarding this subject?

C. F. STODDARD (U. S. Bureau of Labor Statistics): I would like to make a

statement regarding visits to various plants. I have had occasion in field work to do this and I have visited several in this city and in other cities, and I want to take occasion to say a word in regard to plant cleanliness in some of the plants I have visited here. I have visited those plants, looked at them pretty critically, and I couldn't see anything to condemn—one was the National Biscuit Company plant, and one was the General Baking Company plant. I wish you gentlemen would visit those plants if you haven't, and possibly get some pointers from the way these things were carried out. I was very much impressed by the very large amount of space devoted to the work. Operations are not confined to a crowded section. The men are not crowded at all—lots of room. I want to mention that in the General Baking Company plant the superintendent took me around and he didn't say a word or call my attention at all to the condition of the plant. He didn't need to, the facts spoke for themselves. I want to mention also another plant of the same calibre—the Ford Motor Company in Detroit. We know more or less about the efficiency methods of the Ford Motor Company. The plant man took me around and he said "Mr. Ford is a perfect crank on cleanliness," and it was very evident that he is something along that line. While I was going through there a man was mopping up a floor that was so clean that it didn't look as if it needed to be mopped up.

CHAIRMAN HASSE: We will now proceed with the third and last number on our program this morning. This subject will be presented by Mr. H. P. Warren, Manager, Production Department, Minute Tapioca Co., Orange, Mass. I take great pleasure in presenting to you, Mr. Warren.

Safety Problems in the Small Sized Food Factory

By H. P. WARREN

Production Manager of the Minute Tapioca Company, Inc., Orange, Mass.

The essence of the safety movement is the same, whether in the large or the small factory. As I see it, it is to effect a safety organization adequate to the needs of the industry and to make this organization function as nearly 100 per cent as possible, to reduce the number of industrial hazards, educate workers to safeguard themselves against accidents and to take proper care of the injured and teach hygiene. The difference, if there is any between the safety problem in the large and the small factory, lies in the size and effectiveness of the organization. I shall attempt to outline a safety organization that I believe any small sized food factory, let us say one of less than 100 employees, can and should have. I shall then state a few methods or mediums that are most effective in getting the safety program across to the employees and shall close with a suggested method of exchanging safety experiences regularly between members of the Food Section.

In most small sized food factories whatever is accomplished with a safety organization must be done through the superintendent's department; that is to say, the industry is too small to afford a specialized safety department. If the superintendent is far enough removed from the ranks and has been in touch with the work of the National Safety Council, in all probability an effective safety organization is at work. In too many small factories the old methods still persist. The superintendent does not get much interested in anything that smacks of an organization where some of the men will be telling him how to run his factory. In such industries questions as to how many accidents they have and what the scope of the safety organization is bring discouraging replies. Fortunately, such industries are few and growing fewer.

In the small factory, just as in the large factory, the successful safety program must have the force of a sympathetic, understanding company policy behind it.

(Example: superintendent leaves safety work to master mechanic, who, in relation to his fellow workers, resents suggestions. When the factory is rushed master mechanic is busy with production problems and equipment not up in shape as regards safeguards. Employees use defective equipment many times because they are afraid to say anything for fear of getting someone in wrong.)

No industry is too small for a safety committee. The committee may be composed entirely of those of foreman rank or below, or it may have the superintendent as one of the members. While the personnel of the committee is important, the essential question is, how effectively is it doing its job? The safety committee should meet monthly. This may seem commonplace, but the tendency in the small factory where everyone sees each other several times during the course of the day is for members of the committee to exchange ideas and the secretary of the committee to make out the monthly report as a result of these daily chats. The value of the meeting, with discussion and leadership in safety matters, is thereby lost. First, then, a safety committee of at least five members, meeting monthly and discussing the recommendations of its members.

In the factory with which I am connected, this committee consists of six members. It is organized and functions as follows: Three men of the committee are known as the "Inspection Committee." At present they happen to be the power engineer, one man of the repair department, known as the "trouble man," and the boss carpenter. Their job is to actually make an inspection once a month and to report their recommendations monthly to the safety committee, which consists, besides them, of the master mechanic, my assistant and myself. We go over their recommendations. The secretary takes full minutes of the meetings and the master mechanic is given job tickets covering the recommendations to be carried out. The secretary presents weekly a follow-up report as to the suggestions complied with and those outstanding.

It has been our custom for some time to hold group meetings for our employees. These are held usually at the close of the day's work, the company providing a supper, which is followed by an hour's discussion. At such times some one of the safety committee states what is being done, asks for suggestions and gets over any special safety appeal. Such meetings are not safety rallies.

They are a part of our factory organization. Right here let me say that in the factory with which you are connected, especially if it is a small one, if such meetings are not being held, the most effective means of publicity is being passed up. At such meetings, if you will discuss any questions affecting the quality or quantity of production, working conditions or the various personnel problems in a frank, honest, friendly way, attempting to create in such groups an interchange of personal confidence, you have gone a long way towards getting your operating problems, including your safety program, across to the men. Your problem then becomes one of leadership in safety matters, rather than in selling the idea. So much for the safety organization.

Let us now consider what equipment is necessary to properly take care of those injured. There should be a central first-aid room with a person in charge. This is possible and desirable even for the small factory. A small factory may not be able to have a graduate nurse in charge, but this is not necessary. It is possible to have a girl in charge who has an aptitude for such work, and to see that she is properly instructed. Depending upon your local conditions, perhaps all that would be necessary would be to have this girl take a course in first-aid which your local district nurse is usually very glad to provide.

I shall not dwell upon the elaborateness of the first-aid equipment. All that is necessary is a stretcher, couch or bed, hot and cold running water, with the usual first-aid supplies and whatever instruments experience has shown are necessary. Anything except the minor cases are taken to a local doctor.

It is important, even in the small factory, that there should be established a

central first-aid room, and a continuous and most energetic campaign should be aimed to put into disrepute the habit of employees being their own doctors, together with its attendant evils. With a first-aid room, providing the spirit of the person in attendance is of the right sort, it is possible to get over the idea to the employees that it is a convenient and safe measure to have even minor injuries attended at this central place.

So much for the organization and equipment that is needed for a safety program. It is not elaborate. Any factory not only can but must have a similar set-up if it is going to get the best compensation insurance rates.

Now, what are the mediums of publicity to use to drive home the safety message? I have already mentioned probably the most effective one, the group meeting of factory workers.

In talking safety to this group, the economics of industrial hazards should be thoroughly discussed. Injuries mean reduced earning capacity with its train of consequential effects on the family. With this group and with the safety committee we try to teach, if you please, because after all, the safety program is only an educational program, that to guard machines, keep the aisles clear, take precautions in handling materials are all fundamental, that the safety movement has progressed far beyond these things which are now taken for granted. Those responsible for the installation and repair of machinery should be instructed that they are to consider the proper guarding of the machine just as essential as to bolt the machine to the floor. We have no sympathy for a foreman who has an accident in his room caused by a man using a defective step-ladder, for example. By stating our policy in such matters to the group, not only the foreman but the men know where we stand.

The result of such an attitude is that foremen watch out so that equipment in their rooms will not be found sub-standard. In a small sized factory, those that I may here refer to as foremen may only be persons in charge of an operation, with just a few helpers. Be that as it may, they are your key men just the same and they are the ones that must thoroughly understand what is expected of them.

The second medium of publicity for a safety program is the use of safety posters and other literature on the bulletin board. Not all posters will apply to your particular factory or its problems. We cull out from the posters received those that to our minds have the message that fits in with our local conditions and then change the bulletin boards frequently to keep that message fresh. Just a word about the necessity of keeping fresh material on the safety bulletin board. I realize what I am saying is "old stuff," but it applies to the small factory much more than to the big one. Just as we do not care to buy shop-worn articles, so does a safety program fail to give the proper "kick" if the posters are dusty with age. If no posters are available that exactly hit the mark, it is far better to have some of your company's advertising displayed, or some other poster of general interest, rather than to keep old stuff on the board.

Posters should be selected from time to time that cover the common points of carelessness in public, attempting to get over to the man in the shop the idea of personal safety when outside the plant. In carrying the gospel of safety beyond the factory walls you are not wasting effort, from a strictly business standpoint, because any employees carrying out the idea of safety during the sixteen hours of each day that they are outside the shop are certain to have caught the habit and will naturally be more careful during the eight hours spent at work.

The next medium of appeal is by the distribution of the safety calendar, which is distributed by many factories to their employees. One has to carry this method of appeal on for a few years in order to really get full benefit, but we have found that employees now look forward to getting each new safety calendar and many of them make novel use of the safety first and health hints that appear on the back of the calendars.

Before we leave the subject of publicity, let me speak of the problem of the careless worker. Experience has shown that the greater number of accidents are of the non-machine variety. This is true in the small shop as in the large. In other words, thanks to the effective educational campaigns carried on by such agencies as the National Safety Council, great improvement has been made in the guarding of machines. The great problems now are those of non-machine hazards and the careless worker. We believe the approach to the problem of the careless worker is first to attempt to show him the common sense of being safe. Some see the light while others do not. The careless ones must be taken in hand personally by the foreman, by a member of the safety committee or by the factory executive.

Those who will not or cannot work safely should be asked to find another place of employment, not so much because they may injure themselves as because their fellow employees can do more and better work when they are not fearful of their companions. If you are going to make the importance of safety sink in and give your safety program the proper backing, this action must be taken when necessary.

Now as regards a suggestion for the Executive Committee of this Section. The National Safety Council compiles statistics having to do with the standing of the member companies as regards frequency and severity of accidents. This information comes out once a year and is worth while, but to my mind it only points the way to the real job that should be done.

I feel quite sure that each month the members of this Section would be willing to send data pertaining to accidents for the current month to a statistical department of this section. A simple method of supplying this information would be to forward to this department a copy of the accident report. If for any reason this was not feasible, blanks could be provided by the statistical department. The essential data which we would be interested in would be the cause of the accidents noted for the month and where possible, the precautions taken against a recurrence of the accident. The information from all members of the section could be assembled periodically throughout the year, say quarterly, or whatever time is agreed upon, and each member, under a key arrangement, could get the net results of all members, with a résumé of the accidents and the safety precautions taken.

This would provide a system to obtain effective material which members could use in discussing safety with their safety committees, or any group meeting of employees. I can well imagine that appearing on some quarterly bulletin would be an account of an accident that occurred just the way that same executive had maintained might occur in his own plant, but which idea was scoffed at as being of remote possibility by employees who have not caught the real significance of the safety movement. If the accident happened in some plant, it would be an effective argument for other plants having like conditions to put their house in order to make impossible the occurrence of the same accident.

To sum up, then, the small sized food industry cannot afford to have a specialized full-time safety department. It can, however, have a factory safety organization worked into its regular factory production set-up. This might well involve, as I have stated, an inspection committee making regular inspections, reporting to the safety organization and getting the results of this meeting over in the larger factory group meetings, if they are held. Safety posters, safety calendars and other forms of literature pertaining to safety displayed upon the bulletin board, if properly managed, are all that is necessary to do an effective job of publicity. A central first-aid headquarters is a necessity. Few employees make close personal contacts possible, and this is probably the most effective means of driving a safety program home.

Foremen, or men in charge of operations are the key men, even in a small factory. It is all a matter of education. If the key men are properly instructed, what is taught to them will be caught by others and the safety program, even in a

small factory, is out of the "hit or miss" class and is conducted as an integral part of the plant operations.

J. J. SHERIDAN (Royal Indemnity Co., New York City): I believe Mr. Warren was a little too modest in his opening remarks. This is one of the most interesting talks I have listened to. Do you have any difficulty with your type of men? Have you any foreigners? Can you get close to them?

MR. WARREN: Your group meeting is effective just the same. We have a 100 per cent American factory. I appreciate that you have your foreign type that cannot understand and then you have more of a problem, and I think because you have more of a problem it is all the more reason you should do it. If you will pardon the first part of this, I would like to just give you a brief sketch as to the conditions that existed before and after we started the group meetings.

One of the most persistent evils of factories—I don't care if it is where you have 100 per cent Americans or not—someone gets an idea and gives it to the foreman and the foreman passes it to the superintendent and they think it is a good idea and it is put in and the fellow down there says, "They get the credit for that and what did I get for it?" That happened in our place. When the foreman said, "You know I think maybe I will do so-and-so. We have had a lot of trouble and I think we should do so-and-so." I listened to his story and then I said, "Is that your idea?" He said, "Yes," and I said, "You know that is Alfred Johnson's idea, and if you had come to me and said that was Alfred Johnson's idea I would have thought more of you, particularly if you had told me it was his idea and that you thought it was worth while," and I said, "Don't you think I am right?" and he said, "Yes." Then I said, "Go and get Alfred Johnson and we three will talk it over."

V. D. SUTTON (Postum Cereal Co., Battle Creek, Mich.): I would like to ask Mr. Warren if he considers it advisable in his plant to have a permanent Safety Committee or rotate the members?

MR. WARREN: I am glad that you asked that. We have done both ways. We have had the rotating members, and I am making a point when I say that we have had the rotating members to try to create interest, but we have found it is better to have one standard Safety Committee. In other words, it is a thorough-going part of our organization. There is the cooking room; there is the packing room, and then there is the room that has the three men of our Safety Committee. That illustrates the point that we have it as a standard part of our industry. When they won't do the job, take that Safety Committee out and put another in.

MR. HAMPTON (Franklin-Baker Co., Hoboken, N. J.): In a larger organization, say four or five hundred, where you have six or eight departments, should a Safety Committee be drawn one from each department or should you have an organization of men, say the master mechanic or the assistant superintendent, who are present in all of the departments? The point is, if you don't take a man from each department, the men will be backward in another department.

MR. WARREN: You know far better about your larger factory than I do. I think you could answer that question far better than I could. I don't know anything about the larger one, but it would seem to me that your organization ought to have representation down to each room, so that carrying the thought, that idea in mind, of carrying the company policy along, then you should have representation, so that there would be a contact man for that particular room—but I would rather that men in the larger factories would answer that question.

CHAIRMAN HASSE: Before adjourning this final session of the Food Section of the Seventeenth Annual Congress, I should like to make just a few closing remarks. The first one is that the attendance at our meetings this year was far beyond our expectation. It has been a pleasure for me to act as chairman. We have tried in preparing this program to give subjects that would closely cover

as many industries as would be interested. Perhaps we covered it—perhaps we didn't. However, I would suggest that when consideration is given to our 1929 program and when you receive a questionnaire asking you what you would like to have discussed at the next congress that you sit down and answer it, because when the questionnaire for this program was sent out we received so very few replies that it was more or less discouraging. We want to keep away from criticism, but we do want to give our membership what they are entitled to, that is, give them subjects that will be of interest and from which they will receive information that will be of value to them.

We take memberships in the National Safety Council because we feel that we can get information that will be of assistance. We have a membership at the present time of one hundred and forty. Our membership is diversified. In order to cover all the subjects that we need, I would like to impress upon you all here, and on all of you that might read these remarks, that when the questionnaire is sent around next year that you will answer it fully so the committee will know what you desire. Another thing—I would like to ask that you cooperate with your officers that were elected the other day to the fullest extent. It is only through cooperation that we will all succeed, and unless there are further remarks I move that this meeting be adjourned.

W. H. COOPER (Stevens Hotel, Chicago, Illinois): I wanted to offer a resolution. Monday, I think it was, I started a discussion here about the uniform accident report plan, and Mr. Sutton stated that he thought that the place to handle that would be in our *Nexus Letter*. I sat down and didn't say any more because I felt I didn't have all the facts for the necessary discussion, and since then I have ascertained from some of the members of our organization that that matter of a uniform report blank has been agitated from time to time and let die down and then nothing has been done about it. If you are to bring that up in the *Nexus Letter* it will be a very satisfactory method of handling it as far as this section is concerned, but in order to have it properly taken care of all the sections should take it up. I would like to offer the resolution and we might have a discussion on it. Here is the resolution. It is my personal view on the thing and you won't any of you hurt my feelings if you get up and say, "That is rotten":

"WHEREAS comparisons are necessary for the proper carrying on of accident prevention work, and

"WHEREAS to obtain these comparisons similar data are necessary regarding all accidents, which data cannot be obtained without a standard form for reporting accidents, and

"WHEREAS there is at the present time no standard form in use,

"BE IT RESOLVED that the Food Section hereby requests the National Safety Council to submit this matter to all other Sections during the coming year with the object of submitting at the next annual convention a standard accident report form for the use of all members of the National Organization."

CHAIRMAN HASSE: You have heard the resolution that has been offered.

H. P. WARREN (Manager, Production Department, Minute Tapioca Co., Orange, Mass.): That hits right along my idea, and I am very happy to second that resolution because it seems to me that the Food Section would make a contribution to the National Safety Council by lining this thing up. I attended the meeting when Mr. Heinrich questioned what the causes of accidents were. This is the Seventeenth Annual Meeting and if we are not educated, if you please, to distinguish between accidents and the cause of them, we have to get right down to the fundamentals. I am very glad to second the resolution.

CHAIRMAN HASSE: All those in favor of the motion say "Aye." ("Aye" by majority of those present.)

ADJOURNMENT.

SEVENTEENTH ANNUAL SAFETY CONGRESS
NATIONAL SAFETY COUNCIL

Marine Section

New Section Officers

- General Chairman*—ARTHUR R. BUSH, The Barber Asphalt Co., Maurer, N. J.
Vice-Chairman (In Charge of Publicity)—ARTHUR M. TODE, The Texas Company, New York City.
Vice-Chairman (In Charge of Posters and Slides)—ROBERT F. HAND, Standard Shipping Company, New York City.
Vice-Chairman (In Charge of Information and Service)—CAPTAIN R. C. BRENNAN, Oceanic Terminals, Portland, Oregon.
Vice-Chairman—F. P. FOISIE, Waterfront Employers' Association, Seattle, Wash.
Secretary—CAPTAIN W. P. KAIN, Shipowners' Claims Bureau, Inc., New York City.
Program Committee Chairman—JOHN S. HUNTER, The Atlantic Refining Co., Philadelphia, Pa.
Membership Committee Chairman—W. E. WELCH, The Travelers Insurance Company, New York City.
Research and Statistics Committee Chairman—CAPTAIN IRVING L. EVANS, Munson Steamship Lines, New York City.
Stevedoring Committee Chairman—FRANK A. FRITZ, T. Hogan and Sons, Inc., New York City.
Engineering Committee Chairman—CAPTAIN G. BARTLETT, Cosmopolitan Shipping Company, Hoboken, N. J.
Executive Committee: THE OFFICERS AND
E. F. DALY, Morse Drydock and Repair Company, Brooklyn, N. Y.
R. F. EDWARDS, The Prudential Insurance Company, Newark, N. J.
CAPTAIN REGINALD FAY, The New York Central Railroad Company, New York City.
CHARLES H. FLATHERS, Eastern Steamship Lines, Inc., Boston, Mass.
W. A. KIGGINS, JR., A. H. Bull and Company, Inc., New York City.
ELLIS KNOWLES, C. D. Mallory and Company, Inc., New York City.
CAPTAIN C. A. MCALLISTER, American Bureau of Shipping, New York City.
D. J. MURPHY, Murphy, Cook and Company, Philadelphia, Pa.
CAPTAIN C. H. POTTER, Potter Transportation Company, New York City.
W. E. STEWARDSON, Colombian Steamship Company, Inc., New York City.
C. STORY, JR., Cities Service Transportation Company, New York City.
FERN WOOD, Williams Steamship Company, Inc., New York City.
J. WRIGHT, Export Steamship Corporation, New York City.

Retiring Officers

- Chairman*, A. R. BUSH, The Barber Asphalt Company, Maurer, N. J.; *Vice-Chairman (In Charge of Membership and Publicity)*, ARTHUR M. TODE, The Texas

Company, New York City; *Vice-Chairman (In Charge of Posters and Slides)*. ROBERT F. HAND, Standard Oil Company (N. J.), New York City; *Vice-Chairman (In Charge of Information and Service)*, CAPT. R. C. BRENNAN, Pacific Steamship Company, Seattle, Wash.; *Vice-Chairman (In Charge of Stevedoring)*, F. P. FOISIE, Waterfront Employers Association, Seattle, Wash.; *Secretary and News-Letter Editor*, W. S. WELCH, The Travelers Insurance Company, New York City; *Program Committee Chairman*, JOHN S. HUNTER, The Atlantic Refining Company, Philadelphia, Pa. *Executive Committee*, THE OFFICERS AND CAPT. G. BARTLETT, Cosmopolitan Shipping Co., Hoboken, N. J.; R. F. EDWARDS, The Prudential Insurance Company, Newark, N. J.; CAPT. REGINALD FAY, The New York Central Railroad Co., New York City; CAPT. W. P. KAIN, Shipowners' Claims Bureau, Inc., New York City; ELLIS KNOWLES, C. D. Mallory and Company, Inc., New York City; EUGENE F. MORAN, JR., Moran Towing and Transportation Co., New York City; CAPT. C. H. POTTER, Potter Transportation Co., New York City; C. STORU, JR., Cities Service Transportation Co., New York City; FRED WOOD, Williams Steamship Company, Inc., New York City; J. Wright, Export Steamship Corporation, New York City; D. J. MURPHY, Murphy, Cook and Co., Philadelphia, Pa.; W. A. KIGGINS, JR., A. H. Bull and Company, Inc., New York City.

October 1, 1928.

A. R. BUSH, Chairman

Personnel Manager and Safety Engineer, The Barber Asphalt Company
Maurer, N. J.

The first session of the Marine Section at the Seventeenth Annual Safety Congress, was called to order at one-thirty o'clock by the chairman, Mr. A. A. Bush.

CHAIRMAN BUSH: Gentlemen, as Chairman of the Marine Section, National Safety Council, it is my pleasure to greet as our special guests the members of the Propeller Club, who today participate with us as joint sponsors of this luncheon meeting.

Keynote Address

By A. R. BUSH

Chairman, Marine Section, National Safety Council; Personnel Manager and Safety Engineer, The Barber Asphalt Co., Maurer, N. J.

As Chairman of the Marine Section, National Safety Council, it is my pleasure to greet as our special guests the members of the Propeller Club who today participate with us as joint sponsors of this luncheon-meeting. I bid you welcome. With equal cordiality do I invite you to attend any or all of our Section sessions, or indeed, to those of any Section which may arouse your interest. The Congress activities are of unusual diversification, with entertainment liberally interspersed. An opportunity to acquaint yourself with the world's outstanding safety organization—its accomplishments and its aims—is afforded. I urge you to take advantage of it.

Naturally, the meetings of this Section hold for most of you the strongest appeal, for there the problems of maritime safety will be fully presented and freely discussed.

For sixteen years industry ashore has recognized and accepted safety as an integral part of operations, as a fundamental of management, declaring that

maximum production is dependent upon accident reduction to an irreducible minimum: 13,898 plants contributed data to the American Engineering Council's report, "Safety and Production," which sustains the fundamental. The records consistently show that those plants and industries which have the highest production performance also have the lowest accident rates.

The direct cost, however, is only a part. The indirect cost staggers the imagination. May I again refer to "Safety and Production," the American Engineering Council's report, the most recent contribution, which sets forth some startling figures on "productive time lost by injured and non-injured." As an example, "The productive time lost by injured employees was reported for 688 accidents: 22,403 hours were lost by the injured, or approximately 33 hours per accident. When 76 accidents occurred, 689 employees, other than the injured, gathered around the point of the accident or were otherwise distracted from their work. The number averaged 9 men per accident. The 689 non-injured workers were away from their work 447 hours. This means that each accident cost the company approximately 6 hours of productive time other than the time lost by the injured."

These figures, of course, pertain to manufacturing enterprises. Comparable tabulations covering the maritime industry are not to be had. Diligent inquiry was made and of sources believed able to satisfy requirements. But to no avail. Indeed, one company informed me that the maintenance of accident statistics was too expensive. They paid their insurance premiums and with that their interest in accidents terminated.

Yet the underlying principles of safety are everywhere the same. Only in specific applications do variations occur. That procedure which is feasible and practicable in one industry will be found, with perhaps minor adaptations, equally so in another. For guidance, then, we needs must turn to where experience beckons.

Organized safety is a term frequently encountered and rarely defined. It sounds formidable, yet actually there is nothing forbidding about it. Organizing for safety signifies no more than the formulating of a practical, balanced program for accident reduction and prevention and providing the machinery for continued and complete functioning. Many ship operators have evinced interest in accident prevention, yet hesitate to initiate it because of a belief that effective safety work calls for an enlarged personnel and an elaborate technique. Such is pure surmise entirely out of line with the facts.

Fundamentals of the Safety Plan

What then are the essentials of a workable safety plan?

1st. Sincere promulgation by the executive head. Unless officially launched by the management the movement lacks needed impetus or direction and soon will perish of neglect or mal-nutrition.

2nd. Selection of a competent man as supervisor who embodies all those personal attributes demanded of a leader. Upon the possession of these qualities will largely depend the success or failure of the undertaking.

3rd. The keeping of adequate, accurate and accessible records. Remedial measures may be applied only when analyses of causes reveal their character. Without statistical records no accident prevention campaign can be intelligently organized.

4th. The establishing of a safety committee or committees—the very back-bone of any accident prevention effort. Among veteran safety engineers there is unanimity of opinion on the value of safety committees. To them is assigned that part of management which has to do with the minimizing of accidents. They

assist in locating hazards; investigate and report on all accidents; have immediate contact with the men whom it is desired to reach and enlist their co-operation for safety. They also form a link for the securing of co-operation in many other directions and it cannot be gainsaid that more cordial relations between employer and employee exist than where safety committees are part and parcel of the safety set-up. Their importance cannot be over-stressed.

5th. Inaugurating and promoting the educational features of the campaign. Here the program must be modified to meet special conditions. Certain basic considerations, however, are common to all. Regular committee meetings; display of appropriate posters, frequently changed, on attractive boards, prominently located. For effectiveness the value of home-made posters photographically depicting local hazards, especially cargo-handling, should not be overlooked. The distribution of printed matter; occasional group addresses, etc., constitute standard practice according to the specifications which good policy or precept may prescribe or suggest.

Within brief compass, I have tried to outline the cardinal principles of safety organization with especial reference to maritime operations, whether afloat or ashore. Personal injury claims are a besetting evil which afflict the shipping industry. In consequence insurance rates have soared to unprecedented heights. High premiums impose an oppressive burden which is reflected in excessive operating costs and in lowered net operating revenue. The economic aspect is indeed disturbing, but the humanitarian, involving as it does a wanton and needless sacrifice of human life, beggars emotional description.

Thorough Organization Essential

What means are at hand to correct these conditions? There is but one—the adoption of measures for accident reduction and prevention.

Already such measures are being developed. Within the month the Eastern Steamship Co., of Boston, perplexed by the problem of stevedoring accidents, held their first safety meeting at which President Eugene E. O'Donnell presided. A safety committee was created and is now at work. The American Export Line has recently devised a system of ship safety committees. Competition between individual ships of that line has been carried on over a considerable period with bonus payments awarded to contest winners. An important petroleum company has just designated one of its marine department officials to shoulder full responsibility for accident prevention and to assign to subordinates many of his present duties that safety may have his undivided thought and attention. The Lake Carriers' Association for years has stood in the very forefront in matters of marine safety on inland waters. They have published information on their scheme of ship safety committees which may be had for the asking. You will find it well worth careful study.

Thus the movement advances. Surely, it is to our own advantage that we keep in step with the march of progress. Shore industries fell in line only when the bugle call of legislative mandate compelled. They saw themselves the victims of an avalanche of laws which they did not want. The passage by Congress in 1927 of The Longshoremen's and Harbor Workers' Compensation Act denoted governmental interest in existing abuses. Governmental intervention will be the next step, which only the co-ordinated efforts of all allied groups in shipping can forestall.

It is now my pleasure to present to you, Mr. Ernest M. Roberts, the President of the Propeller Club.

Address

By **ERNEST M. ROBERTS**

President, Propeller Club of the United States, Port of New York

It is a great pleasure and privilege to have the Propeller Club open the annual sessions of the National Safety Council's Marine Section. Never before in maritime history has the trend toward safety through accident prevention been more pronounced than at present. It is bound to expand in the future and with increasing success as safety affects the financier, the shipowner, the shipbuilder, the ship repairman, the equipment manufacturer, the supply man and all those affiliated with or dependent upon them.

The Propeller Club is vitally interested in the prevention of accidents. Every person or firm doing business in the marine field should be. You are all more or less familiar with the risks necessarily involved in the shipping business. The building, operation and maintenance of ships successfully, so far as accidents are concerned at least, requires the exercise of eternal vigilance in all departments and no one can deny that the persistent campaign being carried on by the National Safety Council is having a good result.

Accidents Can Be Prevented

Accidents will not happen when each man is wholeheartedly "on the job," but the frailties of the human element are difficult to overcome. It is to the credit of the National Safety Council that it is constantly appealing to the human element and we, as a club, should cooperate wherever consistently possible to prevent the loss of life and limbs, the suffering and misery which are the results of carelessness.

For the benefit of the National Safety Council members present, let me say that we feel highly honored in having been chosen to open the Marine Section meetings. Any legitimate cause having for its purpose the saving of lives and the prevention of sickness and injuries deserves the recognition of every one.

The Marine Section of the National Safety Council may well have a just pride in their joint successes. The Council should be equally proud in having the Marine Section as an integral part of their organization.

Your association is one of the best examples we have before us today, of what systematically organized effort, having a worthy objective, honestly and aggressively administered, can accomplish when minds are set to succeed.

The Propeller Club's Attitude

The Propeller Club has always been and always will be an advocate of the promotion of good will among the fraternity and we are happy to be a part in the activities of this week.

The club congratulates you on your achievements and wishes you continued success in your work, with the assurance that it can be depended upon at all times to support any movement tending toward promoting the best interests of the American Merchant Marine.

CHAIRMAN BUSH: Gentlemen, we are all naturally interested in the operation of the Longshoremen's and Harbor Workers' Compensation Act. We are fortunate in having with us today the Deputy Commissioner in charge of this District, Mr. Jerome G. Locke who will now briefly address you.

Address

By JEROME G. LOCKE

Deputy Commissioner, W. S. Employees' Compensation Commission
New York

I was born out in the Great North West, at a spot that was then nearly a thousand miles from a railroad. As I grew from childhood to young manhood, I saw three great transcontinental railway systems span this virgin territory from the Great Lakes to the Pacific Coast. That was in the days before compensation acts and before there were safety organizations.

I think I can well illustrate some of the changes that have taken place in the intervening time by relating an instance that occurred during the construction of one of these trans-continental railways.

A large construction firm had taken a contract to build some 400 miles of road-bed. It had stretched an improvised telegraph wire along the right of way and had established construction camps every ten or fifteen miles. Each one of these camps was in the charge of a foreman who had one or more sub-foremen or straw bosses.

One day the main office of the construction company received a telegram from some one who was a sub-foreman or straw boss out in one of the camps. The telegram read:

"Boss hurt to dead. What to do."

The main office wired back:

"Be sure whether the boss is dead. If so, bury him. Will send a new boss."

The next day they got another telegram reading:

"Made sure boss dead. Hit him on head with shovel. Ready for new boss."

The incident was typical of the times. Life was cheap and personal injuries were unknown. There were many workmen in those days who went back too soon and were buried on the railroad grade and the incident was closed. There were no reports, no investigations, no damage suits and no compensation awards.

In the thirty-five or forty years that have intervened times have changed. The practices and methods of the employers of those days would bankrupt the employer of today and send him to the penitentiary. With the advent of damage suits and compensation acts, safety work has become a necessity, not a fad.

From the standpoint of the money involved, we are driven to this work because it pays in dollars and cents. From the standpoint of humanity, we are seriously engaged in the work, because we know that we can no longer regard the loss of life and limb as incidents in the day's work, that cannot be avoided, as was true twenty-five or thirty years ago.

We know now that thousands of lives are saved every year and that tens of thousands of anatomical members are kept whole through the continued spread and increasing effectiveness of safety campaigns.

And, gentlemen, may I say here, that from the standpoint of the workman, from the standpoint of the employer, from the standpoint of society as a whole, the work which you safety engineers do is of vastly greater importance than the work that we compensation administrators perform. You may not get much commendation. You may get no commendation at all. But when through your efforts there has been prevented an accident that would have severed a man's arm, or his leg, or a fracture of his skull, you have performed a service that is ten times better than any service we can perform when we adjust the loss under a compensation or liability law.

I take it that the luncheon here today is for a specific purpose and that purpose

is to lay the foundation for a more widely spread, better coordinated, and more effective work toward accident prevention among the maritime workers of this country.

The meeting here is not to inaugurate safety work. Many of the employers have already done that. It is, I take it, rather to get this work on a basis that will make its place more nearly universal and more uniform and that will give it greater efficiency and bring a larger result.

I need not argue with you gentlemen on the humanitarian benefits of greater safety. You are in the business and you know what can be and is being accomplished toward the alleviation of physical pain by accident prevention.

If, however, some of you are obliged to deal with managers or presidents or directors who do not have the same mental picture that you and I have, I invite you to bring them to the Compensation Office for a few hours any day, and there hear some of the hundreds of tales of tragedy that are unfolded, each one of which is the aftermath of an industrial accident.

Neither need I argue with you gentlemen that greater safety pays. You who are in the business know it pays. You may have, however, to present the financial side of a program to men who are not so well acquainted and who are more concerned with overhead costs. If so, may I suggest that this port alone furnishes, under the Longshoremen's and Harbor Workers' Compensation Act, more than a thousand industrial accidents every month. I don't know how many accidents occur outside this act and still on navigable waters.

Now, gentlemen, each one of these accidents costs money. It costs, under the Federal Compensation Act, maybe only a few cents or a few dollars, or it may run to \$9,000 or \$10,000. If the accident is under the Admiralty Laws, the cost may go up to several times \$9,000 or \$10,000.

Every accident has a cause. There is nothing that happens in this world for which there is not a cause.

The problem that is presented, I take it, is a problem of deciding how, when and where to apply preventive measures to these causes.

It occurs to me that aside from the so-called acts of God, such as sunstroke and lightning, all accidents originate in either one or the other of two great causes. Either there is a mechanical cause or there is a human cause. By mechanical causes, I mean slippery floors, open hatches, unguarded piers, unprotected work places, improper equipment, faulty tools, and dozens of other things and places that might have been protected by mechanical means so as to foreclose most of the possibilities of accidents.

By human causes, I mean carelessness, lack of foresight, slovenly work, unnecessary rush, improper training, physical imperfection such as impaired vision or loss of hearing, and dozens of other elements of the human equation. These human causes may be and generally are due to the workman himself. But sometimes they may be and are due to some lapse of the human equation in his superior hatch boss, foreman, or a superintendent.

I can think of but one way in which to combat the mechanical causes of accidents, and that is by continually improving and safeguarding all the mechanics of the various operations until imperfection is largely eliminated.

That is much easier said than done. Nobody hopes for the attainment of such mechanical perfection that there will be no accidents, because there are no mechanical imperfections. But it is possible, gentlemen, and it is profitable as well to gradually raise the mechanical standards and to fix a minimum of safety below which work shall not be performed.

This can only mean, to me at least, the working out and adoption on the part of all concerned of a safety code, governing maritime work. I doubt whether such a code should be drastic at the time of its adoption. It is better that it be a moder-

ate code, a reasonable code, not a code that will fly a red flag in the face of the employer who is prone to look upon all changes with skepticism.

This world was not made in a day. It will not be revolutionized in any one movement. But once employers generally have adopted a code and the results begin to flow, as they surely will, they will then voluntarily and gradually raise the standards as the desirability becomes manifest.

Now the adoption and enforcement of a code which standardizes and fixes to some extent minimum safety requirements in mechanical operation will not solve the entire problem. There will still be the human causes and no one can control or even largely affect these human causes. There is the ever-present human equation.

I can think of no way to combat this side of the problem, except through the organization on the part of employers generally for the purpose of spreading the safety propaganda of an educational nature. Men must be taught to avoid accidents. It is a difficult task, I know. But it is not an impossible task.

The elimination of yellow fever and typhus appeared as impossible tasks twenty-five or thirty years ago. Those things are accomplished facts today, and the solution of those problems involve not only mechanical control of the causes but education of masses of people to the point where they naturally avoid the causes. What has been done in the way of education of Central Americans can certainly be done with harbor workers in these ports.

I presume that the purpose of inviting me here today was to obtain some expression relative to the program and policy of the United States Employees' Compensation Commission on this act. I am not going to attempt to define the Commissioners' program and policies, for the very good reason that my superior, Commissioner Smith, is here today. He can and will, I am sure, tell you of their interest in the work in the way that is more effective than I can possibly do it.

What I have said today has been said from the standpoint of a compensation administrator who has abundant opportunity to learn of the pressing need for greater safety, but who has under the law no power or authority to act. Such power and authority is vested in the superior commission in Washington.

Deputy commissioners generally are interested in this movement to the extent they may further where possible the policies of their superior commission and to the extent that they may render where possible service to the workmen and the employers in the respective districts.

In conclusion, let me congratulate the employers on the start that has been made toward preventing accidents and toward a reduction in compensation costs. May I also thank the National Safety Council for the very whole-hearted way in which it appears to be tackling another difficult problem. I do not believe that beneficial results of greater safety will follow over night. Safety work is like music or advertising; it takes months, sometimes years, of never-ending, painstaking, intelligent effort to get the desired results.

"The constant drop of water wears away the heart of stone,

The constant mastication eats away the toughest bone,

The constant cooing lover carries away the blushing maid,

And the constant advertiser is the one that gets the trade."

And so, gentlemen, it will be with the greater safety campaign that is organized and launched as a result of this meeting.

CHAIRMAN BUSH: I was unaware of the presence here today of Commissioner Smith. I would be glad indeed to have him rise and say a few words, if he would care to do so.

H. A. A. SMITH (Commissioner, United States Employees' Compensation Commission, New York): Mr. Chairman, I didn't come here for the purpose of saying anything, but the Commission is very much interested in this subject of safety. It has certain duties under the Longshoremen's Act. Those duties require

it to make studies and investigate and to make recommendations to Congress and employers. What is included in those recommendations to Congress ultimately will depend very largely, if not entirely, upon whether or not this Council follows the concluding recommendation of your Chairman.

If the coordinated efforts of those interested, those most vitally interested in the safety problem, result in the adoption of all the proper safety measures that can be asked for, I don't think there is much doubt that as far as the Compensation Commission is concerned, no action toward drastic recommendations will be made to Congress.

We prefer, we ask, that this body and other bodies interested in marine safety will take such action as may be necessary to adopt safety measures, including such a thing as a marine safety code, which is practicable, which does not go to the extreme but which will insure that the very best thought of those interested is given to the subject.

If you will do that, then as far as we are concerned, we will simply stand by and urge you to go as far as you can in extending throughout the broad scope of the Longshoremen's Act, the benefits of safety measures.

Of course, the National Safety Council, as I understand it, does not, possibly, take into its body the foreign lines. I may be mistaken on that, but you have got not only the American lines, you have the foreign lines, you have the employees, and others, that are subject to the Longshoremen's Act. All of these should be considered, and when the National Safety Council, following the plan outlined by your Chairman, has adopted the proper measures, then all we can say is that we will simply ultimately if necessary urge the adoption of those measures upon Congress in some form, not in final legislative form, but some means whereby we can get at the recalcitrant operator, the one who is not willing to go the fullest extent the owners are willing to go. That is all we want and all we ask for.

ADJOURNMENT

October 2, 1928

New York Maritime Exchange Day

A. R. BUSH, Chairman**Personnel Manager and Safety Engineer, The Barber Asphalt Company
Maurer, N. J.**

The second session was called to order at ten o'clock by the chairman, A. R. Bush.

CHAIRMAN BUSH: I think we will dispense with the first item of the morning's business,—the reading of reports. There being no objection we shall defer calling for the reports until a later time.

I am sorry that our first speaker has not arrived. In consequence it will be necessary to rearrange our program somewhat. Mr. D. N. Hoover, the Supervising Inspector General of the U. S. Steamboat Inspection Service, was here yesterday fully intending to deliver his paper this morning. Unfortunately he was unexpectedly recalled to Washington last night and we must therefore forego the pleasure of his presence.

I will ask Mr. Flathers, of the Eastern S. S. Lines, to read Mr. Hoover's paper entitled,—“The Human Equation in Safety.”

The Personal Equation in Safety

By DICKERSON N. HOOVER**Supervising Inspector General, Steamboat Inspection Service.
Department of Commerce, Washington, D. C.**

We live in a mechanical age. Our efforts are directed toward the devising of machinery that will enable us to live in ease, enable us to do a given task with less effort, and that will relieve us, if possible, of all worry or anxiety or the necessity of thinking about what the machine is supposed to do. I do not mean to give the impression that this development of modern life is to be cast aside, or to say that it is not a success; but I do wish to point out that in this mechanical age we have, in a large measure, become the slaves of things, and I wish to show, if I can, what the remedy may be in connection with this condition.

In this country, probably more than in any other, we have come to believe, almost unconsciously, that all things can be corrected by legislation. Without going into the merits of the case, I do not think that I am wrong in saying that the prohibition legislation is an example of this effort to make people moral by law instead of by teaching and instruction. The law has its place. The rules and regulations that are made by bodies properly constituted and which are intended to carry out the provisions of the law have their place. But laws and rules and regulations all have their limitations, in this, that no matter how intelligent the human mind may be, no such mind has yet been discovered that will not overlook some detail or condition which should have been foreseen, and was not, and which brings about the well merited criticisms of laws and rules and regulations that they are not adapted, in every respect, to meet the conditions that they are supposed to correct.

The result is that there has been a marked tendency in this country toward paternalism, and anyone who looks back over the last 25 years can himself see the many respects in which the Government has sought to control and direct many of the human relationships that our fathers and grandfathers adjusted for themselves. If a disaster occurs, the first thought is to pass a drastic law, to pass

rules and regulations even more drastic, and then to go to bed at night and sleep, feeling that everything has been done that is necessary to be done, and that, in some mysterious way, this inanimate thing that we call a rule or a regulation will correct the condition which animate beings have failed to correct.

I wonder whether, when we indulge in such slumber, we are not doing a dangerous thing? That is to say, are we proceeding wisely when, no matter how excellent the apparatus may be, we, in our effort to make it foolproof, also convince our foolish selves that it needs no attention? May it not be that the very perfection of the apparatus becomes, in the last analysis, its weakest element, because we look to that very perfection to do all of the things for us, when there must always remain something for us to do ourselves?

Some years ago, it was decided to place placards upon steamers, subject to inspection, reading:

SAFETY FIRST
Department of Commerce
United States Steamboat Inspection Service
TAKE NO CHANCES

Some wag suggested that the sign meant that no one should take the chance of riding upon an inspected steamer under any conditions; but an amusing incident occurred one summer day in front of the Commerce Building, and, remember now, that this building was the home of that safety first placard to which I have referred.

An automobile, on fire, came slowly along Pennsylvania Avenue. The operator of the automobile wished to stop the car, but was apparently unable to do so. He concluded, however, that if he could bring the front wheels of the car at right angles with the curb in front of the building the car would stop. The car slowly approached the curb; slowly, but nevertheless surely, climbed that curb; it proceeded across the pavement to a coping in front of the building; it climbed that coping and then proceeded across the lawn right up to the walls of the Commerce Building, where, the building being some eleven stories high, the automobile found it could go no farther. I happened to see the progress of that automobile from the tenth floor of the Commerce Building, and immediately phoned down to the watchman at the door to get a fire extinguisher and go out and extinguish the fire. The watchman acted upon that suggestion. Six or seven extinguishers were brought out of the building, but only one really functioned effectively—and this from the home of safety first, and all of these extinguishers were of an approved type, not only by the Underwriters but by the Board of Supervising Inspectors. They were all really good fire extinguishers, but the difficulty was that apparently they had not been tested periodically with a view to determining that they were actually in working order.

Here comes in "The Personal Equation in Safety." The device could be invented, it could be made of the very best material, but it required the human supervision to see that, when the moment arrived that it was needed, it would function properly.

Take another illustration. Some years ago, I was making an examination of a western river steamer. As I went aboard that boat, I was impressed with the fact that there was a large fire hazard, due to the manner in which the package freight was being stowed. I spoke to the inspector of the district who was accompanying me, and asked whether there had been any fires on that steamer. The inspector spoke to the master, who promptly stated that they had had a fire the preceding week, but, pointing proudly to a handsome mechanical fire extinguisher, he said that with that extinguisher they had extinguished the fire and that he

would, under no circumstances, be without a supply of such fire extinguishers. The inspector asked the captain whether the extinguisher was now fully charged, ready for action. He stated that it was not. The inspector asked the captain if he did not know that he was required to carry extra charges. The captain stated that he did know it but that he had not obtained extra charges. So there before the eyes of the inspector and myself, we had brought home to us again the personal and human equation in safety; and while the master of that boat was compelled immediately to put that extinguisher into condition, and carry additional charges, yet it is possible that a fire might have occurred and the vessel been destroyed, simply because some one had failed to do his duty.

We require that on certain classes of steamers so-called releasing hooks for the lifeboats be carried, and many are the efforts that have been made by inventors to get foolproof releasing hooks, to get releasing hooks that need no attention whatever, to get releasing hooks that combine in themselves, not only all of the elements of machinery, but of able seamanship as well. And I have sometimes thought that in the effort to develop such releasing hooks, a dangerous condition has been brought about, that leaves too much to this innocent looking little releasing hook to do, and takes away too much from the human responsibility, because the responsibility of the men who must handle the lifeboats cannot be taken away. In other words, it may be that the best releasing hook is that one which would not release when water borne, but would require manual action to cause it to be released, even when in the water. The European nations have, I understand, been moving toward the direction of not requiring releasing hooks, such as are required in this country.

All of you have read the story of the efforts of the Dutch people to reclaim the land and hold back the sea. In so doing, they have built great dykes and dug canals. And you recall the story of the little Dutch boy who, on one occasion, noticed a tiny stream of water seeping through near the bottom of one of these great dykes. The dyke grew out of the imagination or mind of man. It served a good purpose, yet if that little Dutch boy had not had the initiative to put his finger in that tiny hole, the Low Countries might all have been inundated with great loss of life.

What is the conclusion of all of this? It is very simple. It is not that we shall cease to continue to invent devices, but it is that, no matter how perfect we make these devices, we must remember that we yet must discipline ourselves. We are told that man, before he can rule others must rule himself. We can continue and say that man must also control these inanimate slaves that he has made to serve him, and this can be done by eternal vigilance, by constant supervision, by constant drills of employees, as well as of people who are not employees, though in the drilling of people who are not employees, one must not go too far and introduce the possible element of panic. What it means is that we must have competent men. We must first of all have real *men* and when I say real men, I do not only mean animate beings that have two eyes and a set of teeth and ears and feet and who breathe. Many such things may be seen upon the street every day but they are not the kind of *men* of whom I am speaking. I mean men who are disciplined, and who under the direction of competent authority are taught absolute *obedience*, for it is by obedience and by self-discipline that we shall come to have that greater freedom and real liberty which is sought by all intelligent human beings.

CHAIRMAN BUSH: Gentlemen, the meeting is open for discussion.

CHAIRMAN BUSH: Gentlemen, we will proceed to the consideration of the next paper.

I am personally very much disappointed that Mr. Henry Heberman has been called to Washington. He is one of the outstanding pioneers of the safety move.

ment in the maritime industry. The American Export Line has gone into the subject of safety whole-heartedly and what is of vastly more importance, they have actually accomplished real results.

In the absence of Mr. Heberman, Mr. E. R. Kraetzer of his company will deliver the paper.

Making the Safety Movement Attractive to the Personnel

By HERBERT HEBERMAN

President, Export Steamship Company, New York City

It is quite unnecessary for me to go into the early history of "Safety First" when it was looked upon as an "unnecessary evil;" this is an old story to you; but I do believe you would be somewhat interested in hearing what a Steamship Company is doing to prevent accidents on its vessels in port and at sea, and the results obtained.

You are quite familiar with the practices in large plants ashore for the prevention of accidents, and the procedure followed when an accident does occur. Now the situation on a vessel is somewhat different in that we do not have access to all facilities such as doctors, nurses, appliances, ambulances, etc., but nevertheless the seagoing personnel are amply protected and cared for. When an accident occurs, or an illness develops, at sea on a freight vessel, the master becomes the doctor and nurse, as well as comforter of the patient. The master, to secure his license as master, must have passed certain medical examinations, so you will see the patient is not entirely in the hands of an amateur.

"Safety practices" and the reduction of accidents and illnesses among the floating personnel have been uppermost in my mind, both as to the welfare of the men and efficient operation of the fleet. Believing that if our officers and crews were in perfect health before signing on for the foreign voyage, a great number of illnesses would be eliminated, and to bring this about, we have established our own medical department, under the direction of an experienced physician. Each officer and man applying for a position must undergo a most rigid physical examination to determine his fitness and upon the doctor's recommendations the applicant is either accepted or rejected. The medical office was completely organized and began operation February 11, 1927. During the year 2,246 examinations were made. Of this number 1,686 were original examinations and 560 were examined one or more times. Employed on all vessels as of January 1, 1928, there were:

- 779 men who had 1 examination
- 303 men who had 2 examinations
- 131 men who had 3 examinations
- 55 men who had 4 examinations
- 8 men who had 5 examinations
- 1 man who had 6 examinations

Of the 2,246 men examined there were about 10 per cent disqualified for physical defects. Some of the causes for disqualification were: heart disease, color blindness, hernia, cataracts, very poor vision, tuberculosis, dental cases and others.

Dental cases were largely responsible for over 50 per cent of the disqualifications. From this you can readily see that had these rejected men gone to sea in an unfit condition, the number of cases of illnesses would naturally have increased with resulting claims and other expenses.

During the year 1926 our statistics show 135 cases of illnesses and 189 injury cases. In 1927 statistics show 151 cases of illnesses and 186 injury cases. These

figures show an increase in 1927 over that of 1926 on illness cases of about 12 per cent, and a slight decrease on injury cases in 1927 as compared to 1926.

The expenditures, however, for the same period show really what can be done by consistent effort. Those for 1927 were less than 50 per cent of those for 1926. This proved very gratifying to us for we knew that although the reported illness cases had increased and the injury cases had remained approximately the same, that the reasons, therefore, were due to the increased efforts of the ship's officers in reporting all illnesses and injuries as we had insisted should be done.

In order to instill in our organization the necessity of safety on the piers and aboard the various vessels, we created a safety committee consisting of the heads of the various departments vitally interested in the actual operation of the steamers and the pier terminals. This committee consists of seven members, who meet once a month to discuss safety recommendations made by members of the committee or any other individual of our organization. While the recommendations, in some cases, have been quite expensive, we have not as yet disallowed any expenditure applicable to the common safety on board steamers or in the dock terminals.

Each individual vessel in the fleet has its own safety committee consisting of the master, as chairman, chief engineer, chief officer, and chief steward. Meetings are held during the voyage at the discretion of the master and recommendations and minutes of their meetings submitted, upon the return of the vessel, to the committee ashore for disposition.

Now, having what we believe to be a perfectly healthy crew, through the efforts of the medical department, and having formed a committee on board ship so that the members of the crew could be taught to take care of themselves and be protected from accidents as far as was humanly possible to do so, we felt that we must go further than this and consequently created a "Safety-First Bonus Program."

Although the safety-first campaign is a somewhat new departure amongst the sea going fraternity, it must be emphasized that it has achieved a marked degree of success in other walks of life. We, therefore, could see no reason why the results should not be equally successful aboard ship. To encourage the safety-first policy by men in the employ of the different ships, it was proposed that the vessel having the lowest expenditure for illnesses and injuries over a period of one year, which constitutes four consecutive voyages in our trade, would fly a "Safety Pennant," and all officers and members of the crew, who were part of the ship's personnel for that entire period would receive a bonus equal to two weeks salary, or a part proportionate to the number of voyages they made as members of the personnel of the successful vessel.

With a plan of this kind of course you realize it is necessary to place some restrictions on account of the floating personnel, and at the same time have the proper flexibility. Consequently it was decided that in order for the ship's personnel to take advantage of this bonus system they must be in the employ of the corporation at the termination of the fourth voyage. The officers and members of the crew of the successful vessel would be entitled, if they had completed four voyages, to two weeks salary; if they had completed three voyages to three quarters; if they had completed two voyages to one half of two weeks salary; and if they had completed one voyage to one quarter of two weeks salary. This plan has worked out even better than we anticipated and has created a spirit of friendly rivalry amongst the personnel which has been of great benefit both to the employees and to the corporation. It has further reduced the medical and hospital expenses, reduced injuries, and has eliminated much loss in time by men engaged in a business which involves a certain degree of hazard.

Our safety first scheme is somewhat a departure from the usual practice inasmuch as we have never engaged the services of a safety expert. This is in no way a reflection on safety experts, but was the result of very serious consideration on our part.

As you gentlemen well know the sea-going fraternity (particularly the "old salts") are very set in their ways and in many instances would resent suggestions from a person inexperienced in the ways of the sea. We, therefore, considered it better to use our own employees in developing our safety first measures rather than to introduce a stranger into our midst who would undoubtedly enter our organization with many radical ideas and would not in all cases understand the whims of many of our employees.

We inaugurated our safety first campaign as a matter of education, and felt that this could best be put over as a gradual process rather than an attempt to revolutionize the existing practices in the steamship business. It is a great pleasure to me to state that our scheme has worked successfully, and many whom we regarded as difficult subjects have taken hold of the safety ideas with considerable enthusiasm; and with all due respects to safety experts as a body I feel that our problems can best be dealt with by our own employees and such as are sufficiently familiar with our business to be able to know what can be done today and what could be required later.

Also we had to consider expenditures involved in developing this campaign, and as the steamship business, under the American Flag, has not been particularly lucrative in the past, we had to consider the financial aspect as one of the salient features. Therefore, we were not able to afford radical changes in design which involved a considerable expenditure, as all of our vessels were practically of the same type, and an expenditure on any one vessel meant a similar expenditure on the other twenty vessels of our fleet.

We have had considerable assistance in the form of safety recommendations from outside persons, and have availed ourselves of literature and posters from the Marine Section of the National Safety Council; and I am, therefore, concluding my brief remarks with an expression of thanks to the Marine Section of the National Safety Council and to the Marine Safety Council in developing safety first in the marine field.

CHAIRMAN BUSH: Thank you very much, Mr. Kraetzer. The meeting is now open for such questions as you may care to ask. I am sure Mr. Kraetzer will be glad to answer them.

W. E. WELCH (The Travelers' Insurance Company, New York City): There is one point that struck me quite forcibly in that paper. About six years ago, when this section was organized, some of the officers talking with Marine men in New York, the matter of ship safety committees was discussed. It had been done on the Great Lakes and the reply was that that could never be done on sea-going vessels. And in six years you see what has developed in that.

I think that is one of the most important things that can be done on any vessel—the Ship Safety Committee. That shows how this accident prevention work has advanced in the last few years.

W. T. DONNELLEY (Consulting Engineer, New York City): I wish to state a matter of appreciation of that paper, as being primarily that the organization is within. This man has the fundamental American spirit. He takes his men and materials as he has them and starts an organization of those for their own benefit.

It has been my opportunity to command men and material from far points and near, and I have always found that if you will approach them in that American spirit from within and ask them not to do what they are ordinarily expected to do but to do the best they can, you will find a ready response. If you will arrange, as this man has, that they have a record and shall be commended where

they have achieved, you will find that no one will follow you further or quicker than the American men.

I had occasion to start a piece of work within forty miles of Alaska, in the wilderness on the West coast. When we began everything was at sixes and sevens. The foreman came to me, and said, "Mr. Donnelley, we are going to do the best piece of work we ever did in our life."

Within a week it had gone around and the men did do a better job than they had ever done before. Men will do that anywhere, if you will put it up to them and build from the bottom up.

If we had many more men starting in to build up the American Marine on this basis, from the inside, from the ground up, we would make more rapid progress.

R. L. McALL (American Seamen's Friend Society, New York City): The crux of the handling of the physical health of seamen depends on the way in which it originates in the operating office.

What I mean is this: If a company is so physically located in the operation of ships with relation to its managing officers and so on that it can assign the problem as first business to a certain man, as his job and his first job, he will be able to do it on the lines of the paper just read.

I will be willing to bet one thing, and that is that in the Export Steamship Company there is more than one man who makes this thing his first business under the direct mandate of the operating management of the company. So it is put on the man as an enterprise which is at least worth the best attention.

This is not a new story. In a certain chapter of a certain old book, you will find a man saying that the whole of the ship was going to be lost and the whole of the cargo but none of the men, and his cargo was worth more than his crew to him; yet he came around and accepted that, throwing out the cargo, and they didn't lose a man. I have often thought that that is the same old problem we are solving today, by simply elevating the man question to the point where his care is absolutely first business.

To make this accident prevention and the care of injured seamen a matter of first business, to be intelligently handled, with no laxity anywhere in the operation, if you will only drive that home so there are no exceptions to the splendid rule, then you will really have won the day.

CHAIRMAN BUSH: There is one point I wish to stress and it can't be stressed too much. With the Export Steamship Company, it was President Herberman who promulgated the order officially establishing safety as an integral part of operations. You cannot assign safety work to a subordinate and expect it to get anywhere. This the Export Steamship Company recognizes.

Recently in Boston, the Eastern Steamship Lines held their first safety meeting at which President Eugene E. O'Donnell presided. A safety committee was organized and is now at work.

I repeat: It cannot be overstressed. It is fundamental. Unless the chief himself gives his whole-hearted support, the thing will not get across. That is the principal reason the American Export Line has had such distinguished success in the work they have undertaken.

E. R. KRAETZER (Attorney for Export Steamship Co., New York City): First of all, I am not really connected with the organization of the Export Steamship Corporation. But I do have very close contact with it, and particularly along the lines of *personal* injury cases.

I want to say first of all as to the personal element—and I think I can say this because I am not connected with the Export Lines—I know as a matter of fact that Mr. Herberman's day starts at somewhere around half past six or seven o'clock in the morning, over on his docks, watching the unloading of his vessels. That is just one phase of it.

The second phase is this: I have frequently, in examining reports of the accidents, found situations where the master of one of the Export Line boats, who had an injured seaman on board, put into a port rather than carry that man on, trusting to his own ability to minister to his physical injuries.

I know of one case, for example, where a ship which would not otherwise have made the port of Gibraltar, did run into Gibraltar at a considerable loss of time and money, in order that an injured seaman could have the best kind of professional assistance.

Throughout the course of all their work, I find exactly that spirit and that kind of treatment of the men.

JOHN P. MAGILL (Special Representative, Maritime Association of Port of New York, New York City): The paper just read is a very interesting one in many respects, as a way-shower and as a way-mark along a definite line of progress.

It is not only a question of dollars and cents. In fact, I believe—and I speak as a shipping man—that the question of the dollar is not the paramount issue with the owners of vessels. They have always at heart the thought of protecting the life and health of their men at sea, and no expense is ever spared, no expenditure is ever considered of vital importance when a crisis arises. And that is proven by the readiness with which our largest, most expensive vessels will deviate from their course and go way beyond to rescue and render aid to the members of the crew of some obscure tramp ship in distress.

The real actuating impulse to any movement is sincerity of purpose. If the management of the properties involved are seriously sold on the question of a systematic measure of safety, that will naturally develop into activity of their organization the same as any other activity, and if the policy of the management is defined along these lines and made known to the personnel, it becomes a part of their daily routine, just the same as keeping a proper pace on the engines.

All of these movements must of necessity have a beginning. We must have a pioneer, someone with greater vision than the rest of us, who sees these things and acts on them. Many of us see them but our minds will run in other directions.

I am sure that Mr. Herberman has done a very definitely beneficial thing in inaugurating this most systematic activity and carrying it out in the thorough manner in which he is doing.

GEORGE ACKERMAN (Personnel Manager, American Export Line, New York City): Mr. Herberman has recognized that in connection with any safety-first campaign, he must have first of all the men who can read English.

Before August 1, our ships carried a very large percentage of aliens, particularly Greeks and Spaniards, who could not read English. Since August 1, we have placed on board the ships of the American Export Company 100 per cent American citizens or aliens who have gotten their second papers, which requires that they can read English.

Before that, if we put a safety-first poster on the ship, the aliens could not read it. Mr. Herberman recognized that, and we do receive very whole-hearted cooperation from the various school ships in supplying us with intelligent, clean-cut, young, trained American men, whom we make every effort to place as officers in our company after they have put in a few trips as training for merchant service.

Since August 1, we have had a complete turn-around in this line. You will find that by having American boys aboard the American ships, you will go a long way to reducing accidents. In this way they can understand all orders given to them and read all descriptive literature on their own safety as presented to them.

CHAIRMAN BUSH: In the preparation of today's program, we were very fortunate in securing the cooperation of the New York Maritime Exchange. I have great pleasure in presenting Mr. John P. Magill, Special Representative, New York Maritime Exchange, New York, who will now speak to you.

The Interest of the Maritime Association in the Work of the National Safety Council

By JOHN P. MAGILL

Special Representative of the Marine Association of the Port of New York

The Maritime Association of the Port of New York, in the very nature of things, is vitally interested in and an ardent advocate of any movement, having for its object the extension and betterment of the marine activities in not only America's premier port, but the world's greatest port, New York.

This organization was incorporated April 11, 1874, and granted a perpetual charter, the objects of which are written in Section two, which reads:

"The object of this corporation shall be to acquire, preserve and disseminate valuable business information, and to do such other proper and needful acts as will tend to promote the maritime interests of the Port of New York."

The Maritime Association consists largely of ship owners, agents and operators, representatives of kindred interests, such as: Dry Docks, Construction and Repair Yards, Tug Boat Owners and Operators, Barge and Lighter Owners and Operators, Ship Chandlers, Stevedores, etc., and the question of accident prevention naturally receives the careful consideration and cooperation of all our members.

The problems affecting ship operation are of course of vital interest to our organization, and may properly be divided into two classes, each class having its various subdivisions: (a) those relating to the safety of vessels at sea; and (b) those having to do with the handling of cargoes while in port.

There is probably no subject affecting the welfare of life and property that has received more attention in recent years than that relating to safety at sea. International conferences have been held and international agreements entered into, looking to the closer cooperation of the various maritime nations in a movement to minimize as far as possible the dangers attendant upon ocean travel and transportation. The wireless telegraph, the radio compass, the fathometer, and improved aids to navigation have served to greatly reduce the perils which beset the navigator and endanger the lives and property placed in his charge. Great progress has been made in this respect, and while it is inevitable that just as long as men go down to the sea in ships, accidents must and will necessarily occur, we may well look with pride and satisfaction upon the results achieved in the promotion of safety at sea. In view of the fact that the Marine Section of the National Safety Council has been functioning for many years past, your organization has without doubt largely contributed to the attainment of the present high standards prevailing as affecting the conduct of the ship upon the high seas.

On the other hand, problems affecting ship operation while in port, particularly with respect to the loading and discharging of cargoes, do not appear to have been solved to the extent which has been possible as regards those affecting safety at sea, and this in spite of the fact that much consideration has been given to this important matter. I will therefore take the liberty of discussing one or two phases of the situation, which no doubt have been touched upon in former years, but which, I am sure, will bear repetition. I refer particularly to accidents to longshoremen, conditions aboard ship, also on lighters and on piers, when loading and discharging cargo.

Labor conditions, as applying to stevedoring work, in common with varied other industries, have changed greatly during the past twenty to twenty-five years. The men formerly engaged in this work were more familiar with ships and shipping than those of the present day. Many of them had formerly followed the sea, and by reason of this experience, were probably better qualified to satisfactorily perform the arduous duties devolving upon the longshoremen. They knew what to do and how to do it.

Twenty-five years ago, there was not the competition prevailing in the stevedoring trade that there is today. The rates received by the contracting stevedore enabled him to pay current wages, render a splendid service and receive a reasonable return for his initiative and effort, while the men on the job were interested in their work and satisfied with conditions. For their own protection, the men were careful to see that all equipment used, as far as possible to discern, was in good condition and their preparation for a job was thorough; slings, falls, rigging, staging, etc., were carefully looked after and the entire burden was not left on the shoulders of a hatch boss or foreman, the men themselves being competent judges.

It is apparent that under present day conditions, a much greater responsibility rests upon the contracting stevedore than was formerly the case, and it is gratifying to note that stevedoring operations, as carried on by the largely predominating element in the trade, indicate a full realization of this responsibility on the part of the contractor, and a sincere effort to meet it by throwing every possible safeguard around the lives of those employed in this work.

It must be further apparent, however, that the competition above referred to, coupled with increased labor costs, is not conducive to constructive achievement. The fixing of a price for stevedoring service below the actual cost of performing such a service can only result disastrously to all concerned. While we heartily concur in the necessity for reduced cost as much as is possible consistent with good business principles, our own experience has taught us that it is as difficult to get something for nothing in the shipping trade as in any other.

In an effort to break even, the party who undertakes to engage in stevedoring work at a rate actually below the cost of performing the required service, is compelled to resort to various extremities, such as the use of second or even third hand gear, the utilization of skilled or unskilled men who will serve him for the least pay, etc. The Ship Agent or operator who receives a tender for work on such a basis is placed in somewhat of a predicament, and (unless he is unusually alert and has sufficient support from his principals) he is forced to give consideration to such tenders, even though he knows the price named will not yield a decent return to the stevedore. If he refuses to consider the proposition, and the stevedore addresses his Superior or Principal, they are not only apt to accept the lowest bid, but censure their representative for not properly caring for their interest, and may possibly assume that there is collusion between the old stevedore and their representative.

I know of a concrete instance within a short time past, where an agent for a foreign line was tendered a bid by an organization of this latter type, which on the face of it would have shown to anyone familiar with the cost of handling cargo, that there could not possibly be an honest dollar of return in it to the contracting stevedore. Unfortunately, the agent had no discretion and was forced to accept the tender, fearing criticism should he fail to do so, and the work reflected the character of the bid; when an effort was made to secure competent service at a fair price, the management could not see what was involved and insisted that no change be made. This condition continued until two serious accidents occurred and the stevedore was compelled, by the nature of the accidents, to retire from the business.

This instance is but one of many, and we believe that the Underwriters can assist materially in correcting this if they will adopt and enforce rigid rules covering the moral as well as the financial standing of the applicant desiring coverage, also on the important question of experience, not only in handling goods but in handling men.

We also do not believe it good practice to work a gang more than ten hours, or at the utmost twelve hours, and think better work and fewer accidents would result if this plan was followed out. When the regular eight hour day has passed

and it is necessary to work overtime, fresh gangs should be substituted included hatch bosses, foremen, etc., as obviously a man who has worked all day and part of the night cannot be as alert as when freshly started and, therefore, more liable to accidents.

Strict sobriety should be insisted upon in all instances and no excuses taken from intoxicated or even semi-intoxicated men. They are a liability of the worst type.

The practice of smoking in the holds of vessels, frequently with the connivance of the hatch bosses, is indefensible and causes many serious accidents, and will, to some extent, at least continue until such time as the man in authority is made to feel his responsibility. One of the best ways to do this, is to properly differentiate as between his wages and that of the men under him, and in conclusion it is my belief that low-priced stevedoring is one of the chief contributing factors in the question of accidents around ships.

It is remarkable that, notwithstanding the fact that a ship is nothing more or less than a floating warehouse, practically no improvement is made and adopted in mechanical devices for handling general cargo. Surely a little thought devoted to this important item will aid materially in not only preventing accidents, but also in legitimately reducing costs and expediting transit.

CHAIRMAN BUSH: Gentlemen, the meeting is now open for discussion on this paper.

I might say that we are honored today by the presence of the Dean of American Shipping, Mr. John B. Seager. Mr. Seager, would you care to make a few remarks?

JOHN B. SEAGER (New York): I have been engaged in shipping for a good many years. But times have changed, and when I look at these new boats, I realize that the stevedore has to learn something about the machine he has to work with.

I didn't expect to be asked to talk here today, but I never was a talker anyway. I have been watching the shipping here in the last sixty years, and to be candid, it is remarkable the progress that has been made in shipping, as far as building is concerned.

Mr. Magill has given a good deal of attention to this, as you notice, but I think the stevedores ought to be around here today. I haven't seen very many of them. It is a lesson to them. They have to try to save life and I am sure they are all willing to do so. But I think if they go aboard some of these new steamers, with what they have to do with electricity and one thing and another, it requires a competent man to handle it.

I am very glad to be with you.

CHAIRMAN BUSH: I think Mr. Seager made a very good suggestion when he said we ought to hear from some of the stevedores. Captain Blanchard, we would be glad to hear from you.

CAPTAIN P. B. BLANCHARD (President, Turner & Blanchard, Inc., New York City): Mr. Seager didn't see me when he came in. He seemed to hit it right when he said there have been changes. I am not as old as he is, but I remember when we had a horse to hoist the guards in and eight competent men to store it after we got it in. We didn't have any accidents then.

Of course such men as Mr. Seager drove the horse and the eight men off the beach, because they brought steamers here. One gang increased to two, three, then four, and then day and night. I really think Mr. Seager is responsible for a lot of that speed.

Then, of course, the war came on; and we broke up the gangs, increased the number of longshoremen working, and we got a mob. Stevedoring changed from stevedoring to wrecking. That is about what it was. We are suffering now from

that war condition. We have not gotten down to our feet yet, and we are looking at the records of injury during that period.

After the war, California started to flood her lumber here. We didn't know much about lumber and the result was that some of our steamship men didn't know much about it, and sent it here in ships with little hatches and we had to hoist it out on end, and a lot of it slid out of the drop and the men couldn't dodge it, and we had another wrecking institution.

But that is about all cleared up now. We are putting lumber into the ship, bigger ships, bigger hatches. Our accidents have not stopped, but they have been reduced, and really I feel that a lot of the hazard of the past has left us. We are making better speeds and are not injuring as many employees now. We have fixed gangs. The mob is leading us. We are back again to the old longshoremen or the new one that is better trained. We are making good headway toward safety.

It is pretty difficult to start even to talk safety on the beach because the longshoremen are like any men raised around ships, and shipping is very suspicious. If you stick up a poster and tell him to be careful, he will say, "Oh, what is the matter with them! They are trying to save a dollar!" That is just what he says.

But that is wearing away and we are getting better cooperation and notwithstanding what has been said here, we find that it pays; and after all, sentiment in business is all right, but you have to put an argument up that it pays. We all have the sentimental side, but the paying side is the one we have to sell, and the stevedore, the steamship man, and the longshoreman are thoroughly convinced that today it pays to be safe.

C. H. FLATHERS (Eastern Steamship Lines Co., Boston, Mass.): Mr. Magill spoke of the men who are in the habit of getting intoxicated. In our drives that we have just inaugurated and our safety campaign, which has recently been put into effect, we took three initial steps.

The first was the elimination of what we call repeaters. I think one of the speakers intimated yesterday that longshoremen do not purposely get hurt. But we find in our experience there is a certain class of men who will purposely injure themselves for the benefit of drawing compensation. We have had several instances of that kind, in connection with our campaign work.

We have analyzed our accident records for the last two years and selected those men who have been in the habit of getting hurt frequently—two, three or four times a year. I think we selected forty-eight men, and those forty-eight men in two years had been injured 158 times, from two to three times each. Now we have established a procedure whereby those men do not get work again. I think that is a very effective method, and I am placing that before the committee for those interested.

These men are not, of course, the usual type of longshoremen. We have good men, who work earnestly and I think most of the members here are in the same situation. Some of the longshoremen will work for years and years. This repeater is a dangerous man to have, and he is not only going to be injured himself but sometimes will be the cause of another man being injured.

Then we have another type—the troublesome employee who is always carrying the chip upon his shoulder and looking for trouble, and sometimes will run his trouble into another fellow who is injured. This fellow worker resents that and will probably turn around and give him a poke in the nose, and we have two injury reports in place of one. We have had that happen twice recently.

We have impressed upon the men employing longshoremen, the necessity of selecting men physically fit for longshore duty. We have at the present time two or three striking cases where men were employed and were unfit for the work, and they received a slight injury; and as a result of some trouble which originated

before their employment with the company which was increased, we would have them on our hands for some time.

So there are three types of men, I think, other than the one who is in the habit of becoming intoxicated—the repeater, the dangerous man, and the man who is physically unfit for the task of stevedoring.

FRANK A. FRITZ (T. Hogan & Sons, New York): I rise first with the idea of hoping to present a solid front for the stevedoring interests represented here today, and in addition to what has already been said by Captain Blanchard and those others who spoke from that viewpoint.

I should prefer to hear from those who have had more experience in this line and who represent some of the oldest concerns, but I don't feel that I could remain silent on this subject in view of the fact that the company which I represent, and which is another good-sized company, has tried to do in the past year and a half some real active work.

I think I can safely say for our company that the work has proved itself in a considerably short space of time.

It is undoubtedly true that the game has hazards, and there are various and devious kinds that are too long to narrate now. A good many of them have been mechanical and a good many are represented by what we call the human equation. But this much I think is fundamental—that men come to work to support their families, with the idea of working out a livelihood, and certainly with the idea of working out that livelihood with safety, so far as they conceive it to be compatible with their work. I mean, if we have accidents due to the human equation, they are due perhaps to the fact that the idea has not sufficiently been brought home to the particular man who is doing the particular job.

Now maybe I am wrong in stating that is the problem that confronts the long-shore industry today—How to get the idea of safety to the man who is actually doing the work. But I think primarily we can only hope to reach some degree of success along those lines if first of all we start from the top of our business and work down.

Of course, it is a long row to hoe. You have your executive level and you have your superintending force, and you have your minor supervisory levels. But my short experience has taught me that you have to simmer from the top down to each one of those levels before anything of a constructive nature can hope to be accomplished in the lowest element that you have. And by that I mean simply the range of the employees working in the hold or on the docks of your ship.

Now, of course, a question which has been frequently asked and which is always addressed to us when we talk generalities is: How is it to be done?

I take it, when accidents occur, they all have a cause. I further take it—and I have seen it demonstrated—that you arouse the interest of the men concerned only when the heads of the companies take the particular causes and try with some sincerity of purpose to eradicate these causes.

At the expense of dealing with something of a private nature, but which I think may be of interest, I may say that in the past year we have paid very close attention to accident causes and have tried to analyze them so far as possible; and we have at least ten accident causes.

By cooperation on the part of our executive force, on the part of our superintending force, and on the part of our foremen, we have been able to devise rigs and appliances which to a large extent have obviated certain kinds of accidents which were repeaters on our accident statistic records.

I say that is not so difficult a situation, and I say you can't hope to get cooperation or enthusiasm or interest in your working force unless you first demonstrate by some such concrete things as that, that your company itself has at heart the reduction of accidents and demonstrates it by concrete methods.

It is true that there is a certain proportion of men who don't cooperate, and it is true that there is a certain proportion of men who are suspicious. But I find that after having conducted weekly safety committee meetings, made up of foremen or headers taken from various gangs, that they become convinced after awhile that you are not shooting solely at the dollar. They become interested, and give you credit for trying to do something that will eliminate hardship for injured men, and their families. And by and by they do begin to lose some of the suspicion that they had in the beginning. There is no question but that we are confronted with suspicion when we start out.

If any of you have tried to sell safety shoes to your men, even at a low cost, you find it doesn't make very much difference whether you are selling them below cost or not; there is a certain element that is suspicious about that proposition. And it is true about everything else you tackle. I say, unless the safety business is approached in the frank spirit of laying all your cards on the table, and you are willing to take your lowest man into the safety meeting and have him express an opinion as a man not as an employee, a longshoreman or dock walker, and give attention to that opinion as you do to the opinion of the president of your concern, you are heading for failure in safety work. I think the sum and substance of safety work is cooperation, giving the topic of business and making it filter through until you get the last level.

CHAIRMAN BUSH: The place of the physician in industry has been touched upon in Mr. Heberman's paper, and also by Mr. Flathers and others. The next speaker is a physician who had had a wealth of experience. He is the port physician of the United Fruit Company, with headquarters at Boston. Dr. Francis X. Crawford will now deliver his paper.

Medicine in Industry

By DR. FRANCIS X. CRAWFORD

Past Medical Officer, United Fruit Company, New York City

Ever since medicine has been practiced as an art, preventive ideas against disease have been uppermost in the teachings of all medical writers. Preventive medicine, therefore, is nothing more than "Safety Measures" applied to the practise of medicine. Today more than ever before we are constantly teaching methods of how to prevent disease, either by avoiding the occasion to infection, or by vaccination.

Physicians always have been striving to lessen the liability to disease and many have sacrificed their lives in this most worthy object. During the last century, the expectancy of life has increased from about 30 years till at present it is about 54 years; an increase of 80 per cent, a wonderful extension of life. All this is due to the great discoveries of the causes of diseases and their prevention, which is, as I said before, the safety measures of medicine. Diphtheria, which a few years ago had a mortality of about 30 per cent, is now down under 10 per cent, due to anti-toxin. Small-pox which has had a mortality in some epidemics as high as 70 per cent, is now down to below 5 per cent in well vaccinated communities, this due to the safety measure of vaccination.

Industry recently has been endeavoring to reduce its liability due to accidents for two reasons; first, reduction of expense in production; second, humanitarian ideals toward its employees. (This is the preventive medicine of industry.) So great is the movement toward safety that we see in all industrial plants great efforts made to prevent accidents; and being unfortunate enough to have them, every effort is made to have the injured employee given the best medical attention. So medicine and safety measures must go hand-in-hand, and that branch of

industry which neglects to use a campaign of safety must fall behind its competitors in cost of production.

The physician should have a prominent place in all safety projects, since by his training he naturally seeks the causes of things and the means of avoiding the dangers. His position in industry should be one of very great importance. He, together with the safety engineer, should have charge of all safety measures applicable to the plant. The method of treating and handling all injuries and industrial diseases should be planned by him. He should act in an advisory capacity to the safety committee and deliver, at certain intervals, talks on "First Aid" and preventive measures which might be of advantage to the industry. His advice in medico-legal matters appertaining to injuries and disease should be carefully sought and as carefully given. He ought to have the interest of the employees so much at heart that they would feel free to approach him for advice, not only in obscure medical cases but also in the social phases of life. Such interest in the employees of an organization tends not only to make the physician a great help to his employer, but wins the love and respect of the employees, so that his efforts for safety are more eagerly carried out.

Such efforts by the physician are especially applicable to the shipping industry. Captains of ships which sail without a doctor on board have a great responsibility in caring for the health of their crew. Every captain should have a small amount of knowledge relative to the care of simple ailments and minor injuries; also to realize when some one of his crew is actually injured or sick. He should also watch how work is done aboard his ship to see that the proper safety methods are carried out, and if faulty methods are used, these should be corrected. The marine department of industry should have a physician give talks on first aid and safety campaigns to the officers of their ships regularly. They in turn should hold school with their subordinates in all departments on board ship and should discuss with them the best methods for avoiding accidents, the examination of gears, and the tendency of any of their various personnel to have frequent accidents or work in a careless manner. Such efforts tend to bring careful methods among the crew and if a friendly rivalry can be started among various ships of a line as to which runs longest without accidents, it will stimulate the men to be constantly on their guard. I believe some sort of bonus should be given every year, or every six months, to the ship personnel having the least number of lost time accidents during the period.

Again the personnel of industry should have a physical examination before being hired. This is most important both as regards the employer and the employee: for the employee's sake, so that it may be found out if he is physically able to do his allotted work; for the employer's sake, so that he may be assured of a fit man. All officers of an organization, I believe, should take a physical examination every year to ascertain their physical fitness to carry on. Every man receiving a promotion should take a physical examination and a record is kept of his condition so that it may be seen if he is fit for the extra work. Many costly mistakes have been made by men in important positions who were not physically fit for their job. This should apply particularly to marine officers.

The doctor in industry should act as an advisor to the officers and safety committee, and should watch most carefully the follow-up campaign of its accidents. He should watch their methods and if a particular department of the work is having more accidents than he thinks is normal, a rigid investigation should be made relative to the physical condition of the men in that department and ability of the officers to guide them. He should be generous with his advice and time, and his right to have errors corrected should extend to the officers as well as to medical supervision in general.

I believe the medical department should receive and accept this tremendous power of judgment and should either rise or fall with the results obtained.

There should be no loophole through which might be "passed the buck" to some other department for poor results that should be chargeable directly to the medical department. A doctor accepting this high position in industry should be willing not only to fight for his firm but also for the employees, and unless he shows this spirit of goodwill and friendliness toward those in the lower strata of his plant, he will not receive the help that is so absolutely necessary for the success of his work. He must be exceedingly careful in the treatment of employees even in the lowest grade of work, for it must not be said of him that he neglected anyone or treated him in any way carelessly.

CHAIRMAN BUSH: Gentlemen, the next paper has to do with a new device which is a distinct aid in the navigation of vessels. I have great pleasure in calling on Mr. H. J. W. Fay, Vice President, Submarine Signal Corporation, Boston, Mass.

Echo Depth Sounding to Promote Safety on the Surface of the Seas

By H. J. W. FAY

Vice-President, Submarine Signal Corps, Boston

It gives me great pleasure to review briefly some of the work which has been accomplished in echo depth sounding to make the sea a safer and a better place for navigation. This subject is one which has received extensive research and the best efforts of our organization.

The vital importance of an efficient sounding apparatus and the necessity for its use when "on soundings" can hardly be exaggerated. There are many times when the safety of the vessel and the lives of those on board will depend to a great extent on the accurate and rapid determination of the depth of water underneath the ship. Reference need only be made to the existing facts in almost every case of stranding on record to substantiate this statement.

There is no doubt in my mind that anyone who will review the records of marine disasters for the past few years will freely admit that there is need for an improvement in our present methods of safeguarding navigation to prevent strandings. During the year 1926, an aggregate of 146 ships or 234,000 gross tons were total losses due to stranding, striking rocks or other obstacles, according to Lloyd's Register of Shipping. A conservative estimate of the value of these ships is \$25,000,000 not including the cargoes.

According to the U. S. Shipping Board Bureau of Research, 1,799 vessels of over 500 tons each were partial losses due to stranding in the year ending May, 1927. Beginning with July, 1927, and ending with June, 1928, the total number of disasters recorded are 1,962, of which 621 were due to groundings.

The majority of these strandings and groundings, I believe, are due to a lack of knowledge of exact position on account of fog and storm. Therefore, I feel you will be interested to hear something of the development of an instrument designed to keep the navigator well informed at all times of the depth of water underneath his ship. I refer to the Fathometer (*Figurer*), an echo depth finding instrument infinitely more effective than the time-honored lead and line.

The first use of the lead and line is lost in the haze of man's first attempts at navigation. The application of soap or grease to make particles of sand or mud adhere to the lead and give an indication of the nature of the bottom was recorded by Herodotus more than four centuries before the Christian Era. One of the most important improvements on the earlier methods was the Kelvin Sounding Machine, in which a device encased in the lead records the hydrostatic pressure. In spite of the tremendous advantages of this system a mechanical contact with

the bottom is required. Subsequent efforts have mostly been bent to the task of eliminating the line and utilizing solely the difference in the physical characteristics of the water and the bed of the sea for obtaining depth measurements.

The recent improvements in depth sounding methods are a radical change from the simple but slow system used throughout the centuries. Everyone knows that a cliff will send an echo back across a valley, and submarine signaling had shown

Figure 1. The Fathometer.

that water is a far more perfect medium than air for conducting sound, but it was not until Professor Reginald A. Fessenden created sounds under water with his oscillator and timed the return of the echo that the marvelous possibilities of echoes were applied to depth soundings.

Professor Fessenden's discovery of this new method of depth sounding is linked in its history with the "Titanic" disaster. It was this appalling disaster which led Professor Fessenden to propose experimenting with his oscillator for the purpose of detecting the presence and proximity of icebergs by means of an echo.

In 1914, Professor Fessenden made tests on the Revenue Cutter "Miami" while the latter was on its usual ice patrol off the Grand Banks. In these tests Professor Fessenden found that the oscillator could be used not only to detect the

Figure 2. Operation of fathometer red-light method. As the neon tube "A" passes its zero position on the depth scale, cam "B" closes contactor "C," which sends an alternating current from motor generator "D" through oscillator "E." This produces a sharp sound which is transmitted through the water to the bottom and is reflected, so that a hydrophone "F" placed in a tank of water adjacent to the skin of the ship receives these sound waves, transforming them into electrical waves of the same frequency. There are other sounds or noises about the ship which set up currents of various frequencies, but these are filtered out by the filter "G," and only the current caused by the echo is allowed to pass on to the amplifier "H." Here it is amplified to such an amount that it will operate a relay, breaking a circuit of the primary of a transformer, which induces a current in the secondary of the transformer of sufficient voltage to cause a momentary glow of the neon tube, indicating the proper depth on the dial. This operation is repeated each time the neon tube passes its zero position.

presence and nearness of icebergs, but also to determine the depth of water that the Revenue Cutter was in, by measuring the elapsed time between the sound of the oscillator and the return of the echo.

The first experiments gave promise of success, for echoes were heard from great depths, and sound waves created by the Fessenden oscillator have been echoed from the ocean floor near the Azores in 3,000 fathoms of water, a distance down and back of nearly seven miles. However, the problem was not a simple one, for sound travels in water with a velocity of 4,800 feet, or 800 fathoms, per

Figure 3. Profile of the sea bottom.

second, so that if one is measuring the depth in 40 fathoms, only a tenth of a second elapses between the instant when the sound is created and the moment when the returning echo is heard. If it is desired to know the depth within a fathom, the measurement of the time interval must be accurate to 0.0025 seconds, a precision which is readily obtained in a laboratory but which has heretofore been extremely difficult to realize on a pitching ship.

Many different applications of the echo method of depth sounding have been proposed and much research has been done in the last few years with a view to finding the most suitable way in which to utilize echoes.

In this country where the first experiments were carried out by Fessenden, interest has not lagged and experimental work of great accuracy and importance has been carried out by the United States Navy, the Coast and Geodetic Survey, and by the Submarine Signal Corporation.

Figure 4. Chart showing lines of soundings of the sea bottom.

The following is a brief description of the work done by the Research Laboratory of the Submarine Signal Corporation in developing the "Fathometer."

Many problems confronted the experimenters who first endeavored to make accurate measurements of the time elapsing between the production of a sound under water and the return of an echo from the bottom. If the submarine sound produced had a duration of a tenth of a second, the initial waves of the disturbance had time enough to reach a depth of 40 fathoms and return before the initial sound ceased, and the echo blended in with the original so that it was impossible to make any measurements in these depths.

Whatever was used to produce sound waves it was imperative that the disturbance be over in less than three thousandths of a second if any great accuracy was to be obtained. A sound producer was developed which gave a short musical note and could be excited in a very small interval of time.

The sound producer used in the universal type of Fathometer is known as an oscillator. It consists of a steel plate firmly clamped at the edges and having the properly chosen dimensions so that it vibrates with a frequency of 1,050 cycles giving a short musical tone under water. The plate or diaphragm is actuated by a powerful electromagnet energized by an alternating current.

The echo itself is detected by means of a special hydrophone enclosed in a water tight case and connected to a diaphragm in contact with the water.

The diaphragm takes up the under water vibrations and transmits them to the hydrophone button where they produce variations in an electric current which are faithful reproductions of the under water disturbances.

The current from the hydrophone goes to the Fathometer indicator where the time required for the echo to reach the bottom and return is accurately measured and the depth of water is automatically indicated on a dial graduated in fathoms.

The indicator mechanism is sturdy and will operate in any position as it contains no delicate adjustments which can be put of order by the rolling of the ship or even severe shocks but it is extremely accurate and gives depth readings that can be relied upon within a fathom. In operation a luminous finger points to the spot on the scale corresponding to the depth, varying when the ocean floor is shelving and remaining fixed when the depth is constant.

The light itself is not continuous but flashes several times a second giving the illusion of a nearly constant light as shown in *Figure 2*.

With the completion of the development work and extended trial installations of the Fathometer on our part it then became incumbent on us to prove its accuracy and reliability to the various Marine authorities.

The generally recognized high standard of the sounding work of the U. S. Coast and Geodetic Survey led us naturally to this service to prove the accuracy of echo depth finding as embodied in the Fathometer.

The extent to which we have done this is best told in the following extract from the 1927 Annual Report of the U. S. Coast and Geodetic Survey:

"During the last year the apparatus successfully passed all tests and was accepted for use in hydrographic surveys. Steps have been taken to procure additional echo depth finding machines and install them on nearly all of the vessels of the survey.

"By means of this echo-sounding apparatus, known as the 'fathometer,' it is possible without stopping the vessel to take soundings in any depths from a few fathoms under the keel to at least 2,500 fathoms (15,000 feet), and probably to greater depths. The advantage of this apparatus for survey service is that soundings can be taken as rapidly as desired—as frequently as four per second—with the vessel steaming at full speed. It is, therefore, possible to survey more than twice as much area per day with this apparatus as would be possible by any other means. This apparatus, however, is not confined to the use of the surveyor. In fact, it is of even more value to the navigator since the master of a vessel equipped with an

Figure 5. Profile of deep sea sounding.

echo sounding machine can feel his way at night and during stormy weather without stopping the ship. He can also find his position at sea by comparing a series of soundings with the depth shown on his chart, and with this information lay out a safe course to his port of destination.

"While the primary purpose of this bureau in going into this subject, and cooperating with a commercial firm in the development of the fathometer, was to secure an apparatus that would enable the bureau to speed up its hydrographic survey, it was, nevertheless influenced by the belief that the perfection of this apparatus would be of great benefit to marines everywhere and would contribute toward greater safety at sea. I am glad to report that our estimate of this apparatus has been fully

justified and that our cooperation has been of material assistance in bringing to perfection a very important contribution to navigation."

The value of the Fathometer to cable ships was apparent from the start as it was evident that any method that would give practically a continuous line of accurate soundings and thus show the most desirable cable route to adopt would be of great practical value both to the cable laying and repair ships. The "Cyrus Field" was one of the first of the cable ships to be equipped with a Fathometer in May, 1925. *Figure 3*, showing a profile of the sea bottom between Nantucket Lightvessel and Halifax, N. S., made from continuous Fathometer soundings is the first echo depth sounding work done by the "Cyrus Field."

Naturally, the efficiency and accuracy of the Fathometer as demonstrated in the Coast and Geodetic Survey, in the Navy, and on cable ships attracted the attention of owners of commercial vessels, for a sounding device that could prove reliable in such exacting services most certainly held advantage for commercial navigation.

One of the first lines to equip a vessel with the Fathometer was the North German Lloyd S. S. Company. And incidentally, the Fathometer on their S. S. "Columbus" is used for position finding as well as depth sounding. The officers of the vessel have plotted lines of soundings (*Figure 4*) on charts in the form of courses and when making Nantucket or Bishops Rock, in fog or thick weather, they pick up one of these courses and follow it to their objective.

A fact significant of the value of the Fathometer is its use by such representative ship operators as the United States Lines, North German Lloyd S. S. Company, United Fruit Company, Clyde Line, and Eastern S. S. Company.

The last few decades have witnessed many startling applications of science to industry, and these inventions have nowhere shown themselves more fruitful than in increasing the speed and safety of navigation.

The rapid progress of recent years in the development of echo depth finding is all the more noteworthy when compared with the centuries that the lead and line remained the unchallenged means of measuring ocean depths.

The echo method of depth finding which requires no mechanical connection with the bottom represents a radical and brilliant step in man's mastery of the sea.

CHAIRMAN BUSH: The meeting is open for discussion.

P. B. BLANCHARD (Turner-Blanchard, Inc., New York City): Mr. Chairman, here is a case where I am going to deviate from the stevedoring and go back to sea. If that is as we heard it, I consider it the greatest invention that has been handed to the shipping world. I say that not in idle talk.

I have gone out on this coast in a sailing vessel, in the dead of winter, making the land, and seeing neither hide nor hair of the sun for days, and we used to take the old lee line and carry it forward and take the sail back to the main tops of the quarter, and take a sounding and go a little ways and take another.

We wrote that on a piece of paper that we put a blotter on so we could read it. We plotted that along and took a slide on the chart until it matched the soundings that were on the chart.

That is the way we found our position, and it is a fact, those that have tried it know that the ocean bottom is very regular, and if it is possible to plot along at different distances it is like finger prints. At the bottom of the ocean it is different everywhere. You can plot on a piece of paper and slide it along on a chart.

I consider this the finest way of finding your position that is known to the navigator, and I feel that is one of the most wonderful inventions ever made.

M. T. DONNELLEY (Consulting Engineer, New York City): I had occasion to sail quite extensively in the North Pacific Coast. I want to bring up here that they use echo there in navigating, to a very surprising degree.

I have laid awake in my boat for night after night and listened to the "toot toot."

and inquired next day what it meant. The man kept pulling that whistle all night and kept me awake.

I found that was the way they navigated. It was a long "toot" long enough to kill the first echo. Then he gets the echo from the further side. In that way the man on the bridge without any apparatus at all except what God has given him, can navigate by echo. In talking with the captains they say they can even catch the echo from a log on the water when conditions are right.

That isn't all. We have had, at the entrance of Vancouver Harbor, British Columbia, a narrow inlet and a great deal of fog. The entrance is about 300 yards wide, with hard rock on each side. I have hit one side and gone through many times. Through that they can sail down the big fog and commence to "toot" the whistle and by and by get an echo.

The captain stands there with a watch in his hand. He knows how far he is from port. They have set up against that house, a board, two boards at right angles. They don't get the echo unless they come within right angles. As soon as they cross the line at right angles the echo will go and strike one point and then cross the other and come back.

The reflection is the same as the turn of a billiard ball on a billiard table. If you shoot at the one pocket it will cross over and come back parallel.

They can tell then that they will sail down this line and first get the echo, and then they get a certain distance—a second or two seconds or three seconds away—and swing on the course and hit through this narrow passage.

That has been done for a good many years. I would like to ask the speaker if that instrument has been used in connection with a set board or if it is practically possible to navigate with your instrument in that way, being guided by an echo on a board?

MR. FAY: The fathometer is essentially an accurate time-making instrument, and if the echo came back accurately, there wouldn't be any difficulty in measuring it. I think there is a good possibility in the future of working something toward the line of prevention of collision at sea by giving the ship speed and distance just as we are giving now the distance from the bottom. But that is too far ahead.

MR. DONNELLEY: I wonder if anything has been done in putting up these boards, other than just by chance in Vancouver?

MR. FAY: Not that I know of. We recently were testing a whistle at Execution Rock and got some echoes from a house. And then we got echoes off boats that passed. But I don't know of any special boards that have been set up.

On the Coast of Maine, going up near the Penobscot River, you get wonderful echoes there. You can time them beautifully. I think we are just coming into the utilization of echoes in safety work; as you all motor, you hear the echoes off the picket fences as you go by, and off trees. And maybe echoes will come into the navigation of airplanes in helping landing. I think the usefulness of the echo is just being appreciated.

MR. DONNELLEY: There is no reason why you shouldn't navigate a river like the Hudson by an echo board.

R. L. McALL (American Seamen's Friend Society, New York City): Is there an element of direction in the reception of the echo wave? In other words, can it be turned? I didn't quite catch it, not being a technical man. Can it be turned so as to direct the echo in another direction, or is it a spherical wave which does not have the directional element?

Supposing you were going through a very narrow and very deep channel, the Canyon of the Colorado, we will say, under water. Would you get an echo from the side if you are in the middle, at an angle, or would you get the echo from the bottom? Can you make the instrument tell the distance from different angles?

MR. FAY: You could do that, if you wish to install the instrument so that it will need to be directive and could be rotated, but we get the echo from the nearest point. We have echoes from icebergs and the bottom at the same time. But the echo which we obtain from icebergs at a distance of from two to three miles, we do not recommend for high-speed ships as we get too close to the bergs.

ADJOURNMENT.

October 3, 1928

American Steamship Owners Association Day

A. R. BUSH, Chairman

Personnel Manager and Safety Engineer, The Barber Asphalt Company
Maurer, N. J.

The third session convened at nine-fifty o'clock, Chairman Bush presiding.

CHAIRMAN BUSH: The first paper this morning, gentlemen,—this being American Steamship Owners' Association Day, that organization having greatly co-operated with us in the preparation of today's program—is "Safety in the American Merchant Marine," by a man who needs no introduction.

I am pleased to present at this time, Mr. H. B. Walker, the President of the American Steamship Owners' Association.

Safety in the American Merchant Marine

By H. B. WALKER

President, American Steamship Owners' Association, New York City

Accident prevention in all lines of human endeavor has passed the doubtful stage and is now considered essential in all branches of industry. From a humanitarian point of view its worth has never been doubted but to gain a permanent place in business its economic value had to be demonstrated.

Despite the splendid results which are being obtained as a result of the work being done by the National Safety Council, local organizations and individuals, there is urgent need for increased and extended effort. Some idea of the appalling loss caused by accidents may be gained from a statement recently issued by the New York State Department of Labor:

"Compensation was awarded during the year ending June 30 last for 1,129 deaths and injuries to 93,565 persons in industrial accidents. Figured on a time basis, this means 'society lost the productive labor of 45,000 men and women for one whole year' the Department pointed out. The total spent for compensation was in excess of \$28,000,000!"

Assuming that there are 300 working days in the year and that the average wage is \$4 per day the injuries in New York State for the year ending June 30 resulted in a direct economic loss amounting to about \$54,000,000—with no account taken of the indirect loss of production due to the stoppage or slowing up of work when the accident occurs or of the loss occasioned by the replacement of the injured person.

Authorities are of the opinion that from 75 to 85 per cent of this loss was avoidable.

With higher wage rates and more liberal compensation provisions the cost of the average industrial accident is increasing which results in a higher cost to industry and which can only be offset by a reduction in the number of accidents.

In the shipping industry the value of accident prevention is being more generally realized. Shipping executives are taking a keener interest. On the Great Lakes safety education has been carried on through Ship Safety Committees for a number of years with splendid results. Each committee is composed of six men and holds a meeting once a month upon call of the master of the vessel, at which the master and chief engineer are present in an advisory capacity. These committees consider various questions of safety, discuss accidents, give instructions to new

men, etc. The members of the committees are paid for their attendance at the meetings and if no accident occurs to any member of their crew during the season, necessitating his absence from the ship, a bonus is paid to the members of their committee. The number of vessels receiving the bonus has increased regularly. The minutes of the meetings of the various Ship Safety Committees are sent to the manager of the lines as well as to the office of the Lake Carriers' Association. These are very carefully examined for constructive suggestions.

As result of their experience a Code of Recommendations has been issued covering the following: ladders, tackle, gear and stagings, machinery, lights, hand rails and gratings, pipe lines, boilers, valves, hatches, cables, loading and unloading, fire, life preservers, etc.

In Seattle, safety education is conducted by the Waterfront Employers' Association in which both employer and employee have representation. This association, by means of careful employment selection, has greatly reduced the high labor turnover in the stevedoring industry, which has resulted in a more steady employment for the men, with increased earnings. The safety work, which is in charge of a competent engineer, has made for a steady reduction in accidents. The results of the work have been gratifying.

In San Francisco there is also a cooperative movement. The Pacific American Steamship Association, the Shipowners' Association of the Pacific Coast, and the Waterfront Employers' Union have organized an Accident Prevention Department which began to operate in 1927. The different organizations interested have appointed representatives which meet and form the governing board of the Accident Prevention Department. A safety engineer, who devotes his entire time to the work, is in charge. Each company of the steamship owners' association has designated an executive to cooperate with the Accident Prevention Department. He is responsible to the company for the accident prevention work, and is known as a Safety Contact Executive. Monthly meetings of these executives are held, where the methods of conducting the work are discussed.

Dinner meetings for executives, for chief stevedores, for gang bosses, and others are held, and have done much to stimulate safety thinking. Bulletin boards and special safety slogans, standardized first aid kits, and first aid stations are being used with success. Special safety letters and reports and studies on various subjects are issued from time to time. Accident statistics are compiled and regularly submitted to the membership. These reports are carefully analyzed, the accidents segregated by causes, and used in various ways to impress upon the personnel the necessity for "safety" in their daily work.

Recently the accident prevention campaign has been enlarged to include the harbors of Los Angeles and San Diego. Several of the companies are developing safety departments within themselves, and in some instances have safety committees working both on shore and on ships. A program of accident prevention for ships at sea is also under consideration. Rules governing safe practices, duties of hatch tenders, stevedoring foremen, etc., are in course of preparation.

Galveston is also carrying on an active campaign.

On the Atlantic Coast the cooperative movement of shipping organizations and individual steamship companies in combating the great evil of avoidable accidents has probably had its greatest impetus. This has been accomplished through the activities of the Marine Section of the National Safety Council in which many of the leading American shipowners and operators hold membership and whose representatives meet monthly for the exchange of information. The work has produced excellent results. One company, it is reported, has saved \$70,000 in one year in the cost of accidents occurring among the longshoremen and other employees, through an organized safety movement costing less than \$500. The methods used by various companies differ to some extent, but can, in general, be classified into two groups, (1) those having well-developed safety departments in charge of a

safety engineer, and (2) those who contract with outside organizations for accident prevention campaigns.

The American Steamship Owners' Association has recently become interested in this very important subject and has appointed a safety committee. This committee has in mind the formation of safety recommendations based upon the practices of those of our members who have been carrying on campaigns of accident prevention for some time. It is believed that this will do much to interest the executives of other companies in the work, and that it will materially increase the number now engaged in it.

It must not be forgotten that the industry faces certain difficulties which are not as marked in other lines. For example, the labor turnover, both ashore and afloat, is very high. Stevedores are not regularly employed on many docks, and seamen do not stay with a ship sufficiently long to be influenced by safety propaganda. It may be possible to develop some plan, as was done in Seattle, whereby this turnover will be reduced. Then too, as you well know, the shipping industry has had and is having a hard struggle to make both ends meet. There is, therefore, a hesitancy to undertake anything which would appear, at least, to involve additional expense.

It is the constant goal of operating officials to increase the ship's turn-around. The officers and men, therefore, have little time in port to devote to the study of accident preventions. The method of conducting these campaigns requires considerable attention and unless the work is entered into with a whole-hearted spirit on the part of the company's executives it is, in my opinion, doomed to failure, for employees are suspicious of the company's motives in welfare work.

There can be no doubt that the preparation of safety regulations or safe practice handbooks, such as have been prepared on the Great Lakes and in Seattle and are under consideration in San Francisco and by the American Steamship Owners' Association, is a distinct forward step. Under the Longshoremen's and Harbor Workers' Compensation Act, which was enacted by the Sixty-ninth Congress, the United States Employees' Compensation Commission is authorized to "make studies and investigations with respect to safety provisions and the causes of injuries in employments covered by this Act and shall from time to time make to Congress and to employers and carriers such recommendations as it may deem proper for the best means of preventing such injuries." It is reported that steps have already been taken by the Commission toward an investigation of the subject with a view to the formation of a marine safety code.

Personally I feel that better results for all concerned will be obtained if the industry undertakes this work itself or if the Commission should give the industry the opportunity of cooperating. A code, if developed, in my opinion should set forth only minimum requirements, for the reason that past experience has proven that whenever codes are prepared they are likely to be enacted into law. The chief objection to this procedure is the difficulty with which they may be changed. For this reason it is generally believed that it would be better if the code could be the regulations of a department of the government. It would, in fact have the force of law, but would be more easily changed if modification was deemed desirable.

I have purposely refrained from going into great detail concerning the work of the various organizations which are now functioning as this has been described at previous meetings of this Section. The progress which has been made to date and which to you must be most gratifying I believe can be attributed directly to the splendid work done by the members of this Section, individually and collectively. That shipping executives are becoming more interested in this subject I think is amply demonstrated by the fact that this Section has increased its membership from 57 to 150 in a period of two years. You are to be congratulated upon

this splendid showing, and I extend to you our best wishes for your continued success.

CHAIRMAN BUSH: In opening the discussion on Mr. Walker's splendid paper, I am going to call first on Mr. A. C. Holzepfel of the International Composition Company of New York City.

Discussion of Mr. Walker's Paper

By A. C. HOLZEPFEL

International Composition Company, New York City

Mr. Walker's paper gives us valuable information on what has and is being done to assure greater safety in connection with our industries and shipping. The existence of the various committees referred to gives us the assurance that this work will be progressively developed.

May I be allowed to diverge somewhat from the scope of Mr. Walker's paper?

In view of the fact that so many gentlemen prominently connected with the oil industry are identified with this Congress, I have deemed it permissible to offer some remarks on a subject in which the mineral oil industry as well as the shipping community are likely to be interested.

Ever since tank vessels were built, it has been found that they are more subject to internal and external corrosion than other vessels. The same is the case with the fuel tanks for passenger and cargo ships, although to a less degree.

The deterioration referred to has been caused by the formation of acids, chiefly sulphurous, formed by the mixture of water with oils containing sulphur, also by the formation of sulphide of iron, due to the contact of steel surfaces with hydrogen sulphide gas. This sulphide of iron sets up electrolytic action, thereby accentuating corrosion.

Practically all mineral oils contain some sulphur, but lately, chiefly in Texas, many oil wells have been opened up, the oil from which contains a much higher percentage of sulphur, with the result that damage to storage tanks, refinery plant, tankships and tank cars has been considerably increased.

Protection against such damage by ordinary paints is out of the question, for not only would they be quickly dissolved and removed by the mineral oils and their condensation, but they also possess no adequate resistance against sulphurous, sulphuric and other acids, with which such surfaces may come in contact. For years the Oil Industry searched for a material capable of protecting their plant against such damage and it is only during the last three to four years that new synthetic gums have been developed, which are capable of being made into a protective paint against such damage. Such paints have been introduced to the Oil Industry and are being extensively used in refinery and storage plants, but they have not been so far adopted for use in tankships, because of the difficulties and loss of time in connection with efficient application. The inspection of the internal surfaces of a tank steamer will convince members of this Congress of these difficulties.

Not only has a viscid mass of oil film to be removed, a matter of great difficulty, but underneath is generally found a heavy layer of rust which has to be removed before any protective can find firm adhesion to the steel surfaces. To carry out the effective cleaning and painting of a modern tanker would occupy probably two weeks or more, a sacrifice of time which oil companies would not readily consent to. I have, therefore, suggested that such cleaning and painting may be done during the return voyages in ballast of the tankers. Two or three capable men might be carefully instructed in such work and carried on board, provided with

pneumatic or electric scaling tools, with a sand-blasting outfit and painting tools, also the necessary staging. They could clean and paint one tank at a time, while the vessel is on voyage from discharging to loading port, and in this manner, perhaps in six or twelve months, all the tanks may receive a protective coating, so as to prevent the serious damage and resulting danger to which they are now exposed. The principal thing is to have expert men for this purpose, who could then be moved from one vessel to another together with their outfit, till all the ships of a fleet had received adequate protection. In this connection, it may be mentioned that the loosening of rivets by lubrication of the oil would be avoided, also the damage from electrolysis, which is caused by the formation of sulphide of iron on surfaces in contact with hydrogen sulphide gas emanating from sulphurous oils; lastly, the danger of explosions in tanks *after* they have been degassed, resulting from emanation of gases from the thick layer of rust present on unprotected surfaces in the tanks.

It is, however, not only in tankships but also in other vessels carrying fuel oil or Diesel oil that careful attention should be given and, if possible, to a protection such as I am suggesting. In this connection, it should be borne in mind that fuel oil tanks and tanks containing Diesel oil are also attacked in the bottom by acids. Last year while I was in Los Angeles I was informed that some fuel oil tanks of the Southern Pacific Railroad were having their bottoms renewed on account of corrosion. A large Norwegian firm of shipowners, owning not only tankships but also Diesel-driven ships, wrote me as follows:

"Corroded and slack rivets in tank steamers is a well known fact and have given us a lot of trouble, so if there should be a possible cure it would be worth considering. We have also had the same experience with other ships carrying fuel oil in the ordinary tanks, and I am afraid we shall also have similar experience in the motor ships carrying fuel oil in the bottom tanks."

It is also well known that fuel oil tanks, whether containing regular fuel oil or Diesel oil often need repairs. In this connection, it might be borne in mind that many vessels carry their fuel oil in double bottoms which are rather shallow and inaccessible. The presence in the bottom of these tanks of a thick viscid mass of oil makes inspection for damage extremely difficult. For this reason, there is all the more need for adequate protection against damage by acids emanating from these oils.

During the last few years a number of oil deposits of very high sulphur content have been developed in Northwest Texas. Fuel oils and Diesel oils from these deposits are much more dangerous than the oils with which industry formerly had to reckon.

Classification societies no doubt realize the enormous responsibility under which they are in connection with the protection of these fuel oil tanks; at least one classification society has written me on this subject, stating how anxious they are to obtain adequate protection, but there is one difficulty which should be appreciated by this meeting. The protection of tankships and other vessels is under the responsibility of engineers. Now, to the engineer a paint is a "dark horse." In connection with his business he deals mostly with engineering apparatus, whose effect in actual use he can easily appreciate from their drawings and from practical tests, whose results are quickly obtained. In regard to a paint, however, particularly a new protective material which is not yet in general use, he is apt to be extremely skeptical, as he is unable from his own experience to judge its efficiency and the permanency of protection offered by it. In this connection, the engineer ought to get the assistance of the chemist in order to enable him to form a judgment; by so doing, he would be able to decide much more quickly than otherwise on the adoption of an efficient protective.

CHAIRMAN BUSH: If there is no discussion, we will proceed to the consideration of the next paper by Mr. Joseph J. Farrell, Senior Engineer, Travelers Insurance Company, Brooklyn, New York.

MR. FARRELL: Before starting to read the paper, I wish to state that a lot of our trouble in the stevedoring business has been in the past and will be in the future, the uncertainty of the business. When we have been on the ship for discharge or load, we have no idea at that time just what the cost of that production is going to stand us. And so it is with accidents. We start loading and discharging a ship; we do not know or realize how many accidents we are having. We can't foresee that.

I believe, due to this uncertainty, that we should diagnose the situation. I have tried to do it now here in a simple manner, with this paper, that I am about to present, and I think that a lot of men who have spent a good many years in the Port of New York will realize that a lot trouble will lie behind these facts.

Now let's diagnose:

Safe Practices for the Prevention of Accidents in Stevedoring

By JOSEPH J. FARRELL

Senior Engineer, Travelers Insurance Company, Brooklyn, N. Y.

What is the cause of the accident frequency in stevedoring?

The majority of persons engaged in this business or associated with same will state either equipment or labor are the responsible factor.

I disagree with them in this respect and state that it is the lack of executive participation and poor supervision on the part of the supervisors that is responsible for the frequency. Let us discuss these features in the order named.

Labor

There is a certain element among the Longshoremen of the Port of New York who are compensation experts. It is commonly known that cases prevail where men are drawing compensation and while being compensated are working for some other stevedore under an assumed name. Can the responsibility of this element be placed upon the shoulders of the majority of men associated with this organization or upon the labor organizers? No, the responsibility lies right at the doorstep of every concern engaged or associated with this business for not getting together and formulating some plan to eliminate this practice. Aside from this practice labor on a whole can be properly controlled if the supervision is properly selected.

Equipment

Everyone who has been associated with stevedoring for any period of time will certainly concede that at no time during the history of the business has better equipment been in use. Lighters, piers, ships along with the stevedore's gear has shown a marked degree of improvement during the past five years. Having taken this into consideration, we will all have to exclude equipment as responsible for the frequency in accidents.

Acting in this capacity our principal duties refer us to cost accounts and the proper remedies for the reduction of same. Stevedoring executives are no different from those engaged in any other line of business. Therefore, the most costly item is the first problem. Labor being their subject they tackle it with all the ingenuity and experience within their respective organizations for devising means of better

dock transportation or new equipments and methods of adjusting better production at a lower cost.

All efforts being concentrated on this one subject in most cases the second highest cost item, insurance, is overlooked. Therefore, no time or energy is spent on this cost in ascertaining whether or not a plan could be formulated to reduce it. Having the executives' efforts in regard to the cost, it will be evident, after going down the line of supervisors in that organization what interest is taken by the hatch bosses in accident prevention work. This lack of interest on the part of the hatch boss relative to accident prevention work is only to be expected when the executive interested in cost does not know what each foreman and hatch boss is costing him in insurance premium. The amount of premium you pay each year is based on your accident frequency or experience as it is commonly known in the insurance field. Can you lay the responsibility on the foreman or hatch boss for not being interested in safety work if it is not just as an essential qualification by their employer. In my opinion, there is no safer practice for the prevention of accidents than that of executive participation.

Supervision

Everyone knows well we have a hatch boss to every hatch, particularly in unloading operations. It is not because of any custom but for the purpose of greater production, in eliminating over-stowage, property damage and the increase of tonnage which can only be had by close supervision.

Every member of the stevedore firm considers the supervisors, such as foremen and hatch bosses the backbone of his organization and due to this fact places the entire operation in their hands with little interference, if possible. Due to this prevailing situation, the foreman is not annoyed by the executives with being held responsible for accidents occurring under their supervision.

I do not believe there is another line of work where such an excess of lost motion which, coupled to poor supervision, is the greatest problem of stevedoring. Show me the foreman or hatch boss with the highest accident frequency record and I will show you the poorest producer in your organization. Safe practices and efficiency go hand in hand and no practice that is not efficient is safe.

A review of your accident file is the greatest measuring stick by which you can judge your foremen or hatch bosses. Very often an accident will come to light that would show you that through poor supervision on the part of the foreman, men were required to work under unsafe conditions which caused a serious accident. You cannot blame labor or equipment for this accident but you can certainly blame the foreman and the executive. Executives of an organization following an accident of this type are responsible due to their lack of participation in accident prevention work and keeping of records which would acquaint them with every case that arises which tends to increase their insurance costs.

Through the following safe practices for the prevention of accidents in stevedoring which, if installed in every organization engaged in this line of business I believe they will be the greatest factor in reducing insurance costs also tonnage cost of handling cargo.

Plan for Placing Accident Responsibility

Superintendent or head foremen should be held just as responsible for accident supervision as they are for efficiency and production. All insurance costs and rates are governed by experience, therefore, it is one of the most essential duties of a supervisor to keep the accident frequency under control at all times.

Insurance to a stevedore is one of his largest items of expense, therefore, his personal interest should be given to see that everything is done, to the end, that this

cost is kept as low as possible. Low insurance can be had by good accident supervision on the part of the stevedore and his employees.

In order to control the accident frequency arising from stevedore operations the following action should be taken.

A—Charts should be kept at all locations where operations are more or less of a steady nature, charging all foremen and hatch bosses with the accidents occurring under their supervision. Where an assured does not operate at a steady location, this charge should be maintained in the office.

B—Charts should be reviewed monthly by officials of the company, and the men having the largest number of accidents at each location should be censured by them. It would be a good plan, in our opinion, if the hatch bosses having the best accident record would receive more consideration in regards to employment as it is very often the case that less hatch bosses are needed in the loading and discharging of certain vessels.

Officials will find from the keeping of this chart system, they will be able to know the most careless men in their organization. This man will be generally found to be the one who has the most property damage to cargo handled by the men under his supervision. We find from our records today, that supervision is a responsible factor for 90 per cent of the accidents occurring in stevedore operations.

This system will be of great assistance to foremen and hatch bosses, due to the fact that if censured by executives for production they can state that if their accident record is taken into consideration they are more of an asset to his organization than the man who has the highest tonnage record, plus the highest accident record. Combining the two records, the cost per handling a ton is higher than that of the man having the best accident record.

In conclusion, gentlemen, I wish to state that the building of a safety organization within the confines of each individual organization, must have some responsible person designated for carrying out of safe practices outlined, agreed upon and sponsored by all supervisors.

APPENDIX

Safety Meetings in Stevedoring

1. Meetings to be held at least twice a month.
2. Meetings to be from 15 to 20 minutes duration and to be held when they will not interfere with operations.
3. The personnel of attendance should consist of—
 - a. Members of Firm
 - b. Representative of Insurance Co.
 - c. Superintendents
 - d. Foremen
 - e. Hatch Bosses
 - f. Timekeepers, and
 - g. if possible, representative of Steamship Company who is directly responsible for the equipment of the vessels and terminals.
4. Subjects to be considered at meetings:
 - (a) Prevention of accidents.
 - (b) Review and analysis of accidents that have happened since previous meeting and necessary recommendations for the prevention of like acci-

dents in the future. In this review of accidents an effort must be made to determine the BASIC CAUSE and to place responsibility for faulty physical conditions or for failure to enforce safety rules.

- (c) Use of proper equipment for the handling of various commodities and the condition of equipment.
- (d) Proper handling of hatch covers, beams and strong backs.
- (e) Proper use of ship's equipment in the handling of heavy cargo.
- (f) Necessity of notifying the proper authorities immediately when any equipment of the stevedore or the vessel is unsafe.
- (g) Proper method of tiering cargo on docks and in holds of vessels to prevent it from falling.
- (h) Necessity of wearing gloves for preventing cuts and lacerations.
- (i) Necessity of receiving prompt first aid for all minor injuries.
- (j) Reporting of accidents immediately after same have occurred to hatch boss, foreman or timekeeper.

It may be impossible to discuss all of the foregoing subjects at one meeting, but it is probable that one or more items will necessarily receive consideration in connection with the review of accidents.

These meetings should be controlled by the employer and a talk should be given by him when possible or by the Superintendent in charge of operations.

Minutes of meetings and copies of accident notices that have occurred since last meeting should be placed on file for future reference.

Accident notices should be numbered and a record of the nature and cause of accidents should be kept so that an idea of the frequency of different types of accidents may be obtained for a given period.

Joint Inspections of Vessels and Piers

The equipment of piers and vessels should be inspected by representatives of the Steamship Companies, Superintendent or Foremen of Stevedore to determine safe conditions. The following items should receive consideration.

1. Piers with reference to flooring, doors and lighting systems.
2. Gangways or ladders used for boarding of vessels.
3. Tackle and gear in connection with the use of derricks and booms.
4. Flooring in holds of vessels.
5. Ladders leading into hold of vessel.
6. Hatch covers and identification marks using proper names so as to permit replacement on proper Hatch.
7. Guarding of all steam lines on decks especially those running abreast of hatch coamings.
8. Proper functioning of winches and guarding of gears.
9. Furnishing of sufficient light for men working on deck or in hold.
10. Getting the proper information in regard to the tested strength of booms.

All of the above conditions should be inspected immediately after arrival of the vessel at pier and the necessary action for the immediate repair or replacement of any poor equipment should be insisted upon.

Now in conclusion, I will refer briefly to the general situation around the Port of New York. We have improved considerably as far as equipment and the building of the steamers of today are concerned. We have improved in certain portions of the port of our terminal or dock conditions. And we have improved considerably on means of dock plant transportation from the end of the tackle to point of storage on the dock.

But I maintain that unless we improve conditions on the part of our supervisors and foremen and our own interest as to their qualifications for preventing accidents, we will never come to the point of success, whether or not we have national

codes for safety of longshoremen, whether or not we install resting places on the piers for them, no matter what we give them. You and I and every man in business is held responsible for a certain duty.

Therefore, I think that a lot of the conditions that exist in stevedoring today are due to the fact that when we start an operation we turn the entire thing right over to the foreman and neglect to instruct him that the organization is large enough, that the superintendent of pier is responsible for controlling accidents, that he is responsible to the pier superintendent, and that the hatch boss is responsible to the foreman; and therefore, pass the responsibility down to the point where the thing lies, and back to the highest point of the organization, the executive officer, who should see that these men are properly disciplined, properly censured and given some remuneration for the good work, whether they have been twenty years in an organization or whether they have been one year.

We are all in business to make money, and that is the primary purpose of any line of business. We all admit the humanitarian standpoint of accident prevention work is the outstanding feature of it, but down in our hearts, the almighty dollar is the main point we are in that business for.

Therefore, I wish to get this across to everyone; that the day when we hold the supervisors of stevedoring organizations responsible for accident frequencies, we will come to a point where we will reduce our second largest cost.

CHAIRMAN BUSH: The meeting is open for discussion, gentlemen, on Mr. Farrell's paper.

Mr. Welch, would you care to make a few remarks?

W. E. WELCH (The Travelers Insurance Company, New York City): Mr. Farrell has arrived at his conclusions in that paper by long experience, and they are all facts. I believe the main point is a safety organization in connection with all or every type of industry, and particularly in connection with stevedoring. And I believe that Mr. Farrell was the first to present that to stevedoring in the Port of New York.

I think that is all I have to say in connection with that paper. There are some practical stevedores here.

FRANK A. FRITZ (T. Hogan & Sons, New York): There has been a wealth of material presented here this morning in the two papers thus far read.

Realizing as we all do, the necessity for safety education, realizing that we can't get anywhere without it, I imagine we have all come to the point where we felt we were completely stumped. And by that I mean you get to a point in your organization where you feel that the preliminary feeling of suspicion or lack of cooperation perhaps has passed to a great degree on the part of your supervisory force, but you still wonder how you are ever going to get down to the individual man that does the job.

To my mind, that is the paramount problem we have to meet in the stevedoring industry. I think Mr. Farrell is correct when he says the supervision is the crux of this proposition. But I would like to hear, if we could, what the experience of some of our people has been with respect to getting a dribble occasionally of enthusiasm or interest, down through the strata of supervision among the lowest in rank of employees in connection with this work.

I think we often see that the problem of undertaking to educate men in an industry which has as high labor turnover as stevedoring is certainly no small problem. And it has struck me as it has all of us from time to time that what Mr. Walker outlined this morning, namely, the cooperation of the companies on the West Coast, is perhaps a very distinct step in that direction.

I think we all appreciate that if all the stevedoring companies interested in the reduction of accidents could get together and cooperate to employ standard methods, not so much standard mechanical methods of handling the work, because

there you have a variation due to structure of ship and due to location of piers and structure of piers and whatnot,—but there isn't any room for doubt that we could standardize on the method of educational campaign, and there isn't any doubt that by cooperation among all the stevedores who employ help that we can make the educational campaign a much more universal thing than we have today.

I think if there is lack of success in the safety work among stevedoring companies today, it is not so much because it is not done properly or because it is not done with proper enthusiasm but because of our high labor turnover. I mean by that, that we get men today who have worked for a company which has given little thought and devoted little time to safety work, while the men at whom you have been pounding for the past week leave you and go to work for that particular company. So the benefit that you might expect and that you would actually receive by a steadily employed force is lost to you.

Then it has struck me that placing upon your hatch boss or placing upon your foremen of the gang, the responsibility for accidents, is undoubtedly theoretically sound. My observation leads me to suggest that your foreman is ubiquitous; he is not only a hold man and deck man, but he is likewise a dock man. And his opportunity to observe accidents is not so great as we might think it could be, and certainly not so great as it is on the part of foremen who are employed in a particular place with a steady gang. So it seems to me you have a very serious problem there to solve.

I don't know exactly what the solution is. I suppose if I did, I would be the leading stevedoring safety engineer in the country. But the problem is to get through, below your supervisory strata or supervisory level, the information the man ought to have; which we have all got, but which doesn't do a lot of good, because we don't do the work. Get it down to the man who is actually doing the job.

Then comes the question of stimulus of interest, and I am frank to say that I have always been afraid to advocate stimulus of interest by some of the means which we recognize in safety work, by prizes and bonuses. First of all, I think we can eliminate certain prizes that are offered because that is no stimulus in my opinion to the longshoreman. Second, if you once decide what the form of remuneration is going to be, the next question is: How are you going to fairly allot it and fairly apply the principle so that it is obvious to everybody that you have done the fair thing?

I am inclined to believe that simply expecting safety work from the average employee because that is included in his daily wage and is included in the instinct of self-preservation, is a trifle beside the mark, just as it is beside the mark to take a man that has been hurt and criticize him because he is an old and experienced man and ought to know better. We have to assume that the best man we have will often lapse into carelessness, because that is human experience, whether it be due to the fatigue period or not, it is all present in the most careful of men. So you have to assume that you are going to have accidents sometimes even with your best men.

JOSEPH J. FARRELL (Senior Engineer, Travelers Insurance Company, Brooklyn): I quite agree with you, Mr. Fritz, that as far as the individual is concerned in stevedoring, we would all like to educate that man.

But I have had occasion often to work in ships where I would tell the hatch boss, "I think you had better take another section of hatches off." He would tell me to mind my business, he was the hatch boss.

So I think after we get our supervisors instructed and hold them responsible for the conditions that the men working under them have no accidents, I think our next step is to work on the individual, because there is one of our captains who used to say, "There is sometimes more brains in the forecastle than up in the bridge."

CHAIRMAN BUSH: Is there a representative here of the Southern Pacific Company?

MR. COOPER (Southern Pacific R. R.): We have been conducting a safety campaign for several years. I think we are practically pioneers. I feel proud of that. We have accomplished very successful and gratifying results. We have done it by a system of education.

We hold frequent, periodical meetings of our foremen, and discuss our safety problems and arouse their interest. We have posters. We have a definitely well-defined plan. We change them from day to day as conditions seem to warrant.

We would be glad indeed if anyone is interested, to have you come down and visit us. We will show what we have and what we are trying to do. But to enter into a detailed discussion of what we are doing is a large order.

CHAIRMAN BUSH: There are a number of practical stevedores here. The purpose of these meetings is the exchange of information and ideas and experiences.

R. L. McALL: I would like to ask a question. The point has been raised by every speaker this morning about the uncertainty of the duration of the employment of the individual laborer, that is, the casual type of laborer, which constitutes really the greatest problem.

If you could be sure that your laborer was going to stay with you for any decent period of time, you naturally would be bound to that man and he to you. You could do something with him. If he is with you for some time he begins to expect that sort of friendly interest which all good companies are showing.

I don't know why some attention cannot be given to making that a quest to see how stevedore labor can be made less casual. A fugitive laborer comes to you, whatever he does on ship or pier, for just one trip, for just one job, and has no other object than just to draw the hourly wage of the day's pay or just for that job. You know nothing about him. You don't know his right name.

It seems to me the point of attack has been solved partially by some steamship companies. At the risk of repetition, I feel most strongly convinced that the thing you have to build up is another bond with your laborer than to just say, "Now, John, do that. Go up there. Haul this. Look out for that." There must be something else, and that something else comes in a proper relation of supervised employment for a period of time, the longer the time, the better.

Therefore, I believe that one of the unsafe things and perhaps the ultimate unsafe thing is the small degree of contact between the employee and the employer. I will go further and say if you are interested in the employment and the length of employment, and it develops to the point where you know somebody in the company knows something about his home, knows a little about some personal problem that may come up, knows when the wife has two or three children or practically a new born child, and knows the terrible load at home and the anxiety of the men, knows when the man is getting a rough deal at home, knows perhaps when his wife is, a close friendly relation might be built up. I know there are complications. I am only outlining a few things that come to my mind.

It is a very uphill job. The stevedore will tell me, I have no doubt, that it is impossible to have that sort of relation. I don't believe it. I think to a certain extent it can be done. It is a discouraging job. But I think it can be done to some extent.

Then you will find when you have that, the question as to how you award by bonuses, the methods of encouraging the safety movement, will more largely solve themselves. They are very difficult, when you can't count on the continuous labor of any man for a long period to form a unit in your distribution, to mention only one practical problem.

Yesterday we heard from the Export Steamship Company. They mentioned those who made two trips in the year and those who made three trips. There

was the recognition of the partial percentage of duration of employment, and a very wise one, because in a year, even if you make four trips, you will have four three-months' periods, which is a time long enough to form a self-respecting basis of award. And I can see why that would be respected.

All distributions or bonuses or encouragements must be respected by those who won them and by those who didn't win them. You have both sides to consider there.

Six or seven years ago it was almost impossible to attack, eight years ago let us say, at a time when I first got to know steamship men, and they were absolutely grabbing every man who had shoes on his feet and a pair of trousers to wear. They were getting men who were no more seamen than I am, and they were being fleeced by the undesirable element. We all know that element is being weeded out. The process of weeding out always goes on and must go on in any potential business organization. It is the essential part of efficiency. But while you are weeding out the unfixed, the repeater, and the physically unfit, the encouragement to the man whom you would like to have stay, will be one of the greatest assets of good will any business can have.

DR. FRANCIS X. CRAWFORD (Port Medical Officer, United Fruit Company, Boston, Mass.): I wonder, in doing this work, why we can't get every day the same workmen we had the day previous. We certainly get a very large proportion of them.

I think if we hold those whom we have today to a certain type of work, and when we put that same crowd to work tomorrow, put them in the same work, we are solving a part of the problem. In our experience we have been using quite a few men and putting them on the same job every time we hire them. The new ones we get we fill in, putting some experienced men in. In working along those lines our experience has been extremely gratifying in the type of accident. I think through an education of that kind, making the new men fall in with the old, we get a very good working machine most of the time.

MR. FARRELL: I thank Dr. Crawford for his remarks, for the simple reason that it brings us back to that point that I expressed this morning, that supervision is the mainstay of the stevedoring business.

Take your hatch boss. He has his regular hold men following him all the time. He has his regular deck men and regular dock men. Naturally if he needs another hold man and his men are busy, he will take a dock man and replace him, and put a new man on the dock.

Therefore, when the supervisor of the gang is able to distribute his labor to the best of his knowledge and experience of the business, we have the best results and, therefore, the supervisor is the man responsible for giving us the best result and reducing accidents from the higher standpoint.

MR. FRITZ: This might be an appropriate time to say that perhaps an approach to the problem which we have been discussing for the last fifteen minutes could be made, if we would see a greater cooperation, which I think we can get, from our labor organizations.

I have been impressed, in the short time that I have been associated in this capacity, with this stevedoring company, with the absolute fairness and integrity and business ability of those who are conducting and are at the head of our labor organizations in this city, and I refer particularly to the longshore industry, because I know practically of no other.

It has seemed to me at times that perhaps if we would ourselves take the step forward to meet labor organizations on this particular point, we might be able to reach a greater group and with more emphasis than we do through our own individual activities on the plant.

CHAIRMAN BUSH: I am prolonging the time for discussion, gentlemen, because of the importance of the subject. Is there anything further to be said?

If not, we will pass from the handling of cargo to the boiler room of ships. The next speaker is an expert of established reputation. For forty-eight years he has been actively identified with the gauge glass business. I take pleasure in presenting to you, Mr. William A. Tucker, Manager of Moncrieff-Rogers Division, Jenkins Brothers, New York City.

Gauge Glasses—Their Make, Use and Abuse

By WILLIAM A. TUCKER

Manager, Moncrieff-Rogers Division, Jenkins Brothers, Inc., New York City

In order to understand some technical words and expressions, it may be wise to commence this paper with the raw materials which contribute to the making of glass and then proceed with its manipulation to produce a gauge-glass.

We will avoid giving the several quantities or proportions in the many formulae; but most glass is made by fusing together some form of silica (as sand), an alkali (as potash or soda), and some other base (as lime or lead oxide). These parts when put together are termed "the batch." The purer the several ingredients the better the batch, which should be well sifted and thoroughly mixed. The oftener the batch is sifted the surer it will be properly mixed and the larger particles segregated; and the sooner it will melt when heated in the furnace, the required heat nearly reaching 3,000 degrees Fahrenheit.

Many formulae are constantly in use (some of which are said to be trade secrets) and they are of endless varieties depending on the ultimate use of the glass product. To a chemist in the laboratory of a large glass factory was put the question, "I suppose you have as many as 26 formulae which you are constantly using; how many have you?" The chemist withdrew a record book from his desk and announced, "The latest one is numbered 1,109; all have been tested and a large part frequently used."

It is evident the glass factory should be well informed when you have unusual problems for them to solve, and thus deliver to you the perfect article required.

Even with gauge-glasses you must know and decide, or impart, the pressures to be exacted, whether they be steam, hydraulic, hydrostatic, gas or air pressures; or is the glass merely for thermal purposes or refrigeration. Also to withstand the action of various alkalies contained in water.

To emphasize the point, although it may seem anomalous, the several qualities will stand by comparison as follows:

	Steam Pressures	Hydraulic Pressures
Standard Quality.....	150 lbs.	4,000 to 5,000 lbs.
High Pressure Quality.....	500 lbs.	2,000 to 3,000 lbs.
Red Line, Interlayered.....	150 lbs.	1,000 lbs.
Red Line, Superimposed.....	250 lbs.	1,000 to 2,000 lbs.

Tubular gauge-glasses are mostly hand-made, but some, recently, have been made by machine.

As to the hand drawn process, the method of manufacture has changed very little in the course of years. The extraordinary accuracy of diameters, the exact roundness, and the even distribution of the glass are the result of great skill on the part of the workmen concerned, as no moulds are used. A brief description of the process of manufacture is as follows:

On the end of a hollow "blow-pipe," a certain quantity of glass is gathered from a tank or pot filled with molten glass. The glass so gathered is manipulated and

air is introduced by the operator blowing down the "blow-pipe" until the shape resembles somewhat that of a pear, thus creating a central chamber of air in the glass. After this operation the glass, having cooled to a certain extent, is plunged into the molten glass again and by a continuous turning movement a fresh coating of glass is added. This larger body is then withdrawn from the furnace and shaped on a "marver" or steel plate, retaining its pear formation, and

Sketch 1
Correct

Sketch 2
Correct

the central air chamber. It is then placed in a subsidiary furnace or "glory hole" and heated until quite pliable, without adding more glass. When it is withdrawn the base is placed on a saucer-shaped piece of hot glass formed on the end of another blow-pipe by another workman. The mass is then pulled out and elongated by the two men slowly moving in opposite directions, a rotary movement being given to obviate ovalisation, until a length of 60 feet or upwards of accurate tubing is produced. While the glass metal is being elongated, so also is the chamber of air in the center of the pear-shaped ball, thus giving us the hollow center in the gauge-glass. The length of each draw varies according to the diameter required.

You will appreciate while making the "small ball" and larger "pear-shaped ball,"

that the workman's skilled eye and "feel" is constantly on the glass under manipulation; further, the marvering makes the glass compact and expels the small air bubbles; the second dipping into the pot of molten glass gathers a second layer on the ball; then more marvering compels the two layers to fuse together, thus these two layers are laminated making them a stronger construction than to create the pear-shaped ball of one solid mass.

Sketch 3. Incorrect
This gauge and glass are not in alignment, because the bottom cock is screwed into the boiler further than the top cock.

The skill of the two workmen, as they go in opposite directions drawing the glass tube, affords them an additional observation and "feel."

From this brief description it can be understood readily that it takes many years for a set of skilled men to achieve the extraordinary accuracy of diameter and uniformity of bore required of the modern gauge-glass.

This marvering of each layer and the laminating of the two layers in a particular way is not done on "machine made" glasses which are a single thickness, not marvered in any way nor strengthened.

The main advantage of machine made glass tubing is the economy of production, which is very marked in the case of small diameters made from soft glass. There is a disadvantage, however, in this process, particularly as regards the manufacture of gauge-glasses. Accuracy of outside diameter and bore are difficult to regulate, and further there is a tendency that the glass in a machine made tube is not of the same composition or structure throughout, nor as compact as is the case with the hand drawn tubing.

Sketch 4. Incorrect

This gauge and glass are not in alignment, the glass tilts to the right because the holes tapped in the boiler are not true to each other.

Sketch 5. Incorrect

While the holes above are in alignment the lower nut does not align with the top, thereby causing the lower end of the glass to bear against the metal.

Tubular gauge-glasses today are, generally, of two classes—those known for standard steam pressures (say 150 to 200 pounds) and the other for high steam pressures (say up to 500 pounds).

There is one factory which produces a high pressure gauge-glass which will withstand 500 pounds working steam pressure, and these glasses have frequently withstood 750 pounds steam pressure (in a recorded case the glasses withstood 750 pounds steam pressure for 122 days without breaking and were still in service—

able condition). Such a glass is worthy of your consideration, if you value the time of your engineer and his continued services, and the safety to engineer, bystanders and the adjacent machinery.

In an open vessel or tank a gauge-glass must indicate more than the height of water or liquids, for it must be able to withstand pressures. The large oil tanks do not simply use transparent glass tubing, but must have a gauge-glass for registration and to sustain the power exerted within the glass by the pressure created by the static heat of the liquids. These glasses, on these large tanks situated in the open, are exposed to atmospheric pressure and climatic variations.

Rather than purchase long glasses, up to thirteen feet for tanks, I suggest you buy three glasses five feet each and stagger them, so that if one breaks, less loss and initially less expense are involved.

Boiler room practice sometimes indicates the gauge-glass is not only sustaining the heat and pressure exerted by the steam and water throughout its length, but overcoming the occasional or continual frigid blasts of wind issuing through an open door or window, which sudden changes break many a gauge-glass of poor quality.

One is apt to forget that a gauge-glass, when performing its important duty of indicating the water level of a steam boiler, is subjected to the same steam pressure as the metal plates or tubes of the boiler. There is an instinctive impression in one's mind that glass is easily broken, but here we have a fragile looking glass tube resisting the highest steam pressure efficiently and safely.

Glass to last indefinitely is a mooted problem. Some samples have lasted for many years, but it has a recognized life and death. What about a gauge-glass? Within itself, if unused or undisturbed, not distorted, nor purposely or intentionally crushed, it will outlast a human life.

By far the greatest cause of breakage of gauge-glasses is occasioned by metal interference. Glass and other metals are as homogenous, seemingly, as the proverbial mother-in-law with her daughter-in-law.

I have seen a cut-nail purposely passed through a gauge-glass, then the glass was laid aside and undisturbed for the night; but the next morning particles of glass were found, but not tubular; for the nail, in its passage through the tube, had scratched the inner wall, set-up a strain, thus causing the collapse, due to the difference of coefficient of expansion and contraction of the two layers.

There is no doubt in my mind as to these two layers, that the tendency of the inner layer is to expand outwardly, while the tendency of the outer layer is to expand inwardly, thus making the amalgamation stronger; but if the inner layer is given any abrasion it destroys its initial power to expand outwardly against the outer tube. Thus the inner layer in its endeavor to compensate for the abrasion now seeks escape by moving inwardly, then the outer layer takes the opportunity to move inwardly.

These new forces working contra to each other and their endeavor to overcome the displacement causes a collapse of one or both layers and ultimately the destruction of the tube.

Again, a thrifty engineer, desiring to clean a gauge-glass, passed a piece of much used, wet and gritty cotton-waste through the inside of the tube with like result.

And yet, a customer purposely passes wire through a gauge-glass without initial harm or unfortunate result. In this case he had better results with high pressure gauge-glasses. Others have endeavored to do similarly but with signal failure.

But it is where and when the gauge-glass and its metal holder meet which cause many breakages.

The alignment of the water gauge makes the trouble. Probably more glasses are broken through faulty alignment than from any other single cause. Tipping the glass to the right or left, or backward or forward may bring it in contact with

the metal supporting it, thereby causing an early break. While the rubber washer at the top and bottom of the glass may temporarily keep the glass from touching the gland or nut, after a time the washer may become displaced allowing the glass to bear against metal.

It is important to have the boiled or water column properly tapped so the water gauge will be in alignment when installed and the gauge-glass in alignment when inserted. Glass should not be too long, as it gives greater opportunity for steam end to be worn thin or broken down. For instance, if boiler is tapped about 9 inches, center to center of holes, the gauge-glass should be about 7 inches long. Purchase regular listed sizes thus avoid cutting the glass and re-fusing the ends. If you must cut the glass to a shorter length and have not the facilities to again fuse the end, install the cut end at the bottom or water end of the gauge.

The rubber washer, used at the top and bottom, should be of highest quality. The washer should be of such size that it falls easily into the nut without force.

Do not use a wrench when screwing the top and bottom nuts into position. They need not be any tighter than can be screwed up by the thumb and finger. If screwed too tightly sufficient clearance is not allowed for expansion of the glass. The nut may leak a little at first but this is overcome when full steam is turned on and metal and glass are fully expanded.

Three points have recently come to our attention, which may be explained here. Some engineers have asked for glasses with extra-thick wall, others with very thin wall, and others have admitted they are using improper washers.

While glasses vary somewhat in the thickness of the wall, they are practically correct. The wall can be too thick and not allow for the expansion and contraction of the glass. The wall can be too thin and thus the glass break too readily.

The outside diameter of Moncrieff glasses are invariably undersize, and for a good reason. If the nut for the glass is exactly $\frac{5}{8}$ inch, you will appreciate you cannot insert a glass that is absolutely $\frac{5}{8}$ inch in diameter. If too near the diameter of the gland, the glass is too closely surrounded by metal, and expansion of the glass under steam heat cannot occur, so the glass, being weaker, must break.

The glasses are purposely scant in diameter and wantage is overcome by a rubber washer surrounding each end of the glass. This washer must be flexible and of correct size, so that it will hug the glass by a slight pressure of the nut attached to the gland; and the washer must be of dimensions, thickness, etc., to fully fill any aperture or inequalities in the gland, to avoid emission of steam after the glass and metal have reached their fullest expansion under steam pressure.

Any stiff washer made of hard material or even a cloth-insertion washer, if not sufficiently flexible, is to be avoided, for they do not compress enough—neither to hug the glass nor fill inequalities of the gland. Should a larger glass be furnished the glass must break, due to insufficient space for expansion.

Quite naturally I present, as follows, the correct way of testing a gauge-glass, adopted by a marine user who uses a greater quantity than any one concern, because its many vessels of varied construction traverse all seas.

Specifications for High Steam Pressures Up to 500 Pounds

Gauge-glasses shall be of the best quality, free from internal strains and all imperfections, cut to proper length, fused at the ends, shall be straight and of uniform bore and diameter throughout its length.

The maximum outside diameter shall not exceed the nominal diameter of the glass called for and the minimum acceptable diameter shall be $\frac{1}{16}$ -inch less than the nominal diameter.

When subjected to the "Steam Shock Test" described hereafter, the average of the total operations withstood by the glasses under test shall be not less than ten. No glass shall be subjected to the test for more than fifteen operations.

Each glass shall be tested for straightness by rolling on a plane surface. The diameter shall be determined by means of a "Go" and "No Go" gauge of suitable material. The "Go" gauge shall be the nominal diameter. The "No Go", $\frac{1}{16}$ -inch less than the nominal diameter.

The following is a description of the Steam Shock Test:

The glass to be tested is installed in the fittings; the valve in the water line is opened until the glass becomes half filled with water at a temperature of 75 degrees Fahrenheit; the quick opening valve in the steam line is then opened and the glass is suddenly subjected to steam pressure of 275 pounds gauge pressure. At the end of one minute the quick opening steam valve is closed and, by opening the discharge valve, the steam and water are allowed to blow from the apparatus. Cold water is then passed through the glass until it becomes cool, when the above operations are again repeated, until fifteen operations have been successfully withstood or the glass breaks. Three glasses shall constitute a complete test and the average number of successful operations shall not be less than ten. In order to protect the operator from injury by flying particles of glass, a heavy wire screen guard and a sheet metal guard are placed around the glass and the apparatus during the test.

Unific gauge-glasses pass the above tests.

The specifications for Standard Steam Pressures less than 125 pounds are similar to those mentioned for high pressures.

These gauge-glasses shall be capable of being heated in boiling water for two minutes and immediately quenched in water at 43 degrees Fahrenheit; eight times, without spalling or cracking.

The maximum outside diameter and testing with "Go" and "No Go" gauge shall be the same as for high pressure glasses.

Fused ends will not be required on gauge-glasses for standard steam pressures.

These tests have not been determined as a matter of course, but only after much experimenting and research.

About one hundred years ago the English Parliament was asked to forbid engineers to carry greater than 20 pounds steam pressure. They feared the boilers would not stand greater pressure.

As pressures increased so was the strain on the glass greater, thus constant improvements to meet the altering conditions were necessary, until now a gauge-glass will withstand 500 pounds working steam pressure or more.

On the tubular glasses it is the steam end which is attacked by the steam until the steam end of the tube is as thin as your finger nail. One such glass of "standard steam pressure" type was in use for twelve months without breaking on a boiler carrying 150 pounds steam and where the fire was drawn every night.

Another instance was a "high pressure glass" in use for six weeks operating the boiler constantly on an average of 275 pounds steam pressure but they used strong boiler compound which severely ate away the glass. (Where boiler compounds are used, you can expect some effect on the glass.)

Further, in this last case, the engineer was using a glass $14\frac{3}{4}$ inches long whereas it would have been more resistant if the glass had been 14 inches long, or even 13 inches long. The extra length of glass received the initial force as the steam and condensation were driven from the boiler to the water gauge. This extra length of glass acted like a baffle and the forceful steam in transit surrounded the circumference of the glass, thus creating excessive erosion.

The introduction of high pressure steam boilers demanded improvement in the quality of gauge-glasses, and in like manner it necessitated improvement in methods of packing and in quality of packing material used in fixing a glass into a gauge cock.

High pressure gauge-glasses will stand a steam pressure of 500 pounds, a hydraulic pressure of 2,000 to 3,000 pounds. They may be heated in oil to a temperature of 400 degrees Fahrenheit, and after being so heated for two minutes, taken out and plunged into cold water. Yet notwithstanding these capabilities of resisting sudden variations of temperature, breakages sometimes occur. Our experience, the result of prolonged experiments, is that breakage is almost invariably due to the expansion of the glass being interfered with, or the packing material giving away.

Interference with expansion may be caused by the gauge cocks not being in absolute alignment as stated heretofore; the glass having been ordered of too large

CHAIRMAN BUSH: We are very much indebted to Mr. Tucker for his very informative paper. Is there any discussion, gentlemen? It seems to me he has covered it very well.

MR. TUCKER: In the program you see my name and address. I would be delighted to get a letter from anyone who wishes to know anything about gauge glasses, and I would try very earnestly to answer all questions.

CHAIRMAN BUSH: Thank you, Mr. Tucker.

The next paper, gentlemen, is to be delivered by a gentleman so well known that I am sure that no introductory remarks are necessary on my part. The mere mention of his name is sufficient. I therefore present to you, Captain Charles A. McAllister, President, American Bureau of Shipping, New York City.

The Relation of Classification to Safety of Ships

By CAPTAIN CHARLES A. McALLISTER

President, American Bureau of Shipping, New York City

At the International Shipping Conference, held in London in June of this year, the following statement was made: "In the last fifty-five years British shipping has averaged 4,000,000,000 passenger miles per annum and 200 passengers have been drowned per annum, or one passenger to every 20,000,000 miles.

"Although it has been said that one can make any kind of a case from statistics, this is surely a remarkable record and shows wonderful progress from that of the seven years 1846 to 1853, when no fewer than 61 British emigrant ships were lost at sea, a state of affairs which resulted in the Merchant Shipping Act of 1854, the beginning of active government control in British shipping so far at least as the laying down of safety regulations was concerned. There is no doubt travel on the high seas is becoming increasingly safer, and this is due in a large measure to the growth in size of ships, the change from wood to steel as a material of construction combined with the application of scientific methods to structural design, the change from sail to mechanical propulsion, to superior navigating equipment and aids to navigation, to government safety regulations, the licensing of officers and engineers, and last but not least, to the beneficent influence of the various classification societies' rules and regulations.

We are by no means out of the woods yet when one recalls the mysterious disappearances at sea, with losses of all on board even within the last few years, of vessels which were seemingly swallowed up without any known or apparent cause. The risks to which ships were subject in the good old days are described in the marine insurance policy as follows:

"Touching the adventures and perils which we the assurers are contented to bear and do take upon us in this voyage, they are, of the seas, men-of-war, fire, enemies, pirates, rovers, thieves, jettisons, letters of mart and counter-

mart, surprisals, takings at sea, arrests, restraints and detainments of all kings, princes, and people, of what nation, condition, or quality soever, bar-ratry of the master and mariners, and of all the other perils, losses, and mis-fortunes that have or shall come to the hurt, detriment, or damage of the said goods and merchandises and ship, etc., or any part thereof."

The risks to which ships are now exposed are fortunately not quite so formidable, and we need only consider in ordinary peace times the first and third on the list, i. e., "Perils of the seas" and "Fire." The principal casualties to which vessels are subject are foundering through stress of weather, stranding and collision, where the damage may be such that water will enter in sufficient volume to offset the reserve of buoyancy and the ship sinks, in which case the only chance of saving the lives aboard is by the provision of suitable and adequate life saving appliances. From the point of view of safety to the ship herself it is essential that she be what is termed in nautical parlance, "seaworthy." The essentials for a seaworthy ship and the main requisites for safety are, sufficiency of structural strength, a proper measure of stability, suitable freeboard, reliability of machinery, and proper equipment. It is obvious that to be seaworthy for a particular voyage a vessel must also be efficiently manned and have sufficient fuel, fresh water, etc. It is interesting to note that the classification certificate certifies the ship to be in good and seaworthy condition and "fit to carry dry and perishable cargoes," and in the strict sense of the word a leaky ship is not seaworthy, even although she may be able to make port.

In addition to the main considerations of structural strength, stability, and freeboard it is obviously desirable (especially in a ship carrying a large number of passengers) that she be efficiently sub-divided with the largest practicable number of bulkheads, so that the vessel will remain afloat after serious damage or at least keep afloat as long as possible and so increase the chances of getting the passengers and crew safely transferred to the boats and to shore or another ship. There is no branch of engineering where the problems are so complex and varied as in naval architecture. Not only must the designer meet the requirements of the specification with regard to deadweight, speed, fuel consumption, trim, maximum draft, etc.; but due regard must also be paid to the regulations of the government inspection service and the construction rules of the classification society in which the vessel is classed. The safety of the vessel herself and of the valuable lives aboard in the event of a disaster to the ship are essential considerations in the design of a passenger vessel, but ship design is peculiar in the sense that any policy of playing safe entails a serious economic handicap to the owner, for while sufficient structural strength must be provided (and the structural problem does not lend itself to exact mathematical treatment) any excess of hull material not only entails increased costs of construction, but must be carried around for the life of the ship, with resultant loss of cargo deadweight. Every ship would have a suitable measure of stability for the service conditions without requiring undue care in loading, but care must be taken not to render the ship too stiff if she is to be popular with passengers, who, as a class sometimes ignorantly prefer comfort to safety. Again, a high standard of sub-division is desirable and in my opinion reasonable bulkhead requirements should be required by law in the case of passenger vessels, but here again it is obvious that there is a practical limit to the number and disposition of transverse bulkheads in the minimum lengths of cargo holds which experience has shown to be necessary for the carriage and economic handling of certain cargoes. When one considers the many and special types of vessels, ranging from the humble box shaped barge operating in smooth water to the large

passenger liner crossing the North Atlantic practically on schedule, I think you will agree that the naval architect's job is no sinecure.

There is no commercial undertaking in the world today that is regulated to such an extent as the shipping business. This is due to the hazardous nature of the seaman's occupation in earlier days and in some measure to the fact that the shipping business is international in character and highly competitive. Major disasters at sea receive so much prominence that the various governments are from time to time forced by pressure by public opinion to enact new and to amplify existing safety regulations. All maritime countries have shipping laws, promulgated with the best intentions, and while some of this legislation has been admittedly beneficial in its effects some of the enactments have been not so good. It is a truism that the less a government interferes in business the better for the business, but it must be admitted that the enforcement of regulations which have for their purpose the safeguarding of the lives of its citizens is a proper function of any government. Government control is universal and indeed essential in connection with such matters as the admeasurement of tonnage, which besides being the basis of dock dues, etc., is useful for statistical purposes; the entry of vessels into the national registry; the enforcement of rules of the road for the prevention of collisions at sea; detention of ships alleged to be unseaworthy, and restrictions on loading. Overloading beyond the regulation freeboard markings is one cause of detention and prosecution in every maritime country except the United States, which has as yet no compulsory load line law. It is impossible within the scope of this paper to discuss shipping legislation in all its aspects, but a few remarks regarding the safety regulations of this country and Great Britain, respectively, may be of some interest.

The British Merchant Shipping Act of 1854, which was the direct result of public opinion aroused because of the large number of lives being lost at sea, especially on emigrant ships, originated the Marine Department of the British Board of Trade with power to appoint surveyors to investigate and report on accidents and damages and to inspect machinery, boats, and life saving equipment. The Merchant Shipping Act of 1894 extended these provisions, and the Merchant Shipping Act of 1906 not only amplified existing regulations, but enacted that certain requirements of the Merchant Shipping Acts, including compulsory load line regulations be applied to foreign vessels operating out of British Ports. Load line legislation in Great Britain was the result of popular feeling aroused by the agitation of a member of Parliament, Samuel Plimsoll, who alleged that British vessels were being sent to sea in an overloaded and unseaworthy condition. In 1876 a law was passed requiring every British ship to be marked with draft marks and with the load line which the owner considered safe, but it was not until 1890 that load lines were required by law to be determined in accordance with specific regulations issued by the Board of Trade. It should be emphasized that the Freeboard Tables are not embodied in the Act itself, the Board of Trade having authority to modify the regulations from time to time as may be found desirable after consultation with the Classification Societies authorized to assign freeboards.

To give effect to the provisions of various Merchant Shipping Acts, the Marine Department of the Board of Trade controls for all ships such matters as registration, tonnage admeasurement, load lines, collision regulations, signal lights, life saving appliances, and regulates the carriage of special cargoes, i. e., cattle, dangerous goods, and grain. The Board of Trade has also power to detain for survey any ship alleged not to be in a fit condition to proceed to sea by reason of defective hull, machinery, or equipment, overloading or improper loading, etc. In the case of ships carrying more than 12 passengers,

the special rules with regard to survey and inspection are quite extensive, every ship being required to have a passenger certificate which is issued only after survey by the Board of Trade and which is valid for not more than twelve months. The surveyors in their declarations to the Board of Trade have to state:

- a. That the hull and machinery are sufficient for the service intended and in good condition.
- b. That the boats, life buoys, lights, signals, compasses, and shelter for deck passengers are as required by the Merchant Shipping Acts.
- c. The limits (if any) beyond which in the surveyor's judgment the steamer is not considered fit to ply.
- d. The number of passengers which in the judgment of the surveyor the vessel can properly carry.
- e. That the certificates of the officers and engineers are as required by the Acts.
- f. That the boiler safety valves and fire appliances are in such condition as is required by the Acts.
- g. The date of the last load line and whether same is still valid.

For the guidance of the surveyors the Board of Trade issues very elaborate instructions. The "Instructions as to the survey of passenger ships" published recently is important, as the various regulations given regarding watertight subdivision, life saving appliances, etc., will represent the British proposals at the International Convention for the Safety of Life At Sea to be held in London next spring. It is probably the most comprehensive and complete set of safety regulations for passenger ships yet issued by any government authority. Like all other government regulations no rules for the scantlings or construction of hulls are included, but detail rules are given for marine boilers, steam engine shafting, fire extinguishing appliances, oil fuel installations, and survey of passenger accommodation. It is interesting to note that since 1923 the Board of Trade and the British classification societies have had a common set of rules for marine boilers. If a vessel is classed, the hull material test certificates of the classification society are accepted by the Board of Trade, also the hull scantlings, testing of double bottom tanks, etc., and except for the testing of boiler material and the supervision and hydrostatic testing of marine boilers there is no overlapping of inspection between the Board of Trade and the classification society's surveyors.

It should be noted that while the Board of Trade's safety regulations and inspection procedure are quite comprehensive in the case of vessels carrying passengers the inspection of purely cargo carrying vessels is confined to safety appliances, except where on complaint of the crew that a vessel is unseaworthy the ship may be held for survey. The safety regulations of the British Dominions (Canada, Australia, etc.,) are pretty much on the lines of those of the Board of Trade. An important exception is the definite recognition given to the certificates of the classification societies, for example, the Commonwealth of Australia Navigation Act 1912-1920 explicitly exempts from survey all steamships not carrying more than twelve passengers to which classification certificates have been granted by any corporation for the survey and registry of shipping approved by the Governor General.

You have noted, no doubt, that I have dwelt at length on the British requirements for load lines, for the fact is that they have taken the initiative on all matters pertaining to safety of ships at sea, in this respect.

It is most regrettable that there is not a line in our statute books concerning load line requirements, which is fundamentally the basis of safety at sea. Numerous attempts have been made, covering many years, to bring about

legislation of this kind in America, but to date nothing has been accomplished, although bills have several times passed either one or the other of the branches of our national legislature. A bill passed the Senate during the first session of this Congress, but it will require the united efforts of all persons interested in shipping to procure final enactment. Let me suggest that it would be a very wise thing for this organization to pass a strong resolution favoring such legislation at this meeting and forward copies of the same to Congress.

United States shipping legislation so far as safety regulations and inspection are concerned really began with the Act of Congress, 1871, when the Steamboat Inspection Service in its present form was instituted. Unfortunately we have no department at Washington whose sole business it is to deal with matters affecting the Merchant Marine, and the Steamboat Inspection Service, a branch of the Department of Commerce, is only concerned in the administration of the navigation laws relating to inspection. The operation of the Steamboat Inspection Service, in so far as keeping its rules up to date, is hampered and limited by the fact that certain requirements (for example, the method of computing the thicknesses of boiler shells) are embodied in the law and cannot be changed except by act of Congress. Another essential difference between our practice and British practice is that the hulls and boilers of ordinary freight ships are subject to the same inspection procedure as purely passenger ships; in other words, there is no such sharp line of distinction between the inspection of freight and passenger ships as is drawn by the British Board of Trade. The rules and regulations of the Steamboat Inspection Service could with advantage be amended and brought up to date, and it would certainly be advantageous to all concerned if agreement could be reached on a set of American standard marine boiler rules which would be acceptable both to the American Bureau and the Steamboat Inspection Service, the only authorities having jurisdiction over marine boilers built in this country.

The early history of classification and classification societies is extremely interesting, but even to trace the development of our own American Bureau of Shipping would make this paper unduly long. It is perhaps sufficient to say that classification had its beginning in England more than a century ago when wood was the only material of construction, and was the natural result of a desire on the part of marine underwriters to have an authentic record of ships for insurance purposes. As the idea of classification and registry of shipping originated with the underwriters it was to be expected that the classification societies were in the beginning largely controlled by marine insurance interests. As a matter of fact, the control of these technical organizations by committees of management on which all the various shipping interests (i. e., ship owners, underwriters, shipbuilders and marine engineers) are adequately represented is comparatively modern, dating back to 1890, when the British Corporation entered the classification field in Great Britain with ideas on committee representation and ship construction rules which were revolutionary at the time.

The classification societies in existence today are Lloyd's Register, and the British Corporation with headquarters in Great Britain, Bureau Veritas in France, Norske Veritas in Norway, Germanischer Lloyds in Germany, Registro Italiano in Italy, and the American Bureau of Shipping in the United States. Some of the older societies make pretensions to being international as far as the scope of their operations is concerned, but the working alliance and mutual agreement of the American Bureau, British Corporation, Registro Italiano and Imperial Japanese Marine Corporation, by which the surveyors of each society carry out in its own territory surveys on behalf of the other parties to the agreement, is truly international and cooperative

in the best sense. My main purpose in enumerating these well known societies at this time is to emphasize the fact that every maritime country with any pretensions to a merchant marine has found it necessary to develop its own national classification society.

The American Bureau of Shipping, to which I have the honor to belong, had its beginning in 1862, when the Legislature of the State of New York passed an Act incorporating the American Ship Masters' Association, which charter and title was in 1898 changed to the American Bureau of Shipping. The American Lloyd's was combined with the Bureau in 1882. The American Bureau in 1908 absorbed the United States Ship Owners, Ship Builders and Underwriters Association, and in 1916, acquired the Great Lakes Register, which is now the Great Lakes Department of the American Bureau. In 1916 the Bureau was thoroughly reorganized to cope with the enormous volume of tonnage building in this country during the war emergency, since when the Bureau has undoubtedly reached a high standard of efficiency. The Board of Managers is influential and thoroughly representative, and every effort will continue to be made to render efficient service in the interests of the American Merchant Marine. It should be emphasized that the Bureau is not a profit making concern, all funds accruing to the Society from classification fees, etc., being used solely to defray operating expenses, any surplus being utilized for its extension and improvement.

The principal functions of a classification society may be briefly stated as follows:

A.—To provide a Register Book giving essential particulars of the hulls and machinery of the vessels classed with the Society, the classification assigned to each vessel, together with the dates when surveys were carried out, etc.

B.—To issue certificates of character for merchant ships, their machinery and equipment, i. e., classification certificates, certificates of seaworthiness, etc.

C.—To prepare Rules for the Construction of Hulls and Machinery, including material specifications and detail regulations for the carrying out of periodical surveys, etc. The rules are necessarily modified from time to time to keep pace with developments in shipbuilding and marine engineering, and are the standard by which the eligibility of a vessel submitted for classification is determined.

D.—To carry out other work relating to the structural design, construction, and maintenance of merchant ships such as the assignment of freeboards which may be delegated to the Society by the proper government authority; also when specially requested by owners or builders to investigate questions such as sub-division, etc., which affect the safety and seaworthiness of the ship.

The following summary of the work of the Surveying and Technical staffs of the American Bureau may be of some interest:

1—Classification Surveys of New Vessels

a—Examination of Plans

Certain detail plans of the hulls and machinery of new vessels intended for classification are required to be submitted for approval before the work of construction is commenced. Plans also may be submitted by the owners or builders of unclassified vessels or vessels of novel design where the approval of the Society is specially desired.

b—Testing of Materials

The testing and inspecting of the materials of construction, i. e., hull and boiler shapes and plates, forgings and castings for hull and machinery, anchors

and cables, etc., is a requirement of the rules in the case of vessels building to class. Testing of materials going into unclassed vessels is also carried out when this is specified by the purchaser, and material for other engineering purposes may also be tested by the surveyors to purchasers' own specifications. Testing work, including the issue of certificates of test, etc., constitutes an important part of the work of a classification society.

c—Supervision During Construction

The hulls and machinery of all vessels specified to be built to class must be supervised by the surveyors during construction. The services of the surveyors may also properly be utilized for the survey of machinery, etc., not necessarily intended for classed vessels in cases where the manufacturers may desire certificates of test and inspection.

2—Surveys of Vessels in Operation

a—Classification Surveys

The surveys carried out for the purpose of classing vessels already in operation are on the lines of the requirements for periodical surveys, according to the age of the vessel, except that the scantlings of the plating, etc., are carefully gauged and compared with the Rule requirements.

b—Surveys for Maintenance of Class

These include the regular docking surveys, special periodical surveys, and boiler surveys. The scope of these various surveys is detailed in the rules.

c—Damage Surveys

When a vessel is damaged she must be submitted for examination to determine whether the seaworthiness of the hull and machinery has been impaired, and if so such repairs must be effected as will render the ship seaworthy. At the request of the owner efficient temporary repairs may be accepted by the surveyors until such times as permanent repairs can be carried out. If the damage is covered by insurance, the underwriters are obligated to put the ship into the same efficient condition as she was prior to the casualty, and it is the duty of the classification surveyor to require that the repairs are such as will place the ship in a condition to meet the classification standard of the rules. Special certificates of seaworthiness are issued on the satisfactory completion of all damage repairs.

d—Refrigeration Surveys

On vessels carrying refrigerated cargoes the refrigerating machinery and insulated spaces are subject to periodic examination if an R.M.C. certificate is desired. Surveys of insulated holds, etc., if made at the loading port prior to refrigerated cargo being loaded are also carried out at the request of owners and special loading certificates issued.

e—Condition Surveys

Condition surveys are made on unclassed vessels at the request of owners to determine the physical condition of hull and machinery and their suitability for particular voyages and trades, and seaworthy certificates issued in connection therewith if found warranted.

3—Technical Work

In addition to the examination of plans a large amount of work is done by the Technical Staff in making investigations in connection with the preparation of new rules and analyzing reports of vessels in service with a view to determining what amendments in existing rules are desirable. The Bureau is also represented on certain standing committees of the American Society for Testing Materials, American Marine Standards Committee, American Engineering Standards Committee, National Fire Protection Association, American Welding Society, and on important Government Committees, such as Fuel Conservation Committee, Ship Construction Committee, and Load Line Committee.

The American Bureau of Shipping is officially recognized by the United States Government in the Merchant Marine Act of 1920, which states as follows:

"That for the classification of vessels owned by the United States, and for such other purposes in connection therewith, as are the proper functions of a classification bureau, all departments, boards, bureaus, and commissions of the Government are hereby directed to recognize the American Bureau of Shipping as their agency so long as the American Bureau of Shipping continues to be maintained as an organization which has no capital stock and pays no dividends."

The Board of Supervising Inspectors of Steam Vessels at its annual meeting in Washington in 1916 adopted Section 9 of Rule VI as follows:

"In the inspections of hulls, boilers and machinery of vessels the rules promulgated by the American Bureau of Shipping respecting material and construction of hulls, boilers, and machinery, and the certificate of classification referring thereto, except where otherwise provided for by these rules and regulations, shall be accepted as standard by the inspectors of this service."

Although the ship construction rules of the British classification societies are accepted by the Board of Trade as a standard, the recognition is not so definite as is given by the various Dominion Governments except in the administration of the load line law where freeboards are assigned by the classification societies as direct agents of and responsible to the government. In France, Italy, and Japan the national classification societies are authorized to carry out surveys on behalf of their respective governments, and the growing tendency to utilize the services of the classification societies in all maritime countries is undoubtedly to the advantage of all concerned. It should be pointed out that the primary concern of the Government in laying down regulations is safety of life, while the underlying idea of classification is safety of the ship herself. Compliance with Government Safety Regulations is of course compulsory. Classification, on the other hand, is not obligatory, so that the owner who voluntarily builds his vessels to the rules of a classification society and carries out the periodical surveys required for maintenance of class is surely entitled to some consideration from his Government.

The shipping business being more or less international in character, it is extremely desirable that the various maritime nations should reach agreement on general principles governing safety regulations if only in view of the great convenience to ship owners which results from the mutual acceptance of each others national certificates. Largely due to the war, the 1913 International Convention for the Safety of Life at Sea was not generally ratified by the governments concerned. Since that time, however, passenger ships have been built in substantial accordance with the Convention Rules, and the experience gained thereby shows that some modification of the regulations is desirable and indeed necessary before international agreement is possible. It is for this reason that the International Conference to be held in London next spring is so extremely important, and you may be interested to know that a Ship Construction Committee under the chairmanship of Admiral Geo. H. Rock was recently formed under government auspices with a view to investigating the whole question of safety of life at sea in order that the delegates from the United States to the forthcoming conference will be fully informed as to the views of our ship owners and builders. I fully anticipate that international agreement will be reached at this conference and that the 1929 convention will be ratified by all the principal maritime nations. It will then be possible for the Steamboat Inspection Service to bring its Rules and Regulations in line with the most modern safety requirements for passenger ships. It might not be out of place here to express what I consider to be the essentials for safety regulations in general and particularly those affecting merchant shipping:

- a. Government supervision should be kept to a minimum. Regulations should be international in character as far as practicable.

b. The shipping law should provide the necessary administrative machinery, and as safety requirements are concerned should confine itself to general principles, leaving the proper administrative authority, i. e., Department of Commerce, power to lay down detail rules in accordance with these principles and to modify same from time to time with developments in shipbuilding and marine engineering.

c. The rules and regulations should be fairly and equitably administered by competent and proper authorities with due regard to uniformity of action in the various ports and districts.

d. Unnecessary duplication of surveys and inspection should be avoided. In this connection the various governments concerned should as far as practicable recognize the certificates of their own national classification societies.

CAPTAIN McALLISTER: Since that paper was written, gentlemen, much to my amazement, I have found that none of the classification societies have given any credit to fireproofing of ships.

I have traveled a good deal by sea lately, and what I am afraid of is that some of these boats will burn up: In the preparation of plans for these new ships which the Government is going to build, a great deal of attention is being given to it.

We all remember how it used to be that if you stayed in a hotel and didn't burn up you were lucky. But the demand of the public makes it obligatory to follow building regulations that provide fireproof buildings. You are paying for it in your hotel bill, but you don't mind it when you can sleep in safety on the twenty-third floor or on any other floor.

That much attention has not been paid to ship building, yet a ship is a floating hotel, especially the big passenger ships.

I brought the matter up before the Board of Managers the other day, and they authorized me to appoint a committee to give credit in our book for vessels where special attention has been given to fireproofing ships. And it is going to be a matter of attention at the Safety of Sea Conference next June. A committee has been appointed to recommend certain rules for adoption by the Conference, and we are going to make that a part of our rules and in our book give credit to every ship where the fireproofing has been given special consideration. We all hope it will greatly add to the safety at sea.

CHAIRMAN BUSH: Gentlemen, in connection with Captain McAllister's suggestion, as to the passing of a resolution on this proposed load line legislation, I wish that were possible. Personally I am very much in favor of it, and I know the majority of the members of the section are.

But it is contrary to the policy of the National Safety Council to pass resolutions which have to do with matters of legislation. We have tried it before, and when it reached Chicago, we have been successfully blocked. There may be some possible avenue of escape. I will make my own best efforts to see if that can be brought about. But a resolution at this time, under the existing policy of the Council, would not be in order.

CAPTAIN McALLISTER: I want to apologize for putting that in. I was not aware of your rules. It is a very good rule. You might get into trouble. But this being such a broad, such a national thing, I didn't know but possibly that might be done.

CAPTAIN P. B. BLANCHARD (President, Turner-Blanchard, Inc., New York City): The Captain's suggestion on fireproofing is along the right line. We have had brand new ships brought home to us, in the last few years.

In fact, I was reading in a marine paper of a ship in which all kinds of fire-fighting appliances were fitted. The following day I read where she was burned at practically a total loss while at the pier. The Captain will probably remember it.

CHAIRMAN BUSH: It certainly is progressive. Thank you, Captain.

The next order of business is the election of officers. The chairman and secretary of the Nominating Committee are unfortunately both ill, and are not present this morning. So I will ask Mr. Welch to present the slate as prepared by the committee.

SECRETARY WELCH: The Nominating Committee, consisting of Captain Kain, Mr. Tode and Mr. Hunter, have designated these gentlemen for certain offices for your approval.

I will read them.

Report of the Nominating Committee

Chairman—A. R. BUSH, the Barber Asphalt Company, Maurer, N. J.

Vice-Chairman (In charge of Publicity)—ARTHUR M. TODE, The Texas Company, New York City.

Vice-Chairman (In charge of Information and Service Committees)—CAPT. R. C. BRENNAN, Oceanic Terminals, Portland, Oregon.

Vice-Chairman—P. P. FOISIE, Waterfront Employers Association, Seattle, Wash.

Secretary and News-Letter Editor—CAPT. W. P. KAIN, Shipowners' Claims Bureau, Inc., New York City.

Chairman Program Committee—JOHN S. HUNTER, The Atlantic Refining Company, Philadelphia, Pa.

Chairman Research and Statistics Committee—CAPT. IRVING L. EVANS, Munson Steamship Line, New York City.

Chairman Stevedoring Committee—FRANK A. FRITZ, T. Hogan & Sons, Inc., New York City.

Chairman Engineering Committee—CAPT. G. BARTLETT, Cosmopolitan Shipping Company, Hoboken, N. J.

Executive Committee—THE OFFICERS AND

E. F. DALY, Morse Drydock & Repair Company, Brooklyn, N. Y.

R. F. EDWARDS, The Prudential Insurance Company, Newark, N. J.

CAPT. REGINALD FAY, The New York Central R. R. Co., N. Y. C.

CHAS. H. FLATHERS, Eastern Steamship Lines, Inc., Boston, Mass.

W. A. KIGGINS, JR., A. H. Bull & Co., Inc., N. Y. C.

ELLIS KNOWLES, C. D. Mallory & Co., Inc., N. Y. C.

CAPT. C. A. McALLISTER, American Bureau of Shipping, N. Y. C.

J. D. MURPHY, Murphy, Cook & Co., Philadelphia, Pa.

CAPT. C. H. POTTER, Potter Transportation Company, N. Y. C.

W. E. STEWARDSON, Colombian Steamship Company, Inc., N. Y. C.

C. STORY, JR., Cities Service Transportation Company, N. Y. C.

FERN WOOD, Williams Steamship Company, Inc., N. Y. C.

J. WRIGHT, Export Steamship Corporation, N. Y. C.

W. E. WELCH, Travelers Insurance Co., N. Y. C.

CHAIRMAN BUSH: Are there any nominations from the floor?

(The motion was made, seconded and carried that the nominations be closed and the report of the Nominating Committee approved.)

SECRETARY WELCH: I move that the chairman be authorized to fill any vacancies during the year 1928-1929.

(The motion was seconded and carried.)

ADJOURNMENT

October 4, 1928

National Board of Steam Navigation Day

A. R. BUSH, Chairman

Personnel Manager and Safety Engineer, The Barber Asphalt Company
Maurer, N. J.

The fourth session was called to order at nine forty-five o'clock, by the chairman, A. R. Bush.

CHAIRMAN BUSH: The first order of business this morning is the submitting of committee reports. We have deferred this from the opening day, on Monday, due to the absence because of illness of those who were expected to present them.

The first report I will call for is from the vice-chairman, Mr. A. M. Tode, in charge of Membership. Mr. Tode, will you please submit your report.

Report of Membership Committee

By ARTHUR M. TODE

Chairman

Your membership committee, appointed at the 1927 Annual Safety Congress, held in Chicago, reports that during the past year the membership growth of the Marine Section has shown a steady increase, reflecting the continued and added interest in the accident prevention movement by maritime companies and organizations throughout the United States.

From October 1st, 1927, to October 1st, 1928, twenty-four new members have been admitted to the Marine Section. The list of these companies who have actively identified themselves with the maritime safety movement the past twelve months is impressive, and includes:

Alabama Drydock & Shipbuilding Co.	Mobile, Ala.
American Bureau of Shipping	New York, N. Y.
Board of Commissioners of Navigation	Philadelphia, Pa.
Chile Steamship Company, Inc.	New York, N. Y.
Dollar Steamship Line	San Francisco, Cal.
Eastern Steamship Lines, Inc.	Boston, Mass.
Ford Motor Co., Marine Department	Detroit, Mich.
Fyre Freeze Corporation	New York, N. Y.
Goldsmith Corporation, The	New York, N. Y.
Grace & Co., W. R.	Seattle, Wash.
Hartford Accident & Indemnity Co.	Hartford, Conn.
Knickerbocker, Cram & Co., Inc.	Hartford, Conn.
McCormack Steamship Company	San Francisco, Cal.
Merritt-Chapman & Scott Company	New York, N. Y.
Morse Drydock & Repair Company	Brooklyn, N. Y.
National Board of Steam Navigation	New York, N. Y.
National Council of American Shipbuilders	New York, N. Y.
Oceanic Terminals	Portland, Oregon
Pusey & Jones Corporation	Wilmington, Del.
Submarine Signal Corporation	Boston, Mass.
Terminal Engineering Company, Inc.	New York, N. Y.
Van Gordon, J. W.	New York, N. Y.

U. S. Employees Compensation Commission..... Washington, D. C.
 Velez Course Indicator, Inc..... Boston, Mass.

The 24 new members admitted to the Marine Section during the past year are classified respectively:

General freight and passenger steamship companies.....	6
Shipyards and repair yards.....	4
Industrial companies and equipment manufacturers.....	6
Insurance companies.....	1
Maritime associations.....	3
Personal membership.....	1
Nautical schools.....	1
Miscellaneous	2
Total	24

The present Membership Committee has now functioned for two years, and it is gratifying to report that due to the efforts of the several members of your committee, and through the assistance accorded the committee by other members, that there are now on the rolls of the Marine Section 145 members as compared with but 60 at the Detroit Annual Safety Congress 2 years ago; this is equivalent to an increase of 142 per cent.

Number of members in Marine Section as of October 1, 1927.....	127
Cancellations of members received from October 1, 1927, to October 1st, 1928.....	6

121

Number of new members admitted to Marine Section from October 1, 1927, to October 1, 1928.....	21
Subsidiaries and affiliations of Members admitted to Marine Section from October 1, 1927, to October 1, 1928.....	3

Total Increase in Marine Section for 1928.....	24
---	-----------

Total Membership of Marine Section as of October 1, 1928.....	145
--	------------

Among our 145 members are included the majority of the great American petroleum corporations, some of the largest and most influential American passenger and freight steamship companies, the largest railroads operating floating equipment, important shipyards, repair yards, stevedoring companies, industrial organizations, etc.

A summary of our membership, a large majority of whom are actively and consistently prosecuting accident prevention work in their respective organizations reveals:

Petroleum companies operating steamships.....	26
General freight and passenger ss companies.....	27
Shipyards and repair yards.....	12
Stevedoring companies.....	12
Industrial companies and equipment manufacturers.....	19
Railroad companies operating floating equipment.....	18
Insurance companies.....	6
Maritime associations.....	8
Personal memberships.....	5
Miscellaneous	11
Total	145

Respectfully submitted

ARTHUR M. TODE, *Chairman*, The Texas Company
CAPTAIN R. C. BRENNAN, Oceanic Terminals, Inc.
WM. L. BUNKER, The Texas Company (Calif.)
JOHN S. HUNTER, The Atlantic Refining Co.
FERN WOOD, Williams Steamship Company
G. D. ZEH, Associated Oil Company

CHAIRMAN BUSH: The membership of this Section has been due largely, if not wholly, to the personal efforts of Mr. Tode. He is indeed, to be congratulated.

He also is chairman of the Publicity Committee. I will ask him to present the report of that Committee.

Report of Publicity Committee

By ARTHUR M. TODE

Chairman

During the past year the Marine Section has received a larger amount of publicity anent its activities of the accident prevention work in which its members are engaged, than has been the case in any previous twelve months.

The extent of the publicity work of the Marine Section is probably best attested to by the steady increase in the interest of accident prevention work, which is now being taken by the leading shipping companies and affiliated maritime interests, and the increase of the Marine Section membership from 60 to 145 members in the past two years. Publicity was further secured from invitations issued to various steamship companies who were non-members, to attend the monthly meetings of the Marine Section and become acquainted with the important work which the Section is sponsoring.

A supper meeting of the Section held during February was attended by nearly 40 representatives, including Mr. Homer Niesz, President of the National Safety Council, and Mr. W. H. Cameron, Managing Director of the National Safety Council.

Much publicity has been accorded the Marine Section by the leading American, as well as foreign maritime trade publications. Several of the papers presented at the sixteenth Annual Safety Congress in Chicago, as well as other new articles written by our members, were published in these periodicals. In numerous cases reprints were secured and distributed to our membership in any quantity desired.

Further widespread publicity for the Marine Section was secured at the present seventeenth Annual Safety Congress through the cooperation of the following maritime organizations, all of whom sent advance programs to their members, and whose President in several cases is actively participating on the Marine Section program:

American Steamship Owners Association
Maritime Association of the Port of New York
National Board of Steam Navigation
Propeller Club of the Port of New York
Alumni Association of the New York Nautical School
The Society of Naval Architects and Marine Engineers.

CHAIRMAN BUSH: The next report I will call for is that of the Program Committee, Mr. John S. Hunter of the Atlantic Refining Company, chairman.

JOHN S. HUNTER: The work of the Program Committee was greatly assisted by the active efforts of all the members of the Executive Committee. They cooperated with us very well, and I wish to take this opportunity of thanking them for their help.

I would also like to express to all the gentlemen who have prepared papers and presented them to us, the deep appreciation we feel for their assistance.

CHAIRMAN BUSH: We will hear the report of the secretary, Mr. W. E. Welch, of The Travelers Insurance Co., New York City.

SECRETARY WELCH: After hearing the reports of the Chairmen on Membership and Publicity and the Program Committee, I wish to ask (as did the Toastmaster at the Banquet last night) that you bear with me after hearing such fine reports.

I would like to state that there was a meeting of the Executive Committee every month, with very fine attendance. And I would like to call your attention to the fact that this is the only section that has a monthly executive committee meeting. At those meetings there is helpful information given to new members, in the starting of their safety campaign on their steamers and on the wharves, and it has been a great help to new members and also to old members.

There has also been sent to all the membership a *News Letter*. This *News Letter* was principally the latest in accident prevention work, and has been a help to the membership.

The Executive Committee has started the National Safety Code on cargo handling. And the Marine Section, or the Executive Committee of the Marine Section, is behind this movement, and is more or less of a steering committee and will give it all the help they can in making the code practical.

Also the Executive Committee has started a Safe Practice Pamphlet on "Marine Boiler Hazards," which will be to the benefit of the membership, a little later.

I desire to thank all the members for their very fine cooperation with me, and for their help in getting out the *News Letter*.

CHAIRMAN BUSH: Mr. Hand, the second vice-president, in charge of the Poster Committee is not present, but I have his report which I will read.

Report of Poster Committee

By ROBERT F. HAND
Chairman

The chairman of the Poster Committee has a single objective; to get out posters which will so graphically present various hazards as to lessen their danger and thereby reduce accidents. The Poster Division in Chicago, takes care of the printing and distribution of the posters, which leaves the Poster Chairman with the twofold duty of evolving poster ideas and translating these ideas into suitable pictures.

Conceivably, the Poster Chairman could do this by himself. He could study the hazards of shipping, make use of his experience, and select a number of ideas which he would then have portrayed in photographs or drawings. But this would be unfair, because it would be putting the whole job on one man's shoulders and it would be foolish because the series of posters would be limited by the limits of one man's experience.

The Poster Chairman has felt this, and therefore has attacked the problem from another angle. The membership of the Marine Section is varied; it represents many phases of shipping and many totally different types of hazards which should be posterized. An effort was made, therefore, to draw poster material from all types of members—the operators of general cargo ships, stevedores, lighterers, tanker operators, shipbuilders, etc. On December 12, 1927, a form letter was sent to all members requesting poster material. On January, 9, a follow-up letter was sent to all members.

The response to these two appeals for poster material ideas and/or photographs, was poor. There was an immediate need for poster material; but the members

did not take it upon themselves to give assistance. For that reason it was necessary to fall back on a few willing members, with the result that the entire supply of ideas and pictures for the year was supplied by six members:

The Atlantic Refining Company
 The Barber Asphalt Company
 The Cosmopolitan Shipping Company
 The Hartford Accident & Indemnity Company (St. Louis)
 The Standard Shipping Company
 The Texas Company.

About 40 photographs or illustrations were submitted by these six members. Thirty of these, covering twenty-four subjects were considered good enough for use and were sent to the Chicago Office for production. In some cases two photographs were necessary to bring out the idea, which explains why only twenty-four subjects were covered.

Following is a list of the subjects covered by the material submitted to Chicago:

Ladder Hazards	material for 6 posters
Fire Hazards	material for 3 posters
Draft Hazards	material for 4 posters
Gangway Hazards	material for 1 poster
Poor Staging Hazards.....	material for 2 posters
Dark Places in Hold Hazards.....	material for 1 poster
Inattention to Job Hazards.....	material for 2 posters
Tools laid carelessly on gratings Hazard.....	material for 1 poster
Gauge Glass Hazards.....	material for 1 poster
Steam Hazard to Man in Boiler.....	material for 1 poster
Heavy Lifting Hazards.....	material for 1 poster

A study of this list shows that but a few hazards of the industry have been touched, and it is hoped that in the ensuing year more members will respond to the call for poster material to the end that new hazards may be posterized.

In addition to the above mentioned work, the Poster Committee circulated a letter among members on July 6, 1928, calling for sketches and posters for display at the present Congress. As this material was to be sent direct to Chicago, the Chairman cannot make a definite statement as to the response to this letter. However, it is known that four or five members sent such material and perhaps more did. The display will speak for itself.

CHAIRMAN BUSH: Now, gentlemen, today has been dedicated to the National Board of Steam Navigation, through whose cooperation this program has been constructed.

We are honored this morning by the presence of the President of that organization. And I will now ask Mr. Arthur J. Grymes to deliver his paper.

The Importance of the Human Element

By ARTHUR J. GRYMES

President, National Board of Steam Navigation, New York City

Industrial safety engineering has coined the maxim, "A Safe Plant Is an Efficient Plant." Paraphrasing, it can unequivocally be stated that "The Safe Ship Is an Efficient Ship." In one form or another this thought has been expressed so repeatedly that it has become embodied in the working creed of the safety engineer. The truth of it seems to have been accepted without question—as real truths often are—without critical analysis, without attempt at proof.

On the the subject of industrial accidents, President Calvin Coolidge quite recently wrote, "It is difficult to believe that industrial accidents have reached an irreduc-

ible minimum while the death toll is probably not under 23,000; and the nonfatal injuries approximately two and one-half million each year. Especially should we be hopeful of greater improvement in this record if those who claim that 85 per cent of those accidents are preventable are even approximately right."

Men and women are much the same the world over. Industrial accidents as well as marine accidents have the same root evils, though the conditions and causes which make for accidents in various industries as well as on different types of vessels, for example, will obviously vary according to conditions and standards. The importance of the human element in this subject, however, the men and the women workers, is basically no different, be the employment on board ship or wharf, field or factory, office or home.

It is of significant interest to observe that careful records concerning personal marine accidents, which have been compiled over a period of years by large American steamship operators, have shown that from 85 per cent to 90 per cent of their reported accidents can be classed as "preventable accidents." It is not a mere coincidence that these figures obtained by the compilation of marine accidents are practically the same as the percentage of "preventable accidents" which industrial accident statistics show, but it is conclusive proof that the marine industry is no different from any other industry and that the human element is the same important factor in every industry.

When accidental injury is prevented by protecting the body of the workmen, it does not necessarily follow that the accident capable of causing the injury is eliminated. It is safe to assume that the application of protection alone does not greatly reduce injury occurrence in any industry and cannot, of itself, make a safe plant, a safe wharf, or a safe ship. Engineering revision of the plant, the wharf or the ship and revision of the workers' mental attitude can accomplish it. When injuries are prevented by eliminating the accident cause, as takes place when revision is applied, not only are injuries and accidents extirpated but the lost time is diminished.

Most maritime accidents are not the result of a single cause, but of the coincidence of a number of contributing causes, each of which may be, in turn, the culmination of a long series of events. They may have to do with a ship and its equipment or with a wharf and its facilities for loading and unloading. In each of these some element of inefficiency may have been introduced—improper maintenance, for example, defective construction, bad design. On the other hand there is the importance of the human element, and here is encountered poor technique, lack of skill, inattention, absence of proper supervision, fatigue, defective vision and a host of other contributing causes that affect both safety and efficiency. Eliminate all or any one of them for the sake of preventing accidents or for any other reason, and efficiency cannot help but be improved.

There is, moreover, an indirect relationship. It requires the highest grade of intelligent operating management and responsive personnel to eliminate accidents and to reach that desideratum of maritime safety engineers "to reduce marine accidents to the minimum." There must be effective organization, cooperation and spirit. Exactly the same requirements must be fulfilled in order to attain a high order of operating efficiency. The steamship owner or operator who has attained the one goal will, or can, attain the other.

Marine safety engineers frequently proclaim that virtually all personal injuries and accidents are due either to carelessness, ignorance or neglect. Carelessness is inexcusable, and therefore merits the consequences that always come to the careless. Continual carelessness is indisputable evidence either of ignorance or indifference. Carelessness is a crime that the conscience punishes with great severity, but the conscience does not support the suffering dependents or the injured individuals.

The National Board of Steam Navigation, which I have the honor to represent, has always been much interested in the subject of maritime accident prevention both as relating to ships and their cargoes, and personal injuries. The naval architects design and the shipyards construct ships which are the wonder of the age and virtually unsinkable. The Government, through the Department of Commerce, has given us the rules of the road, and accurate charts of all navigable waters marked with beacons, lighthouses and bouys; and yet with all these factors for the prevention of accidents property and human life are continually damaged or destroyed.

And why? Because that all important element, the human element, is not and cannot function 100 per cent. Many solutions have been attempted and through the instrumentality of the National Safety Council great improvement has been made. Accident prevention work to bring results requires the most consistent and persistent efforts on the part of the management of any organization which must permeate down through the higher and lower officials and the rank and file whereby appreciation and assistance of the human element which is so vitally concerned will be of as high a percentage as it is possible to obtain.

Those steamship and maritime organization officials who are lending their efforts in this great movement of accident reduction deserve the highest praise from their associates and from their employees. To those executives who have not yet seen the handwriting on the wall let it be known at this time that unless they take the necessary steps to encourage accident prevention work on their ships, wharves and terminals, the Government of the United States will undoubtedly soon enact legislation making it imperative for them to bear their share of the responsibility.

CHAIRMAN BUSH: The meeting is now open for discussion on Mr. Grymes' paper.

Mr. Jewett, would you care to give us the benefit of your experience? You are constantly around the shipping centers and the docks. We would be glad to hear from you.

E. H. JEWETT (Elliott Service Company, New York): I came here primarily to listen and learn. If there is any contribution that my brief experience in this work may have made, I wish you would consider it from the light perhaps of the old biblical quotation, "Out of the mouths of babes and sucklings."

There are one or two specific things on my mind that have come out of the past three years very definitely. Mr. Grymes has covered them very ably. The first is the executive realization of the importance of this work. And right at that point I would like to ask a question of those executives, because it comes up almost every day in our work.

Why is \$100,000, \$500,000, or any other real amount of money paid out of the treasury of that company for compensation because of accident or responsibility for accident, to say nothing of the wastages that come from this? Is it of any less value to the treasurer of that company than a similar amount of money spent for any other piece of operating work?

I have had presidents, vice presidents, and other operating officials, seem to think that because they were buying their insurance, either through an American or foreign club, or perhaps buying it from the state, mutual or stock company, they felt they had done their all.

I don't believe, gentlemen, that if they had a single operation, where there was a wastage of \$100,000 or \$500,000, that they wouldn't sit up nights and try to break down and stop that wastage. And yet because it happens to be wastage because of accident, they don't give it the same consideration.

Is \$100,000 or \$500,000, or another similar amount that is lost, of any less value to that company than a similar amount in the handling of lumber, copper, lead, or the operation of a ship?

Summing up on that, I don't believe they have tried to break it down. I don't think they have realized the importance of saving that money as land interests as a whole have done.

There is only one other thing that I would like to say, and that is: After the executives have looked at it from that angle and seen the true significance of respective values, agencies like our own, with due respect to the National Safety Council,—I think we ourselves are partially to blame in not driving home and riveting attention to the actual workman, the actual working personnel, whether pier superintendent or marine superintendent, on down the line, through hatch and gang bosses. There is a difference between what is the cause of that accident and the cause of the injury. That is purely a practical problem.

I think I see here in this room several men who are familiar with that situation in the form of accident reports. I may have been unfortunate. It may have been my unfortunate experience that in picking up 100 or 300 accident reports, I have not been able, even with their assistance, to get from that report the cause of the accident. I can get 100 per cent the cause of the injury.

I think that is one reason why we haven't made headway. I would like to draw two parallels and make my point on that. I will take a serious accident, say where a steam valve on a vessel should either be tightened or removed. His attention is first called to that valve by the escaping of the steam.

He goes to repair it. In many cases he is like the plumber; he doesn't take his tools. He has to go back for them. But if there happens to be—and I am citing now an actual occurrence—if he gets to the steam valve and doesn't happen to have a small wrench, but he sees lying there a huge Stillson wrench, he will not go back. He will not walk thirty feet to get a proper tool. He does, however, take this huge Stillson wrench, and when he puts that on, plus the power of his physical body behind it, off comes the whole valve with live steam, and two men are scalded to death, and three are yet in the hospital. That accident happened nine months ago.

What bearing has that on Mr. Grymes' remarks? This engineer was a competent man. He must have had brains to enable him to get out an engineering paper. But what good was that qualification to him, because, using plain language, he was too "cussed" lazy to walk thirty feet to get his proper tools.

The actual escaping of that steam, the actual blowing off of that steam, was the cause of those deaths. But what was the actual cause? It is just as true in fatalities as it is where a scullion on a ship will use a cleansing agent such as mineral water, full of decayed and deleterious matter to clean his pots and pans, and in that operation pricks his finger and doesn't think enough about it to go and get first-aid, and perhaps we have a serious case of blood poisoning.

You can go from fatalities to the slightest thing, and it is purely a case of the human element rather than the mechanical cause, in other words, human failure and not mechanical failure.

There is just one more thought. If we could get our steamship companies, our stevedoring operators, to look at this movement more from a preventive angle and less from a claims settlement, I think headway would be made in that direction.

I am going to tell one little story, and then I am through. The average man operating in this work, whether he is a stevedore or with a steamship company, heads up to claims department. I feel that is a mistake. I think that he should head up to the operating department.

I don't know what your experience may have been in the claim department, but I have found they would much rather look at it as a good job, well done, if they could make a thousand dollar settlement on a \$2,500 claim, and thereby save their company a considerable sum of money. They think they have done a splendid job; but they should have taken that same amount of time and energy and directed

it to preventive measures so that accident would not have happened perhaps in the first place.

In other words, I believe that the best thing to do in a case of that kind, is to prevent the original occurrence.

And I will say this: It is my sincere feeling that until the medical profession can develop some new or radically better form of cure, we can't expect to make very much advancement from the cure phase of accident prevention work, until the Federal Government and the various state governments provide for practical legislation; and until the legal departments, the legal profession, can make some advancement in the adjudication and settlement of claims, I don't think we can go very much further in our settlement of claims.

Now what does that leave us, if that is true? It leaves us one other avenue by which treatment can be made; namely, concentrate on actual prevention.

CHAIRMAN BUSH: We will proceed to the consideration of the next paper.

I have just been informed that Mr. Burke of the United States Lines is ill and is unable to present his paper, but he has sent a gentleman to represent him. Mr. Owen A. Smith, Passenger Traffic Manager of the United States Lines, will read Mr. Burke's paper.

Taking Steps to Insure the Safety of Passengers at Sea

By DAVID A. BURKE

General Manager, United States Lines, New York City

What I have to say will not be new to you, as you are thoroughly familiar with the technical operation of steamships. To the layman however, this subject is one with which he rarely ever manifests any interest or concern.

I have made inquiry of our various passenger department representatives as to whether any person arranging for a booking on one of our vessels, has ever brought up the subject of safety aboard the ships. You may be surprised to learn that in the experience of our passenger department, no prospective seagoer has ever questioned the safety angle. A person will frequently ask many questions regarding the contemplated voyage, disregarding entirely the question of safety at sea, which I assume is due to the fact that they no doubt consider the feature as more or less a foregone conclusion.

Fortunately there has been no serious accident of any kind or any catastrophe in the North Atlantic passenger service since the war, when of course the submarines were an additional menace to navigation. Perhaps the war has had much to do with the psychological change in the public mind regarding sea travel. Before the war, this question of safety was often brought up by prospective passengers. During the war, tourist travel was at a standstill, and then following the hostilities when events of the war were indelibly carved in the minds of all of us, our pre-war thoughts, if I may use that term, were subordinated.

So, with the submarines eliminated from the seas as a menace to the safety of passengers, it is my opinion that the tourist feels there is nothing to hinder a safe journey to and from Europe.

To the steamship men however, this is quite another question. We regard safety as one of the most important factors in the operation of steamships. During a voyage and while they are in port, vessels are constantly being watched with critical eyes, tests being made, one instrument checking against another, so that hour after hour, the danger to the lives of passengers are reduced to a minimum.

The United States Lines is now at the beginning of its eighth year of operation. It is gratifying to me that those eight years can be recorded as successful from many angles. Financially the company has been on the up-grade and constantly the

number of passengers being carried by the vessels of our fleet has improved, so much so, that during the last year, each of our vessels on several voyages east and westbound carried the maximum number of passengers. The Leviathan alone has established several records for passenger carryings. On a recent voyage, she brought to this country 887 first class passengers, the largest number ever carried by any liner in that class, and during the eight years of steady increase in business in a highly competitive field, I am proud to say that not one passenger transported by any vessel of the United States Lines fleet has lost a life during the course of a voyage. Deaths, of course, have occurred on vessels, due to illness, but not once has any death been the result of negligence on the part of our officers and crews, which is a high tribute to the men in the American Merchant Marine.

The United States Lines is constantly alert and anxious to provide its vessels with the most modern equipment to safeguard the passengers at sea. As an illustration, we recently installed a fathometer which has been found satisfactory. This fathometer consists of an indicator with a clocklike dial mounted in the Chart Room on the bridge, with a receiver for checking up the echo emitted from the sound sender in the hull of the vessel well below the water-line which transmits sounds to the bottom of the sea. The period required for the return of the echo is timed to a split second, and is translated into fathoms of depths on the fathometer, so it is possible for the ship's master to determine the depth at any time. This instrument can be put into operation by pressing a button and continues to operate until it is turned off.

To the man who knows ships, little need be said about the value of the fathometer, which according to tests has accurately measured depths from three to 130 fathoms below the vessel's hull and is of extreme value when the ship is in a fog approaching port.

Of course from the standpoint of safety, stability and seaworthiness of the vessel are the most important factors. The stability of the ship is usually predetermined, and can be accurately gauged on the first voyage. Seaworthiness is a matter that requires constant attention and can only be maintained by efficient supervision. Perhaps the most important hazards at sea are fog and fire. Large sums of money have been spent in the efforts to combat these two elements. As an illustration, let us take the Leviathan, carrying at times approximately 3,600 persons including passengers, officers and crew. Suppose that someone on that ship should leave a lighted cigarette in a stateroom, causing material or paper to catch fire. For such an accident we are prepared. Each of our vessels has hundreds and hundreds of feet of tubing located in passageways and in all staterooms which expands from abnormal heat causing a bell to ring at some certain point on the bridge where the fire prevention instruments are located. In addition to the aero-alarm, as this is termed, our vessels are equipped with the Rich System for fire detection at the fire control station. This system has tubes running to various parts of the ship through which air is constantly being sucked by means of fans to the detection apparatus. The men on watch can tell within a few minutes from what part of the ship the smoke is emanating. For example, recently smoke was seen coming from one of the tubes connected with the after section of the Leviathan. This smoke was not very dense, so the man on watch telephoned to the watchman in that portion of the liner, and he in a few minutes reported that one of the members of the crew was smoking a cigarette.

Any section of the ship can be smothered with steam regulated from the detection room and a fire even though of considerable proportion could readily be extinguished. In addition to this, we have the regular fire fighting apparatus extinguishers, sand boxes and large quantities of chemicals in the Engine Room to located in the various parts of the ship, men constantly on watch, chemical fire preclude the possibility of a fire making headway to sections where oil and coal, used as fuel, are stored.

To forestall the danger of fog, we have the fathometer, compasses, and, most important of all, the radio. As an adjunct to the high powered radio apparatus, each vessel is equipped with numerous auxiliary outfits, that will permit the ship to communicate with others at all times and under all conditions. Our radio operators are at their posts twenty-four hours a day while the vessel is at sea, for the protection not only of the ship itself, but for the benefit of other steamers that might be within radio range and require assistance. To offset the fog hazard the radio direction finder is one of the most valuable instruments for use in arriving at the vessel's position.

Under the trans-Atlantic Conference agreement, certain tracks for navigation are designated for use during certain seasons of the year. Changes are made on specific dates in accordance with information submitted by the United States Hydrographic Office and the Coast Guard Service. The latter has maintained a patrol of the ice fields for a number of years from April until the latter part of July and the Coast Guard patrol boats during that period send out positions, movements and speed of floating bergs and ice fields that may be considered a menace to navigation. Vessels can then change their course to avoid this danger long before they have come in close proximity to the ice fields. Since this patrol has been in operation there have been no collisions between ice bergs and trans Atlantic passenger liners. The navigation on these tracks has been made easier by the Gyro-Compass and the Gyro-Pilot, which by the way, has been referred to as "Metal Mike." With the latter it is possible to maintain a certain pre-determined course for any time without deviating from it, but this course, even when the pilot is utilized, is being checked by the officers on watch with other efficient instruments.

The modern liner is equipped with all kinds of accident prevention apparatus which is employed only when the ship is in danger. Supposing a liner is struck by another ship, an iceberg or some floating derelict in a vulnerable spot below the water line. Assuming the engines go dead, there are located in various parts of the liner gasoline engines and storage batteries to furnish the power required for radio transmission and an auxiliary lighting system. With the vessel illuminated, if only to a moderate degree, there is less likelihood of the passengers becoming panicky than would be the case in utter darkness, thus enabling the officers and crew to better cope with the emergency, the passengers, in the meantime having a sense of security that would be lacking if the ship were in darkness.

Water tight doors are a very important factor in the mechanism of a vessel, and are therefore frequently inspected with great care, both at sea and in port. In the event of a collision, it is possible to prevent a rush of water through the ship by means of these doors. On the vessels of our fleet, they can be controlled either mechanically or by hand, the remote control being from the bridge. Perhaps in the majority of cases, the mechanical control from the bridge is of paramount importance, for it is on the bridge that the officers on watch would be in the best position to judge what doors should be closed first.

When the vessels of the United States Lines are in port there is a regular program followed by the officers and the men to safeguard the liner for the next voyage to sea. Life boat drills are held, the boats inspected, the equipment and provisions gone over and replaced if necessary, the davits are examined and greased, fire prevention equipment tested and all emergency apparatus is given a work-out, in fact every piece of machinery is examined and tested and no detail is left undone in this examination even to checking the steering apparatus from the bridge and the steering gear house.

Recently we placed acetylene torches on all of our vessels. This torch had never been actually used aboard our vessels, but came in very handy not long ago, when the Republic was at her dock at Bremerhaven. The tug, "Serius" which chanced to be near the United States Liner, capsized, and the man on watch on the Republic immediately ordered a life boat lowered and after several men were

pulled out of the water it was discovered that there were men of the crew who had been imprisoned in the engine room of the "Serius." The Republic crew immediately rowed back to the vessel's side, called for the acetylene torch and cut through the steel bulk head and removed the engineer of the tug who was still alive but unconscious. This proved to be a case where the foresight actually saved a life, even though it was not aboard one of our own ships.

On our vessels of the United States Lines fleet, a safety campaign has been conducted under the auspices of the Merchant Fleet Corporation and through the use of placards and other pieces of writing matter and warnings, accidents to members of the crew aboard the vessels have been reduced to a minimum.

There is one more fact in relation to the safety program that is conducted by the United States Line which is worthy of mention to you gentlemen. The Leviathan goes into drydock twice every year and our other ships are frequently taken from their schedule for an under water inspection. Criticism has been directed against the management of the United States Lines and frequently rumors have been spread that the Leviathan is not functioning properly, because she goes to drydock twice a year. I wish to take this opportunity to emphasize that we send the Leviathan semi-annually to drydock because we feel that we are taking an extra precaution to guarantee against any trouble, developing below the water line. By making this inspection, it is oftentimes possible to avoid serious trouble, considerable expense and a protracted lay-up of the Leviathan and the other ships.

Of course, there is an element of luck which cannot be overlooked, when accidents of even a minor nature are avoided, but to a far greater degree accidents are prevented by care and study, such as you gentlemen have given these problems.

We have been exceptionally fortunate in this country to have various companies and government bureaus co-operating to avoid catastrophies at sea, and due to your surveys and study, such conferences, as the one which will be held in London next year to revise the International Convention of 1914 for Safety of Life at Sea, can really be productive. On the American Committee which is now engaged in making proposals to be taken up by this International Convention, the United States Lines is represented. It is this care, that is constantly being taken in this country to insure the safety of lives at sea that is going to contribute in such a large measure to build up the American Merchant Marine to the position it deserves, and the American people will be proud of the work that you gentlemen have done in assisting us to attain that end.

CHAIRMAN BUSH: The next paper on the program is by a gentleman who has been one of the most active members of the Marine Section. He has been regular in his attendance at the Executive Committee Meetings, and he has given us his cooperation to the fullest extent. He is one of the pioneers in maritime accident prevention work. I take pleasure in presenting to you now, Captain Reginald Fay, Marine Superintendent, The New York Central Railroad Company, New York City.

Marine Accidents—Their Causes and Remedies

By CAPTAIN REGINALD FAY

**Marine Superintendent, The New York Central Railroad Company,
New York City**

As a new member of the Marine Section of the National Safety Council, I am at a loss to understand why I was selected to present a paper for your consideration. Not being altogether familiar with the requirements of such a paper, I have, however, attempted to accumulate some data from our records which I trust may be interesting to this section.

I will not attempt to enumerate the accidents in the several departments, but I would like to outline some of the activities that we are putting forth, not only to avoid a recurrence of accidents, but also to prevent their happening.

At our Marine repair shop where every class of marine equipment is constantly undergoing repair, we are using every precaution that human mind can think of to prevent accidents, for instance:

Portable gangways with suitable rails to pass to and from the boats lying at the piers while undergoing repairs.

Ring bolts fitted to the string-pieces to hold these gangways in place to prevent slipping.

Special gangways, for boarding ferry boats with electric trucks carrying repair material, have already been provided and are of same design.

All air, water, steam and electric lines carried overhead and along the string pieces on piers with metal covers to prevent lines from being caught and to prevent men from tripping at gangways.

Large electric light plug connections properly guarded to prevent men from receiving shocks and burns.

Lumber properly racked to prevent tumbling down and easier of access for any particular piece.

All machines and belting safely guarded. Notices on all machines to use guards and anyone found not using same subject to discipline.

Goggles being used to protect men's eyes.

All air tools returned to tool room and examined each day before using again.

Following some very valuable suggestions offered by our safety representatives, we have been able to show a reduction of "Reportable" or "ICC Entrees" in 1927 in comparison with 1926. Following are the figures for the two years mentioned:

Year 1926: Actual man hours worked.....	4,345,572
ICC injuries	52

Year 1927: Actual man hours worked.....	4,549,288
ICC injuries—one employee killed; 38 injured.	

This shows a decrease of 14 injuries and an increase of one killed, despite the fact that there was an increase of 203,716 man hours worked.

The fact that we were able to make this reduction with the increase in man hours is proof positive that some concrete safety work has been carried on in our department. I might state the fact that we are holding meetings bi-monthly which not only deal with safety, but cover in addition to safety, loss and damage, shortages and everything that has connection with the Marine department. In addition to the above, a campaign of safety education is being carried on through all departments by the heads of those departments with the assistance of the safety agent and with material furnished by the New York Central Safety bureau. Mr. C. E. Hill, General Safety Agent of the New York Central Lines has furnished us from time to time with valuable safety data, such as bulletins, posters, letters, etc., which I think have been instrumental in a great measure in educating our employees to the fact that safety and efficiency go hand in hand. It is my earnest hope that with the assistance of the various supervisors of departments, through their more strict supervision and education, that we may be able to show a much greater decrease in Reportable or ICC injuries at the end of this year.

The New York Central Marine Department consists of the following units:

Ferry Boats	9
Tug Boats	29
Steam Lighters	6
Oil Storage Barges	4
Steam Hoist Barges	4

Gasoline Hoist Barges	16
Hand Hoist Barges	18
Coal and Pumping Barge	1
Scow Barges	5
Covered Barges	114
Refrigerator Barges	37
Grain Boats	23
Car Floats	63
TOTAL	329

I would like at this time to refer to some of the corrections of conditions that have been carried on on our floating equipment, this due to past injuries to employees,

Tug Boats:

On our tug boats and steam lighters an up to date search light has been installed for the purpose of locating boats to be towed, at the same time making the operations safer for the men while making fast and letting go the lines.

All fire room exits are properly railed to prevent men from slipping and falling into the fire room.

Platform gratings are installed alongside the boilers for access for maneuvering main stops, etc.

Guards fitted to all dynamos and other auxiliaries where possible.

Covers over main engines, guard rails, turning gears and couplings.

All ladder ways, rails, etc., examined and kept in safe condition.

Man-holes and gratings welded in place where not called for as emergency exits by law and not used for filling tanks.

Covers and gratings provided for all man-holes.

All exposed steam pipes properly lagged.

All steel decks covered with Tenax Decking to prevent personal injury by slipping.

Ferry Boats:

On our ferry boats, heavy safety posts and cables have been installed across the team gangways on each end with a resisting capacity of 20 tons, thus safeguarding automobiles and vehicles from going overboard.

All sorts of suitable signs have been placed on boats and ferry bridges for the safe protection and guidance of passengers and employees.

The law against smoking in automobiles and team gangways is being rigidly enforced for the safety of the public particularly while the boats are under way.

Small printed notices quoting the law against smoking are being constantly handed to all offenders or violators of fire regulations.

Floats:

On the non-propelled equipment of this department consisting of car floats, derricks, gasoline hoisters, hand hoisters, barges, scows and grain boats, every precaution is taken for safety.

On new equipment of this kind, car floats are having the man-holes eliminated from the deck to the holds and placed in the steel structure under the platform.

All cross-over frogs and guard rails are properly guarded with wooden blocks.

Covered barges are being constructed with extra wide guards to make safe the handling of lines from the tug.

All gangway ladders properly guarded with hand-rails and signs in conspicuous places to avoid personal injury.

I might add that this thought of safety applies to all of this equipment and that an inspector is employed to make personal inspection of the non-propelled, as well as the self-propelled equipment daily, and if any defects of importance are found the boat is ordered out of service and into the shop for immediate repairs.

Marine accidents and causes can be remedied only by strict adherence to safety regulations and personal supervision.

I would like in conclusion to refer to the fact that in 1924, the West Shore Ferries succeeded in going through four months, from June 1 to September 30, without a single accident and the first prize consisting of a large silver cup was permanently awarded to that department.

I believe that this in itself is a very fine showing and indicates that the careful supervision of the supervising officers, together with the efficient and strict compliance with safety regulations by the employees, is proof positive that a "Safety Minded Man" is the best accident preventer and safeguard to the public.

CHAIRMAN BUSH: Is there any discussion on the Captain's paper?

CAPTAIN J. E. BRIGGS (Port Captain, Marine Department, Lackawanna Railroad, Hoboken, N. J.): Captain Fay has spoken of several things that I was thinking of touching on and had in mind.

On the Lackawanna Railroad, we operate four ferries, and while we don't have quite as many tug boats in service as Captain Fay has, we have nineteen. In the first eight months of 1926 we had 63 injuries in the Marine Department; in the same period in 1927, we had 59. This year I am very glad to say we only had 35. That is a reduction in three years of 43 per cent. I think this is a very good showing.

Mr. Farrell and another gentleman—I have forgotten his name—said it would be a great help if they could get the fellow who is really on the job interested in the safety movement, and we do that. We have in our department, three deck hands and three firemen who are members of our local safety committee. They take a very active part in the work and are very much interested in it. So we give them honorable mention at our meeting once a month, and at the end of the year we give them a certificate. There is hardly a day that a certain deck hand of ours doesn't come to me and report some little thing. He is on one of our docks. So the men are really interested in the work. There are many things that we have protected that we would not have known about if it hadn't been for these men.

We have had no deaths as results of injuries this year. Most of our injuries have been slight, the majority of them necessitating only one day's disability.

I think it is a very good thing to get a fellow interested in some job to see these little things that we don't see, and when they report to us, we can correct them. Self preservation is the first law of nature. But these fellows sometimes get careless in the continual performance of a certain duty and do it in a subconscious way.

CHAIRMAN BUSH: There is a representative here from the Pennsylvania Railroad, whose name at the moment I regret to say I cannot recall.

O. D. MOORE (Pennsylvania Railroad): It was my privilege to read a paper on the activities of the Pennsylvania last year, at the meeting in Chicago. But Captain Fay was not present, so he had no opportunity to comment on it, and that gives the Pennsylvania somewhat of an advantage.

The Pennsylvania safety work and its fleet in New York Harbor here run very closely along parallel lines with the New York Central. Their maritime activities are a part of the general railroad safety work. But it has been a noticeable fact, at our various marine departments both here and at other ports, that they have been particularly jealous of their records in a respect.

Captain Fay's paper is very properly drafted along practical lines and outlines the specific activities that they have undertaken against certain definite hazards. The only practical comment that I might add, based on reports and experience of the past year in our work, has been a duplication of two accidents of what might be called a special nature as differentiated from the usual run of slips and falls,

wrenches, slipping, and getting tangled up in line. It might be of some interest to pass it on.

There were two cases where men were shocked into unconsciousness by picking up portable electric light lines in which either the insulation was wet or they were grounded on the wet fireroom floor. In both cases the men were sufficiently experienced to have known better. But in view of the fact that there was a repetition, there is apparently need for some additional attention being given to such things as that.

CHAIRMAN BUSH: Are there any further comments?

In the popular mind, gentlemen, the United States Coast Guard Service is an agency of the Government, whose primary function is the chasing of rum-runners. Actually the service is the life-preserver of the American Merchant Marine. One of the members in active service will tell you of their activities. May I present at this time, Commander W. F. Towle, U. S. Coast Guard, New York City.

Activities of the United States Coast Guard in Saving Life and Property at Sea

By COMMANDER W. F. TOWLE
U. S. Coast Guard, New York City

The duties with which the Coast Guard is charged in peace times are numerous and varied. Of the major duties imposed on it, probably the most important, certainly the most hazardous, is that of assisting vessels in distress and saving life and property from the perils of the sea. The ever present necessity to be at all times prepared for this duty has for more than a century been very largely the determining factor in the evolution of the Service, both as to the development in ships and stations, as well as the tradition and spirit of its personnel.

That is to say, Coast Guard cutters, life-saving stations, life boats, and the character of the men who man them are essentially a product of a century of continuous battle with the sea in the interests of humanity. The old sea, in her more violent moods, is a splendid antagonist. She wages warfare with very terrible results sometimes, but always in the grand manner—a manner not altogether barren of compensation for those who survive it. A type is produced. A particular type of ship, and a particular type of seaman to man it.

There are now in the Coast Guard about 9,950 enlisted men; 840 warrant officers; 360 commissioned officers; and about 100 cadets under instruction at the Academy at New London, Connecticut. Under existing law this personnel is organized, trained and equipped to constitute a part of the military forces of the United States. It operates as a part of the Navy in time of war, and under the Treasury Department in time of peace. At all times the Service is maintained under a rigid system of Naval discipline, drill and training, not only to fit it for war service, but also to fit it for the hazardous emergencies of rescue operation at sea in time of peace. The most essential requirement for such work is a crew highly trained to the sea habit, coordinated team work, and confident readiness to act effectively in the face of demoralizing adversity.

Shipwreck generally results from failure to weather a major hazard at sea. Into that hazard the Coast Guard vessel must steam quickly, resolutely—and not only weather it herself, but also she must undertake to bring the other fellow out with her. Maneuvering at night about a disabled vessel in a winter storm with a heavy sea running,—launching of life-boat,—shooting life lines,—coming in before a blizzard to a stranded vessel on a lee shore. All such operations are “touch and go” affairs, in which the cutter’s success is measured by the superior discipline and training of her people. It is, in a sense, a paradox that the identical military system

which fits the Service to destroy life in war is applied in peace to this highest humanitarian purpose.

As its principal floating equipment the Service has in commission thirty-three cruising cutters, twenty-five destroyers, thirty-three 125-foot off-shore patrol boats, thirteen 100-foot off-shore patrol boats, two hundred 75-foot patrol boats, and some forty harbor cutters and launches. Five first class cruising cutters under construction will soon be completed and in operation.

Along the Atlantic, Gulf and Pacific coasts, and on the Great Lakes, there are 273 Coast Guard stations. These are the familiar life-saving stations. They are located at selected points of danger to shipping and vary somewhat in character, according to the environment and the nature of the service required of them. On less dangerous portions of the coast they are placed only at long intervals, while upon other parts they form chains of contiguous posts designed to cooperate with each other. For instance—Cape Cod stretching forty miles into the North Atlantic, like a threatening arm, is fringed on its Eastern shore with forty miles of shifting sand bars exposed to the heavy winter gales sweeping in from the Northeast.

This constitutes a savage menace to the commerce of the principal ports of New England. Likewise the coasts of New Jersey and Long Island, exposed to the full force of northeasterly storms, threatens the commerce of New York. The Jersey coast is fairly lined with wrecks. It is a veritable grave-yard of ships—a gruesome toll taken from our coastwise traffic all of which passes up and down this coast when bound into or out of New York. Consequently, along the Cape Cod, Long Island and Jersey coasts, the Coast Guard stations are close together—about four miles apart, usually. So that these beaches are under constant observation for their entire length. An overlapping beach patrol is maintained at night by men from the stations. Each patrolman is provided with flares and signal lights which enable him to communicate at once with his station and to signal to stranded vessels that they are seen and help summoned. Commerce bound into the Chesapeake and south of Cape Hatteras is likewise protected by Coast Guard stations along with shores of North Carolina, Virginia and Maryland.

The typical Coast Guard stations are manned by a crew of eight men, superbly trained to the caprices and tricks of the surf, of unchallenged expertness and superiority in the handling of small boats in the broken waters of the beaches, bars and shoals, and capable of taking their life-boats to sea on long journeys of rescue.

The equipment of Coast Guard stations consists of the beach apparatus,—line throwing guns,—hawsers,—breaches buoys, and such,—life boats,—surf boats,—and life cars. Pyrotechnic signals and other signal gear are provided as warning devices. The life-boats and surf-boats in use by the American Coast Guard are accepted all over the world as models for life-saving purposes. They have been developed by the Service and are built in the Coast Guard boat shops at Curtis Bay, Maryland.

The 36-foot motor life-boat is self-righting, self-bailing and is driven by 50 H. P. gas engines. I have seen one of these boats turned over twice in the surf on Tennessee Reef, outside of San Francisco, in an attempt to take the people off the stranded steamer *Hanaleila*. Each time she righted and freed herself and continued. With the loss of only one man she got to the steamer and brought fourteen people out through the breakers. They are beautiful craft.

The 26-foot surf-boat is generally what is called "The monomoy." It is designed for getting off the beach directly through the breakers. It is self-bailing but light and buoyant.

The apparatus for shooting a line to a vessel and getting her people off in a breeches buoy is used when the wreck is within range of the gun. It is also used by cutters at sea to get people off sinking vessels when the sea is too heavy to

get them off quickly in life boats. Cutters have taken people off in this manner with a sea running in which no life-boat could possibly live.

A highly organized and thoroughly efficient system of communication, composed of telephone lines, telegraph lines and radio, has been developed by the Service connecting our stations with each other, with divisional headquarters and with strategically located radio stations. So that our coastal stations are in constant communication with each other, with Divisional Headquarters and, through the radio, with Coast Guard cutters cruising at sea.

The typical modern Coast Guard cutter is a ruggedly built steel flush deck steamer. She measures 250 feet over all, 42 feet beam, and about 16 feet draft. She is driven at a speed of 17.5 knots by turbo electric machinery supplied with high pressure steam by two water tube boilers. Most of her auxiliaries are electrically operated. She carries three 5-inch rifles, a 2-inch anti-aircraft gun, and two 6-pounder r. f. guns. Machine guns and rifles to arm a landing force are provided. She is equipped with the most modern and efficient radio apparatus obtainable. The Ice Patrol cutter on the Grand Banks maintains constant direct radio communication with Washington. Ice reports and weather data being thus transmitted.

She carries life-boats and life-saving equipment which I can assure you are the very best human ingenuity and human experience have been able to devise. She can keep the sea for long periods of time on long cruises for derelicts or into the Bering Sea where fuel stations are rare. Her design embodies the best features developed by a century of Coast Guard work, and I know of no other vessel afloat that even approaches her in excellence for rescue work in the heaviest weather. She is manned by about ninety splendidly disciplined men and eight officers whose lives have been spent in acquiring an expert and familiar knowledge of the inshore navigation of our coasts by actually cruising among the reefs, shoals, currents and such dangers which commonly bring vessels to grief.

Cutters are based at the important ports along our coasts, which for purposes of operation and administration are divided into seven divisions and, during the open season, the Bering Sea Patrol, each with a division commander. Ocean-going cutters operate from Rickland and Portland, Maine, Boston and Woods Hole, Massachusetts, New London, Connecticut, New York, Norfolk, Virginia, Wilmington, North Carolina, Savannah, Georgia, Key West, Florida, Mobile, Alabama, and Galveston, Texas, on the East Coast. On the West Coast they are based at San Diego, San Pedro, San Francisco and Eureka, California, Seattle and Neal Bay, Washington, and at Juneau, Alaska. Three or four cutters operate in the Bering Sea, and on—the "Northland"—in the Arctic Ocean, as far as Point Barrow.

The vessel stationed at Neah Bay at Cape Flattery is a vessel built purely for life-saving. One day during a heavy storm in 1923 she rescued the people from three wrecked vessels, one of which she succeeded in towing in.

Likewise, on the East Coast, in one day during a northeast blizzard the "Gresham" came in from the sea on the coast of Cape Cod at Monomy Point and took the people off three vessels, all stranded on the shoals near Hollock Rip, and all breaking up. It was during this gale that the Monomy Point life-saving crew was lost in attempting to get off the beach in their surf-boat. The Massachusetts coast has been a fatal spot for the Coast Guard. The Manomet Station lost three men there last winter when their surf-boat, returning from the stranded steamer "Robert E. Lee," was upended in the surf.

At present a constant patrol of the coast is maintained by the Coast Guard cutters which cruise to locate vessels in distress and answer SOS calls from vessels equipped with radio. This duty, of course, taking precedence over the anti-smuggling work in which they are also engaged. During the winter, from December to April, under what is known as "Winter Cruising Orders," the cutters

maintain a special rescue patrol from Hatteras to the Maine boundary. Vessels in this force have orders to make every effort to locate and assist vessels in distress. A vessel standing along or approaching the American coast, sending out an SOS signal, receives an immediate answer from an American cutter, and next morning you read in the paper that familiar sentence "A Coast Guard cutter is going to her assistance." As a matter of fact all the cutters within reach go to her assistance and generally keep on going until somebody reaches her.

Say, a vessel strands on the coast at night in a gale. She is seen by the Beach Patrol who immediately burns a colored light which means to every mariner "You are seen and assistance is coming." If conditions warrant another light is burned which means "Do not attempt to land in your own boats—landing impossible." Meanwhile the flares are seen by the lookout in the Coast Guard station who at once calls the crew, telephones to neighboring stations and to the nearest radio station who broadcasts a call to all Coast Guard vessels. Whereupon, all hands within reach light out for the wreck, surf-boats on wheels and beach apparatus wagons light out down the beach. Cutters start in from sea with life-boats and ground tackle cleared away. Beach fires are built. Reserve cutters in port get up steam for a call. Generally speaking, an SOS call certainly stirs things up in the Coast Guard, and the hellish part of it is that they almost always come at two o'clock in the morning with a northeaster in full voice.

Last winter we had quite a crop of wrecks along the Atlantic coast. All of the cutters north of Charleston were busy most of the time, either towing something in or taking people off something that could not be towed in. One day we had four vessels out of New York alone towing barges and schooners and taking their people off. During the past year the Coast Guard cutters of this patrol, alone, rescued 39 vessels in distress, the value of which, including cargoes, was more than 6-½ million dollars, and on board of which were 435 persons.

As to the operation of the entire Service during the year 1927, 3,313 persons were rescued from positions of peril. There were 5,508 cases of assistance rendered, and the value of vessels so assisted, including cargoes, was \$37,801,357. There were 14,496 people on board vessels assisted. The greatest number of cases of assistance rendered in one day was 55. 136 derelicts or obstructions to navigation were removed or blown up.

In addition to all that, during the Mississippi floods, the Coast Guard sent into the flooded area an emergency force of 674 officers and men with 128 vessels and life-boats. Many of the life-boats being shipped overland. This force performed all sorts of rescue work, too extensive to list here. 43,853 people were transported from positions of danger to safety. How many of them were actually saved from drowning we do not know, but we do know that a large part of them would have lost their lives were it not for the emergent intervention of the Coast Guard.

I want also to say something about the International Ice Patrol, the Patrol and regulation of anchorages in important harbors, particularly in the Port of New York. The patrol of regattas and parades and the work of the Service in the Bering Sea and in the Arctic. All of these activities are carried on by the Coast Guard purely to protect life and property. As a result of the "Titanic" disaster there was held at London, in 1923, an International Conference on the Safety of Life at Sea, and the various maritime powers of the world signed a convention providing for an international ice observation and ice patrol service, consisting of two vessels which should patrol the ice region during the season of danger from ice bergs. The United States was invited to undertake this service, the expense to be defrayed by thirteen powers interested in trans-Atlantic navigation. Well, two ocean going Coast Guard cutters have been out there at the tip of the Grand Banks every spring ever since, maintaining a continuous patrol of the ice regions. The vessel on patrol locates the ice bergs and field ice, determines their drift and broadcasts their

presence and location to our Hydrographic and to all ships using the trans-Atlantic routes through that region.

The enforcement of the laws and regulations governing the anchorages in the Port of New York and the transportation of explosives in the waters of the Port is a duty of great importance that is becoming more important as the Harbor becomes more crowded with traffic, essential from a transportation standpoint to the enormous and rapidly growing commerce of New York City. There have been several major disasters in the Harbor recently. Anchorages are frequently overcrowded, particularly off quarantine after a fog where numbers of ocean steamers arrive together. Difficulties of this nature constitute a problem in New York bay which must soon be taken up.

The Bering Sea cruises of the Coast Guard cutters and the Arctic cruise of the Northland constitute a volume of romance in themselves. It is a story of rain and sleet, of Eskimos, Aleuts, Hyaks, Cmiaks, Waheenies, Hucklucs, walrus, polar bears, ice floes, ice packs, stupendous mountain peaks, volcanoes spouting fire and rock, and volcanic islands jumping up out of the sea. Caribou and salmon in incredible numbers and thousands upon thousands of propagating seals. They are all up there, even though they have been somewhat overworked in the more recent travelogues.

CHAIRMAN BUSH: It is certainly a splendid contribution, gentlemen. Do you wish to discuss it? Is there anything further to be said? It seems to me the Commander has covered the subject with infinite care and detail.

ADJOURNMENT

SEVENTEENTH ANNUAL SAFETY CONGRESS
NATIONAL SAFETY COUNCIL

Metals Section

New Section Officers

- General Chairman*—E. G. QUESNEL, Commonwealth Steel Company, Granite City, Ill.
Vice-Chairman—JOHN P. EIB, Illinois Steel Company, Joliet, Ill.
Secretary and News Letter Editor—E. F. BLANK, Jones and Laughlin Steel Corporation, Pittsburgh, Pa.
Program Committee Chairman—E. R. ROSE, Republic Iron and Steel Company, Youngstown, Ohio.
Poster Committee Chairman—H. G. HENSEL, The Youngstown Sheet and Tube Company, Chicago, Ill.
Membership Committee Chairman—JOHN P. MUDD, The Midvale Company, Nicetown, Philadelphia, Pa.
Publicity Committee Chairman—W. E. MEGRAW, H. H. Robertson Company, Ambridge, Pa.
Slide Committee Chairman—JOHN A. OARTEL, Carnegie Steel Company, Pittsburgh, Pa.
Engineering Representative—J. M. WOLTZ, The Youngstown Sheet and Tube Company, Youngstown, Ohio.
Statistics Committee Chairman—J. E. CULLINEY, Bethlehem Steel Company, Bethlehem, Pa.
Foundry Research Committee Chairman—F. G. BENNETT, The Buckeye Steel Castings Company, Columbus, Ohio.
Executive Committee: THE OFFICERS AND
J. A. NORTHWOOD, Bethlehem Steel Company, Johnstown, Pa.
J. A. VOSS, Central Alloy Steel Corporation, Massillon, Ohio.
HOMER J. WEEKS, American Steel and Wire Company, Cleveland, Ohio.
C. M. BRADING, Wisconsin Steel Company, South Chicago, Ill.
T. H. MCKENNEY, Illinois Steel Company, South Chicago, Ill.

Retiring Officers

Chairman, J. A. NORTHWOOD, Bethlehem Steel Company, Johnstown, Pa.; *Vice-Chairman*, E. G. QUESNEL, Commonwealth Steel Company, Granite City, Ill.; *Secretary and News-Letter Editor*, JOHN P. EIB, Illinois Steel Company, Joliet, Ill.; *Program Committee Chairman*, E. F. BLANK, Jones and Laughlin Steel Corporation, Pittsburgh, Pa.; *Poster Committee Chairman*, H. G. HENSEL, The Youngstown Sheet and Tube Co., Chicago; *Membership Committee Chairman*, W. E. MEGRAW, H. H. Robertson Company, Ambridge, Pa.; *Publicity Committee Chairman*, J. A. VOSS, Central Alloy Steel Corporation, Massillon, Ohio; *Slide Committee*

Chairman, JOHN A. OARTEL, Carnegie Steel Company, Pittsburgh, Pa.; *Engineering Representative*, W. H. WINANS, Union Carbide Company, New York City; *Statistics Committee Chairman*, H. G. HENSEL, The Youngstown Sheet and Tube Company, Chicago. *Executive Committee*: THE OFFICERS AND F. G. BENNETT, The Buckeye Steel Castings Company, Columbus, Ohio; T. H. MCKENNEY, Illinois Steel Company, South Chicago; J. E. CULLINEY, Bethlehem Steel Company, Bethlehem, Pa.; J. M. WOLTZ, The Youngstown Sheet and Tube Company, Youngstown, Ohio; JOHN P. MUND, The Midvale Company, Nicetown, Philadelphia, Pa.; E. R. ROSE, Republic Iron and Steel Company, Youngstown, Ohio.

October 1, 1928

J. A. NORTHWOOD, Chairman

Superintendent of Safety, Bethlehem Steel Company, Johnstown, Pa.

The first session of the Metals Section at the Seventeenth Annual Safety Congress was called to order at 12:30 o'clock by the chairman, J. A. Northwood, Superintendent of Safety, Bethlehem Steel Co., Johnstown, Pa.

CHAIRMAN NORTHWOOD: I want to introduce Mr. N. V. B. Zeigler, who is going to lead us in our singing, and Mr. Bill Mahoney, of the Metropolitan Life Insurance Co., who is going to play for us. Mahoney plays every day over WEAJ for setting up exercises.

N. V. B. ZEIGLER (Personnel Director, United States Aluminum Co., New Kensington, Pa.): This is community singing, not solo work. We will probably have some solo work after while. Let's begin with that famous old song, "Hail! Hail! the Gang's All Here."

(The members joined in singing, "Hail! Hail! the Gang's All Here," and other songs.)

CHAIRMAN NORTHWOOD: While we are being served with our coffee I want to announce that the Mining Section has a luncheon in the Waldorf-Astoria on Wednesday, and all the members of our Metals Section are invited to attend.

Our Metals Section's business could not get along without the mining end of the game, and we have a distinguished visitor with us today and I would like to introduce him to this audience at this time. Mr. Robert M. Lambie, Chief of the Department of Mines of the state of West Virginia.

(The members again joined in singing.)

CHAIRMAN NORTHWOOD: We planned this meeting so that we could get a little closer together and know each other better, and I believe it is working out very nicely.

In order that we may know each other and what companies we represent, and perhaps exchange experience, because I believe one of the best things we get out of these conventions is the opportunity of exchanging experiences and talking things over from the safety standpoint, we are going to have a roll call. We are not going to ask the secretary to call the roll, but we are going to ask each man in his turn to get up and state who he is and where he is from, his position with the company and the town.

(The roll was called.)

CHAIRMAN NORTHWOOD: I am sure it did us all good to learn that we have representatives here from pretty nearly all over the country and even Toronto, Ontario. I want to welcome you all here. I don't know how many new members we have who were not with us last year or are here for the first time; but, fellows,

we want you to make yourself known, and if you don't know some of these men step up and introduce yourself.

Let's make it just as helpful and just as home-like as we can this year, and get a little closer together, making our Metals Section go over perhaps a little stronger than ever before.

On our program you will notice the next report is from the chairman. Our Executive Committee are a bashful crowd, hard to get to talk, and at the last meeting they voted that the chairman should make the report for them. I agreed to go along with that, but I am going to call on one or two of these fellows after I read this report.

Report of the Executive Committee

By J. A. NORTHWOOD
Chairman

Your Executive Committee for the year 1927-28 held their first meeting following the Congress, on November 22, 1927, at the National Safety Council headquarters in Chicago. Most of the members, as elected during the Chicago Congress, were present and the year's work was outlined. Various division chairmen reported their activities and their plans for carrying on their particular part of the work.

The program, as presented at the 1927 Congress, was discussed pretty thoroughly and the query, of course, was: What steps should be taken to make our program for this year even more worthwhile?

It was decided that it would be a good thing to have our members know each other and thus become more friendly and be in a position to exchange experiences that would be helpful in their various branches of safety work; and thus the Monday noon meeting, of an inspirational nature, in addition to roll-call, was planned. Just how successful it will be depends on the response given by the members of our section, themselves.

The type of program that we wanted to present to the next Congress was discussed and outlined. As this first meeting was more or less of a preliminary nature, no definite plans were made.

During the year two other meetings were held by the committee; one February 15, 1928, in Pittsburgh, and the other July 14, 1928, at Atlantic City; at which time our program was finally completed and the report of our Nominating Committee for the next year was presented and approved.

During the year we regretted very much having to accept the resignation of C. L. Peake, of the American Radiator Company, who was chairman of our Poster Committee, due to the fact that he resigned from the radiator company and accepted a position as an operating man, and thus could not give this work the attention necessary to make it a success. Mr. Harvey Hensel, of the Youngstown Sheet and Tube Company, Chicago, Ill., accepted this appointment and has since been handling this work.

I am sure we have all enjoyed the good newsy, helpful *News-Letters* that have been issued this year by our genial secretary, John Eib, of the Illinois Steel Company, Joliet, Ill. It's a big job to get these *News-Letters* out in the way that they should be handled and I think Mr. Eib has handled the work very successfully.

Mr. W. E. Megraw, who has acted as chairman of our Membership Committee, has done a splendid piece of work. During the year, from time to time, we received from headquarters a notification of cancellation of membership

of different companies, as well as acceptances of memberships. Mr. Megraw has corresponded with each company, welcoming them to our section and with those who felt compelled to cancel, every effort was made to induce them to reconsider. As you know, our section is the largest section of the National organization, and during this period of decline in business we have held our membership up to par. I feel Megraw is to be congratulated in his efforts.

What the program committee has done, under Chairman Earl Blank, of the Jones and Laughlin Company, will be demonstrated this week and if you like it, tell Blank about it. If you have any suggestions that will be helpful to the incoming officers, I am sure they will be very glad to receive them and do what they can to work them out.

CHAIRMAN NORTHWOOD: I am going to ask Mr. Megraw to read his report.

Report of the Membership Committee

By W. E. MEGRAW
Chairman

The Membership Committee for the past year consisted of twenty members selected with a view of having representation from all those sections of the United States in which the Metal industry plays a dominant part.

I take this opportunity to express my appreciation of the efforts put forth by the members of this committee in this membership work.

The National Safety Council record of membership in this section for the year is as follows:

From September 13, 1927, to September 11, 1928:	
Number of members in Metal Section September 13, 1927.....	775
New members during year.....	88
Cancellations during year.....	75
Cancellations account of consolidation.....	8
Total membership September 11, 1928.....	780

A Net Gain of Thirteen Members

On its face this report is disappointing, but I would call your attention to the fact that eight of these cancellations are due to combinations of one or more memberships under one head; so that in reality we have had a gain of 13 members for the year.

The general depression in the Metal trade during the early part of the year accounts for the large number of cancellations. Many of the smaller concerns forced to adopt stringent retrenchment policies cancelled membership for purely economic reasons. It is notable that none of the larger manufacturers are represented in this group.

CHAIRMAN NORTHWOOD: I just want to say to you fellows that in your district there are companies that are not members of our National Safety Council; you can interest them to come in with us, and they will help us and we hope that we can help them. Just bear that in mind for the next year.

Mr. Harvey G. Hensel, of the Bulletin Committee, who took over the chairmanship of this committee after nearly a half year in which the committee did no work at all, will make a short report.

Report of the Poster Committee

By H. G. HENSEL

Chairman

Late this year, at the request of our chairman, Mr. Northwood, I agreed to carry on as chairman of the Poster Committee; and while I found it impossible to give this work attention as soon as I would have liked, I did finally get started and now have approximately 40 pictures ready for the bulletin editor of the National Safety Council.

I was not told what particular line of accident prevention I was to follow in getting photos for these bulletins, so I chose "Safe and Unsafe Practices."

While we have some photos showing safe and unsafe conditions, these photos run largely to Safe and Unsafe Practices.

It was too late to appoint a committee to assist in the Poster work at the time I was appointed so I called on my own assistants to help, which they gladly did.

During the coming year however there should be a committee appointed so that photos for posters can be furnished, showing items from the various industries represented in the Metals Section.

CHAIRMAN NORTHWOOD: While in New York to attend our National Executive Committee meeting two or three weeks ago I learned that there was a soloist who could be prevailed upon to sing for one of our sections and I immediately asked if she would not sing for our Metals Section. I am delighted to present to you today Miss Gertrude Berggren, of the National Bureau of Casualty and Surety Underwriters of New York City.

(Miss Gertrude Berggren sang a number of songs.)

CHAIRMAN NORTHWOOD: Miss Berggren, I want to thank you in the name of our Metals Section for this delightful music; also your accompanist.

Gentlemen, in looking around and discussing whom we should get as an inspirational speaker as well as a helpful speaker for this occasion, there was one man who seemed to be outstanding. A number of us had heard him and we were unanimous that if possible we would get him for our speaker today. Mr. John Oartel immediately got in touch with him and we found that he was available. It gives me great pleasure to introduce Dr. Charles Herbert Rust as our speaker for today.

Address

By DR. CHARLES HERBERT RUST

Worcester, Mass.

Mr. Chairman and men of this Great Fraternity of Interest in Accident Prevention: I can hardly express to you all that it means to me to come to this happy reunion in New York, and to again meet you whom I have loved for these many years. Men from St. Louis, from Milwaukee, from Pittsburgh, from Youngstown, from Cleveland, and many other cities and towns, whom I have met in this great and divine safety movement. I feel somehow that it is a privilege for me to meet with you men of brain and brawn, of poise and power, of sense and soul, of assets and achievements. I say without flattery that if you take a cross section of men in the Safety Movement and compare them with any men in any class or any profession, including the preachers in this country, there isn't any class who, to my mind, represent more to humanity than yourselves. I count it a privilege to be here with you.

I heard about the preacher who preached to a certain asylum down in Boston. He was anxious to make an impression and he looked out over the great crowd

and found one man who was interested in him, apparently, leaning forward; and in this institution where people were insane this man seemed to have an unusual clarity of mind and appreciated this preacher's sermon. At the close of the sermon the preacher went down to the superintendent and said, "I saw that man come to you and talk with you and evidently he was talking about me; I would like to know what he said about me."

The superintendent looked up and said, "I don't like to tell you."

The preacher said, "Tell me; my skin is thick."

The superintendent said, "Well, this is what he said as he was pointing to you: 'Think of it,' he said, 'he's out and I'm in.'"

Now as I meet you in your conferences; as I talk with you personally; as I get the real drift of your thoughts; as I catch your spirit, it seems to me, without flattery, that you represent just about the finest thing in human life, and I am proud of it. I am glad to have the remembrances that I have of Pittsburgh and other places.

It seems to me that I left that Pittsburgh district too soon. I love New England. I was born there. I love its hills, its rocks, its rivers, its lakes, and its mountains. I do love the clarity of the air. Just a little bungalow on the hill down there in Worcester, and the sunshine certainly does throb. I love its stability, its traditions. I love its history. I love all of it. But, do you know, with all of that—and I am having a good time there, too—I do appreciate the district that you represent and the humanity there and the struggle of the great metals division, the life of the nation.

It makes me think of what a fellow said when I left. He said, "Rust, you're going down to New England. How can you leave Pittsburgh? Think of it, you are going to that cold, conservative, awful place, New England!" As Cameron, of the Safety Council, said to Blanchard, of Springfield, "Blanchard, I can characterize New England. You never do anything first. Never! You always wait to see what the other fellow has done."

So this fellow said to me, "Think of going to that cold, awful, conservative New England." He said, "They may get together down there, but they always get together by freezing together." He said, "Pittsburgh may have the smoke, but, thank God, we have to have fire to have smoke, and we have got it!"

I realize, gentlemen, that in the great field of industry that you are representing there is smoke; but there is fire; and better than the fire which comes to us simply from physical combustion, or the consciousness of the burning up of brain power, I am conscious of the fire of soul; I am conscious of the animation of personality. I am conscious of something that you men have that makes you masculine and strong, and you represent the fire for humanity. It is there, and I am proud of it!

The accident idea is a great and noble one. It was born in the mind and the lucid brain of the members of the Illinois Steel Company, represented by Mr. Eib, and of other members here; and no wonder they are proud out there that they gave birth to it. I was thrilled by it, and they have reason to be proud. We are proud of the people who could follow them. It is a great and noble idea. The accident prevention task is a great and difficult one. It demands everything that is in big men to meet it. Its issues are tremendous. We cannot get away from it. It confronts us everywhere. A man must be at his best to be able to meet it squarely, to conquer it, to put down the dangers that are confronting us everywhere, to prevent accidents and to keep people safe; and as I think of the personnel of the Safety Movement, from the president right straight down through all the great companies, every safety manager, I feel that you have gathered together a group of men who are able to put over a great task.

The accident prevention problem is ever present and a persistent one. You cannot get away from it. I cannot see any end to it. With the increasing number of

cars, with the complex problems of production increasing every day, no wonder we have 25,000 killed in industry. No wonder we have 95,000 killed altogether.

There were only 78,000 Americans killed in the whole European War, 78,000 from America. That was all, and yet we are killing 95,000 every year through accident. They meet us at every turn of the road, in every shop and every mill. Every safety engineer must be on the alert. His mind must be keen. His body must be well cared for. He must come to his task fully fit, or he isn't able to put it over, and I am glad we have such big men who are doing it.

I was thinking of a peasant who walked up from a certain station in Ireland to a friend's house and then back to the station; and he stood there on the platform and listened to some Irish peasants talking, and he heard one of them say, "Where have you been?"

"I have been over to Kilmary; and where have you been?"

"I have been over to Kilpatrick, and where are you going?"

"I am going over to Kilmore."

And he said, I'm going back to England.

As you look it over, it seems that there are many epidemics of killings; it is there on the street and in the factory and everywhere. So that the problem is a persistent one. But the results are tremendous and glorious. Think of U. S. Steel being able to chronicle in less than fifteen years a reduction of 88 per cent in accidents! Think of it! Think of the Clark Thread Company putting down on their books ten million labor hours without an accident in any factory. I say that that achievement is almost beyond thought.

Think of the Union Pacific Railroad Company having a record in the last ten years of diminishing accidents so that they can say: "There isn't any railroad in the country that can report anything one-fifth as good as the Union Pacific." And so all through I realize the reports that are coming in.

Mr. Cameron wrote me and said, "I have just been to a celebration in a town of 3,500. They have 450 people in a certain mill and for three years they have had those 450 men working without a single accident. Recently we had the whole town come out to a celebration.

You can give these same results. Men from Pittsburgh have been telling me all about it, and men from other places have been telling me. So as a preliminary today I would like to congratulate you upon the glorious achievement in the work which you are doing. It is worth while.

How glad I am to talk with some of them like Mr. Morey, of the Commonwealth, who represents the great company of managers today who are humane, who have a big, broad viewpoint, who understand what it means to struggle through life, whose hearts are tender, and yet scientific and efficient. To have them say, "Yes, we are assuming responsibility. It is up to us."

A great change has come. Once it moved in the realm of sentiment. Once it moved in the realm of toleration. Once it moved in the realm of mere mechanical and economic efficiency. Somehow today it has moved out into the realm of a definite constructive, executive objective. So that managers are saying, "Our whole business as a proposition is a failure if we are constantly killing men." So they put their brains and the brains of their managers together, and they have said, "Yes, we are responsible; it is up to us and we have got the brain to meet it, and the soul to meet it and we will do it." And I am happy in that report at this hour.

Another phase comes to my mind. We all recognize the responsibility of seeing the need of safety work and adopting methods and devices for safety development; but now this comes to me. Mr. Howard once said to the safety managers of the Commonwealth Steel Company, "I would like to have you remove all these danger signs around here, just as fast as you can. I want the whole plant of the Commonwealth Steel Company to be absolutely free from danger!"

Tremendous idea! And then the young man looked into the face of Mr. Howard and said, "Yes, Mr. Howard, but don't you realize that the primary danger in the whole business is the man himself!"

You cannot have the mill safe without men being safe; you cannot have men safe without the man himself being safe, and you have got to have the mental and the physical and the social condition in that man himself which makes him absolutely master of a dangerous proposition. It is for him.

The manager of one of our greatest railway systems recently said to me, "Do you know we have gone through the records carefully, and we find that 70 per cent of the accidents in our whole organization are caused by 30 per cent of the men? One-third of our men are producing 70 per cent of the accidents, which proves that the man is the key; that he isn't safe. There is something in him that doesn't prevent accidents, and we have got to get at him."

So once the whole safety movement—we'll say, ten, twelve, or fifteen years ago—was a movement of sentimental exultation. Then it became a mighty movement of scientific device, and we put a safety device here and there, and all of these legitimate devices cannot be perfect. You must have evolution. An idea is born. You use it the best you can and through its use suddenly all the ramifications come to you and you see what it needs to be.

Now we have changed. As a great man said to me, "We have gone beyond it. We do exult. We have our safety devices, but now we are pressing everything upon the individual man himself. We are seeking to educate him to be safe, whether he be on the street or in the home or in the shop, or anywhere, and that demands a condition."

You know, men, the most dangerous part of the automobile, don't you? The most dangerous part of the automobile is the nut behind the steering wheel. And the most dangerous proposition throughout any plant is the man who isn't what he ought to be, mentally and physically and socially.

One of Rockefeller's best stories is like this: He was in an insane asylum and he heard them say: "Do you know we had a group of visitors here last week, and one of our inmates got out and got upstairs to an open window. He stood directly over the entrance of the insane asylum, and he poured almost a whole pailful of hot water upon several people that were coming in. We got hold of him, of course, and got him down, and said, 'Why did you do that; what do you mean?'"

"He replied, 'I decided that if I was going to be an idiot I might just as well be a hell of an idiot.'"

Do you know, friends (I say it absolutely sincerely), there are people who are hells of idiots, and there are men who are in just that condition. That is one reason why we have accidents. There is a man in one of our great Carnegie plants who yelled to a fellow, "You fool up there! Stop! Use your head. Here's where safety begins. It is up to you," and he was right.

In a great match factory a while ago, a man told me of a certain boy who came there to sell fire extinguishers. He had never been in a match factory before, and he was dead in earnest. He said, "I have got something with which I can put out any fire in an instant. Start a fire and I'll show you."

The manager knew he could not, but he said, "I'll take care of you," and so he arranged with the men in the different departments to be ready for him. He said, "I know this boy with the fire extinguisher cannot do it and when the time comes be ready to put that fire out and be sure to turn the hose on him, because I know that he doesn't know what he's talking about."

Did you ever see a fire in a match factory? They started that fire and it went like that, and the little fellow got the fire extinguisher and began to work and saw it was getting beyond him, and he said, "I don't believe I can do it."

The manager said, "I knew you couldn't," and they turned the hose on him. He was the menace. It was his condition. He was the danger. He wasn't right.

Knowledge is the master of everything, and knowledge is salvation if you know how to use that knowledge. If I were talking to a thousand men, I would like to have them just feel the glory of escaping a condition in themselves which makes them a menace to their firm, a menace to themselves, and a danger everywhere they go.

Men, it isn't fair for a man to come to a shop at seven or eight o'clock in the morning in any condition of mind or body or spirit which makes him dangerous to the man next door, to the man beside him, to any part of that plant. It is up to him when he comes there to come with the phosphorus in the brain, with the iron in his blood, with his mind clear, with his body just a little over par, so that he can act like a man all the way through.

Another menace is the fellow who is drinking hootch; and I am glad that you have such detectives at the gates of your places who can detect the breath, and who insist on making the fellow who is the least bit drunk go back home. As a manager said: "The men in our factory won't work beside a man who has been drinking. We have trained them to it. It is too dangerous."

The sick man is a liability. He has dyspepsia, or something else, a sluggish liver, and he cannot act quickly in an emergency. Something happens. He isn't physically fit and he becomes a liability.

It reminds me of a fellow the other day who slipped on a banana peel and sprained his ankle. His wife was excited and said, "Shall I send for a doctor?"

"No," he said, "send for a veterinary. No one but a jackass would ever do a thing like that." And you know sometimes it does a fellow good to come right down to himself and see how darn foolish, how utterly absurd, he was to be in that condition, which makes him a menace through the factory.

The dissipated man; the man who dissipates anywhere; the man who knows that when he goes to bed at midnight he has so diminished his power that he cannot walk out of his home the next morning at seven o'clock all there. He cannot do it. He is dissipated. It is not fair to the firm for whom he works. It is not fair to his family and to himself, and that is the reason why these accidents occur.

Then again this is true. It is the chance getter who is a menace. Do you know, outside of New Haven we have one of the finest lines of traffic anywhere in New England, anywhere in the United States, on that Boston Post Road, where they have laid nine miles (I think it is) west of New Haven a perfect road. Six cars can move on it. Now remember, gentlemen, they have had that only nine months, and in the first nine months twenty-five people were killed on that nine miles.

It is up to us. The Yale boys were racing and others were racing. So in the last analysis, build your roads as wide as you choose, put all your devices up wherever you think best, all through your factories and city. What we need is education of our men which makes them see that they are the ones to be kept fit, and they are the ones to be kept perfect, so that nothing in their lives shall endanger anybody else.

Then just one other. The tired man is a danger. A great man said to me a while ago (a man who has thousands under him): "Do you know, we have checked up this proposition, and we find almost always that the men who were caught in an accident, who did not act quickly, who couldn't solve a problem quickly—we found that those men were working overtime after they left our place. They were taking on extra jobs in the evening and working until midnight, and they never came to us rested. Never."

So I have outlined to you, gentlemen, the fact that it is the man himself who is the menace. It is the child. The woman herself. The individual. And our great question, as we talk to them in the shops, and as we meet them on the street, is, do they have within them an inherent sense of responsibility which makes them feel they must keep their minds and bodies and everything about them fit to meet

the problems of every day so that, not only they themselves but everybody else around them may be safe?

So you are in a great campaign of education, and I am proud of it.

First, the man must keep his brain fit. One of our ablest neurologists said the other day that the brain, which you have and I have, has in it 9,200,000 little cells; and the ability to think reveals this. Any man right here may use those 9,200,000 cells in a variety of 30,000 combinations to meet any exigency of life:

Did you ever look through the old kaleidoscope? Did you ever take that kaleidoscope and watch those little glasses as they fell together in remarkable shapes and iridescent colors; how beautiful they were, and how wonderfully they came together! The coalitions were so perfect. Oh! If you could look into the brains of people who can think—who can size up a situation because they are well—who can meet any emergency! If we could watch the combination in a man's mind when he says, "This is the thing to do."

Now those brains were given to me and were given to you in order that we might keep ourselves fit, and you cannot keep your brain fit if you don't have iron in the blood; you have got to keep your body up to par; you cannot wear it out. It has got to be kept there to keep the mind fit.

Then again you want to keep your liver fit, too. There is a good deal dependent upon the liver, and I find some people don't think so. One of my best physical training directors, Roberts, of the old Y. M. C. A. in Boston, said when I was only sixteen, "Get a hold of that liver every morning and squeeze it for a few minutes. Keep your system clear and keep your body free from contaminating toxins, so that the mind is never clouded; and you can move through life like a man who is all there." Oh! I have never forgotten him. What we need today more than birth control is girth control. Keep it down. The nearer you can keep your body to what it was when you were thirty the better you are. Isn't that right? Keep it down.

Then the next thing to be safe is this: keep your vision clear; your vision perfect so you can see. Representative Barkley had returned from an European trip to Paducah, Kentucky, and he told of his trip through Europe. I think he visited ten countries and he told about all the sights that he had seen. Back in the audience was an old Kentuckian who had been drinking some, and he said to Representative Barkley, "Can I ask you a question?"

"Certainly."

"I just got one question I want to ask you. You have been telling us all the things that you seen. Tell me, did you ever have delirium tremens?"

And Barkley said, "No, I never did."

"Well, I want to say that you ain't never been nowhere and you ain't never seen nothing!"

Now, fellows, I am not advocating you to have delirium tremens, and there isn't a man here who would go to any such extreme, not very many men in our factories. But there it is, half a vision or seven-eighths of a vision. Keep our bodies up and every part of us fine and fit as real men, as people who work, and who are putting over the great production problems of this world.

Think of the steel. I belong to the Universal Steel Company. I believe in it. I am trying to put girders in where men need them. Keep your vision clear, so that no one can get the best of you and you can meet every problem.

Now lastly, gentlemen, somehow this feeling which I have now makes me feel very tender. Oh! Men, we are in something bigger than steel or metals. We are in something that is tremendously human and wonderfully divine. Keep up your moral consciousness. What do I mean by that? Morality in a simple sense means relationship and a true estimate of the values of human life. You are moral as you are rightly related to every other person. You cannot be moral if your con-

dition isn't fit to keep you related. If you are a danger, a menace to other people, you cannot be moral.

Tell the men that. Tell everybody that. In order to be moral we must be right in relation to them, and we must respect the value of a child. My soul was almost torn to pieces the other day in Worcester by a dear little kid that rushed across the street. It wasn't the driver's fault, but the truck's rear wheels went plumb over his head. Suppose it had been your boy! Suppose it happens in the factory, to some fellow that is dear to you!

I say to you this safety business is anything but some little cold-calculated business proposition, purely economic. This safety business is ramified, shot through and through with a feeling for humanity. We are estimating the values of human lives. We are protecting the homes. We are giving men longer lives. We are making life worth while. In the language of Harry Lauder—I'll never forget it—one day when walking down the street, he was asked, "What does it mean to live?"

I'll tell you what it means to live. God? Yes, respect for some power that is bigger than we are. Dealing rightly with the other fellow every day. Giving him a chance, protecting his life, keeping him safe. Doing your work faithfully in the factory or shop wherever you are. Coming to the end of a day feeling that you have done a good job and you have endangered no man. There has been nothing in you that could endanger him. You have been master of every situation. Coming home to your night's supper and supping with your bairn and your wife; and going across to the next door and sitting with Jock and smoking your pipe; and in the evening after all is over, giving Jock a good shake of the hand and pushing your hand way up in his, and saying: "Good night, Jock. See you in the morning." Then going to bed and resting with the angels and getting up the next day and walking down the street—fit, absolutely fit for your job. Not endangering life, but saving life.

CHAIRMAN NORTHWOOD: Your committee did not make a mistake in choosing the man to make our inspirational talk. I just wish that we had ten times as many safety men in this room to hear this talk. It is something for us to take home. To fight hard and to work hard!

Doctor Rust, in the name of our Metals Section, we want to thank you for this stirring talk. It has been worth while.

We will now have the report from Mr. H. G. Hensel, chairman of the Statistical Committee.

Report of the Statistical Committee

By H. G. HENSEL
Chairman

My work as chairman of this committee has been to cooperate with the Headquarters of the National Safety Council in the gathering of statistics, and the results are clearly outlined in the pamphlet entitled: "Industrial Accident Experience of Members, National Safety Council, 1927."

No doubt all members have a copy of this pamphlet. If not, same may be obtained by writing to the National Safety Council, 108 East Ohio Street, Chicago, Illinois.

The first page of this pamphlet gives us the facts of major importance that are revealed by the Industrial Accident Statistics tabulated by the National Safety Council for 1927, and as reported to them by 2,089 establishments.

The purpose of this printed report is threefold:

1. To enable each establishment to compare its own record with the records of other establishments in the same line of business.
2. To provide a typical cross section of the experience of American industries so that the national trends of lost time accidents may be studied.
3. To convince skeptics that accidents can be reduced through organized and well directed efforts.

All members of the Metals Section should be specially interested in the part of the report covering this Section. The Metals Section report is found on pages 14 to 20, inclusive. A brief outline of some of the important features of this report are as follows:

1. 450 establishments reported for 1927, 318 in 1926. Increase 42 per cent.
2. In 1927 326,362 employees worked 818,618,172 man hours.
3. The 450 establishments are divided as follows:
 - 7 Coke plants.
 - 9 Bolt and nut manufacturing.
 - 29 Structural steel fabricators.
 - 28 Gray iron foundries.
 - 14 Malleable iron foundries.
 - 73 Machine shops with foundries.
 - 101 Machinery and machine tool manufacturing.
 - 15 Railway car manufacturing.
 - 82 Steel plants.
 - 21 Steel foundries.
 - 23 Tubular products manufacturing.
 - 32 Wire manufacturing.
 - 16 Miscellaneous metal working companies.
4. 1927 average frequency rates = 26.59. Average for 5 years previous equals 36.06. Reduction 26 per cent.
5. 1927 average severity rate = 1.85. Average for 5 years previous equals 2.23. Reduction 17 per cent.

In closing I would like to urge all members of the Metals Section to report for the year 1928 a summary of their accidents to the National Safety Council, and if you do not receive a blank form for that purpose, write to the National Safety Council for it.

I am advised that all reports for the year 1928 should be in to the National Safety Council Headquarters by February 1, 1929.

ADJOURNMENT

October 2, 1928

J. A. NORTHWOOD, Chairman

Superintendent of Safety, Bethlehem Steel Company, Johnstown, Pa.

The second session was called to order at nine-thirty o'clock by the chairman, J. A. Northwood.

CHAIRMAN NORTHWOOD: We promised to get started right on the dot and we are going to have a couple of songs to get us in real good trim this morning. (The members joined in singing a number of songs.)

CHAIRMAN NORTHWOOD: I have one or two men whom I want to introduce to our Metals Section. We have one or two of the old guard who left our safety game, and boys when the safety game gets into your blood, it just cannot get out and they are back in it again.

I want to introduce Mr. Jack Mulligan, who is one of our past chairmen of the Metals Division.

MR. MULLIGAN: Mr. Chairman, glad to meet you again; boys glad to be here.

CHAIRMAN NORTHWOOD: Mr. Gibson was a past chairman of our section and has been out of the game for a while. Mr. Gibson I would like to have the fellows know you.

MR. GIBSON: I am standing as high as I can stand.

CHAIRMAN NORTHWOOD: We are mighty glad to have them back in the harness again.

Now then fellows to get down to business. We are here all together in a good spirit on a serious matter, and I wonder some times if we realize how serious it is when we have a congress of this kind with 5,000 to 5,500 men and women gathered together for one purpose, and that is to protect lives. It takes in all branches of the safety game from one end of the country to the other; and yet with it all our accidents are going up—particularly our highway accidents.

It means, as I see it, that those of us who are in industrial safety, who are more or less trained in getting the game rolling from an industrial standpoint, are going to have to take more active interest in our public safety work. It means that we have to get in the game and push with all we have.

We have with us this morning a very outstanding man, a man that you are going to be mighty glad to hear. We are going to handle our subject from the various phases and Mr. R. M. Roosevelt, Vice-President of the Eagle Pitcher Lead Co., New York City, is going to speak on safety from the viewpoint of the management, which means the beginning of things.

Safety From the Viewpoint of Management

By R. M. ROOSEVELT

Vice-President, Eagle Picher Lead Company, New York City

I have been asked to talk on safety from the viewpoint of management. I believe there are many different ideas of management, but management to me is something like a tree. It has roots and a trunk, branches, leaves, and some times bears fruit if the roots and the trunk and the branches and the leaves all work together.

All trees have to start from the roots, naturally, which to me is the workman.

After I graduated from college, I went to work. I think the third day I was at work, I came back from lunch and saw two or three men gathered by a tank car. I went over to see what was the matter and they were pulling a man out of that tank car. His face all around was gone clear to the bone. They laid him on the

dock. I took the pulse to see whether he was alive or not, and it was beating good and strong. They sent for a doctor. I held the pulse and pretty soon it didn't beat any more.

They had missed the man at noon. He hadn't come to his lunch. They had gone to look him up. He had been sent into the tank car to clean it out. There was some sludge acid in the bottom. He had gotten overheated or something and fallen forward into the sludge. I suppose they buried him; I didn't see any more of it. I suppose the insurance company paid the bill. It wasn't on our cost sheet, anyway.

I was nothing but a workman, but I always thought if I got to be anything else that such things would never happen. I couldn't do anything then; there was nothing anyone could do. I had no voice in the matters of management. I couldn't go down to the general office and tell them what I thought. So I shut my mouth, the same as every other workman does.

But in that plant I noticed that while the men were on their jobs when the whistle blew in the morning, I have always said that if the fire whistle blew at five o'clock at night that nobody would stop to see where the fire was; they all go home regardless of what happens. That was my impression of the place when I was a workman.

The New Foreman's Viewpoint

Later on I became a foreman in another plant. That was where I was going to stop accidents. We had a roasting department where we took hot ore out of cars, putting them on little elevators and hoisted them up about fifteen or twenty feet in the air. We shoved the cars off over the tops of bins, pulled a lever and dumped the ore into the bin. I stood about one hundred feet away from that elevator one day. The car went up to the top and a man started to shove it off. He got the front trucks off but didn't have his elevator up within about an inch. He could not get the rear trucks off so he started to hoist the elevator another inch. He pulled the wrong rope and tipped the car up on end. The ore ran down on the ground on his buddy who had helped him put the car on the elevator. It burned his buddy and started to burn the man on the elevator. He jumped and sprained his ankle. The elevator kept on coming down with the hot ore. A third man ran up to grab the rope to stop the elevator and it crushed his foot. In the meantime I hadn't gone fifty feet toward that elevator—I had been about one hundred away to start with.

I was a foreman. I was going to stop accidents and there were three of our men hurt in about fifteen seconds. Well, I didn't know what to do then. But I decided that the men had not had enough practice in thinking for themselves. They had not developed themselves. They needed a little more self-governing. If they had had safety drilled into them the man who pulled that rope would first have made absolutely sure that he had hold of the right rope.

I did a lot of thinking. (Please excuse my reference to what I did. I don't mean to say I. I didn't write a paper on safety. Mr. Quesnel, who is responsible, told me that if I would just come over and talk, that he would forgive me for what I said. So I am just telling you these experiences to show you the process that I have gone through from a laborer on up, and how necessary it is, in order to bear fruit, that the roots and trunk and branches and leaves should all work in harmony.) I educated the men under me to think for themselves. We cleaned house. We put in bathrooms—couldn't get anyone to use the bathrooms at first. (The first man who used the shower baths, we had to carry in with his clothes on and put him in.) But we got them accustomed to the water. They didn't die or anything of that kind, and you couldn't take those baths away from them today with a company of infantry.

I went as far as I could as foreman but I didn't stop accidents. I stopped some of the foolish ones, perhaps, but there were a lot more of them going on.

Every accident that happened delayed the operations. We operated twenty-four hours a day. This one accident I told you about, we were probably three hours getting straightened out, and supplying men to take the place of those injured. In the meantime there were so many charges lost. So much below par; so much below the possibility of that department at the end of the month, and the department which followed and depended upon the operation of that department to carry on.

I felt that if I got to be a superintendent some day, I would correct a great many things that I couldn't as a foreman. One day I was offered a job as superintendent in another plant, and took it. I helped my foremen dispense with accidents, but I found at that time that the foreman never realized how much the accidents cost him. He put another man on the job. The insurance company talked to the man who was hurt. The foreman never came in contact with the cost; he never knew whether the insurance company paid one hundred dollars or one thousand dollars when a man hurt his finger; and it didn't mean anything to him.

So I made arrangements with the insurance company that we would settle our own claims, and settle them fairly to both the insurance company and the man. I found out, by the way, that of the money we paid into the insurance company at that time, only twenty-two cents out of every dollar found its way to the workman who was hurt. The rest went to attorneys, for overhead, to the claim agent, etc.; and I was quite shocked at such figures as those. So we took the thing in our own hands. We kept the claim agent out of it, and the foreman and myself dickered about what we were to pay. That was the first time that we ever began to realize that accidents really were paid for by somebody in cash. We had simply turned it over to the insurance company and that was the end of our worries.

We got along pretty well under those circumstances. But still men were hurt, and the foreman and the men themselves said, "Well, you don't think the men are getting hurt for fun. It hurts them to stay in the hospital a darn sight more than it hurts you, as superintendent, to have them hurt. They certainly are not doing it of their own accord." And I couldn't answer that argument.

Later on I became manager of a plant, and then I carried my own insurance. That brought the cost of accidents absolutely home to us, because it came out of our own payroll. If a man was hurt we put him on the payroll for half-time or full-time; and the amount that it cost to operate that plant subtracted from the amount we received, was the profits. If there were no profits, we had to cut wages or do something else, but there had to be profits in order for foremen or men to get raises in wages. That brought the question of the cost of accidents home to both the workman and the foreman and the superintendents of the plants. We went along for quite a while with that.

Then as the plants got bigger we put in a personnel man who did part of my work and kept tab of the men; working with them on many things. We found that a man who had bad teeth and his system all run down, was more liable to accident, than a man who was in good physical condition. Most accidents happened at the end of shifts—when the man was tired, but if a man who had bad teeth, or was sick any other way the result was the same and we had to examine these men. We finally required a physical examination to start with.

I am trying to confine my remarks to management and not how we did all these things. I am trying not to go into detail.

When upon a physical examination, we found a man who had bad teeth we didn't lay him off but sent him to a dentist and had his teeth fixed up. We found a lot of fellows that were absorbing pus from defective teeth. Their vitality was low and they couldn't think and they didn't care. We gradually worked until we had a gang who were proud of their jobs, because it was—I

won't say an honor perhaps—to work at that plant, but it meant that a man who was working there was absolutely fit and clean in every way. It became so that a girl who knew a man in one of our plants, knew that she was acquainted with a man who was absolutely clean and fit; and it meant that when a head of a family was working at one of our plants his whole family knew, and the merchants and everyone else he dealt with knew, that he was on the square, mentally and physically.

This department continued working along such personal lines; worked in sickness and outside accident compensation, and things of that kind which help a man retain his mental alertness. If a man was out hurt or sick for two months and came back with everyone pressing him for grocery bills, he couldn't have his mind on the work. The result was he would get hurt. You have to have that man so that he can think 100 per cent of his work while he is at the plant. He cannot have family worries; he cannot have bills to pay; he cannot have anything the matter with him physically; and he must have a certain pride in the place he works, and a certain confidence and pride in that company; until you get that you cannot have a low cost of accidents.

We worked along these lines until about 1925 and our cost of accidents had been reduced to about \$12.09 per man per year. That is only one dollar a month for every man you have working for you, and we thought that was quite wonderful. But we hadn't gone the limit yet. We found that could be improved upon, but it couldn't be improved upon except by the men themselves. We had the men clean; we had their minds on their work; but we had to turn still further the management of affairs over to those men so that they would have an increased amount of pride in the records which they made; and we did that.

We appointed the men on committees. We brought about competition. We had sign boards and with discs for each department showing the record of that department each day—green discs if they didn't have an accident and a red disc if they had an accident. At the present time those sign boards have little automobiles racing across from one end of the month to the other. When anybody has an accident, his automobile is turned over the day that he had the accident; and while there may be a certain amount of psychology in that, it is simply to make a man look at the board oftener. But the real thing at the base of it is the pride which he has in his department. We did that in 1925 with a loss of \$12.09 per man per year. In 1926 we reduced that to \$2.69, a decrease of about 80 per cent, by turning things over to the men themselves and letting them run their own business. In 1927 we showed a further improvement and reduced our cost per man per year. When a man hurt his finger, if he went five times to a doctor that was always thrown in. We have reduced cost of compensation and doctors bills to \$2.24 per man per year, and we are still going.

I am telling you this to show you that the management—whatever the word management may mean—has to know how the man thinks, the superintendent thinks and the plant manager thinks; and that all have to work together. The plant manager has to help the foreman, and the foreman has to help the man; and when you get them all working together, as a tree should work together, you can bear fruit.

The cost to the company of these accidents has been a very, very great amount, but it is small compared with the savings in operations by the reduction of accidents and the increase in the health, the increase in the interest the workman has in his company and his plant. That has come about and been built up at the same time we have built up safety work.

I told you that when I was a foreman, there were many shutdowns due to accidents. I suppose that in a department working twenty-four hours, we averaged nearly two hours lost out of the day—that is I won't say two hours out of the day shut down, but if we were supposed to make twenty-four charges in twenty-four

hours, there were probably two charges a day that were lost on account of accident or an elevator breaking down or something of that kind.

Today the man in charge of that same department is allowed one hour and a half a month lost time on that department. Then he gets a bonus of so much a minute for every minute less than one hour and a half that that department is shut down during the month.

We have increased the output of this department; without changing the type of the men. The same man who is foreman of this roasting department today was one of the workmen in the accident that I told you about which happened twenty years ago. We haven't more intelligent men; we haven't men with more education; we have the same type of men. And still, from two hours a day then our shut-downs now are considerably less than one hour and a half a month.

I don't know whether you gentlemen go into the cost of production or not, but any foreman can get 98 per cent efficiency from his department. The extra 2 per cent is your profit, and it is what you get out of that 2 per cent which either makes a profit or a loss to your company on that plant. That is cutting it down pretty fine, and when we get our loss of time down from two hours a day to one hour and a half a month, we have our profits, the entire profit of the plant, on what we have saved in shut-downs. So that the profit of this plant might be said to depend, on the safety work that is going along with it to create a mental condition in the men that makes these time losses so small.

I say that the men have not changed. We haven't hired better men. I remember one accident when I was superintendent of construction. We were building a stack and passing the bricks up in the center of the stack. The man on top was a brick layer. He called down to one of the men on the ground. The man stuck his head in through a hole at the bottom of the stack. The brick layer moved over to talk to him, rushed back and pushed a half dozen bricks off the stack. The man down below was in a trap and broke 3 ribs. The man who caused that accident has no more education than he had that day but is now one of our superintendents, and one of the strongest men that we have for safety.

It is not the men, it is the management that has improved—that has taken the same man and educated him to the place where we can do these things. Today we have numerous ways of noting the change in the men. For instance, I was telling Mr. Quesnel at breakfast this morning that a couple of Sundays ago a man had gone away on an automobile trip about 125 miles. He had car trouble and couldn't get back for work Monday morning. He sent us a wire at his own expense that he was stalled and that he couldn't get back and he would be back at a certain time. He thinks just that much of his job. He didn't have to do that, but he wouldn't think of not being on the job Monday morning when the time came for him to take his shift, without letting us know ahead of time so that there would be a man in his place and it would not spoil the record of his department.

All these things, I call management; and without this management, and without the harmony between its different branches it is absolutely impossible for safety work to go on; and we would lose the benefits from it and they are so great that they are almost immeasurable.

I'll say another thing, that even if your plants are doing very well you must realize there are lots of plants that are not doing as well. I was talking to an old classmate of mine last Friday night and he told me that they had made a survey of a certain district of workmen in the United States and found that between 50 and 52 per cent of those workmen had lung adhesions or something else—spots. I thought that over. So, because certain plants are good, it doesn't mean that they all are. And you gentlemen who have good plants, and the workmen who are working under you gentlemen, must realize that you are not only working for yourselves, but you are working for districts that have not yet gotten out of the

hole. You are working for districts where 50 per cent of the workmen are afflicted with lung trouble at the present time. While in your own plant you may be helping a thousand men or five hundred or two hundred, you may be helping fifty thousand men outside your plant by the example which you set and the notice which you attract to this safety first, by your conventions and the published articles and the example.

CHAIRMAN NORTHWOOD: I want to know now if there is any discussion or any question that you want to ask Mr. Roosevelt. I think Mr. Roosevelt has given us a splendid talk, just the kind of a talk that we wanted, and there may be a number of men who have some questions to ask him at this time.

A. BERQUIST (Youngstown Sheet & Tube Company, East Chicago, Indiana): I would like to ask Mr. Roosevelt if the statement he made relative to that 50 per cent, was the country as a whole or was it confined to the zinc mining industry?

MR. ROOSEVELT: I didn't say that 50 per cent was subject to tuberculosis, because I do not know just what form of lung trouble these men have. I mentioned adhesions, which in my mind does not mean tuberculosis. I mentioned spots which do mean tuberculosis.

The only reason I mentioned this was to show you that there are places where the safety work has not gone on to the extent that it ought to; and while you are working your men and meeting here, you are not only improving things in your own factory, but you are pulling these other districts out of the rut, these districts which you have never heard from before.

H. J. WEEKS (American Steel & Wire Company, Cleveland, Ohio): Statistics prove that 95 per cent of the lost time and fatality accidents are among the foreign born Americans; and I would like to ask Mr. Roosevelt if, from the management viewpoint, a foreman or superintendent orders a laborer to do a certain piece of work, and in the estimation of this laborer it is too dangerous, should he be subject to dismissal for refusing to do the work?

MR. ROOSEVELT: I am trying to find some fitting way to answer your question. I know what the question is, but to say "Yes" or "No" is not a sufficient answer to you.

I remember a case in the war where a certain general came back and reported to headquarters that he had done everything he could to gain a certain objective: that he had laid out the plans; that he had ordered his men forward time after time, and still the objective was not taken. That man, high in rank as he was, was immediately relieved, and another gentleman, who happened to be an engineer, was put in his place, and that night the objective was taken.

I think a foreman or superintendent who orders a man to do anything that he is not willing to lead that man into, that he is not willing to do himself, should be relieved the same as this general was, and some one who will lead the men instead of ordering them to do a certain piece of work be put in charge.

I never ask a man to go in any place that I am not willing to go in first.

A. T. MOREY (General Manager Commonwealth Steel Company, Granite City, Illinois): I would like to ask Mr. Roosevelt if they have periodic examinations or just upon employment.

MR. ROOSEVELT: We have examination on employment. Then we watch our men pretty carefully and the foreman makes a report each month on how that man is doing his work. That is, he rates him 80 or 85 or 93 per cent on a card in the personnel department office.

We don't want to make every man go through a physical examination every month, but that man can go to the personnel department office and see his card any time he wants to see it. And he will see, if he goes there once a month, exactly how he stands with his foreman. On that personnel card the average or the rating is gotten from five different parts. That is, such as workmanship. I can-

not remember those things off hand, but they have the workmanship, the way he gets along with his fellow men, his disposition, and such things as that on that card; and then these are all averaged up and the total average is the standing of that man.

Now if that man's standing drops down, there is some reason for it. If he doesn't come in to see his card of his own accord, the personnel man sends out for him and shows him the card and asks him what the trouble is. If he says he has not been feeling well, he is sent to the doctor and it is found out why he has not been feeling well. If he has family trouble, the personnel director may go and see his wife. When I was doing that work I settled quarrels with one man's family as many as three times in one month, but I had to do that to get the desired efficiency out of that man. So that is the way we keep tab on the men without the necessity of putting them through a physical examination every month.

TOM McCARTUS (Standard Steel Works, Burnham, Pennsylvania): Mr. Roosevelt spoke about the company getting the men's teeth fixed up and putting him in a general state of good health. Was the cost of this included in the cost of accidents that he mentioned, or did the men pay for this out of their wages?

MR. ROOSEVELT: The cost of taking care of a man's teeth or sickness is not charged to the cost of accidents. It would not be fair, I think, to charge bad teeth or diphtheria, or any other disease, to the cost of accidents.

L. O. WHEELER (Union Carbide Company, Niagara Falls, New York): I would like to ask Mr. Roosevelt regarding the \$2.24 cost; how many men that covered?

MR. ROOSEVELT: That covers a plant. It doesn't cover our whole company. It covers the plant which I had charge of before I came to New York; and that covers from 200 to 250 men, according to whether production is going on or not.

S. E. SANKEY (National Tube Company, Elwood City, Pennsylvania): Can a manager or a safety department put safety over if the manager doesn't think more of the men than he does of the output?

MR. ROOSEVELT: I told you that management was like a tree. If you plant a tree in an orchard and it doesn't bear fruit within the first six months, you have to keep on watering it. You have to take care of that tree. You have to keep the ground spaded up around the roots. You have to keep the bugs off the trunk and you have to keep disease from getting in the leaves. You have to baby it just the same as you would a baby of your own before you can ever hope to get any fruit off that tree.

Now some people can cultivate other people. By that I mean, they can appear to be friends to them when they really are not, in order to get orders from them. I don't think that such a thing really can be done successfully. You have to like a person in order to mix with him or that person (unless he is dumb) will see that you are trying to cultivate him. You have to like a workman in order to take the proper care of him. You cannot dislike him.

If you have been a workman, as I have, and a foreman, etc., you can never be anything else except part workman and part foreman and part superintendent and part manager. If you have come down from the top, I hardly know how you can ever be successful in handling men. On the other hand it is possible for a man to think too much of or spend all of his time on the workmen without regard to whether the tree ever bears fruit.

If I should answer your question by saying he has to think more of the workman than he does of the output, or more of the roots than he does of the fruit, I don't think that would be a correct answer. Sometimes you have to top a tree to make the roots spread; sometimes it all goes to roots and you will never get any top or any fruit. There has to be a balance between these things.

MR. SANKEY: That is good for small companies, I am sure. Is it not your fertilizing that brought you up to think and put this safety over, as you say in your feeling for the man? Aren't there many managers who cannot see the neces-

sity for fertilization until they see the distress brought down to them?

MR. ROOSEVELT: I don't think anyone is capable of commanding unless he has served.

Now I'll go still further: when I first became foreman and had a very small plant I knew every man who was working for me by his first name. I knew his wife and I knew his children and all of his troubles. As I began to get more duties and went out of town a great deal, I could not make the contacts with these men the way I wanted to. That is the point where the break between what some people call "management" and the workman begins.

With me, I would not stand for the break, so I took a certain man and put him in as my personal representative with those men. Now that man handles about 95 per cent of the contact work with the men that I would like to do, and that I once did, but which I no longer have time to do. About 5 per cent of those things are a little too delicate or a little too important. They might establish a precedent or something of that kind, and he has to bring me in to consult on them. But he can take a great number of things off my hands, since he knows me well enough, and they can be decided upon without bringing them to my personal attention.

When I first put that man in I told the men that he was their attorney, that he was their pit committee. I have never had such a thing as a strike in my life, but if such a thing should happen I would send that man away until the strike was over. Then he would still be their man and not the company's, and would represent their side of the case to me. He would be their spokesman primarily, although he could not help but be my spokesman when he took my answer back.

CHAIRMAN NORTHWOOD: I think this discussion is very fine and we have received a lot from it.

STEPHEN KOROCO (Pittsburgh): One more question with respect to this address. You say from the management standpoint that you got to know your men, and that to get efficiency you must know your man by his first name and you must like him.

I would like you to explain, Mr. Roosevelt, about if a man is injured, instead of being discharged, he is taken into the roasting department. What do you mean by that?

MR. ROOSEVELT: The roasting department was the department in which the man referred to was hurt. The roasting department is not a department where we roast human beings.

I said that when I was foreman in this roasting department and men were hurt, that there was nothing that you could say to those men. It was the system that has wrong in some way. That they had not been educated to use their own minds, they had not been taught to think; they had not the proper safety consciousness.

If a man is safety-conscious and there are two ropes, he will be sure that he is pulling the right one, instead, as that man did, to grab either one of them. But it was the fault of the management that the men hadn't this safety consciousness; it was the fault of the management that the men had not been taught to think for themselves.

Today a foreman is not supposed to instruct a man how to do each one of his daily tasks. For instance, I never send out word and tell the foreman to do a certain thing; I never expect that foreman to tell the man to do a certain thing. I expect to tell that foreman that it is necessary to do a certain thing because we have a shipping order or something that makes it necessary. The foreman is supposed to know his job, and he is supposed to take whatever action is necessary; and I don't want to insult his intelligence by telling him what action to take.

When he tells the man that we have to get out twenty-four charges today, he tells him why. He doesn't tell him to go and take out twenty-four charges. He says that we are behind twenty-four charges, and need them to keep the furnaces run-

ning. We don't insult that workman by telling him what he has to do. We tell him the need of the action and we believe that workman is intelligent enough to do it.

We never fire a workman. That would be foolish. I don't think there has been, in this plant that I am talking about, a workman fired in the last ten years. Not one. A workman who cannot get along with one boss, comes to the personnel department and he is given to some other boss. If he cannot get along with that boss, he comes back and he is given to some other boss, and we try to find the notch or the hole in which that plug will fit and work. If after we have done that four or five times, there is no hole in which that man works, he will come into the personnel man, "Well, Jim, what the ——— is the matter with me?" And Jim will tell him what is the matter with him; and he will either correct it, or say, "I have tried to correct it and there is only one thing for me to do and that is to quit." But a man is never fired.

A man coming to the plant is carded. He is asked his ambitions, and there is a record kept of them. Different numbers for the different departments are put on the cards. If his ambition is to get an office job, he is tagged No. 1. He never needs to apply for a job in the office. Whenever there is a vacancy in the office, we go through the cards of these men who are tagged No. 1. There may be seven who are tagged for office jobs and we will pick the best. If the other fellows come in and say, "Why did you pick Jim instead of me?"—we will tell them why we picked Jim; and that if they would correct these things, maybe they would get the next chance. However, we never fire a man. That has passed out of existence years and years ago.

CHAIRMAN NORTHWOOD: We would like to continue this discussion for another hour. I know that it would be worth while, but we have the rest of our program to follow out.

I want to introduce our next speaker. We have heard from the plant manager's standpoint. The next speaker is the foreman. We are going to hear something from the foreman's standpoint from Mr. Dominic Samuel, foreman at the Youngstown Sheet and Tube Company, Youngstown, Ohio.

Safety from the Viewpoint of Supervision

By DOMINIC SAMUEL

Foreman, Tube Galvanizing Department, Campbell Plant, The Youngstown Sheet & Tube Company, Youngstown, O.

With the difficulty I experience in expressing my thoughts in English I hesitated for some time before accepting this invitation. I also feel that the men speaking before this convention are specialists on safety, and as I can only offer a review of safety as it applies to my own department it may be that many of my remarks are repetitions of safety ideas brought before this council on previous occasions.

Right at this time I wish to say that when this safety drive first started in earnest, our management, through our superintendent, instructed myself and other foremen what was expected of us, advising us also that we would be held accountable for the safety of our men. He also advised us that his office would give every possible assistance and backing, and explained that the safety first idea was to be given preference over production.

I am foreman in the tube galvanizing department, Campbell Plant, of the Youngstown Sheet & Tube Company. To those of you who are not familiar with the procedure in a galvanizing department I will mention that we have, as major hazards, caustic soda, salomoniac, muriatic and sulphuric acid, and also molten spelter to contend with, and until this safety first drive was in force the appear-

ance of the accident investigator was a daily or weekly occurrence in my department.

From my own experience, bringing this thought to sub-foremen and men was no easy matter; their idea at first being that it was only a fad and that it would soon die out. Needless for me to say that after attending meetings conducted by our superintendent, my ideas were different. As a foreman it was my duty to carry out the instructions of my superior, and I went into the matter heart and soul to eliminate as far as possible the hazards in my department. It was not long until I realized that our most serious hazard was the attitude of my men toward safety, and after making a few mechanical safeguards I set out to drive home to each man a safety thought.

After a short while I specified that on a certain day and hour each week I would conduct a safety meeting and advised the men that they would have to attend. What transpired at these meetings was recorded and a copy of the minutes was sent to the superintendent and the safety director. At these meetings I explained to the men the hazards of their work and how they could best guard themselves against danger. I explained the actions of the different acids used in connection with galvanizing, and how this material coming in contact with their bodies would cause serious burns, and how easily eye sight could be destroyed. With the exception of very few, the men in my department are compelled to wear goggles. In order to keep safety on the minds of my men I also placed signs at each pot bearing helpful safety suggestions.

As many first aid ideas as possible have been demonstrated at these meetings and on several occasions application of these ideas have been beneficial. Just recently the clothing of a man in our department caught on fire and, as seems to be the natural thing for many men to do, he started running; but one of his fellow workmen remembered the teachings as conducted in my office and immediately grabbed him and threw him to the floor, smothering the flames with his own coat. These acts are also given consideration by our management and this man was given a silver medal, and his act given publicity throughout the plant.

My men have all been instructed to be on the lookout for hazards and to make a report of conditions that they think can be improved upon. It is not unusual for my men to speak to their fellow workers if they, in their mind, think that they are not following the safety first ideas and practices as closely as possible; and I have had men report to me on several occasions where these men have resented having their attention called to this matter. I then make it a personal matter to caution these men, and if I could not thoroughly impress them with the importance of safety they did not remain long in my department.

I notified my men that, owing to the possibility of acids splashing, they would have to wear high top shoes and that the soles would have to be in first class condition. Inspections were made to see that these instructions were complied with, and if a man reported with shoes that were not in good condition he was immediately sent home. I do not hire my men direct. My calls for men are placed with what we call the "labor department," and it was only a short while until the foreman in charge knew it was useless to send a man to my department unless his shoes were in good condition.

Safety discussions at our meetings were not confined only to our own department but covered entering and leaving the plant, and also urged that the safety idea be carried back to the home. They were urged to explain the first aid ideas and artificial respiration to other members of their families. Men were cautioned that if they were placed in some different work that they were not familiar with they were not to proceed until they had been thoroughly instructed concerning the hazards of the job. Where men have been instructed concerning these hazards and violate instructions, even though no accident occurs, they are disciplined. I sometimes suspend or dismiss them depending on the attitude they take towards safety, or sometimes demote them.

It is difficult to explain here the proceedings of these meetings and the various items that we discuss, but everything that concerns safety as it applied to this department was given consideration; and, as stated before, my men did not take safety seriously at first but it was not long until they all realized and fully appreciated what we were driving at and they took a very active part toward furthering safety first. With all my men taking this active part in safety it is needless to say that accidents have been almost entirely eliminated and during the past year I have not had a lay-off case in my department.

In closing I want to say that I think we should talk to our men on the job, be careful to see that new men know how to do their work safely and right; and in our talks, go over and over the same safety ideas, told a little differently each time. I am voicing the appreciation of my men and myself for the insistent stand that our company took on the safety question, and I also thank this National Safety Council as the originator of this great move.

CHAIRMAN NORTHWOOD: We certainly want to thank Mr. Samuels for this paper. We have now heard from two sides of the game, the supervision and the management. Are there any questions you want to ask?

We have a question that was asked. "Have we yet outgrown the fatalistic idea that some accidents are inevitable? Do men control accidents or accidents control men?" I wonder just what your reaction is to those questions.

R. M. ROOSEVELT (Vice-President, Eagle Pitcher Lead Company, New York City): I do not think there is any such thing as luck. That is a personal opinion. The fellow that is lucky is generally the fellow who gets down and does some hard work, and I think I would stake a fellow any day that works hard against the fellow who trusts to luck.

If there is no luck, then accidents don't control the man. The man can control the accident, but he can very easily get careless. If he doesn't have any accidents for a long time, that's the time he has got to watch his step. Throw out your cautions and tell them that they have not had any accident for a long time, and you may be sure that some one is going to get careless; and generally he gets hurt pretty badly.

I have been all through this thing of the men saying that they don't get hurt of their own accord, because certainly they are the ones who get the worst end of it.

For example, we had a mechanical department and when we began analyzing we found that the mechanics composed about ten per cent of our plants and were having about 90 per cent of the accidents. They said that their duties were very hazardous, and that they could not get along without the accidents.

We didn't want to fire any of those men, but we posted the names of the fellows who were having accidents. That made them as sore as boiled owls. But those men whose names were posted quit having accidents. I don't know whether it is luck or what you call it, but our mechanical department that used to have 90 per cent, on September 7th, had gone 974 days without a single lost time accident.

CHAIRMAN NORTHWOOD: There is a whole lot in what Mr. Samuels said, getting the story right to the man down the line.

L. O. WHEELER (Union Carbide and Carbon Company, Niagara Falls, New York): I would like some information on safety committees. What they are worth and what they should do and how many there should be to a plant. How long a man should serve on a committee. This has worked out very well at our plant, and I want to get a few ideas, if there is any such thing.

Today we have a record we hung up last Saturday, 1,200 men in our plant working ninety-eight days without a minute of lost time.

J. M. WOLTZ (Youngstown Sheet and Tube Company, Youngstown, Ohio): I have here in my hand a report of the auditors of our employees' relief association that might contain some interesting information.

This organization is composed of the employees of the company and there are 11,873 in the Youngstown district who are members. In looking over these schedules I found that last year there were 88 deaths out of these 11,800 employees. They schedule 11 of those 88 deaths as accidents. Three of those are accidents that occurred in our mills. Eight fatal accidents occurred outside of the mills. Those were automobile accidents, street car accidents, and in two instances hunting accidents where guns were discharged and the men were killed.

Among the various things that we have been trying to put across to our men is the fact that their own work in the plant in reducing accidents and fatalities, makes our plants safer places than the streets and the home and we are using this report to show them that our statements during the last two or three years bear some measure of truth.

G. H. McCLAIN (Johnson and Laughlin Steel Company, Pittsburgh, Pennsylvania): We have a plant in Pittsburgh, called the Southside Plant. It is thirty months tomorrow at ten minutes to four since they have had a fatal accident (unless something has happened since I left home); and in that time we have positive proof through our employment office and elsewhere, of 12 fatal accidents having happened elsewhere to our employees of that mill on the South Side. There are about 5,800 men on the payroll in that mill.

Out of that thirty months without a fatality in the plant, I know of twelve drownings, gas asphyxiations in their own homes, automobile accidents which was the big thing, and so on. So when in our steel mills they are safer than when on the streets or in the homes.

TOM McKINNEY (Illinois Steel Company, Chicago, Illinois): While Mr. Roosevelt is here I want to ask for a little information pertaining to the last question that was sent up. I don't believe in luck either.

The question was, "Does the accident control the man or does the man control the accident?" Somewhere, some place, I read something about the right combination of causes. I cannot get that quite through my head. I would like to get some enlightenment on the right combination of causes. I got into an argument a short while ago with a gentleman with reference to that subject.

I argued that you can beat it, and their explanation of the right combination of causes was this: Here is a man who is driving an automobile for the first time over a road, and he comes to a crossing and crosses where the Twentieth Century is about to come, and the Twentieth Century is one minute late, or one minute ahead of time. Why should the man with the automobile meet the Twentieth Century at that particular time? The first time he ever went over the road, the Twentieth Century is a minute late or early, or whatever it might be. They call that the right combination of causes.

Can there be such a thing? I think the man driving the automobile could have protected himself. He could beat that right combination of causes by the proper protection, such as getting out and looking for the train.

Does that exist in the plant? You know that every day in our plants we are having a new kind of accident. We are trying to forestall and we are trying to protect ourselves, and we go along, and then we have another accident. We never had one like it before, and we get busy on it and we remedy it so we cannot have another one; and we don't; but in a short while we have another kind, a new accident, and we protect ourselves against that.

I just cannot get this right combination of causes into my head, and I think Mr. Roosevelt and Mr. Morey, and perhaps some of the rest of you gentlemen can give me a little information on the subject.

A. T. MOREY (Commonwealth Steel Company, Granite City, Illinois): I think where we have a principle involved, we do not have to start with the hypothesis that we have got to have that principle wrong. A thing that is wrong in principle

doesn't have to be. Where there is light, there is no darkness. A positive displaces a negative.

It seems to me that this matter of accidents is just a measure of our own growth. For instance, wood working machinery used to be considered the most murderous there was. Through intelligent study of the problem and through cooperating with you men in such meetings as this, we have learned to safeguard wood working machinery in our plant. In our new shop about 100 men have gone nearly 1,300 days without a lost time accident, and our old shop went 700 days before they had an accident. Now, it seems to me that was just a measure of our intelligence and understanding, as we rise above these conditions.

You take Tom's illustration; I don't see that there was any fatalistic condition there. The man wasn't experienced in driving and he didn't stop, look and listen.

If he had obeyed the safety rules that intelligence has taught us he wouldn't have been hurt.

We never get the same combination of circumstances. No two plants get the same combination. We keep having new kinds of accidents, but I think we can stick to the principle of the thing, and say the thing wrong in principles doesn't have to be.

When we get the wrong answer in mathematics, we know that the principle involved is right, and we persevere until we get the right answer because we know it is there; and if it isn't there you feel that it is your own fault that you haven't got the answer correct. That is what I think is in this accident situation. You get just as much safety as you intelligently think and understand, and as you circumvent so-called negative conditions.

E. T. TIMMERMAN (The Steel Company of Canada, Limited, Montreal, Canada) : Several speakers have spoken of lost time accidents. Will they tell me what they mean by lost time accidents, or what they classify as a lost time accident?

CHAIRMAN NORTHWOOD: The National Safety Council standard on lost time accident is a man failing to return to work on the turn or shift following that

during which he was injured. I think it is pretty general in all plants.

E GREEN (Louisville Car Wheel and Railway Supply Company, Louisville, Pennsylvania): I don't believe you have put quite enough in there. He has to return to his own job. Many of these men are being brought back to work as watchmen, etc., but he has to return to his own job on the next trip.

CHAIRMAN NORTHWOOD: My interpretation of the National Safety Council ruling is that if he returns to work he is not a lost time accident. Some plants hold to that religiously.

S. E. SANKEY (National Tube Company, Elwood City, Pennsylvania): There are only three elements in safety. They are these: For the company to do its part, cleanliness and education.

C. W. HANKO (Pittsburgh Steel Company, Massen, Pennsylvania): Mr. Roosevelt made the remark that he did not believe in discharging, or in other words, disciplining. I just wonder if Mr. Roosevelt meant that a man who does not live up to safety rules or otherwise, or is very indignant to his foreman, should be kept on the pay roll.

We had an accident which was very serious and which we regretted very much. After twenty-three months and two days we had a fatality in our plant of 4,200 men, that was caused simply because the man absolutely would not listen to his foreman or the men around him.

It was at a point that we knew to be very dangerous and we have a man stationed at that point to warn men of the dangers. This man said, "John, stay back there, because that bar of iron is liable to fall out of the chain." This man instead of staying there, stuck his finger up to his nose and kept on coming. As he came on, he looked up at this piece and sure enough it broke from the chain. The result was the man tried to get away but tripped and the piece of iron fell on him.

I think if a man takes the attitude that man did, it is best to get him before there is an accident; or do you think it is best to keep him at work, just giving him a talking to?

CHAIRMAN NORTHWOOD: I think the question of discipline is up to the management of the individual plant, dealing with the case as they find necessary, and remembering that we are making men as well as making steel or iron or whatever it is.

J. CHORE (Standard Steel Co., Burnham, Pennsylvania): When I hear these reports of the time elapsing since the last fatality and the last accident in your shops, I think that I ought to say something for my own plants.

I believe that the men of the Standard Steel Works are about as thoroughly sold on safety as are any plants in the country, and I believe that our men are, as Mr. Roosevelt said, proud of their jobs and proud of their plants.

Only a few years ago—I think about 1923—the Standard Steel Works was known as the slaughter house. Never a day went by but a man was taken to the hospital, and never a year went by but there was one or two or three or more, up to six in one year, who were killed. We employ in the neighborhood of 2,000 men. We have had one fatality in the last three or four years, and that was so manifestly a case of absolute carelessness that I would almost question whether it should even be charged to the plant.

About the twenty-sixth of January we had our second fatality this year and second lost time accident, and since that time we haven't had one single lost time accident in the entire plant.

I have heard some very nice reports of the time that has elapsed between lost time accidents in other departments. We employ in the neighborhood of 150 men in our own department, and it was three years on the twenty-sixth day of last April since we have had a single lost time accident.

A. BERQUIST (Youngstown Sheet and Tube Company, East Chicago, Indiana):

I heard a talk by Mr. Homer L. Ferguson, President of the Newport News Ship Building and Dry Dock Company, Newport News, Virginia, yesterday, in which he expressed just a few words concerning discipline, which I think expressed the attitude of any management.

He said, "Safety is the simplest problem of the management because he can be arbitrary about it without fear of criticism," and I think that expresses the attitude on discipline. It is their problem and they can handle it any way they see fit without having any fear of criticism.

ADJOURNMENT

October 3, 1928**J. A. NORTHWOOD, Chairman****Superintendent of Safety, Bethlehem Steel Company, Johnstown, Pa.**

The third session was called to order at nine-thirty o'clock by the chairman, J. A. Northwood.

(The members joined in singing a number of songs.)

CHAIRMAN NORTHWOOD: It has been customary at all our Metals Section Meetings to devote one of our sessions to foundry practice, and the meeting this morning will be turned over more or less to the foundry end of our work. Our first speaker is Mr. Nelson H. Kyser, Safety Engineer, Studebaker Corporation of America, South Bend, Indiana.

The Correction of Unsafe Practices in Foundries

By NELSON H. KYSER

Safety Engineer, Studebaker Corporation of America, South Bend, Ind.

Several hundred years ago, the idea was conceived that castings could be made from molten metal. At that time, no doubt, the process was very crude, and development up until now has been next to phenomenal, as the modern methods and devices for handling molten metal have been steadily improving each year. Even in the light of this remarkable progress, I am very firmly convinced that there is yet a world of room for further improvement.

In years past industry was conducted on what might be termed a "miniature basis." Our huge manufacturing monuments of today were mere blacksmith shops of one or two rooms. The foundry proudly boasted of a cupola of a ton capacity per day and the personnel consisted of a handful of men who were all very closely associated with their employer. Every one of these men was working with, rather than for, his superior. The amount of molten metal handled was small and the hazard negligible. Today with our foundries having a capacity of hundreds of tons per day and employing thousands, we are faced with the problem of correcting those practices which make for anything unsafe. The ultimate we are striving for is to obtain that same spirit, that same working together, which we had in years past in the small shop.

Several years ago the corporation which I represent constructed a very modern foundry which occupies 13½ acres of floor space and at normal times employs about 1,300 men and women. When we inaugurated our safety organization we, like all other companies, had our troubles in getting employees educated along lines of working safely and protecting themselves. However, we have made a very wonderful showing, due to the fact that everyone from the production manager on down to the floor sweeper is vitally interested.

This, I think, is the keynote to foundry safety. We must educate every soul connected with foundry work to think, act and live safety. The individual who does not think of his own personal safety or of the injury to others which might result from his negligence is criminal in intent and is the worst hazard a foundry can have. Quite often such a man exists simply because he has never been educated to safe practices.

The foundry superintendent, the foremen, the gang bosses, all hold their positions because they have a superior knowledge of foundry work and, secondly, because they are executives in some degree. It is with these men that the safety school must start. These men must get the safety habit

and believe in it. They in turn must pass it on to their men and in the case of a wayward one give him a little personal contact to show how much better off he and his fellow workers will be if they are all working safely. Men should be picked for the particular job for which they are most fitted and in case of an unsafe move should be shown where they are at fault. However, a man who is continually working unsafely is a hazard to himself and his fellow workers and should be discharged for his disobedience and unsafe practice.

The actual education of the men will vary according to the specific problems of each individual foundry, but there are a few fundamentals that will apply to foundries in general.

Every man must be taught to be a good housekeeper, as a clean, orderly shop means careful workmen and greatly reflects on the quality of the product. If aisles and passageways are blocked or are strewn with foreign matter the possibility of spilling a ladle filled with molten metal is greatly increased. If flasks are piled so that they may topple over, the hazard of crushing or badly lacerating a fellow workman is present. Many other instances might be cited where a poor housekeeper was the cause of an accident, but this is really a problem for each individual foundry to work out. If each foundry superintendent would call his foremen together and outline a program of getting clean and keeping clean, good housekeeping would no longer be a task and would become a habit and the unsafe practice of poor housekeeping would no longer exist.

Two Ways to Do the Job

There is always a safe way and a dangerous way to do a job. We may show a man the safe way to do the job by calling his attention to the danger of the different operations, but it would be folly to set forth a hard and fast set of rules for him to follow. In my judgment, it would be better to allow the man himself to develop the safest method of doing the job without injury to himself because of the vast difference in human element. It would be ridiculous to expect men of different status and temperament to work with identical movements. The employee should be cautioned against using a rusty skimmer or rod when skimming or stirring molten iron and should be told of the danger which results. The pouring of molten metal into moist ladles should also come in for its share of caution, as should the watching of a mould up through the risers without the necessary goggles. There are many other things in this connection which are dangerous and where the new man is very liable to encounter sorrow. Here again is where the executive in charge functions as a teacher.

Proper clothing must come in for its share of consideration in the correction of unsafe practice in foundries. We insist that all men engaged in the handling and pouring of molten metal in our foundry must have good, solid Congress shoes without the slightest defects; either asbestos trousers or slow combustion leggings; wool shirts preferably and regulation safety goggles. Without these articles they are not given any metal from the pour-off man who has charge of the large distributing ladle. This rule is enforced 100 per cent and the results are gratifying, as very seldom is a man denied metal due to his being unsafely clothed.

The time to teach the employee that burns and injuries caused from unsafe clothing result in intense pain; loss of time and money, both to himself and employer; and often permanent injury, is before he has to personally undergo these tortures. It is much easier to enforce rules relative to proper clothing if each workman realizes that he is not being made to wear certain articles because it is so much red tape, but as a safeguard to himself. We have

attempted to teach safety with kind words, and this always is our first method of attack, but in some instances we must resort to what is called "hard boiled" procedure, as it is strongly human for some individuals to disobey rules which have been inaugurated for their own welfare, and in rare cases we have resorted to immediate discharge of an old offender.

Thus far we have dealt only with personal education as a means of correction of unsafe foundry practice. Now we must turn our attention to the hazards which are directly due to the foundry layout. The more mechanical devices we are able to install the less will be the possibility of accidents. In our foundry we have attempted to do as much work by mechanical means as seems practical. Although we are not as yet 100 per cent, we hope in the near future to install mechanical means of doing certain jobs that further remove the employees from the danger zone.

Let us start with the raw pig and follow through until the castings are ready for machining. The opportunity first presents itself to do the work mechanically in the handling of raw stock. Magnetic cranes can be brought into use for the pig and scrap, while hopper bottom bins make a safer and easier way to handle the non-metallics. All the ingredients of the charge may be loaded into small cars, weighed and transferred to the charging floor untouched by the human hand. This practice will eliminate crushing injuries and also the possibility of hernia, which is frequently caused by the strain of overlifting.

After the charge is on the charging floor it should be mechanically dumped into the cupola. This method will avoid hand shoveling of the charge, where a man is apt to slip and fall into the mouth of that raging hell. Serious thought should also be given to proper ventilation, as the gases on the charging floor are very poisonous. In cases where the ventilation is poor or the ventilating system temporarily inoperative, the workman should be furnished with suitable respirators.

In the pouring of molten metal comes one of the most important applications of mechanical means and also one that is used the least. When a full ladle of molten metal has to travel hundreds of feet over the heads of a great many workmen the hazard of dropping and slopping over may result in serious burns. If instead of this dangerous practice of transferring the molten metal a great distance the conveyor system for carrying the moulds could be installed, one of our greatest foundry problems would be solved. The moulds could be placed on conveyors and transferred to a point 25, or not over 50, feet from the cupola and poured. This would bring but relatively few men into the danger zone.

The installation of a conveyor system of this type would require a sizable expenditure, which at the very outset might look somewhat unreasonable, but when we enumerate the benefits derived from its installation we can easily see where it would correct one of the most unsafe foundry practices. The peace of mind of all concerned would be without price; the inspection of long monorail systems would be eliminated; the danger of slop over would be cut to a minimum; and the use of hand ladles, with their many evils, would be history.

After the moulds are poured they continue on the conveyor to the shake-out, where extreme care must be exercised whether done mechanically or by hand.

The shipping and grinding department should be in a separate room from the rest of the foundry. This room should be well lighted and ventilated. All workmen should wear goggles and hard toed shoes to avoid eye and foot injuries. The various tools should be frequently inspected for their suitability and condition. The use of chisels with mushroom tops is very dan-

gerous and should always be avoided. The chipping room should be large enough to allow considerable distance between each chipper, as flying chips often are responsible for serious injuries.

In closing, let us summarize the high spots in the correction of unsafe practice in foundries. First of all, the safety engineer can only be the watch dog and must have the cooperation of every foundry employee. To obtain this cooperation every man must be educated in the school of safety to be a good housekeeper, a safe worker, to dress properly and, where the occasion demands, wear his goggles or respirator. Secondly, the management itself must give serious thought to the safest layout possible in order that it may make use of all possible mechanical means, thereby removing the employee from unnecessary and avoidable dangers.

Our ultimate aim must be to safeguard our foundries so completely that when day is done and the rank and file are homeward bound that each and every wife and mother may anticipate, without the slightest trace of fear, the greeting of their loved ones, whole and unmaimed; that every man, robust and strong, healthy and of a light heart, may caress his own little ones as the sand-man comes, knowing that on the morrow they will not be sorrowing his untimely injury or death.

CHAIRMAN NORTHWOOD: Gentlemen: You have heard this splendid paper read by Mr. Kyser. We now have time for discussion, and if there are any questions you want to ask Mr. Kyser, please make them short and concise, and let's have a quick-fire discussion.

L. O. WHEELER (Union Carbide Company, Niagara Falls, New York): I would like to ask Mr. Kyser regarding safety shoes. He speaks of Congress shoes and hard toe shoes. What is your problem in getting the men to pay the price of a hard toe shoe when they can get a cheaper shoe? The majority of the men can buy a cheap working shoe for about \$2.25, and our shoes are about \$4.50 a pair.

MR. KYSER: That is absolutely optional with the employees. We have those things for sale in our storeroom and he is at liberty to go there and get them. If he doesn't want to buy them of the Studebaker Corporation, he can buy them anywhere he pleases, but he must have them before he goes on the job. It doesn't make any difference to the Studebaker Corporation where he gets them or what he pays for them, but he must have them before he starts to work, or he doesn't start. There is no compromise on that.

I want to say right now that I believe in the straight-line foundry, absolutely. I want to see the day come in my life when the molten metal is not carried, because I don't believe that is necessary. Let's thrash that out right here. I know it can be done.

Our foundry is a very modern place, and cost a lot of money. It is sometimes necessary for us to go to Pueblo to get two tons of metal. It travels down here a block and a half and this way two blocks before that metal is poured, and when you try to keep every employee out from under that ladle you have some job on your hands. It cannot be done. Some jaywalker is bound to walk under there despite all you can do, and those are the corrections that I would sometime like to see brought about. A system universal all over the country whereby the metal can be taken from the cupola just a short distance and poured, put in conveyors, and travel your molds on that, and if necessary put in smaller ones—smaller units. Let them scrap the big units.

J. A. COLTRIN (National Radiator Company, Johnstown, Pa.): The speaker brings out something rather new in the idea that more machinery will make the place safer. That has been my idea all along, but I never have had the nerve to express it. Most people will tell you that the more machinery you get in the place, the more accidents you are going to have. I think the speaker, however, illustrated

very clearly, especially in some of the operations that he named, that a foundry can be operated more successfully and safer with machinery than by hand.

RALPH W. HAYS (Employees' Liability Insurance Corporation, New York City): One of our insurers has recently installed a mechanical equipment in connection with pouring molten iron and I am glad to say that they have reduced their accidents over 75 per cent; which bears out what the speaker has just said.

JAMES WARRACK (Ohio Brass Company, Mansfield, Ohio): The speaker made a statement about wearing goggles when pouring metal. We have had much trouble in finding the proper kind of goggle, one that will not steam up. Will you kindly tell us what you use?

MR. KYSER: We use several different kinds of goggles. When I became the safety engineer of the Studebaker Corporation we had a houseful of goggles—all kinds. Some wanted this kind and some the other, and finally we decided on two different goggles. They are both very good, and I will be glad to answer that question to you by mail, brother. I don't like to boost anybody's game before this convention—only the Studebaker car.

J. A. COLTRIN (National Radiator Corporation, Johnstown, Pennsylvania): I have studied the subject of goggles rather thoroughly. I am not going to boost anyone's goggles, either, only a type of goggles. I find that all goggles steam. Any gentleman in this room who wears ordinary spectacles with all the ventilation possible around them, knows that when he gets into atmosphere under certain conditions his glasses will steam. Therefore, you cannot expect goggles that are enclosed not to steam. There is no argument there.

You can, however, use little devices that will prevent goggles from steaming to some extent, such as putting ordinary white soap on the goggles and wiping them off with a soft paper. That will prevent goggles steaming for several minutes. Another thing that we use in the goggles is a green colored lens. It is expensive and will cost you twice as much as the others, but we find that the men will wear this type of goggle when they won't wear others.

It seems that there is an annoying and probably harmful ray that comes out of molten iron that really hurts a man's eyes. It makes his eyes tired before the day is over, and if you can take this annoying ray away from his eyes he will wear his goggles. You can buy this green glass from a number of goggle manufacturers.

Then you must have goggles that are light and comfortable, and we have found that the most comfortable goggle is one that fits over the man's ears rather than a band around his head, and the enclosure is made of leather rather than metal so that they are light and comfortable.

MR. WARRACK: It wasn't a question of the kind of goggles so much as it was the question of the safety of the goggles. We have found in our business that wearing goggles is a safe practice.

We have gone one year in our factory without a lost time accident. We think this is very good for a foundry, in the safety movement only two years.

CHAIRMAN NORTHWOOD: How many men?

MR. WARRACK: Three hundred.

MR. KYSER: We have about 1,300 men, and I think in August we had 21 men out of these 1,300 go into the hospital with something in their eye, nothing serious at all. We have no trouble at all. We don't have any trouble with them breaking and we don't have any trouble about their wearing them, because it is goggles or no job.

CHAIRMAN NORTHWOOD: In the state of Pennsylvania when doing the various operations mentioned, regardless of whether we as a company are in favor of the goggles (which we are) the state department insists that we provide them. We could do these various operations without goggles.

N. V. B. ZEIGLER (United States Aluminum Company, New Kensington, Penn-

sylvania): The gentleman from Ohio must have been lucky last year. We insist on our men wearing goggles where we think they are necessary, and if we had them here we could show you goggles that without doubt have saved three eyes.

CHAIRMAN NORTHWOOD: That is the answer.

In line with Mr. Kyser's paper I have a question that was sent to me, which reads: "Organized safety has accomplished much in reducing accidents in industries, but cannot some of the decrease in accidents be attributed to modern improvement and development in machinery, methods of operation, improved physical conditions of the plant and shorter working hours?"

Unquestionably I would say, "Yes;" they all help. There isn't any question about that, but there is nothing that will take the place of definite safety operation even with all our machinery. We can have some mighty serious accidents without safety practice.

The Problem in the Small Foundry

N. E. GREEN (Louisville Car Wheel and Railway Supply, Louisville, Kentucky): Our problem is entirely different from Mr. Kyser's and the rest of you gentlemen here because we have such a small foundry. We don't have over a hundred men, and these discussions here are about mass production, so that we don't come in contact with the same problem.

Mr. Kyser has mentioned the mechanical shop. That is all right where you can get out the production, but where you have these small shops and a few men it is entirely impractical, from an investment standpoint, to put in all that machinery.

I agree with everything he said. It will be a grand day when everybody can have a mechanical shop. If you can run your molds right up in front of the ladle and pour the metal, you are getting away from carrying the metal and its incident hazards; but I would like to have somebody who is running a small shop come to these meetings and tell us about it. Most of the men are running large shops and they don't have the same problems that we smaller fellows do.

We have been very fortunate—of course we have done a lot of work too in our plant—in having gone over 500 working days without a lost time accident.

We have adopted the method of counting a lost time accident if the man cannot report for his job—not just for any job—the next day. I don't know whether we are handicapping ourselves or not.

I do hope, however, that some of these years you will have a speaker here who will attract more of the smaller employers.

CHAIRMAN NORTHWOOD: I might say in answer to your inquiry that that is one of the biggest problems of our National Safety Council today. Interesting the smaller plant, the hundred man and under, and getting them organized in safety work.

They go on the basis in some cases that the insurance companies are handling their compensation, and others say they are not having any accidents. They say they never have an accident; but man after man goes to the hospital and man after man is injured, and they don't remedy it because they are not paying direct compensation bills. You get my point on that?

It is mighty hard and we are taking steps, I know in the National Executive Committee, by furthering and encouraging various types of competition work, awarding trophies and prizes and so on, with the idea of getting the smaller company interested in the safety work. Does that answer your question?

The next order of business on our program is the election of officers, and Mr. Jim Woltz, of the Youngstown Sheet and Tube Company, was some time ago appointed chairman of the Nominating Committee. I am going to ask Mr. Woltz to at this time report.

Report of the Nominating Committee

J. WOLTZ (Youngstown Sheet and Tube Company, Youngstown, Ohio): Mr. Chairman and Gentlemen: Your committee has had two or three meetings and we presented a report at Atlantic City in July. There were one or two changes made after that meeting, and we now have the complete report to submit for your consideration.

Chairman—E. G. Quesnel, Commonwealth Steel Co., Granite City, Ill.

Vice Chairman—John P. Eib, Illinois Steel Co., Joliet, Ill.

Secretary and Editor of *News Letter*—Earl F. Blank, Jones & Laughlin Steel Corporation, Pittsburgh.

Chairman Program Committee—E. R. Rose, Republic Iron & Steel Co., Youngstown, Ohio.

Chairman Poster Committee—H. G. Hensel, Youngstown Sheet & Tube Co., Youngstown, Ohio.

Chairman Membership Committee—John P. Mudd, Midvale Co., Nicetown, Philadelphia, Pa.

Chairman Publicity Committee—W. E. Megraw, H. H. Robertson Co., Aimbridge, Pa.

Chairman Slide Committee—John A. Oartel, Carnegie Steel Co., Pittsburgh, Pa.

Engineering Representative—J. M. Woltz, Youngstown Sheet and Tube Co., Youngstown, Ohio.

Chairman Statistics Committee—J. E. Culliney, Bethlehem Steel Co., Bethlehem, Pa.

Executive Committee to consist of the officers, F. G. Bennett, Buckeye Steel Casting Co., Columbus, Ohio, and J. A. Northwood, Bethlehem Steel Co., Johnstown, Pa.

These are the last and the next preceding Chairmen of your section: J. A. Voss, Central Alloy Steel Co., Massillon, Ohio; C. M. Brading, Wisconsin Steel Co., Chicago, Ill., and Homer J. Weeks, American Steel & Wire Co., Cleveland, O.

MR. GREEN: I would like to move the adoption of the nominating report, and that the Secretary be instructed to cast one ballot.

(The motion was seconded and carried.)

CHAIRMAN NORTHWOOD: I so declare that the officers as put before us by our Nominating Committee are duly elected as executives of our Metals Section for the coming year, and I would like to at this time introduce your new Chairman, Mr. Ed. Quesnel, of the Commonwealth Steel Co. Mr. Chairman, congratulations, and I want to say that he is a real Chairman and a real man.

MR. QUESNEL: Good morning! You can take that for what it is worth. I am not going to make a speech, but now you can see what you have done. You have me and you will have to put me to work this year. I see a lot of wild Indians eyeing me, so I am afraid that I am going to have to do some work. I want you gentlemen to help me.

Seriously, I appreciate the honor of being elected as your Chairman. I also appreciate the fact that this office carries with it a great deal of work and obligation, and I will do my part to further the interest of the Section for the coming year.

I think we are all concerned in the fact that 1929 is going to be a rather remarkable year. From the records already quoted here you know that some wonderful strides have been made, and that in 1929, in order to surpass our 1928 record, we are going to have to do some very clear and practical thinking. The nearer we approach perfection, naturally the harder we will have to work, and I think the Metals Section will show the way in accident prevention this year.

I just want to leave one thought with you and I hope that you will concur

with me in it. That is, in attacking the problem of accident prevention, let us think this year in ideas and not so much in personality. I think we are not concerned so much about who gets hurt, but why was he hurt and how was he hurt? And that brings us down to this one thought: There are no industrial accidents other than those we create ourselves. Now if we can create them we most assuredly can prevent them. I want you to take the thought back with you, that if these conditions are created by ourselves and our associates, we should be clever enough and wise enough to have the forethought to prevent them.

CHAIRMAN NORTHWOOD: I would also like you to know Mr. John Eib, the incoming Vice-Chairman. I think if there is any one man whom you probably know better than anyone else of the Executive Committee of the Metals Section, it is Mr. Eib, through his splendid *News Letters* of the past year.

The News Letter Deserves Your Cooperation

Our new Secretary is Mr. Earl Blank. Mr. Blank, I wish you would come forward just a second, please. We are just acknowledging your election as secretary of the Metals Section and as editor of our *News Letter*, and I am going to ask all the members of our Section to help you in getting out that *News Letter*, because I know it is a real job and anything that you fellows can do to make that *News Letter* more interesting and more helpful will be appreciated. Just drop Earl Blank, of Jones and Laughlin Co., Pittsburgh, a letter or a note and tell him that you are with him.

I am not going to ask any of the other gentlemen just elected to stand, due to lack of time. I would like very much for you fellows to know them all but I am afraid we are going to have to continue with our program.

Mr. Woltz has something for us at this time.

MR. WOLTZ: At our first Executive Committee meeting in Chicago, the matter of seeking the responsibility for accidents and attempting to find some way by which they could be prevented was brought up and that has been continued in our discussion at our meetings since.

At that meeting it was suggested that the Metals Section attempt to develop a series of safe practice pamphlets applicable to the work of our Section. It was suggested that the first one be on coke plant operation, and I was asked to head up the committee to do that work.

It is going to mean that we will have to have the assistance of everyone operating a coke plant. They are not all the same and the problems are different in the different plants, and later in the year we shall send out letters asking the cooperation of every person who has any knowledge of coke plant operations, and for a summary of their accidents and what they have done to prevent similar accidents or other accidents that might happen.

We want to make this a practical safe practice pamphlet. We want to make it something that is easily understood, and we want to make it something that is going to be of help to us. So when you get these letters kindly respond as promptly as you can and give us all the information available.

CHAIRMAN NORTHWOOD: I have an announcement to make that I regret. Our Program Committee has invited Mr. L. A. Hartley, Director Educational Department, National Founders' Association Chicago, to be our next speaker. Just before leaving for the convention we received a telegram from Mr. Hartley that due to unforeseen circumstances he would be unable to be here.

He, however, has written his paper and forwarded it to us and I am very pleased to introduce to you Mr. Fred Bennett, of the Buckeye Steel Casting Co., who has kindly consented to read Mr. Hartley's paper. Mr. Bennett is one of our past chairmen of the Metals Section and I think most of you fellows know him.

Developing a Safe Human Factor

By L. A. HARTLEY

Director of Education, National Founders Association, Chicago, Illinois

Safety is a direct result of constructive thinking. Constructive thinking is a result of progressive experience. As science is an orderly arrangement of facts, so safe conditions are the evidence of orderly habits. "As a man thinketh, so is he." Shiftless thinking always accompanies shiftless actions. Unsafe thinking always results in unsafe conduct. The supreme task of the safety engineer is to lead workers to think constructively. When workers and employers "think safety," workers will be reasonably safe. These are well-known facts and every safety operator is acquainted with them. These statements may be said to be fundamentals of the great safety movement.

A fundamental is a principle upon which all normal individuals agree. For example, normal persons agree that one must eat, that sufficient clothing should be worn, and that mankind should have adequate shelter. These are known as the fundamentals of physical life. Normal persons agree upon marriage as an institution, recognized government as a means of social organization, and observance of law as an aid to order in community life. These are known as fundamentals of social life.

Persons of regular habits of thinking agree that industrial organizations as we know them, organized trade and commerce, and our present systems of manufacture and distribution are effective means of progress which have been developing since history was first recorded. These are fundamentals of production and distribution.

Occasionally persons are found who disagree with the opinion of the majority. Occasionally some one conceives the idea that eating is unnecessary or that clothing and shelter are unessential. These persons are objects of ridicule or sympathy. As long as their peculiar mental attitudes do not interfere with the comfort or safety of others, they are allowed to remain at large. Whenever a person or a group of persons actively ignores an accepted fundamental, such person or group is deemed to be a menace to the welfare of organized society and immediate measures are taken to restrain that individual or group.

Since safe thinking is generally known to be fundamental to safety, the real question is *how to promote safe thinking*. It is with this question that this discussion is concerned. All regular persons believe that sound thinking leads to safe operation, and they want to know how to get people to think safety.

Since a fundamental of safety is that the human factor must be guided into safe thinking, it follows that those who are directly responsible for safety organizations should know at least as much about human beings as persons who operate and maintain equipment are expected to know about this equipment.

This is all the more important since it is commonly understood that there is no such thing as a perfectly safe man. Equipment is designed to perform certain operations; and before it leaves the factory where it is produced, it is thoroughly tested to insure its performance. No such complete test is applied to workers. Indeed, it is questionable as to whether tests can be devised which will reveal the full extent of human possibilities.

Safety is a relative term. Production must be carried forward if human beings are to live, and every operation carries with it the possibility of danger. The inexorable fact that all human activity incurs a relative risk is the reason for continuance of safety programs. In the absence of dependable tests regarding human beings there is only one course of procedure which promises success. Human beings must be trained for safety; and before training is begun,

those responsible for this training must study the whole situation of which safety is but one of closely associated parts.

The first great fundamental of industrial safety work is that improved measures of safety always result in improved production. Mr. L. A. DeBlois, in his "Industrial Safety and Production," has well said, "Safety and efficiency are unquestionably linked together." Industrials who tolerate unsafe conditions are agents of inefficiency. In other words, efficient production and distribution and safe working conditions go hand in hand.

Sidney J. Williams, in "Waste in Industry," comments strikingly on this phase of the subject: "A piece of material falls off a truck and injures the workman's foot. We call this an accident and we know that it results in an economic loss. But there are other times—perhaps a hundred or more—when a piece falls off the truck but does not happen to fall on the workman's foot." This is the heart of the great safety program. Safety in industry is irrevocably linked up with every other industrial problem.

When industrial leaders understand that safe working conditions promote efficiency they appreciate the second fundamental which is that those working conditions under which the average man does his best work are also the safest conditions. The development of a safe human factor becomes therefore a matter of general development of production environment.

In the language of Dr. Harry Myers, of the Frigidaire Corporation, "It has been demonstrated that a healthy, happy, contented worker is a better worker than an unhealthy, unhappy, discontented worker," and it is just as accurate to say that a healthy, happy, contented worker is a safer worker than an unhealthy, unhappy, discontented worker. If this fundamental is accepted, the way is opened for a broad constructive program which should interest not only the specialist in safety but should stir the imagination of every type of industrialist.

What are the things that promote health, happiness, and contentment in production? Of all the reasonable answers that might be given to this question there is one upon which all thoughtful persons will agree: Genuine interest in the work at hand will do much to promote health, happiness, and contentment. How may this interest be developed?

No man is safe who is not interested in his work. A high authority has stated that "A double minded man is unstable in his ways." No man can be safe and be out of sympathy with his co-workers or his employers. The blame for this lack of interest should not always be placed at the door of the worker.

Too often employers have endeavored to purchase the interest of workers by distribution of Christmas turkeys and prizes for the observance of rules and regulations. Such a system of open rewards, which is usually accompanied by punishments for violations of the code, cannot be expected to appeal to the higher type of employee who wants to do right for the sake of being right. The whole idea of reward and punishment as a means to promote production and distribution is based upon the principle of coordination. Cooperation must come from within. Cooperation cannot be enforced. There are great possibilities in rewards intelligently given but considerable harm may result from too open reward for services and cooperation which should ordinarily be expected from employees.

All that needs to be done to secure the interest of normal workers is to practice exactly the same neighborliness with workers that is practiced in the neighborhood and in the home. Personal neighborliness is not possible in the case of busy managers who seldom have opportunity to meet workers. Their friendship must be reflected. One difficulty sometimes observed in modern industry results from the lack of adjustment to new methods. The old-time machine was a two-wheeled affair—the manager and the worker working side by side. Then the manager rolled around to the front office and the foreman was placed on the main axle opposite the workers.

These three groups are as fixed by circumstances as are the wheels on some powerful three-wheeled truck. The manager gives the directions and the foreman and workers respond. As industry has grown, many other intermediate wheels have been introduced under different names—personnel, welfare, education, safety, medical service, pension plans, housing programs, and others too numerous to mention.

Every one recognizes the value of this additional industrial equipment, but there is ample reason for the belief which is rapidly growing in industry that the foreman should be given more responsibility in the general plan. Foremen should be given a larger share in all personnel activities. One factory has been highly successful in having the foreman assume direct responsibility for all personnel work. Instead of referring workmen of his departments to the personnel department for loans or other assistance of this nature, the foreman takes such matters up with the personnel superintendent who decides in the light of the foreman's recommendation. The management of this plant has let it be known that foremen are responsible for maintaining agreeable relationships in their departments. If production falls off or unusual accidents occur, these foremen look to home conditions as well as to plant conditions. It is assumed that worry over home conditions such as sickness, unfortunate financial situations, or accumulated bills may be reflected in production. This plant has a very active safety department. Its employment department is even more energetic than most, for it works both ways. It selects men for the plant and endeavors to find work elsewhere for every applicant who is good enough but who cannot be placed in the plant.

Men are not urged to observe safety regulations as a means to their own protection. Instead, there is a continual program of training designed to interest employees in their work and in the business. Along with this interest-arousing campaign is a consistent program of education the aim of which is to acquaint every one in the organization with such information as will make it easier, cheaper, or more interesting to perform the various operations necessary to the manufacture and distribution of their products. Safety rules are presented as operating information, together with methods of performing various jobs.

The system of rewards in this plant is interesting. Punishment seems to have been overlooked except as it may be recognized in the absence of reward. Apparently foremen are not on the lookout for violations of rules. On the other hand, they are constantly on the lookout for unusual achievements and the moment a worker is known to have demonstrated unusual interest in any kind of activity which will make it easier, cheaper, or more interesting to produce and distribute the products of the plant, he is marked up for a suitable record. These rewards are not always material. Neither are rewards announced.

Everything in this connection is done very quietly. The foreman confers with the personnel superintendent and department heads immediately interested. The first aim of this conference is to decide, if possible, the kind of reward that would be most satisfactory to the one who has earned it. In one case, it may be advancement to another job; in another, it may be a few days off on pay to go hunting or fishing.

In one instance, a man who had proved himself unusually interested and cooperative was advanced funds for the purchase of a small grocery store which a member of his family operated until it was sold at a neat profit. This man simply was asked by his foreman to go to the office of the superintendent of personnel where he was told that it was understood that he wanted to buy the little store. When the information was confirmed, the man was informed that the company would advance the money to make the purchase. This seemed to be quite acceptable, and the loan was made returnable by installments from his wages. After the loan was completed and the company representative had advised

regarding the details of the purchase, the subject of the unusual service which led to the reward was casually mentioned and the workman was given to understand that such cooperation is appreciated.

The methods pursued in this plant are cited merely as examples of the application of fundamental principles to plant operation. The plant has an excellent safety record. Many companies duplicate certain methods followed in this plant and the general principle of human development as a means to safety is well understood. This example is cited because in this particular plant there is a systematized program based upon fundamentals of human development.

The third great fundamental which should govern all programs of human development is that human progress is a result of reasoning in given situations. Safety cannot be promoted to any great extent without taking steps to insure that those who are to improve conditions reason upon the need for improvement.

Man is distinguished from the beast by his capacity for reasoning. A man's mental activity marks his degree of intelligence. The progress of the race has not depended upon the strength of the bodies of men nor upon the memorization of rules. Progress has depended upon the strength and activity of the minds of men in connection with the skill of the human hand. The brains and the hands of a race indicate their relative development. Developed brains and skilled hands are associated in gaining increased control of environment. While man has developed but few really new ideas, beginning with the use of fire and of the continuous lever or wheel, he has gained control of many of the scattered details of a planet, he has assembled the ocean liners, the thundering locomotive, and the marvelous structures and inventions of our civilization.

Safety programs, like all other human activities, are dependent for success upon obedience to natural laws. There are many such. Only one will be mentioned as an example of another application of fundamental information.

One of the many natural laws which apply to safety programs is that of action and reaction. Every action is inevitably followed by its corresponding reaction. If fear or other strong emotion is used to stimulate man to act above his usual performance, he can be depended upon to descend in his effort to a correspondingly lower level of achievement as soon as the inevitable reaction has set in. Safety programs which depend upon fear or other strong stimulants as interest factors, in reality accomplish little and eventually reduce the ability of workers to respond consistently to the requirements of safety.

The need for closer coordination of safety programs with every other industrial activity suggests that there should be a more specific relationship between medical departments and safety departments. It cannot be expected that foremen and leading workers will possess information which some one connected with every plant should know about human beings as such.

To illustrate the possibilities of understanding of special biological information by some one directly connected with safety development, two physiological facts will be used as examples: (1) The brain requires an adequate supply of blood in order to function normally. If the brain does not receive an adequate supply of the right kind of blood, the individual will not be normal in his thinking. (2) Directly related to this is the fact that ordinarily blood is distributed throughout the body according to the activities of different parts.

For example, a laborer who uses the large muscles of his back, thighs, shoulders, and legs must have sufficient blood for those parts in order to rebuild the muscles. Furthermore, the blood must be of such quality as to insure the rebuilding process. Long ago Mosso demonstrated that carrier pigeons after long flights were less able to see clearly, and found their wings and breast muscles dark with blood while their brains were pale because of inadequate supply of blood. Many of the cases ordinarily known as fainting are simply the result

of insufficient supply of blood in the brain. This may be caused by a number of things, but the fact remains that ordinary fainting is a temporary condition of insufficient supply of blood to the head.

Workers who perform hard manual labor cannot be expected to see every detail as clearly nor think as accurately while doing this work as after they have rested and there is opportunity for diversion of the blood supply to their brains. Numerous experiments upon birds and other animals suggest that many of the industrial problems involving the human factor are due to a considerable extent to pale brains. This again suggests an approach to the problem of human relations in industry which should lead to understanding appreciation of the human factor as such. All sorts of questions arise in the wake of understanding of even one fundamental physiological fact like the circulation of the blood. What makes blood of good quality? What foods produce good, rich blood? What is the effect of worry and fatigue upon body-building processes? What is the effect of fear on the maintenance of a healthy body? To what extent do living conditions affect maintenance of bodily health? What about agreeable working conditions? These physiological facts point the way for new appreciation of the broader scope of medical service to industry.

To summarize: That method of procedure which assures the greatest number of workers thinking most constructively about their jobs is the safest method. When executives and foremen see the safety program from a broader angle than mere accident prevention, safety work will mean more to production. Since disinterested and untrained workers are unsafe workers, every effort made to develop workers along right lines is in the interest of safety and of production for human service.

CHAIRMAN NORTHWOOD: We are indebted to Mr. Hartley for this paper, and we regret very much that he could not be here to deliver it himself. We are also indebted to Mr. Bennett for the splendid way in which he read this paper.

I am sure there are a number of things in it which you fellows would like to discuss. This is the vital part of our safety game as I see it today—the development of the human factor in our industries, and I think there is a lot of good meat here for a good live discussion.

N. E. GREEN (Louisville Car Wheel & Railway Supply, Louisville, Kentucky): In the beginning of the paper it stated that it was practically an insult to the worker to bribe him by rewards and prizes, and later on, as I understood it, he told us specific cases where they gave rewards, etc.

We have been very successful in giving rewards. Of course, we have a number of colored people working for us and possibly they are more susceptible to that kind of thing than many of the people in the Northern plants. I don't know, but I do think that you have to take all that into consideration when you are laying out your program. We cannot lay down a program that would be applicable to Buffalo or Cleveland or Chicago, any more than they can do the same for us.

We have found by giving the men a package of cigarettes when we hold our monthly meetings, which doesn't cost very much when you spread it over the whole month, that they appreciate it. They sit down and smoke. Men like to be comfortable. We have these safety meetings and they are comfortable when they are smoking. That wasn't mentioned in the paper but I think it is something for us to think about in our safety get-togethers.

Might I take just a little time to cite two instances in Louisville?

We have this last year started safety in the high schools. Heretofore we have not been able to do very much, but we found that we could get an opening in the girls' high school—we separate the sexes in Louisville—and we have the girls' schools and the boys' schools. We have a full time safety program in the girls' schools, and those in the English department write essays and speeches on safety.

In May we had several of the best speakers speak in our industries. In those industries where the men were comfortable we got results.

In the industries where they didn't care much about safety and they made the girls talk out of doors with the wind blowing and the dust flying in their eyes, we didn't get results. I don't know if any of you today are trying to hold outdoor meetings, but if you are I don't believe you are getting very far. If you can have your meetings indoors where the men are more comfortable you will accomplish, well, I'll say 1000 per cent more.

I thought it would be nice if any of you could put over a program like that with your girls, and of course most of you have co-educational schools. Our men were intensely interested in these two young ladies who came and spoke to them. They didn't tell them anything that they didn't know. They didn't bring a program. Their first statement was, "We do not intend to tell you how to guard your plants." Most of it was public safety, and as brought out by Mr. McClain and a few others, more of your employees are being killed on the way to and from work than are killed while at work, and we must impress upon them that safety is to be carried not only in the plant but on the streets and in the their homes. I believe that if some of you can put this program across in your schools in some form of safety advertising that is novel, you will get results.

F. G. BENNETT (Buckeye Steel Casting Co., Columbus, Ohio): I think the writer of the paper brought out a very interesting point on that reward system. He states, "There are great possibilities in rewards intelligently given, but considerable harm may result from too open reward for services and cooperation which should ordinarily be expected from an employee."

I think the big point he is bringing out there is the abuse of the reward system, and using it where there is no need.

CHAIRMAN NORTHWOOD: Right in line with that, I believe at one of the first Metals Section meetings I was privileged to attend they had a debate on that reward system, between Carl Smith, of the Inland Steel, and Phil Stremmel from down in St. Louis; and we brought out some tremendously interesting points of that award side of our safety work.

It does work in one place and not in another. Some fellow may get it over with awards and another fellow may get it over some other way, but any way just so we get it across to the men. Dealing with the human element is the vital end of our safety game as I see it.

Are there any further discussions on this paper?

We are dealing with the man from day to day and your committee felt that our program would not be complete without having something from the plant surgeon, and we have asked Dr. A. W. Colcord, Plant Surgeon, Clairton Works, Carnegie Steel Co., Clairton, Pa., to discuss with us, the placement of men. It gives me great pleasure to introduce Dr. Colcord.

The Placement of Men or What the Plant Surgeon Can Do for Safety

By A. W. COLCORD, M.D.

Plant Surgeon, Clairton Works, Carnegie Steel Company, Clairton, Pa.

I do not need to waste any time on this audience telling you that the physical and mental condition of the worker have much to do with his getting hurt. You were convinced of this years ago. Stoeckel, Commissioner of Highways of Connecticut, has well shown in a recent paper that a large proportion of automobile accidents are due to the mental condition of the driver. This is no more true of motor accidents than of those in our mills. The saying: "A sound mind in a

sound body" is as old as civilization. If we accept the newer psychology basing every mental action on an external stimulus and a response through the reflex arc, we may change our saying to: "A sound mind is a sound body."

There are accidents that are accidents in the pure sense of the word. Then there are accidents due to wrong environment of the worker—faulty machinery, poor guards; poor lighting; slippery floors; an untidy mill; the carelessness of the other fellow, etc. But a certain percentage of personal injuries is due to the mental condition of the fellow who gets hurt *at the time* he gets hurt. There may be worry, fatigue, hunger, thirst, loss of sleep, pain, physical weakness, effects of heat, cold, or poisonous gas. There may be bodily disease as tuberculosis, syphilis, Bright's Disease, diabetes, cancer, heart disease, and so on through the long list. Any of these will tend to make the man let down in his safety habits.

The worker's day is made up of a thousand reflex acts unconsciously done as a result of years' of training and experience until they have become fixed habits. The causes above enumerated break into these habits all along the line of efficiency and safety. When a new situation arises one must *think*. Intensive attention is called into action. If this situation involves danger, his safety will depend on his alertness—on his ability to keep cool and think clearly in spite of fear and excitement. If we analyze those accidents in group III, depending on the mental condition of the injured at the time of the accident, we will often be able to find the cause. One man had been up all night with a sick child; another had an aching tooth; another was recovering from an attack of influenza; another was developing tuberculosis. There is more than one concrete instance of a passenger locomotive engineer wrecking his train with loss of life and property from a beginning paresis. Syphilis of the brain and nervous system is no doubt responsible for a considerable number of industrial accidents.

I have recently had a severe case of toluol and Benzol poisoning requiring long and vigorous use of the pulmotor to get him to breathe at all—then some two hours of oxygen and a prolonged convalescence. He claims he needed money badly and had starved himself for weeks before the accident. He knew better than to enter alone the chamber containing the poisonous gases. We don't know why he did it, and believe that this starvation was responsible for three things:

1. His lack of caution.
2. His lowered resistance to poisonous gas which came near being fatal.
3. His slow convalescence.

The question of lowered resistance is a broad one—of great importance to all of us who have to do with safety. There is an interdependence between the effects on the human body of fatigue, hunger, heat, cold, shock, infection, mental strain, poisons, or disease. Each one of these lowers resistance to the rest. A man affected with any one of these has his safety affected in two ways:

1. He is more apt to get hurt on account of less caution and alertness.
2. His resistance is lowered to the effects of any injury. He is more apt to have his wounds infected, is in greater danger of dying from shock or poisons, and will be longer recovering from an injury.

The industrial surgeon can do much to prevent them in two ways:

1. Watch for these hazards in the mill and not only keep the hazard away from the man but keep the man away from the hazard.
2. Keep the man in the mill physically fit so that when exposed to such a hazard he will have a high resistance.

The first of these covers the whole ground of sanitation and safety as far as these can be influenced by the industrial surgeon. I believe the company surgeon can and should get out into the mill from time to time, study the conditions under which the men work—heating, lighting, ventilation, toilets, rest rooms, lockers, shower baths, drinking water and eating places. He should study special hazards; danger to eyes, where goggles, colored glasses, etc., are needed; danger to skin

from chemicals, oil, etc.; danger from poisonous gases or dusts. He should study the exposures to heat, cold, electricity, etc. His contact with the men who come to the emergency hospital will enable him to observe the effects of these various hazards and confer with the management or safety department as to their betterment.

The surgeon should be a valuable member of the general plant safety committee; he should attend all meetings and take an active part. This contact with the general safety committee is one of the most valuable the surgeon has. These men are always interested in safety. It should not be hard for the earnest, enthusiastic surgeon to sell them the idea of better health in industry.

In his talks to first-aid classes, he should devote a certain time to personal hygiene, home sanitation and even community health. One of the valuable things about employment examination is the personal contact with the men. The surgeon can not only find out the man's bad habits and his correctible defects, but he can advise him how to get rid of them. Just after examining a man's heart, a word of warning about his excessive use of cigarettes has a telling affect. It is not enough to teach the men about health. We must *sell* them health. To sell a thing we make a man want a thing he didn't want before—to want it so badly that he will give up something valuable to get it. To sell *industrial health* we must be thoroughly sold ourselves. The industrial surgeon must not stop at the mill. He should make his influence felt through the whole community. The worker spends sixteen hours outside of the mill. What he does and how he lives have an important bearing on his health and safety, and the surgeon should take a keen interest in the employee's family, his wife and his children, the workers of tomorrow. He should direct the work of the welfare nurse in her health teaching in classes and in the homes. He can use clubs, churches, schools, newspapers, boards of health and the other doctors of the town to spread the gospel of good health.

My views on periodical examination, have already been given before the National Safety Congress. They have been twice published and may be found in your Transactions of the Milwaukee Meeting of 1920.

It costs about \$2,200 to raise a boy in Pennsylvania, send him through the eighth grade of school and get him old enough for a job in the mill. It costs several thousands of dollars to train him for a skilled job. When trained, his earning power for his life expectancy is from \$15,000 to \$40,000. The human machine, the most perfect of all machines, is the most delicate, the most easily injured. More and more our great corporations are becoming convinced that it pays to conserve their greatest asset, man-power—to examine it periodically, to keep it in repair and to raise it to the highest point of efficiency. Such an examination should include:

1. A thorough general physical examination—chest—abdomen—nervous system.
2. Eyes and ears including vision and hearing tests.
3. Urinalysis and blood pressure.
4. Functional heart test.
5. A Wassermann where syphilis is suspected. Some would do it in all cases.
6. Teeth and tonsils.
7. A follow-up in each case to urge the correction of bad habits; the cleaning up of the mouth and throat; correction of errors of refraction; treatment of curable disease. Especially the case of incipient tuberculosis should be aided in every way—needed period of rest—adjustment of job—care of his family—institutional care when needed—freedom from want and worry—medical advice as to sunshine, fresh air, climate,

food, medicines, personal hygiene, and avoidance of exposing others to contagion.

I am not sure whether it pays and is really wise to have, at the company's expense, our employees' teeth repaired, their diseased tonsils removed, their error of refraction corrected with glasses, and their salvasan given. All these, I feel are still in the experimental stage. The company may aid its men to get this service at a small cost, and if it desires, pay a portion without going to extremes of paternalism. The all important thing is *to follow up every case and see that the men get this service when needed.*

In the placement of men when employed the surgeon and chief employment officer should work together. The prospective job is written at the head of the examination card and the surgeon keeps this in mind when examining the man. When any doubt arises he should confer with the employing officer. There are some jobs that require special fitness, as cranemen or locomotive engineers. The work of this group involves more than usual responsibility with special hazards to themselves, to their fellow-workmen or to property.

The examination should include:

1. An estimate of mentality as to
 - (a) Alertness.
 - (b) Power of attention.
 - (c) Reactions. These should be prompt, certain and accurate.
2. There should be freedom from syphilis, epilepsy, apoplexy, alcoholism, drug habit, uncompensated heart lesion, uraemia, or other serious disease.
3. The standard for vision and hearing should be well above that of the ordinary employee.
4. There should be periodical physical examinations—best annually.

In our employment examination, we find three main groups:

1. The sick man—too sick to work—we either defer his acceptance or reject him and try to aid him or advise him as to his care and treatment.
2. The well man—the normal—who grades as well as the average physically and mentally.
3. The subnormal, mentally or physically. If we can use him, we should select his place with care. He should be watched by superintendent and foremen to see how well he does his work; by the surgeon to see how he stands it.

The placement of men after recovery from disabling injury requires unusual tact and hearty cooperation of the management, the employment officer and the department superintendent. These men fall naturally into four groups:

1. Minor injuries with short disability period returning to former work.
2. More severe injuries, usually general hospital cases with prolonged disability. These usually are best put at some light work for a few weeks before going back to the old job. This is "occupation therapy," a very important part of the treatment. It is not good for man to loaf—or, conversely, it is wise to get him back to some kind of work at the earliest moment consistent with his recovery. During this period he is watched and treated and the surgeon and department superintendent keep in close touch. There is a tendency on the part of many men to try to prolong the hospital period, the loafing period and the light job period. The surgeon must cut each of these short at the proper time.
3. In a third group the man is so maimed or crippled that he can never return to his old job, and must be taught another one. A large plant affords ample opportunity for this. Great care should be taken in its selection—it should be one the man likes and is fitted for mentally and physically. One of our brakemen lost a leg. We gave him three years of apprenticeship in our roll shop. He is now a full-fledged roll-turner

getting within 2 cents per day as much as he would get as brakeman.

4. A fourth group which is rare in the larger mills consists of men who can find no place in their own mill and must be turned over to the community or the state for vocational training. In my 26 years at the Clairton Mills, I have never found one of these.

If we study the workman in his relations to himself, his fellow-workmen, his employers and the company surgeon, we find four important things that stand out. On these things depends largely his success or failure in life. On these depends almost entirely his value to the company:

1. Loyalty.
2. Health.
3. Efficiency.
4. Safety.

These four things are so interwoven that we can hardly think of one without thinking of the other three. If the company surgeon is the right kind of a man; if he has the confidence of the men in the ranks, of the department superintendents and of the management, he can do much to promote all four. Every contact with the men is his golden opportunity. He may get this confidence:

1. By being fitted by *nature* and *training* to be a real company surgeon, falling in love with his work and putting his soul into it.
2. By having his department *organized for efficiency*.
3. By being *up-to-date in equipment and methods*.
4. By securing
 - (a) Full support of the management.
 - (b) Hearty cooperation of superintendents.
 - (c) Obedience of rank and file.
5. By being *square* with every man. *See that he gets "his."* Let the surgeon stand up for the man's rights just as honestly and fearlessly as he does for those of the company. If the man has tried to put across something crooked and deserves penalizing it should be swift and certain.
6. By having a *real interest* on the welfare and happiness of *every man* and his family.
7. By being kind, without coddling, courteous, without being obsequious, painstaking, dignified and firm.
8. By *making good*—getting results—"Nothing succeeds so well as success."

CHAIRMAN NORTHWOOD: Dr. Colcord, I want to thank you very heartily for this splendid talk that you have given us. I believe it touched us all where we live. We all have had practically the same problems that you speak of, and I am sure it has done us a world of good to have you speak so frankly and so earnestly on these things that are so vital to us in our industries and in our various plants.

JAMES TEAIGY (National Cash Register Co., Dayton, Ohio): I might say that our safety department works in conjunction with our medical department, and our system is practically the same as outlined in Dr. Colcord's paper.

We have one other item, though, that I think helps a great deal to keep our accident record and lost time record down as low as it is. So far this year we have had 83 lost time accidents which averaged about one hundred hours each. Our supervisor or foremen or job foremen all are requested when a man or woman in the employ of the company gets lax on their work for any reason, to send these people to the medical department, and in this department is thrashed out whether it is physical sickness or whether it is some home condition that causes him to be lax in his work.

I have spent practically all my time in the factory—that is about seven hours a day—among the employees; and there are numerous cases where employees have

noticed this in some other employee. As I said, we call these people into the medical department, and it is astounding how many cases we find that come from home conditions.

In order to overcome these, we make an investigation and if it is necessary the company advances money (if it is money that is causing the trouble) and they take so much out of his pay each week. I think that is one of the best ways of reducing accidents and lost time.

N. E. GREEN (Louisville Car Wheel & Railway Supply, Louisville, Ky.): I just want to set myself straight on the question of rewards, etc., and I am glad that the Doctor mentioned it.

We have long since done away with the individual reward. Ours are all mass or team work, and I am glad that he brought it up because I feared you might have had the wrong impression.

C. B. KING (Wickwire Spence Steel Co., Worcester, Mass.): We have a problem of a man earning a high wage developing a physical condition which made him a hazard to himself, but probably not the other employees. We could find no work on which he could earn as much money as he was earning, and he had a large family to support.

What are you going to do with a man like that?

CHAIRMAN NORTHWOOD: Sometimes those cases seem pretty hard. Doctor, what do you say?

DR. COLCORD: The answer to that would depend largely upon whether that condition was one for which the company was responsible.

If his was compensable, then if he could not go back to a job that was worth as much as he had been earning before, give him the kind of a job where he is the most useful—that is an important thing from the psychological standpoint—and then pay him in compensation the difference between what the old job was worth and what his new one is worth. I think that is fair to the man.

If the condition was outside of compensability then I don't know that the company can do anything for him, unless they want to do it in the way of charity. Their obligation to him is to furnish him with the best kind of a job they possibly can. If it isn't one that he can support his family on, then there is the question of help from somebody.

CHAIRMAN NORTHWOOD: A few years ago we had a man who lost both legs in our plant. A brakeman and a man of very little education. We helped him learn typewriting and shorthand. When he first started to typewrite for us his fingers were so wide he would hit about three keys at a time, but he persevered. That is what I wanted to bring out, and he was able to graduate from the business school to which he was sent by the state of Pennsylvania Rehabilitation Division, which provided that course for him. When he finished his course we gave him a job in one of our offices and today he is earning more than he did as a brakeman.

CHARLES W. WIENER (Union Rolling Steel Co., Union Falls, Ohio): Dr. Colcord mentioned psychology in connection with his talk. I believe that is a subject that is not generally understood by the layman.

I think it can be illustrated by this little story. There was an old Darkie being told that every person had a time and place where they had to die.

He came back at this man, and said, "If that is the case and I just knew when and where that was, I wouldn't be there at that time."

I think that is a good thing to remember in connection with safety. If we could foresee these things, accidents wouldn't happen, and Dr. Colcord brought that point out by saying that the safety committee or the safety engineer had to do the thinking.

It is a pretty hard job for the safety committee or the safety engineer to be around to do the thinking before the accident happens. After it has happened, it is an easy matter to figure out a way to prevent another accident like that. My

thought is to get the employees to try to foresee accidents on their particular jobs.

A. T. MOREY (Commonwealth Steel Co., Granite City, Ill.): If we knew when an accident was going to happen, we would be there. We can know when an accident is going to happen. I think that is a big point that we have worked on this year. As a general rule the first carelessness does not produce an accident. If that is true, it gives us a chance to head it off. If we will watch the careless tendencies and be strict when the first carelessness occurs, we won't let that go on until the law of averages operates and eventually an accident happens.

I think it will give us a great deal of hope to attain the goal of no accidents by working with the idea that the first carelessness doesn't produce the accident. It is the repetition that finally results in an accident; so we can, as a rule, know

Time To Get Dressed

Tools like these
should go to the
repair shop or
junk pile. They
are dangerous.

where and how it is going to happen and circumvent it. I don't see how we could hope to attain the perfect record without some such situation.

MR. WEINER: The gentleman seems to have objected to my statement that a man cannot foresee the accident. I didn't mean that we couldn't, those of us who are imbued with the idea of safety. I realize that we can see it, but we cannot think for the other fellow unless we know what he is going to be up against.

J. J. HOBAUGH (Pittsburgh Plate Glass Co., Ford City, Pa.): I would like to ask Dr. Colcord how he handles employees who have hernia, or men for employment whom the examination discloses have some hernia, or employees who have incomplete hernia.

DR. COLCORD: Some years ago I made quite a study of hernia. I examined 9,000 employees with regard to hernia. I made a record of all open rings, and of cases of hernia. I found that one man in 60 had an open ring, or about one man in 1,100 one or both open rings, and one man in sixty had a hernia, and its discussion would be a long one.

The word potential hernia I am getting away from. Of these 9,000 cases that I examined, in the next three years, 25 hernias developed among those who stayed with us. They didn't all stay; and of those 25 hernias, only three were recorded as having had open ring at all. I have come to the conclusion that we cannot recognize a potential hernia.

I don't know just what you mean by potential hernia. If you mean open ring, there is a type of senile hernia occurring in Greeks and Turks and Armenians which is due to a sloppy condition of the whole belly wall which produces hernia. When we find an extremely thin wall developing at about thirty-five or forty, that comes nearer to being a potential hernia than anything I know of. But open rings is not to me an indication that the man is going to get hernia—somewhat the opposite.

If you brought me a man and said, "Here's a man who has never had smallpox although he has been exposed many times," I would say probably he never will get smallpox. But if you brought me a man with an open ring and I know he climbed trees and played football, and a good many other things, and had not got hernia up to the age of thirty, I don't care if he has an open ring, I don't believe he will get hernia.

You ask what to do with the man. If I examined a man whom I thought had that potential hernia I should hesitate about recommending him for employment. Either he has a hernia or he hasn't. I classify them a good deal as Grant did music. He could recognize two tunes. One was Yankee Doodle and the other wasn't. If the man has hernia and we are not hiring hernias, we won't hire him. If he has an open ring I do not advise against his employment.

MR. DREY: I would like to ask Dr. Colcord if he considers some hernias as being sudden?

DR. COLCORD: If I were to answer that I would have to say "Yes" or "No." There are two kinds of hernias: hernias of slow development and traumatic. Just what proportion are traumatic depends upon what you mean by traumatic, and in my hernia paper I dodged the question by making three groups. The intermediary group I called sudden hernia. The sudden is one of slow development in which the sac has never had anything in it but a dilation, which acts as a wedge and through the year slowly forms and stretches the sac, getting it ready for the entrance of a gut later on. Perhaps it would be two or three years before that gut would enter the sac under normal conditions, unless the man goes to lift a heavy casting, weighing 600 pounds, with four or five other workmen, and the foreman gives the signal to drop it and they all drop it but the one, and the sudden weight forces the gut into the sac which was not ready for it. There is pain and there is soreness. I have proved in such a case that it was a hernia of slow development, and yet that is nearly a traumatic hernia, so near that I would advise payment of compensation in such cases.

The ordinary hernia of slow development usually comes to us when the man appears in the office and says, "I lifted something last night and this morning I felt a lump in the loin." You examine him and you find that he has a hernia. Now if there is a well developed sac, and I think the trained fingers can detect one before it opens, it doesn't grow in five hours any more than an oak tree grows in twenty-four hours. It is a matter of years for a well formed hernia sac, and we classify those as hernias of slow formation.

I. S. PERRY (Ohio Brass Co., Mansfield, Ohio): About four years ago I had a man working for me who lifted a heavy weight and claimed he sprained his back. He was in bed for something like a year. We had several doctors and the state doctor, and we finally put him on enforced treatment and got him back on his feet and to work. We gave him light work and almost forbid him to lift anything. For some reason he insisted upon lifting and he claims he sprained his back again. The man can get out and walk and everything, but the doctor claims that we are

going to go through the same thing that we did before. It will take probably a year to get him back to work, and the last time it cost us about \$1,800. -

I would like to ask the Doctor what he would do in that case?

DR. COLCORD: I perhaps wouldn't do anything different from what you did. The problem of lame backs is with us. When I say "us" I mean all of us. I see Dr. Foster smiling over there.

Dr. Foster and I know about one case that has put crow's feet around our eyes and grayed our hair. A man came to me just last week whom I had worked hard with for a year, and he wore two or three kinds of braces and he came to me and said, "I have sprained my back." I said, "I thought I told you if you were going to hurt yourself again, to do it in a place other than your back." "Yes, I promised you but I did sprain it again." I have him on my hands again.

There are all kinds of sprained backs. There are genuine sprained backs and they are quite a serious matter and they have to be put to bed and treated; but I find a great majority who say they have a sprained back, really haven't. They either have a congenital weakness of the lower spine, a lumbar on the sacrum, or they have what I call auto-intoxication. I look at the man's tongue when he comes to me with a sprained back and if I find a dirty tongue, decayed teeth and rotten tonsils and signs of intestinal trouble, I feel more like giving him a dose of castor oil. And about 70 per cent (I don't think I am exaggerating) of the cases of sprained back are some form of intoxication or intestinal.

ADJOURNMENT

October 4, 1928

J. A. NORTHWOOD, Chairman**Superintendent of Safety, Bethlehem Steel Company, Johnstown, Pa.**

The fourth session was called to order at nine-thirty o'clock by the chairman, J. A. Northwood.

(The members joined in singing a number of songs.)

CHAIRMAN NORTHWOOD: It has been customary for a number of years for us to receive a report from Dr. Chaney of his work from a statistical standpoint, particularly our metals section end of the game, and it gives me great pleasure this morning to introduce Dr. Chaney to this Section. Dr. Chaney is of the Bureau of Labor Statistics, United States Department of Labor, Washington, D. C., and he is to be our first speaker this morning.

Accident Experience in Iron and Steel to End of 1927

By DR. LUCIAN W. CHANEY**Bureau of Labor Statistics, Department of Labor, Washington, D. C.**

For some time it has been the custom of the Bureau of Labor Statistics to present an annual review of the accident experience of the Iron and Steel Industry. For this purpose two groups of concerns have been considered.

The first consists of plants which were pioneers in efforts at accident prevention and have maintained continuous and vigorous effort in that direction to the present time. The second group includes both the plants of the first group and all others for which information has been available.

You will, of course, readily see that the purpose of this selection is to present to you the most outstanding achievements in accident prevention—the very best that the iron and steel industries have been able to do. The general trend of matters in the iron and steel industry has been satisfactory, but this group of plants which have been longest in the game and have developed the most successful methods is an illustration of the best that can be done.

Compare the Year 1913 With 1927

In group 1 the changes which have occurred are best illustrated by comparing the year 1913 with 1927. This comparison is limited to frequency rates since the data necessary to the computation of severity rates could not be obtained.

From 1913 to 1927 frequency rates changed as follows: *fabricated products* from 100.3 to 18.0; *wire and its products* from 59.3 to 3.5; *sheets* from 61.6 to 8.4; *tubes* from 27.2 to 2.5; *miscellaneous steel products Group A* from 70.9 to 5.1; *miscellaneous steel products Group B* from 41.3 to 2.7; *all products* from 60.3 to 5.3.

Comment is scarcely necessary to enforce the remarkable character of these results.

Another view may be taken of the data presented above. It is always possible that an unsatisfactory condition is concealed by the association of several of different conditions. To shed some light upon this question rates have been developed for the various accident causes to show how they have changed from year to year and what is their relative importance.

This treatment of the material brought out very clearly the fact that the effects of accident prevention effort are distributed with surprising uniformity among the different causes.

It has been a popular impression that with the progress of the safety movement machinery has become relatively less important as a cause of accident. When it

is noted that from 1913 to 1927 the frequency of accidents due to machinery dropped from 7.3 to 1.3 the popular impression seems to be justified by the facts. A further scrutiny of the rates however discloses that there are a number of other causes which register an equal or greater decline. It becomes evident that machinery is influenced by accident reduction effort quite like other causes. For example while machinery declined some 83 per cent the handling of objects dropped down 90 per cent.

The fact that these plants, and indeed the entire iron and steel industry, has made a commendable record is something of an offset for the discouraging fact of increased cost in general industry which has been noticed in recent years.

We are now to consider the more extended group which includes these special plants and all others for which information was secured. For a portion of this group it has been possible to determine both frequency and severity rates for a five year moving average beginning in 1907 and ending in 1927.

The insurance companies have been having trouble, and you will recognize that it is quite serious trouble when I give you a figure. In a period of about five years the returns from premiums have been \$44,000,000 less than the payments for casualty insurance. Now it happens that the insurance companies have other resources than premiums, and so they haven't had to go over the hill to the poor house on account of this loss. But you will recognize, I think, that it is not possible at all for a concern like an insurance company to go on indefinitely taking in less in premiums than is going out in its payments, and for some years past the insurance companies naturally have become a good deal exercised as to what the cause may be. They are hesitant to raise the premium rates if it can be avoided, and I think that the outcome on the part of the insurance companies is going to be a very much intensified effort on their part of accident prevention and reduction; and if you get the cooperation of that particular insurance company it is going to be a great help to the industrialists who are carrying on this accident prevention work.

For the first five year period ending in 1911 the industry showed frequency of 69.2 and severity of 5.0. When the five year period ending in 1927 is reached frequency has dropped to 24.7 and severity to 2.4.

The changes which have occurred in the departments of the industry from the five years ending in 1911 to the five years ending in 1927 for frequency, blast furnaces 76.1 to 28.7; Bessemer 101.5 to 16.7; open hearths 84.2 to 28.3; foundries 60.1 to 62.8; heavy rolling 61.0 to 16.6; plate mills 69.4 to 25.6; sheet mills 44.1 to 30.6.

The changes in severity are blast furnaces 10.6 to 4.7; Bessemer 7.6 to 4.0; open hearths 7.5 to 4.6; foundries 2.7 to 3.2; heavy rolling 4.4 to 2.6; plate mills 5.1 to 2.6; sheet mills 3.1 to 1.8.

There is one feature of this showing which must be mentioned with regret. That is the fact that neither in frequency nor in severity do the foundries register any improvement. This is the more regrettable since the experience of some foundry companies and of individual plants has amply demonstrated that foundries can be operated as safely as any department of iron and steel.

The Annual Review

I think that is enough to indicate to you what has happened. We consider it in this way. Possibly the term "moving average" is unfamiliar to some of you. We know that the volume of material on which you work statistically is an important item. If it gets too small, then the figures have no particular value as an index, and by doubling up in this way and taking five year intervals, we get volume enough in each interval to be indicative of what actually has happened.

The five year periods of which we have been speaking are over-lapping five year periods. They differ from each other by single years.

For some 18 years the Bureau of Labor Statistics has maintained a record of annual accident rates and has computed rates for consecutive five year periods upon their completion. *Period 1* extends from 1910 to 1914; *Period 2* from 1915 to 1919; *Period 3* from 1920 to 1924. Three years of a fourth period have now elapsed. The greater volume of data involved in these periods makes them more reliable than the individual years. For this reason further comment will be largely directed toward them.

Rates for the Industry

Frequency *Period 1*, 59.2; *Period 2*, 41.6; *Period 3*, 33.6.

Severity *Period 1*, 4.1; *Period 2*, 3.6; *Period 3*, 2.8.

In 1926 frequency declined and severity increased. In 1927 both frequency and severity declined.

Blast Furnaces

Frequency rates: *Period 1*, 62.3; *Period 2*, 39.0; *Period 3*, 30.7.

Severity rates: *Period 1*, 7.0; *Period 2*, 6.1; *Period 3*, 4.5.

In 1926 both rates rose slightly and in 1927 frequency dropped sharply while severity remained stationary.

You will notice that the decline in the severity of injuries is by no means as rapid as the decline in frequency, and that is perfectly natural. Minor injuries, those which we include in our consideration, not undertaking to bring in those cases which have no lost time. The frequency of accidents can much more readily be influenced than the severity, for which reason I believe that it is still true that the severity of accidents deserves a larger share of attention than they are getting.

The cost of the accident, which we mentioned a moment ago as troubling the insurance companies, is a matter of greatest importance. They need to cut off the deaths and serious injuries if they are going to cut down their costs, and I am going to say again what I have said a good many times to this Section: If you want to cut off the serious injuries you must improve the conditions of your plants. Improvement of conditions in the plant itself is the most effective means of cutting off serious injuries, outside of course, of the attitude of the men themselves which you need to cultivate most assiduously.

The blast furnaces have a deserved reputation for hazard. If an extra hazardous operation like that of the blast furnace can show such improvement as that indicated by the rates shown above any department should be able to show improvement.

Some of you, I presume, heard what Mr. De Blois had to say with regard to the significance of our long periods of operation with no lost time accidents. That indicated that it is perfectly possible over a very considerable period to reduce the hazards to zero. Now I remember vividly the time when it wasn't believed at all that you could get below 50 cases per million hours of exposure. That was regarded as highly satisfactory, probably the best we could do. We have gone a long way beyond that, but we still have a considerable way to go.

Bessemer Converters

Frequency rates: *Period 1*, 89.8; *Period 2*, 57.7; *Period 3*, 24.9.

Severity rates: *Period 1*, 6.4; *Period 2*, 6.9; *Period 3*, 2.6.

In 1926 both rates rose while in 1927 both rates went down sharply. Such erratic behavior of the rates is rather characteristic of the Bessemer. The operations of this department are particularly difficult to safeguard. For some time the Bessemer process has been becoming relatively less important and exposure has declined to a degree which contributes to unstable rates.

Open Hearths

Frequency rates: *Period 1*, 75.0; *Period 2*, 50.5; *Period 3*, 32.9.

Severity rates: *Period 1*, 6.6; *Period 2*, 6.5; *Period 3*, 4.2.

In 1926 frequency declined while severity sharply increased. In 1927 a marked decline occurred in both rates.

The safety problem in open hearths is much complicated by the associated transportations.

Foundries

Frequency rates: *Period 1*, 63.6; *Period 2*, 61.0; *Period 3*, 62.7.

Severity rates: *Period 1*, 3.6; *Period 2*, 3.4; *Period 3*, 2.8.

In 1926 both rates somewhat decline. A further decline occurs in 1927. When the details are considered it becomes evident that on the whole the foundries have not kept pace with the other departments of the industry. This is the more disappointing when it is observed that some foundry organizations have made an excellent record.

No. 10, p. 5. Following the paragraph on "Foundries."

However, the figures are cast up, whether we look at the changes in causes in foundries, or whether we look at the frequency of accidents, they all run pretty much the same way, almost on a level and 63.6 is a rather high rate as steel plants go; so that something needs to be done so far as the foundries are concerned. I have an idea of my own, that this is part of that problem which the safety council is now facing—how to reach the small concern. The point being that the operators of small plants, not only in foundries and others, but throughout industries, are not conscious of the fact that they are making a bad record. Their occurrences are so widely scattered that naturally they don't have any idea that their record is an excellent one.

I am showing you these figures so that those of you who see them will be stimulated to inquire: What are the difficulties so far as the foundries are concerned, that they make the only unsatisfactory record in the whole group of iron and steel industries? It certainly cannot be true that the natural hazards of the foundry operations are greater than the natural hazards of the operation of blast furnaces, but their record is considerably less satisfactory than that of the blast furnace.

Heavy Rolling Mills

Frequency rates: *Period 1*, 46.1; *Period 2*, 32.4; *Period 3*, 21.2.

Severity rates: *Period 1*, 3.6; *Period 2*, 3.9; *Period 3*, 2.3.

In 1926 both rates declined and a further decline occurred in 1927.

The 15 years which are under consideration include the war period with its extraordinary demands upon the industry. There can be no doubt that under such industrial stress there is a strong tendency to rising accident rates. It is very probable that in this case changes which were made in the mills in order to meet the situation created by the war were a considerable factor in a reduced hazard. With the calling of many workers into war service it became necessary to substitute mechanical devices for the manual power which had before been used. In the development of machine design attention was given to safety of operation with the result in many cases the tendency to rising rates was held in check.

Plate Mills

Frequency rates: *Period 1*, 49.9; *Period 2*, 39.2; *Period 3*, 29.4.

Severity rates: *Period 1*, 3.9; *Period 2*, 2.5; *Period 3*, 2.4.

In 1926 both rates declined and in 1927 a further decline of both rates occurred. The plate mills have shown about as regular a lowering of the rates as has happened in any of the departments which have been covered.

Sheet Mills

Frequency rates: *Period 1*, 51.1; *Period 2*, 32.7; *Period 3*, 35.1.

Severity rates: *Period 1*, 2.6; *Period 2*, 1.5; *Period 3*, 2.1.

In 1926 both rates declined and in 1927 there was a further sharp reduction.

Tube Mills

Frequency rates: *Period 1*, 40.5; *Period 2*, 22.4; *Period 3*, 22.7.

Severity rates: *Period 1*, 2.2; *Period 2*, 1.8; *Period 3*, 1.9.

In 1926 frequency slightly increased and severity slightly declined. In 1927 the reverse was the case. These changes are not sufficient to be of great significance.

The foregoing give an idea of the trend of events in the iron and steel industry to the close of 1927.

J. S. BENNER (Carnegie Steel Co., Munhall, Pa.): I would like to ask Dr. Chaney a question on the foundry proposition, whether it is possible for you people in Washington to segregate foundries one hundred men and under, and in the other group any foundries above one hundred men, to see whether your figures prove out that you are getting it all in the small foundry or you are getting it in all kinds of foundries.

DR. CHANEY: We have done that, but not so thoroughly and completely as we desire to do it, and our indication is that the small foundry has the least satisfactory rates, right along, right through. Now whether it is sufficiently pronounced to be the real explanation, we don't know.

MR. COFFEE (Department of Labor and Industry, Philadelphia, Pa.): The question has come up at different times about statistics on light foundries and heavy foundries, and I would like to know whether you have any statistics in this respect.

It is brought up especially in regard to insurance rates. The fellow who is engaged in the light foundry work claims that he shouldn't pay the same rate as the fellow in the heavy foundry work, that his hazards are not so great, and I have never heard any statistics.

DR. CHANEY: We haven't anything to offer as yet. There are a number of these things which we propose to go into as soon as we can. So far as we have any indication at all, it is that the light foundry man is justified in insisting that he ought to have a better rate, as the heavy foundry is naturally a greater hazard.

HARRY GUY (Keystone Roller Co.): I would like to ask why it is that there are no statistics on the small foundry proposition, employing 100 or less men?

DR. CHANEY: The reason is, so far as we are concerned, that it never suggested itself until recently, that it was a factor in the case. We thought a foundry was a foundry, and we hadn't thought that there might be a serious difference between those employing under one hundred and those employing up to five hundred. We ought to have thought of it sometime ago, but we didn't.

We are trying now to segregate the returns which we get and see what the indication is. Of course, you are aware that the National Safety Council made some investigation along this line. It is confined to foundries, and inasmuch as foundries are the spot where the safety effort has apparently been the least successful, it demands some more thorough and careful attention, and we are going to try to give it that.

RAMAGE EDGAR (Thompson Co., Braddock, Pa.): With reference to the \$44,000,000 premium loss that the insurance companies are claiming, I would like to ask first if your statistics show how much is foundry and how much is steel plants; and whether it is through their own inspection or through the plant inspection that they operate?

DR. CHANEY: So far as that is concerned, I really don't know anything but the

figures. Those come from the insurance companies—that they paid out so much and took in so much.

MR. EDGAR: I was wondering if they could help the Safety Council any if they gave in their figures the kind of plants in which these losses occur, and possibly the size of the plant.

DR. CHANEY: I think the rate making council of the insurance companies is undertaking to do something of that sort to determine where that loss arose. We haven't been able to touch it yet.

F. G. BENNETT (Buckeye Steel Casting Co., Columbus, Ohio): We operate one of the largest type foundries and are having a very satisfactory accident experience. Our rate now in the industrial commission (I think throughout the country) is a thirty-one cent rate—extremely low. I say that our experience has been very satisfactory for a large foundry. I am sure that is true with the Commonwealth Steel Co.

What I believe we had better do, is to pay attention to these figures and facts that Dr. Chaney has presented this year and last. Last year I was presiding at the meeting and had to stand on the platform and listen to Dr. Chaney tell how disappointing the foundry interests were. It wasn't very pleasant and was the only sore spot in the entire meeting.

I think, Mr. Chairman, that the Executive Committee of the Metals Section during the coming year should give special attention to this matter of the disappointment in the accident statistics of the foundry operation, dig into it from every source possible to see what can be done, and try to bring in a definite report next year.

I think it is the small foundry that is causing the trouble, as there is an extreme hazard in the handling of molten metal that we don't have in our foundry at all. It is all over-head pouring. I move, Mr. Chairman, that this matter of foundry accident experience be taken up at the first meeting of the Executive Committee of the Metals Section, and be made a special order of business for investigating during this coming year by a special committee on foundries.

(The motion was seconded and carried.)

CHAIRMAN NORTHWOOD: I believe that Mr. Bennett would be a good man to put on as chairman of that committee. I think that is real constructive work and getting right down to the source.

S. A. SANKEY (National Tube Co., Elwood City, Pa.): I can give you a miniature start with just these figures. Here's what happens to shops employing one hundred men and under. Those men are required to do combination occupations, forge work, lifting the metal, etc., and it requires several different kinds of safety devices to protect them. A man doesn't want to change each time as he goes from one occupation to another, and as a result he doesn't wear any safety devices, and he goes right at it, bullheaded, without any guards whatsoever. In the larger plants you stop manufacturing until he puts on his chin guards, goggles, or whatever it may be, and you come out ahead of the small man.

One thing more—there are not enough small foundry men who belong to the National Safety Council and learn that they should protect human life.

RICHARD L. SLOSSON (Lamrox & Hammis, Buffalo, New York): I just want to say for your benefit that the insurance companies have divided industries into three groups, and they know what the rate shows for each group and that can easily be obtained. It shows not only in the metals industry, but textile, and everything else, that the small industry has the high rate.

MR. EDGAR: As far as Pennsylvania is concerned I understand from the rating bureau that the same rate applies to the light iron foundry as applies to the heavy as far as Pennsylvania is concerned.

I know of one case where a foundry, engaged in light work, appealed for a better rate, claiming that they should not pay the same rate as the heavy grade foundry,

and they couldn't get it. Of course that foundry was forced to self-insurance, and their record for ten years has been wonderful.

J. M. WOLTZ (Youngstown Sheet & Tube Co., Youngstown, Ohio): Doesn't the experience have something to do with it? If you have a bad experience, you pay for it. Simply because one plant was able to have a good experience, that fellow was paying for the other man, and it pays to educate the other man to help you out. There is the secret of the whole thing, to my mind.

MR. EDGAR: In answer to that, I claim (and I would like to hear this discussed further) that there isn't the same hazard in the light foundry as there is in the heavy. Therefore, they should have a different rate, a lower rate of insurance than in the heavy foundry.

MR. WOLTZ: If your rate is based upon experience, that would be true, but evidently it isn't.

MR. EDGAR: As far as the rate goes, they have the same basic rate and then they are given credit on experience, but the experience is based on that one rate, on that flat rate or basic rate covering all foundries, and the man with the good foundry gets it better than the fellow with the bad foundry. He is credited with a good record, but at the same time the basic rate in the light industry is the same as in the heavy, and they claim it should not be.

MR. SANKEY: You are mistaken. The fellow with the small foundry says, "Why should I do anything? I don't get any reduction." And therefore he doesn't do anything and produces those figures. Now the danger of a larger foundry and a smaller foundry is they don't prepare the floor properly. They don't give them the proper equipment; therefore the small foundry is just as dangerous as the larger, because the large foundry sees to the occupation of the man and that he has devices to wear for the occupation he does.

MR. EDGAR: There seems to be a misunderstanding on this. I am not speaking about the small foundry employing a few men. I am speaking about the foundry doing light work compared to the foundry doing heavy work.

MR. SANKEY: Suppose we tell a man to fill up the cupola, he goes there for a while. Then we have him work for an hour on the floor, and maybe in the foundry, and he goes up and turns on the gas in the cupola; he may have six occupations in one day, and therefore he disregards all safety devices.

CHAIRMAN NORTHWOOD: We were discussing the light and heavy foundries and not large and small.

MR. WOLTZ: I am afraid that the only way we can dispose of the proposition you have is to get the insurance man on the platform and ask him about it. I don't think we can settle that question here.

CHAIRMAN NORTHWOOD: Is there any other discussion regarding Dr. Chaney's figures.

H. G. HENSEL (Youngstown Sheet & Tube Co., Chicago, Ill.): I would like to ask Dr. Chaney if his figures show that all of the foundries are reporting their accidents. Are they getting the reports from all the foundries listed?

DR. CHANEY: No, we are not, but we are getting what we believe to be adequate examples. We get about 85 per cent, and we think that is enough to show how things are going. The probabilities are if we got all of them, they would look still worse. I think you can see how that would be. The man who has a bad record is the one who is going to be slack about reporting. The good plant is going to report. But here's the situation: If any are left out, it's the poor plants.

CHAIRMAN NORTHWOOD: We could go ahead and discuss this the rest of the morning, but we are going to have to go on with the rest of our program. I am sure that Dr. Chaney will be glad to answer any questions that you send to him personally, and to give you any information that he can.

T. MCKINNEY (Illinois Steel Co., Chicago, Ill.): We have had Dr. Chaney with us for many years, and I think that he has done more than any man in the

safety movement to bring to our section his concrete figures. The doctor said a few moments ago that perhaps this might be the last Metals Section convention he would participate in, and I would like to take this opportunity to make a motion that we give a rising vote of thanks to Dr. Chaney for the splendid assistance he has given the Metals Section.

(The members arose and applauded.)

DR. CHANEY: Thank you. I have in an unfortunately small way been able to assist you, as our division in Washington has not been able to put on a staff to do all the things we would like to do; but we have made an effort, and I am very grateful and touched at the spirit shown.

CHAIRMAN NORTHWOOD: The next number listed on the program for this morning is a debate on the subject, "That the Foreman Is Responsible for Accidents that Occur in His Department." While this number is listed as a debate, it is in reality a dialogue. The gentlemen who have prepared this subject and who will present it to you are both men who have had prominent parts in the safety movement for a number of years.

The Foreman Is Responsible for the Accidents Which Occur in His Department

By MICHAEL P. GRADY

Foreman, Pennsylvania Shops, Canton, Ohio, and President, Stark County Foremen's Club, Canton, Ohio

By J. A. VOSS

Director, Safety and Compensation, Central Alloy Steel Corporation, Massillon, Ohio

ACT I.

Mr. J. A. Voss, Director Safety & Compensation, Central Alloy Steel Corp., Massillon, Ohio, takes the part of the safety agent. He has made a life study of the safety movement and he is President of Stark County, Ohio, Safety Organization.

Mr. Michael P. Grady, who takes the part of the hard-boiled foreman, has been in the employ of the Pennsylvania Railroad for eighteen years as a shop foreman. He has a national reputation as a poet, humorist and philosopher, and is widely known for his writings, lectures and poems on the safety first movement.

The presentation is being made (supposedly) from a machine shop, but the same can be applied in any kind of a shop, in any department in any kind of an industry. The safety man's problem in industry and the foreman's problem in industry are generally universal.

JOE — Hello, Mike! How is everything this morning?

MIKE—Hello there, Joe! What are you doing around here? Want to look around the shop I suppose. Well, go to it, you'll find we're all right.

You know you safety guys remind me of a fellow that died. His name was O'Brien. Like all good Irish he had to die. They held a wake and the neighbors came in to look at him one after another. And they felt sorry for him and they said what a good man he was—you know they never knock a dead one—and the women came in and condoled with Mrs. O'Brien, and there was one woman in particular—her name was Mrs. Murphy—and she said, "Mrs. O'Brien, Mike was a fine man."

Mrs. O'Brien said, "Indeed he was, Mrs. Murphy."

"He was an excellent man, Mrs. O'Brien."

"He was Mrs. Murphy."

"In fact he was just the finest man on this street, Mrs. O'Brien."

"Yes, Mike was a good man, Mrs. Murphy. He brought his pay envelope home to me every Saturday night. It was always empty, but it was the principle of the thing."

And so it is with you safety men coming around here. You get good pay and you kinda want to make a bluff that you are earning something. Sort of the principle of the thing.

Well, do you want to go out into the shop? Come out, you'll find we're all right!

JOE — I certainly would like to look over the shop, but before doing so would like to talk over with you our Safety plan, as well as the standing of your accident record. If you can spare a couple of hours this morning I will show you how you can get your department out of last place on the Plant Safety Standing Report.

MIKE—Can't do it now; too busy. Smith, my assistant, has been off for a couple of days with a sore eye; got emery in it.

JOE — That's too bad. How did that happen?

MIKE—Right over there on the grinder. He had a pair of goggles in his pocket but failed to wear them while grinding.

JOE — That is very often the case; goggles are furnished to protect your eyes not to carry in the pocket.

MIKE—Yea, great stuff. If we made fits on our machines like you guys make on the goggles we couldn't give them away; they wouldn't even start. When you fellows furnish goggles you got the same width goggles for a hunkie with a big wide head as you have for some little narrow panned guy. A number two head or a number eight head all the same. That's why Smitty couldn't wear the damn goggles; they didn't fit.

JOE — That is a good point. I will look into the fitting of goggles on the faces of the men. You know we get special lenses for those who require them. Mike, I know you are a busy man and have very little spare time, but inasmuch as I have set aside the morning for you, let's do it now.

MIKE—All right, Joe. I see that I can't get rid of you this morning. You are like all other safety men I know. So persistent that I can't refuse you. Some of you fellows could sell electric fans to the Eskimos. Let's go in the office.

JOE — All right. Now you are talking. I never tried to sell electric fans to the Eskimos, but I am going to try to sell you the idea that safety work if properly enforced by the foremen will reduce accidents in their department, and will take you out of last place on the Safety Standing Report. Look here, Mike; here's the last-month's report for the Corporation, showing your department in last place with a severity of 1.05 per cent. That is not a good advertisement for your department and I know that you would feel very proud of your department and your men if you could move up in the first division. And, Mike, others have done it and there is no reason why you can't do likewise in your department.

MIKE—That's all right, but some of these departments don't have the hazards that exist here in our shop, and we are bound to have more accidents in this department because of the large amount of work that we are required to handle here and everybody is busy all of the time. What I'm paid for is production. This company don't sell safety. It sells a manufactured product that people buy because they can use it to an advantage.

JOE — I can't agree with you, Mike. If your department is as hazardous as you claim it is, that is all the more reason that you should put forth greater efforts for safety than any other foreman. Furthermore, safety will assist you to increase your production rather than retard it. You have under your direction about 200 men. If your men fail to get out their work, operations

of the entire plant will be slowed down. If the work they turn out is not right, production in some other part of the plant is stopped, or at least delayed. It takes a real man, Mike, to keep things going in a shop of this kind.

MIKE—You're right. I know it takes a real man to run this place, and I have 190

The "Ferguson" Track Target for night and day service for protection of employees working on or near cars undergoing repairs, loading, or unloading; also used by section foremen to indicate unsafe track.

A—Track disc painted red with outer ring of white. Lantern in center of disc to show red light in both directions at night.

D—Clamp for securing target to rail. Padlock is used in pin for holding keeper in place, making it impossible for the target to be removed by any person other than the one placing same in position for protection.

E—Padlock on lantern to prevent removal of same from target.

men in this shop, some of them have been with me a long time. Things are different than they used to be. There was a time when every machinist was a good mechanic. I served my time and worked on every piece of machinery made before I could call myself a machinist. Nowadays a lathe hand can't run a planer or a shaper, much less cut gears and I am constantly changing men and getting new men in the department. Nevertheless, we haven't killed a man in this shop for five years, and the cause of our department being in last place is largely due to some of these fools that won't keep out of trouble. I tell you a man has to look out for himself around a place like this.

JOE—That's just the idea that we want to get across to every man in your department. Get them to think safety, work safely, report dangerous conditions and dangerous practices and cooperate with you in preventing accidents.

MIKE—Well, that's your job, big boy.

JOE — I know that is my job, but I need your help to put it across, and I am going to show you why the general superintendent wants every foreman to guard his safety record in the same manner that he guards his production record. Do you know that the general manager and general superintendent holds each foreman responsible for accidents that occur in his department?

MIKE—How do you figure that? It's my business to get out the work. It's my business to have that work accurate and get it out on time. It's my business, as you say, to do my work so that production will not be delayed. And production, Joe, is what we're getting paid for. This place is no pet charity for the stockholders, we got to make money. We don't aim to hurt men, but I can't be eyes, ears and mind for all these men. Who takes care of me?

JOE — I am just as interested in making money for the company as you are, and as I said before safety will increase your production and accidents are very costly to your department, the company and the workmen. Accidents cause delays, disturb the morale of your organization and may cause suffering and hardships to your best men and if you and I work out these safety problems in this department and reduce your accident severity, we will both feel proud of our accomplishments, in that we have saved your men suffering and misery and saved the company delay and expense caused by accidents. I know that I can reduce the days lost by men in your department 50 to 75 per cent the first year if you will give me your support, and if you would view this safety work from the proper angle.

MIKE—That 50 to 75 per cent reduction sounds interesting. What do you mean by giving you my support?

JOE — I mean just this—that I will require your assistance in properly safeguarding your machinery; that you must encourage your men to report unsafe conditions and unsafe practices and instruct every man in your department that you will not tolerate any more dangerous practices.

MIKE—You are laying out a big job for me. We need quite a few safeguards that I know of in this department and they are going to cost considerable money. I can't charge this large expenditure to my operating and maintenance cost.

JOE — That's easily taken care of. Our management sets aside every year an appropriation for new safety devices and installations and whatever guards or new devices you require I will send you a Safety Order on this form and your work will be charged to the account number of the appropriation. The account number will be marked on this order and, therefore, all expenditures on account of new safety guards and devices will be charged against this account and not against your operating or maintenance account.

MIKE—That's a fine idea. The management must be strong for this safety work if they make an appropriation every year to take care of new safety installations.

JOE — You said it, Mike. Our management does not want accidents in our plant and they are willing to make necessary expenditures to make working conditions safe, and as long as you and I have the backing and support of the management in this work there is no reason or excuse why you should continue having accidents due to unsafe conditions and unsafe practices. I want to make a survey of your shop and select the most dangerous conditions first and issue Safety Orders for them so that we can immediately

proceed in going ahead with the guarding of dangerous equipment, as I feel that it is the first thing necessary in showing your workmen that the company and the management is behind the safety movement, not only in word but also in action, and that they are willing to spend money to make working conditions safe.

Bench Sander Guard and Exhaust System. Bench Sanders of the type illustrated here are used by the Westinghouse Electric & Mfg. Co. All moving parts are completely enclosed and in addition a small vacuum system is attached to each unit. The vacuum operates automatically with the sander and removes all dust, etc. Each vacuum system has its individual dust collector or bag which is emptied at regular intervals.

MIKE—I like your system regarding the installation of safety devices and I want to tell you right now that I tried to get some of these machines guarded but could never get any action. Let's go out in the shop and look things over.

You know, Joe, this old bunk about management being willing to spend money for some guy's humanity and all that kind of stuff is peddled around a lot. The management is in business to make money. Just like a fellow told me last summer at the National Foremen's Convention we held in Ohio about one of those spell-binders talking about management being willing to do this and that. That is great stuff, he said. I was working for a Scotchman in a small shop, and it was the last day of the year. I was the only one in the shop and the boss called me in and said, "Bill,

this year I have had the most successful year I have ever had since I have been in business. I have cleared over and above all expenses \$30,000.00 and in a great measure you are responsible for this wonderful success I have had, and to show my appreciation for the effort you have put forth I am going to write you a check for \$1,500.00 and if we do as good next year as we did this year I'll sign it."

JOE — All right. Mike, in my experience I have seen many cases wherein men have been killed, lost a hand, arm or a leg on account of unguarded gears and belts and projecting set-screws, and it is, therefore, that I dread to see unguarded gears and belts or projecting set-screws anywhere. Many lives and limbs could have been saved for the sake of a \$10 safeguard. Do you know that in many states today the laws compel employers to guard unsafe machinery, and if the employer fails to do so it may cost him a large amount of money, in addition to crippling his employees if he fails to properly guard machinery.

MIKE—You're right, Joe. I know of some of my best friends who are crippled today because of the lack of safeguards, in fact I got a shot of it myself; 23rd of August, 1901; caught it in backgear of a lathe. Went to put my hand on cone to stop machine after I had shoved the shifters, talking to a fellow on the lathe back of me telling him about a girl I had a date with that night, and got the old finger pinched. All my own fault. I don't blame anyone but myself. I never paid a great deal of attention to unguarded machinery, as I always felt the man operating the machine understands it and would protect himself from getting caught in any unguarded moving parts, but I am commencing to believe we had better guard the machines in the shop and if you will send me a Safety Order to guard all the gears on the lathes, planers, boring mills, milling machines, slotters, shapers, gear cutters and drill presses, I will issue a Service Request to have this work guarded immediately. I never knew so many unsafe conditions existed in our shop until you pointed them out to me this morning, and while I cannot have it all done at once, nevertheless I will pick out the most dangerous places and have them corrected.

JOE — Inattention, girls and work don't mix. You certainly must have learned your lesson and your men can profit from your sad experience and should be taught to keep their minds on their work at all times. Inattention to regular duties causes many serious accidents. I will send you over a Safety Order right away covering this work and our guard man will be over to see you and will build the guards according to your instructions. I won't take up any more of your time this morning, but if you desire any information regarding the guarding of these machines I will be glad to come over if you will call me, otherwise I will see you some time later.

MIKE—All right, that's fine. Whenever you are ready to make the next move, come over. I am going to give this safety work a whirl and see if it will have any effect on our accidents. I suppose I'll have to work like H— to make up the time I spent with you this morning, but I guess it is time well spent. So long.

ACT II.

(One month later)

JOE — You look as though you haven't a care in the world this morning. How are things going?

MIKE—I see you're right on the job this morning, Joe. Things are going pretty good this morning and I want to show you some of the machinery that has been guarded. The boys are very much pleased with these guards and are

glad to see that the company is taking action to guard them against accidents.

JOE—That's fine. I am glad to hear that, and I believe that your next move is to let your men know that you are going to have real safety in this shop from now on. The first move in organized safety work is to interest the manage-

Car shifter constructed with a "Rex" steel heel which "bites" the rail with practically no slip. For detail of large end of bar see picture, page —.

A—Steel disc five inches in diameter, x 1½ inches thick, located 14 inches from end of bar. It may be welded in place with an acetylene welder or pinned. In case bar should slip or turn and man should be thrown forward, no matter how bar may strike the head of rail or ground, this disc provides a stop which prevents injury to fingers.

This bar was originated by employees at the Lorain Works. Note in inset picture the four cornered piece of "Rex" steel inserted in the forging. When one corner of this steel becomes worn it is driven out, turned around, and another corner is used. A very efficient tool and easily kept in repair.

ment; second, superintendent; third, foremen; and fourth, the workmen, and I believe if you could arrange to call your men together one-half hour before lunch time we could arrange to explain to them the company's policy regarding safety work.

MIKE—I can't talk and you might have sold the management and superintendents on this proposition, but how do you know that I am sold. I can't see the idea of wasting one-half hour of a man's time in explaining safety work.

If there is anything wrong in this shop, I know it, but how can you educate some of these fellows against dropping material on their feet and getting emery in their eyes or getting their fingers hurt on cutting tools by merely talking to them.

JOE — Our accident statistics show that 25 per cent of accidents are preventable by safeguards and 75 per cent by education, and there is no better way of getting your men trained to do their work safely than to call them together every two weeks and discuss safety problems with them. I know that you are pretty well sold on this safety idea from the fine treatment you gave me last month and you have a very good start, so let's call this bunch together at 11:30 and tell them what you are going to do and what you expect them to do toward safety. I would like to have you start the meeting by making a few remarks and then you can introduce me and I will explain the company's policy regarding safety and if you have any suggestions to offer or points that you want me to bring out while addressing the group, I will be glad to do so.

MIKE — I can't talk and I resent standing before that group and telling them about this safety work as they will think that I am getting cold feet, but if you say so I will let past be forgotten and start out from scratch.

JOE — Forget that, Mike. This same plan has been followed by every department in the plant and it is not an experiment. Your men will think more of you as a leader if you take a definite stand to guard them against accidents, so let's line up a meeting for 11:30 today.

MIKE — All right. I will see you at 11:30 and will have the men gather directly in front of the office where we can talk to them.

(Same day—11:30 a. m.)

MIKE — Fellows we called you together here this morning because the Safety Man is here and he wants me to introduce him, but I'm just wondering like an Irishman did one time—I'm just standing here wondering who is going to introduce me.

You know there was an Irishman who had a peculiar experience in this introduction stuff, back in the hard-coal regions of Pennsylvania. The great Senator Potts was running for re-election and he was going to a little mining town and hold a political meeting. They built a big platform in the center of the town, and it was just about time for Senator Potts to arrive. The fellows wanted to know who was going to introduce the Senator, and one fellow said, "Not me, I don't want to do it," and finally a fellow named Mike Maloney was told that he would have to introduce the Senator, "Sure, I don't know anything about that kind of stuff."

The fellows said, "You must introduce him," and some fellow produced a prescription that had half a pint in it, and he took a couple of swallows, and then he knew that he was going to introduce the Senator.

Finally the Senator arrived and was climbing upon the platform and the people pushed Mike up to the front, and the fellows gave him the remainder of the prescription, and said, "Now, Mike, there are two towns in Pennsylvania named after this fellow, two towns named after him."

So Mike got up and when they became quiet, he said, "Gentlemen and Mike: We are here today to listen to the Great Senator Potts. He's Senator now and with the help of God and your votes, he'll be Senator again."

"There is three towns in Pennsylvania named after him. There is Pottsville and Pottstown, and—and Chambersburg."

Gentlemen this safety stuff, I got to hanging around with this Safety Agent a couple of months ago and there is more to it than I thought there was. I'll tell you what converted me to the thing entirely and that was about a week ago when he brought me over to poor old Bill's house. You

know Bill lost his leg—everybody knows that and there was poor Bill without a leg. The company gave him a good settlement as far as the law goes and they are going to give him a job, but there was Bill's six kids and they are going to have a one-legged daddy all the days of their lives. No matter how much money they acquire, their father will still be a one-legged man.

You know that safety fellow I thought he was the bunk at first, just trying to draw his pay and get a raise if he could, but I have been hanging around a little with him and its kind of a religion. This fellow talks this

Safety Tie for Piling Rounds. The safe piling and tying of round stock has always been a problem. However, at the National Tube Co. two shaped irons have proved satisfactory. These irons are made of $1\frac{3}{4}$ inch square stock and in assorted lengths to suit the stock being piled. One end of the iron tie hooks over the bottom tier and the other end holds the round being piled. Wooden blocks (2 x 4 inches) are placed between tiers to assist in placing or removing crane chain.

kind of stuff. He believes that he's dedicated his life to the commandment that we are our brother's keeper, and there's a lot in a guy like that when he gets through, and I tell you fellows it's a pleasure for me to introduce to you today the Safety Agent, Mr. Voss.

JOE — Boys, I was highly pleased when your good boss, Mike, asked me to come over this morning and talk to you on the subject of Safety. Most of you fellows have seen in the last month or so that Mike has been taking an interest in the shop and he's fixing up the machinery and trying to make working conditions safe.

He has decided that inasmuch as his department is in last place on the Safety Standing Report that he is going to have real safety in his depart-

ment, and, of course, you know he cannot do it alone. He must have your help. Don't get the idea that we are through when we put the safety guards on the machinery. That's only 25 per cent of the job. The other 75 per cent is safe work, and if you are going to reduce accidents it is right in

Plate Wedge. Wooden wedges of the type illustrated are used by the Carnegie Steel Co. for separating steel plates during sorting and inspection. The design of the wedge is such that the hand of the operator is protected against cuts or bruises from the sharp edges of the plates.

the hands of you men standing before me here today. It is up to you whether or not you are going to reduce accidents in this department. It is up to you to cooperate with your foreman, to give him support and to view this safety problem from the standpoint that it is good business for you and your fellow-workmen.

If I sell you on the idea of safety this morning, I would feel that it was time well spent. If I could take you into the hospitals or into the homes of some of the men who have been hurt in this shop, some that you person-

ally know, and you would listen to the tale of woe, the misery and the suffering caused on account of the indifferent attitude toward safety, on account of carelessness, I know that each and every one of you would take an active interest and cooperate with your foreman in this great humanitarian work.

Realizing the possibility of the crane hook slipping out of place and allowing the tin plate carrier, when landed, to topple over, the Youngstown Sheet & Tube Co. have filled in the hook eye with a solid plate. Thus the usual "slack" is eliminated as well as increasing the efficiency of the unit. As an added feature the jaw tips of the carrier are rubber covered. This prevents slipping and has an operative feature in that the tips do not mark or damage the tin plate.

Now some of you fellows have the idea that safety is a fine proposition for the company because they are going to save money that they would have to pay out for compensation in case of accident. I want you to clear that from your minds. This safety movement is sponsored by the management not for monetary reasons but from the humanitarian point of view.

If any one of you men could sit in the office of the general manager and every morning see the reports that come in from the safety man—Bill was killed, Jack lost an arm, Frank lost a leg, and if you had at your command authority and supervision to stop conditions of that kind, what would you

do? You would take action to stop accidents because there isn't anyone from our management down that wants to see any man get injured and that is why we are appealing to you to help us in this safety work.

It is good business for the company, it is good business for you men, and inasmuch as it is good business for all, why not put it across? Why not help your foreman to accomplish a real safety record? It can be done. Other departments have done it, and I know that each and every one of you if you take the proper attitude in this safety work, that you are going to

At main entrance to the Plant of the Lorain Steel Co., Johnstown, Pa., "Safety Candles" are kept burning with a green bulb or light to indicate that there has not been a lost time accident in the department. Should there be a lost time accident a red bulb or light is placed in the candle representing the department in which accident occurred and the red light remaining until the end of the month when it is again given a clean slate with a green candle. Each candle is 3 feet and 6 inches high.

establish a record in this department that your foreman and that you men will feel proud of, and you will look back to the day when we had our first meeting, and you will say, "Why didn't we start this sooner. This is a mighty fine proposition."

Another thing, boys, that I want you to do. I want you to feel that the safety problem is not a one man's job. It isn't the safety man's job alone. It isn't your boss's job. We must all work together, and if you see anyone taking a chance, or if you see any unsafe conditions report them to your foreman immediately. Don't tell your buddy, "Jack, be careful." Show him how to be careful, and if you are doing that, you are cooperating with safety.

Above all, don't take chances. Chance-takers eventually get hurt, so don't take chances.

In regard to safety suggestions. We don't care what you have on your mind, whether it is mechanical or electrical or operating, you are not going to be criticized if you make a suggestion for safety in this plant. Now, boys, if you know of any unsafe conditions or unsafe practices, we would like to have you tell us about them.

SHOPMAN—Mr. Safety Man and Foreman: I have something I want to suggest. I have worked in this shop about a year. I was in the shop across the

Pit Stairway Housing. Realizing the hazard of men being struck by loads, flying cobbles from mill, etc., when ascending or descending pit stairway, the Youngstown Sheet & Tube Co. have housed these entrances as illustrated. The housing is made of heavy sheet steel and reinforced with angle iron so that it will withstand a heavy blow.

street. He has lots of safety over there. Here I see that our lathes don't have belt shifters. Why can't we have those here like Smith & Co.?

JOE — That's a fine suggestion, Jack. We were talking about that this morning. Get that down, Mike.

SHOPMAN—Hey, Safety Man! I have been working in this place a long time and maybe I get the air for talking now, but I'm going to tell you. I saw a fellow on that planer over there almost get pushed to the wall by the planer bed. He gets so close it pushed him over. I don't care if I get fired, I think maybe some day I get it.

JOE — That's all right, that's a mighty good suggestion. Don't you ever worry about getting fired for making safety suggestions.

SHOPMAN—How about locks? We want locks to lock open these switches. We had them in the other mill when we were working on machines. That company gave us locks. You don't give us nothing. We want our locks on

Skelp Mill Interlock. The hinged gates bar "A" secured by latch "B" closes off the space between end of roller table and face of shear housing on mills in the National Tube Co. When necessary for a man to enter this space, gate "A" is opened which automatically breaks the controlling circuit, located behind gate "A" near latch "B." This deadens the roller table and thus prevents the plate being run onto the man working in this space.

the machines so a fellow cannot come along and throw in the switch. That's the kind of stuff we want.

JOE — That's a good suggestion. We'll see that you get locks when you are oiling or repairing a machine. (To foreman) Did you get that suggestion.

MIKE—Get locks.

SHOPMAN—Do you care if I say something, boss?

I work in that machine shop for about twenty-five years. Over here on the drill press in the corner of the shop, I was working yesterday and had a brand new pair of gloves on and got caught in the drill and it pulled me

around. I didn't get hurt. I didn't go to the hospital and I didn't say anything about it, but I would like to know what can be done.

JOE — We can get brushes to remove those drillings. (To the foreman) Better take that down.

JOE — Anybody else?

SHOPMAN—How about goggles? There's only one pair of goggles hanging on the stand there and everybody is using them. Everybody wants a pair of goggles.

Adjustable plate shields to enclose the top of the cupola when the cupola is not in use or when men are working inside. This is done at Lorain Works, National Tube Co., to avoid the possibility of material being dumped into the cupola for thoughtless charges.

JOE — That is the way it is going to be handled. We are going to carry goggles in the storeroom and every man will have his own pair.

SHOPMAN—Mr. Safety Man, when we get hurt why do we have to wait until we go home to get fixed up. Why can't we go to the First Aid right away?

JOE — Why, don't you go to the First Aid?

SHOPMAN—The boss won't let us go.

MIKE—Some of these fellows have four first-aids, one on every corner right out there.

JOE — Anything else this morning, boys? It's about twelve o'clock now and time for lunch. I certainly want to thank you for your attention. I think you will find that your foreman is going to hold meetings with you men at least once a month. If you have any safety suggestions or know of any unsafe

conditions, don't hold them over until the safety meeting, because some one may get hurt.

There is nothing more today. So we will see you sometime later. Thank you.

(Immediately after the meeting)

JOE — The boys were very much interested in what you said and you certainly put across the idea in fine style. From the way they responded when asked for suggestions and the interest displayed, I believe you're going to have real safety cooperation in this shop. You know when the old boss stands before them and talks to them like a daddy as you did today they are not going to be hesitant about cooperating with you. I have always found that the foreman is the back-bone of the safety movement and he is going to have just as much safety in his department as interest shown by him in the work.

MIKE—Like all safety men, you have a good line and you are certainly making it stick with me. I hope that I can make my line stick with the men as well as you did with me. I never thought I could stir up so much enthusiasm in safety within one month's time and the way the men are taking to it I am commencing to believe that the foreman is responsible for safety and for accidents in his department. What are you going to do with these suggestions you received today?

JOE — You and I will check them over and if they are approved we will cover same with a Safety Order.

MIKE—That's fine. I am going to lunch now. See you later.

ACT III.

(One month later)

JOE — You look as though you haven't a care in the world this morning. How are things going?

MIKE—Everything is going along just fine. Smith, my assistant, came back after losing time on account of the sore eye and believe me I lined him up and told him what was to be expected of every man in this shop from a safety standpoint. He said he learned his lesson and from now on he is for safety. Do you know that since we started safety work two months ago everything seems to be different around here? I am having less trouble, getting better and more work out of the men, and I have more time to look after work other than the regular routine work of the shop. I hope that this enthusiasm will continue and that it will not dry-rot as it has several times in the past, because I have learned now that it is going to be a great help for everyone in the department.

JOE — Our company is strong for safety work and as long as the general manager is behind the movement, you need not fear about safety losing its enthusiasm. However, don't forget, Mike, that while the management and superintendents may be ever so enthusiastic about safety, the foremen must be just as enthusiastic and must constantly plan and scheme in keeping every man in his department enthusiastic. I see that your safety work is moving along in fine style and the safeguards certainly make a neat appearance in the shop.

MIKE—Yes, everything that has been started so far is going along nicely. What do you have up your sleeve for us this morning.

JOE — I want to talk to you about appointing a Safety Committee.

MIKE—I heard about the committees in the other departments, but go ahead and tell me what you want.

JOE — Safety committees are organized to assist in preventing accidents and securing the ideas and cooperation of all employees. In addition to a permanent general committee, a committee should be appointed in each department. The duty of each committee is to take note of defects in machinery, buildings, methods of working or handling material, or of any conditions throughout the work, which may be the cause of accidents to employees, or which may be detrimental to their health. Members of the committee shall at all times bear in mind that the prevention of accidents is one of their most important

A crane wheel fender in use at Lorain Works, National Tube Co., consists of a cast steel Shoe "A" hung in front of wheel by Adjustable Bolt "B" and Links "C." Shoe "A" is of sufficient width to entirely cover the exposed part of the wheel and flanges, and is adjusted by "B" to clear the rail by $\frac{1}{8}$ inch. The Lugs "DD" project down on either side of the head of the rail, preventing a man's hand from being caught between the rail and the fender. The shoe is designed to fit the tread of the wheel on one side and the curve of the bumper on the other side, so that no change is required to bumpers as used at the Lorain Works.

duties. Inexperienced employees and those found indulging in dangerous practices shall be cautioned. Reports on what has been done to promote safety and prevent accidents, as well as safety suggestions, should be turned in to the chairman of the committee each week. The committee shall investigate and file a written report in regard to all serious accidents and should carefully study all accidents in order to prevent their recurrence.

MIKE—That looks like a big job for somebody. How many men should be on this committee and who should be on this committee?

JOE — The work of this committee is very important and I would suggest that you select about five of your best men to serve on this committee, and this committee should make a weekly inspection of your department and the

chairman should send a report of their inspection to you, and, of course, you should take immediate action on their recommendations. You should also meet with this committee once each month and go over their reports with them and advise them as to the action taken upon their recommendation.

- MIKE—Say, Joe, why do you want to rob me of my best men on this committee? Don't forget, boy, I got to get out the work. Why wouldn't some persons other than my best men do the job?
- JOE — The best men in your department, Mike, are none too good for serving on safety committees. Our manager and leading superintendents of the corporation find sufficient time each month to meet with their General Safety Committee and discuss safety matters.
- MIKE—I'll think this proposition over and will follow your suggestions along this line and will endeavor to give this work the necessary attention.
- JOE — All right, Mike; that's fine. One other item I would like to speak to you about this morning and that is installing two safety bulletin boards in your department where we can post bulletins, reports, etc. These boards will be maintained and changed weekly by our department and if you will show me where you would like to have them placed, I will have them installed.
- MIKE—That's fine. I know two good places where these boards can be installed. One at the tool room window and the other on the east wall.
- JOE — I will see that they are installed in the next day or so. The only other item I want to talk to you about this morning is that of safety rules. I have prepared a rough sketch of safety rules for your department and would like to have you go over them carefully and make such corrections and additions as you deem necessary. As soon as they are approved, we will have them printed on "crystalloid" and placed at conspicuous places in the shop.
- MIKE—I will go over them with the members of my safety committee and will return them to you as soon as they are approved. You fellows certainly give us plenty to do.
- JOE — That's all right. After you get going in this work we won't crowd you so much. Have you anything else on your mind this morning?
- MIKE—No, nothing that I can think of this morning. Everything is going along fine.

ACT IV.

THREE MONTHS LATER

- JOE — What are you doing?
- MIKE—Writing a little Poem. What's on your mind?
- JOE — Don't get excited, I am not going to take very much of your time this morning, but I am going to leave a few pads of this "Foreman's Report of Unsafe Practices Corrected Daily" form with you and wish you would distribute them amongst your foremen and explain to them that they are to report daily any unsafe practice existing in their particular unit. You will find that this report if properly used by your foremen will bring to your attention many dangerous practices that are going on in your department unbeknown to you. I might also suggest that you discuss this report with your safety committee. Also whenever you have your gang together like we did the last time I was here, you want to read those dangerous practices and when you have a meeting of your safety committee, discuss them.
- MIKE—I think you're right on this dangerous practice business. Since I became interested in this safety work I found quite a few dangerous practices that

were going on in this department, and I'm going to get my committee and all the rest to use this form.

Want to tell you we're having safety meetings every month and I meet with them. Got it down to once a month, and every week the shop committee inspects the shop. And things are all right. They're going pretty good. Everybody seems to be kind a happy about the thing. It's going along better, and I'm pretty well sold on the idea of safety now myself. I believe I have learned that the foreman is responsible for the accidents that happen in his department.

JOE — Mike, I'm glad to hear you say that! A foreman should be interested in

The safe method of breaking out a runner gate. A shield protects the man from splash of metal, and he is also protected by wearing leggings and face mask. A device used by National Tube Co., Lorain Works.

accidents that occur in his department, because accidents decrease production and increase costs. A foreman is the determining factor in safety, and the attitude of the workmen depends absolutely on the attitude of the foreman.

A safety foreman must have certain qualifications—

He must believe in safety.

He must be sincerely interested in the welfare of his men.

He must be a leader capable of winning the confidence of his men.

He must be informed on safeguards and safe practices.

He must have backbone.

He must be square with his men and show appreciation of their efforts.

A foreman can do a great deal to prevent misery and suffering to his workmen—

He can interest his men in safety by studying their jobs and giving specific directions as to the safe methods of work.

He can start new men in the right direction by showing them that every one in the shop is pulling together for safety.

He should understand and present safety to the workmen as a business proposition.

He should know every dangerous place or practice in his department.

When fire brick is being transported on flat cars there is a great probability that they will be jolted loose. As a precaution the National Tube Co. load the car so the pile is "cross-bonded" and in addition require that wooden corner supports be securely roped in place. Thus the load is handled safely and efficiently.

He should be responsible for safeguarding and should act promptly.

He should see that tools and machines are kept in proper repair and adjustment.

He should insist on the care of slight injuries.

And, Mike, the real foreman of the day is the one who is capable, competent and efficient in his work. A man who is a leader in safety. A man who can lead his men into safety rather than drive them, and a man who has learned that the foreman is responsible for accidents that occur in his department.

MIKE—Well, I guess you're right. Accidents will happen but I don't want any more of them! You know since I finally got that safety spirit of yours in my nut, after two or three months of hard pounding on your part, I never put so much thought to a thing in my life as I have to that, and I think that the greatest service one man can do for another is to preserve human life. You know after all it is a question of how we should live, how we shall make the most of our life and put it to the best use. This is not politics or trade or war, it is pleasure.

Safety Chain Hook for Pipe Mill Cranes—Handle "A" enables operator to manipulate hook without placing his fingers where they might get crushed between hook and loop or link into which it engages. (A National Tube Co. device.)

Hump "B" prevents hook from accidentally engaging any object. This style of hook is applicable only in special instances, such as the above.

The primary consideration is not how one shall make a living but how he shall live, for if he lives rightly whatever his need he will easily find. Life is opportunity; therefore, it's whole circumstance can be made to serve the purpose of those who are bent on self-improvement, on making themselves capable of doing thorough work. Opportunity is a word like so many others that are excellent. We get it from the Romans. It means "near port," "close to haven." It's a favorable invitation to seek safety, to refresh. An appeal to make an escape from that which is low and vulgar and to seek refuge in higher thoughts and worthier deeds. It is omnipresent. What we call alleviating poverty, neglect and suffering, or otherwise opportunity for good.

Valve pit marker, bolted to the manhole cover to plainly identify the valve, so that in case of emergency, by consulting the charts of the water lines, which are posted throughout the works, the proper valve can be located quickly. A bar may be passed through the holes "A" in pipe to lift off the cover. These markers also serve to prevent material being piled on top of manhole cover, and are especially serviceable in winter when there is snow on the ground. The cover is chained underneath to manhole ring, to prevent danger of exchanging covers where two or more manholes are close together.

When you leave for your work in the morning,
 After bidding your family good-bye,
 Always heed well your wife's gentle warning,
 "Do be careful!" is ever her cry.
 Watch each man just like a relation;
 Other workers place great faith in you
 Let's give them safe co-operation—
 Then this great safety dream will come true!

CHAIRMAN NORTHWOOD: I want to introduce your incoming chairman of the Metals Section, and we are going to ask Mr. Ed Quesnel, who will take over the guidance of the Metals Section for the next year, to take charge of the balance of this meeting so that you will have an opportunity to get acquainted with him and help him.

I am going to ask for him the same kind of cooperation that you have given me during the past year, and I want you to know him and know that he is a good

fellow. If you will all help, we can make a big success of your Metals Section for the next year.

(Mr. Ed Quesnel assumed the chair.)

CHAIRMAN QUESNEL: We will now go on without any further preliminaries.

I wish to entertain the motion that we give a rising vote of thanks to our retiring officers and chairman and Executive Committee for the wonderful work and the wonderful success they have made of our section.

(The motion was seconded and the members gave a rising vote of thanks.)

PAST CHAIRMAN NORTHWOOD: In behalf of the Executive Committee I thank you.

Special grease cup for use on crane bearings and other bearings in elevated positions where there is danger that an ordinary cup would work loose and fall on workman below. A—Portion attached to bearing. B—Cup free to turn easily in wire loop "C" located in a circular groove. D—Two lugs on cups for screwing same. E—Washer and chain for anchoring grease cup to some fixed bolt (say cap bolt) on the machine. If cup works loose, it cannot fall. (National Tube Co.)

CHAIRMAN QUESNEL: I think, gentlemen, we are all well repaid for our trip to the Congress by what has just transpired. I think that the experiences and the lessons we have learned from this debate are most valuable and it is good food for thought to take back with you. Use it in your own plant. You can use it in your industrial meetings with good effect.

I would like to take this opportunity to cover the recommendations that were made in regard to appointing a committee on foundry accident experience, so that you men may all know that we are going to take action on it.

I will ask Mr. Fred Bennett to act as chairman. Along that same line I would like the new officers of this section to please remain a few moments after the adjournment of this meeting, in this room.

Now our *News Letter*. Those of you who are receiving the *News Letter* know how valuable it is. Mr. Earl Blank is our new secretary and editor of the *News Letter* for this coming year. He can be reached by addressing him Jones & Laughlin Steel Co., Pittsburgh. I hope you will all remember the name and the place. Let's support this letter, gentlemen. The more we can furnish ideas to our fellow-workers, the better it will be for this section.

I wonder if you know that you can have as many copies of this letter as you desire. Some plants have found it very advantageous to send out copies to each of these department heads. I think in our case we get seventeen copies, and the part in them that pertains to any particular accident and the whole letter is sent out to the department head. That saves circulating the letter around through the shop and permits them all to get the letter at the same time. There is no extra charge. You can get as many copies as you like by writing to the National Safety Council. Just write and tell them how many copies you would like to have mailed to you regularly each month.

Now we will go on to another very interesting part of our program. That is the matter of learning what has been done by actual observation. Our good old friend, the Carnegie Steel Co., has taken a great deal of pains to gather pictures throughout the United States showing safeguards and their methods of use. It gives me great pleasure to introduce to you Mr. John A. Oartel, Chief of Safety Bureau, Carnegie Steel Co., Pittsburgh, Pa.

JOHN A. OARTEL (Carnegie Steel Co., Pittsburgh, Pa.): This is a visual tour of the country on special lines of safeguards or new stunts which have proven successful in many plants.

I want to thank those who have sent in nearly one hundred photos.

(With this brief introduction, Mr. Oartel began to show a series of lantern slides of extraordinary interest, which comprised, in all, more than 80 pictures. It is impossible, of course, to reproduce in the Transactions all of these pictures, but a few have been selected which appear in the preceding pages. In each case, an explanation of the picture is given below it, which is a summary of the running remarks with which Mr. Oartel presented the picture.)

ADJOURNMENT

SEVENTEENTH ANNUAL SAFETY CONGRESS
NATIONAL SAFETY COUNCIL

Mining Section

New Section Officers

General Chairman—GEORGE MARTINSON, Pickands, Mather and Company, Hibbing, Minn.

Vice-Chairman—A. W. DICKINSON, The Union Pacific Coal Company, Rock Springs, Wyo.

Vice-Chairman—J. P. HODGSON, Phelps Dodge Corporation, Bisbee, Ariz.

Vice-Chairman for Statistics—RUSH N. HOSLER, Pennsylvania Compensation Rating and Inspection Bureau, Harrisburg, Pa.

Vice-Chairman—F. C. MILLER, The Colorado Fuel and Iron Company, Trinidad, Colo.

Secretary and News-Letter Editor—DANIEL HARRINGTON, United States Bureau of Mines, Washington, D. C.

Poster Committee Chairman—FRED H. NESBITT, Tri-State Zinc and Lead Ore Producers Association, Miami, Okla.

Membership Committee Chairman—C. A. McDOWELL, Pittsburgh Coal Company, Pittsburgh, Pa.

Publicity Committee Chairman—J. M. CARMODY, Coal Age, New York, N. Y.

Slide Committee Chairman—H. G. HENSEL, The Youngstown Sheet and Tube Company, Chicago, Ill.

Program Committee Chairman—THEODORE MARVIN, The Explosives Engineer, Wilmington, Del.

Entertainment Committee Chairman—J. T. RYAN, Mine Safety Appliances Company, Pittsburgh, Pa.

Executive Committee:

B. C. YATES, Homestake Mining Company, Lead, S. D.

B. F. TILSON, The New Jersey Zinc Company, Franklin, N. J.

H. I. YOUNG, American Zinc, Lead and Smelting Company, Mascot, Tenn.

Retiring Officers

Chairman, C. A. McDOWELL, Pittsburgh Coal Company, Pittsburgh, Pa.; *Vice-Chairman*, GEORGE MARTINSON, Pickands, Mather & Company, Hibbing, Minn.; *Vice-Chairman*, A. W. DICKINSON, The Union Pacific Coal Company, Rock Springs, Wyo.; *Vice-Chairman*, J. P. HODGSON, Phelps Dodge Corporation, Bisbee, Ariz.; *Vice-Chairman*, F. C. MILLER, The Colorado Fuel & Iron Company, Trinidad, Colo.; *Secretary*, DANIEL HARRINGTON, United States Bureau of Mines, Washington, D. C.; *Poster Committee Chairman*, H. C. HENRIE, Phelps Dodge Corporation, Bisbee, Ariz.; *Membership Committee Chairman*, H. I. YOUNG, American Zinc, Lead and Smelting Company, Mascot, Tenn.; *Program Committee Chairman*, THEODORE

MARVIN, The Explosives Engineer, Wilmington, Del.; *Publicity Committee Chairman*, C. A. CALLEN, "Coal Mine Management," Chicago, Ill.; *Entertainment Committee Chairman*, J. T. HOSLER, Pennsylvania Compensation Rating and Inspection Bureau, Harrisburg, Pa.; *News-Letter Editor*, DANIEL HARRINGTON, United States Bureau of Mines, Washington, D. C. *Executive Committee*: THE OFFICERS AND B. C. YATES, Homestake Mining Company, Lead, S. D.; B. F. TILSON, The New Jersey Zinc Company, Franklin, N. J.

October 2, 1928

C. A. McDOWELL, Chairman

Safety and Personnel Manager, Pittsburgh Coal Company
Pittsburgh, Pa.

The first session of the Mining Section was called to order at nine-fifty o'clock by the chairman, Mr. C. A. McDowell, Manager Safety and Personnel, Pittsburgh Coal Co.

CHAIRMAN McDOWELL: The Council has rearranged the program for this year to the extent that the report of the past year committees will be made by the chairman. I accordingly wrote each chairman to get his report and I will give you the reports as briefly as possible.

Report of the Poster Committee

Immediately following last year's Safety Congress, we requested your chairman, Mr. McDowell, to appoint certain members of the Mining Section as a Poster Committee; and in order to give individual members an opportunity to express their views, a letter was addressed to each member of the Mining Section, requesting his suggestions and ideas.

During the past year, material for one hundred sixty-three posters was submitted to Mr. Gardiner, Director of the Poster Division. From the material submitted, twenty-four Mining Section posters have been issued, in addition, four other posters of general nature have also been issued. About one-half of the material submitted is still on hand and available for future use.

We wish to take this opportunity of thanking the members of the Committee who have cooperated so effectively with us during the past year and also to express our special thanks to Mr. Gardiner, Director of the Poster Service for his excellent cooperation and assistance throughout the year.

H. C. HENRIE, Chairman.

Report of the Membership Committee

Your Membership Committee begs to submit the following report:

Number of Members in Mining Section, Sept. 14, 1927.....	236
New Members During Year.....	34
Members Transferred from Other Sections.....	4
Memberships Cancelled During Year.....	28
Total Number Members in Mining Section, Sept. 12, 1928.....	246

The above shows a net increase of ten members for the year, four of which were transferred from other Sections, leaving an actual increase of six.

It has been the policy of your Membership Committee not to confine its activities entirely to securing members for our Section, but rather to try to induce industries and schools to join the Safety Council, regardless of the classification under which their membership might come.

A very comprehensive membership campaign was proposed by Mr. P. N. Bushnell, Director, Service Extension. The various letters and circulars put out during this campaign were approved by the officials of the Mining Section. I feel that the program outlined by Mr. Bushnell is responsible for the greater part of the increased membership of this Section.

As you appreciate, the condition in the Coal Industry, where we have lost the greater part of our members during the year, has been such that all companies are attempting to reduce expenditures to an absolute minimum, and some of the coal executives have the erroneous idea that costs can be reduced by cutting off National Safety Service. We, who are thoroughly sold on Safety, know that costs are reduced by expending money for Safety, rather than increased; and we believe that if it were possible for some person representing the National Safety Council to call on the various companies who have dropped their membership during the past year, they could be shown where it would be profitable to continue their membership.

I want to express my appreciation of the wonderful cooperation given by each member of our Committee, and to Mr. Bushnell for his part in connection with the activities of our work.

H. I. YOUNG, Chairman.

Report of the Slide Committee

My report as Chairman of this Committee will necessarily have to be confined to suggestions for next year's work. Practically all that was done during the past year was to meet with the members of the staff of the headquarters of the National Safety Council and to go over the plans of the coming year with them.

An experiment has been tried out in several other sections regarding the gathering of slides to be used by members throughout the year and to be shown at the Annual Congress. It is the belief of the headquarters staff that it would be of much value to the members of this Section to have available film strips which can be borrowed by them and used at their own office and returned to the headquarters to be used at this Annual Meeting. The idea is that a number of members should be selected each year, as members of the Slide Committee, and they are to furnish, to the headquarters staff, photographs on a particular phase of safe and unsafe practices in mining. Each film strip should show a dozen to fifteen photographs, and if a certain member of the Mining Section is assigned a certain phase of safe and unsafe practices in mining, he should furnish from a dozen to fifteen photographs which the National Safety Council will have made into film strip. This seems to have worked out very well in other Sections and we are to hear from Mr. Burns of the headquarters staff and from a member of another section who has successfully gathered pictures for these film strips of safe and unsafe practices and they will no doubt explain to this Section, very clearly, how the job should be done.

It seems that the National Safety Council Headquarters has quite a large number of photographs on hand that display safe and unsafe conditions; also numerous safety devices, all pertaining to mining, but there have been very few photographs furnished showing safe and unsafe practices, and an analysis of most all accident records now-a-days proves that these accidents have been due to unsafe practices and it seems well worth while to make a drive against these unsafe practices.

It would seem to be of much value to all of us who are interested in Mining to be able to send, from one mine to another, pictures furnished by other people showing how they do their work safely and how they have eliminated some of the

unsafe practices. It would seem that such pictures, if shown to foremen under the proper supervision of the management, would do much to stimulate activity to stop unsafe practices in any mine.

I am sure that our people would be very glad to use such film strip on safe and unsafe practices if they were available, and I will be only too glad to assist in furnishing pictures on any phase of this that may be assigned to us.

H. G. HENSEL, Chairman.

Report of the Program Committee

THEODORE MARVIN (The Explosives Engineer, Wilmington, Del.): I would like to acknowledge the assistance of certain gentlemen who aided considerably in being the liaison between our desires to secure the service of certain men and those men; and it is a pleasure to acknowledge the assistance of Dr. H. Foster Bain, Secretary of the A. I. M. E.; Dr. T. T. Read, Assistant Secretary, A. I. M. E.; Mr. Harrington, Mr. Huntress of the National Coal Association; Mr. J. M. Carmody, Editor of Coal Age; and, of course, Mr. Jack Ryan, of the Mine Safety Appliances Co.

Mr. Ryan, as you know, is chairman of the Entertainment Committee, and has arranged some rather interesting breaks in the program which I am sure you will all enjoy. It is due to these gentlemen's assistance that the program has been arranged as interestingly as it is. I am sure it will help. I certainly thank them through you, Mr. Chairman, for their help.

CHAIRMAN McDOWELL: As Chairman, I desire to thank you, Mr. Marvin, and your associates for the program and I assure you that we greatly appreciate your sincere effort and your part in helping to make up such a program.

Now, we have the Chairman of the Engineering Committee, Mr. Carmody, Chairman of this Committee, reports that there is a bulletin in process of review by several experienced safety engineers, and no doubt this will be brought out and accepted in due time by the Mining Section. The committee also approved and sent through one safe practice pamphlet. We thank you kindly, Mr. Carmody, for your time spent in helping the Chairman in this work.

I have attached to this report (appearing on page 233) a statistical analysis of ordinary fatalities from falls, 1920 to 1927, showing the relative pillar hazards and this will be shown with our yearly report. We thank you kindly, Mr. Hosler, and I am sure the membership appreciates your efforts.

The News Letter editor. I think this report of mine would be rather incomplete without thanking our good secretary, Mr. Harrington, for the splendid inspirational and worthwhile *News Letters* which he contributes monthly for our benefit. I am sure that the membership appreciates these *News Letters* greatly. I dare say it is without doubt the best *News Letter* that any section puts out. Thanks, Mr. Harrington, for your work.

I also think the report would be incomplete and we must not overlook another committee that was appointed last year and added to the official family of the Mining Section, and I refer to Mr. Ryan, Chairman of the Entertainment Committee. We do not know what is in store for us this year but I think it would be well for us to keep our eyes open, get to our meetings on time, stay until they are over and don't miss anything. Thanks, Mr. Ryan, for what we may expect and your past record on entertainment committees is such for us to express our thanks at this time.

That, gentlemen, is the report of the various committees and report of the chairman. What is your pleasure?

(Motion that report be accepted and adopted was seconded and carried.)

Ordinary Fatalities from Falls—1920 to 1927—Showing Relative Pillar Hazard

The next part of our program covers a speaker, and the subject is "Safety Pays." At this time, we are glad to hear from Mr. Robert M. Lambie.

Safety Pays

By **ROBERT M. LAMBIE**

Chief of the Department of Mines, State of West Virginia

It was a surprise indeed to me to get a telegram from my friend, Mr. C. B. Huntress, a few days ago to address this meeting. I have been extremely busy for the past several weeks, and I didn't get home in time to answer that telegram. I realize my limitations and that I am not, in any measure, a talker. I did not know whether I should answer in the affirmative or not. However he was so insistent, I did acknowledge it.

Coming from West Virginia, I am rather proud of the fact. I just want to give you a little background of the State before discussing whether safety pays.

West Virginia is a mountainous state. Pioneers of that State had many obstacles to overcome in settling. During that process the spirit of daring was built up within the folks that lived there. They had to battle fiercely against the beasts of the forest and the elements of that country. After many years, one of the greatest geologists, as you know, discovered coal in West Virginia. It was of such quality and such magnitude it attracted many men from all over the world. All of those men brought systems from their own sections of the world, that they had used, and they tried to work those systems in West Virginia. Some of them have been successful. Most of them have not. The result was until the last few years, that they have not been able to really get into what we term a West Virginia system of mining, and that is not universal today.

These men who came to our State had to depend largely on those who already inhabited the mountains. As I say this spirit of daring was built up within them. We had a high accident rate, minor, serious and fatal.

I went with the State Department of Mines in 1918, during the war period. During that time we were making lots of money. We could easily put men on to supervise the work and we had a great number of green men. Supervision was so close that our accident rate during that period was lower than it had been up to that time. However, some of us could see what was coming in the future and today, as you all know, we have every facility for producing and marketing coal. There is no price for it. The result is that coal companies have been taking men off here and there.

However, in 1920 we started, with the consent and counsel of the Governor, an intensive safety campaign that has been continued until today. We started with a first-aid meeting. Clyde McDowell himself had one of the teams. Two weeks ago we held in Bluefield, West Virginia, a meet which attracted 23,000 people and 180 teams to that particular place.

In 1863 West Virginia was created a State. At that time, we were mining less than one half million tons of coal—444,000 to be exact. In 1927 we mined 146 million tons. You men will readily understand that with this quick development, or while this intensive development was going on, safety did not keep pace. The result was that this put the accident rate up until 1918. From 1883 to 1919 it was one man killed for every 175,000 tons of coal produced. From 1920 to 1927 we increased that total of production to 254,000 tons per fatality; and this year we have a far better record—360,000 tons per fatality, with a corresponding decrease in all accidents.

Men, I feel that to get safety, especially in the Mining regions, there has to be some real form of interest to attract the folks. We are trying to do that in West

Virginia. As I say, it was started with a first-aid campaign. We got from that to our mining institutes. We have local mining institutes everywhere. Some of those mining institutes have as high as 650 members.

From that to our safety clubs. We have safety clubs in 500 mining operations in the State today and these safety committees of the men meet with the families, with their wives and mothers. It is the most unusual condition existent in coal mining. Pictures were put on, some form of entertainment, and once in a while a real boxing show. I am not strong on boxing. I am afraid somebody will get knocked out flat, and it wouldn't look good, but these things attract the folks. They come out and we are able to convert anywhere from 15 to 20 per cent of those people who are there to our safety idea.

First, I want to assure you that it is the thing to do today. They don't want any side lights. That is the way to get them out. After you get them out you can talk some about safety clubs. Some mines make it compulsory, ranging from 10 to 300 or 400. They are doing a wonderful work. We have in the safety clubs what is known as the safety court. Men who violate rules and regulations violate the mining laws. They are tried before the miners and before the members. The fine is only 50 cents or one dollar, but the man there has not only endangered his own life but the lives of those with whom he is associated. It has been the most remarkable thing in my life, getting men to do the things that are right and stopping them from doing the things that are wrong. They feel badly about it. Their wives talk to them about it—"Why did you do this and that?" And I want to say that this club wasn't organized or instituted by me to begin with, but it was copied from the Island Creek Coal Co. and put in state-wide use by me. The safety court idea was proposed and put into effect by Thomas Fear of the Consolidation Coal Co. and this combination is doing real honest-to-goodness work.

In 1926, with the consent and advice of Governor Gore, who is my present boss, we put into effect the safety day. The only state in the Union that stops work for one day that men may review the year's activity, to show who are the men who compose this underground army of safety! I want to say that if nothing else ever comes from the safety movement in our State except to see those thousands of members in white uniforms walking down the streets of Bluefield putting over the message to the folks in the town, and led by a band of the National Guard and the Boy Scouts of America and the Safety Patrol of Bluefield, we will have done a great deal. All of these men were dressed in white suits with black belts. There is a reason, gentlemen, for that white suit and black belt which I have never stated. The white is for the brightness of the future; which we all seek to attain, and the black ties and belts are for the men who have passed on. That is the reason for that dress.

Men, this is a great movement. I have two pictures of this day which I think answer the question, Does Safety Pay? I shall be glad to show them to you. I should be pleased if you will look at these pictures and see what can be done. Attracting 23,000 men of the mines is greater than bringing 1,000,000 to just an ordinary event.

Men came from all over the country, and a number of them traveled hundreds of miles. Why do you men do that? Because they are all interested in their fellow men, and being a Scotchman and bearing in mind Bobby Burns having said "Man's inhumanity to man"—that is being changed and "man's humanity to man" is making accomplishment.

Thousands of homes in West Virginia are happy, contented, and prosperous because accidents have been stopped. Men in the past thought only in dollars and cents. We are said to have saved \$900,000 to the operators of West Virginia on accidents alone. Not only from that standpoint does the Department of Mines talk. We want to save those men of the mountains so that their homes will

continue to be happy and the breadwinner will be still there and bring in the things that are necessary.

I know that safety pays. I know the fellow who drove the mule with me down in New River 25 years ago. Two years ago, I saw him with his right arm gone. He was working at the pump and by accident his arm was pulled out. The fellow was big and strong, and he could throw me any time. He could wrestle. Now he is getting only one-third of what he used to get. Does anyone doubt that safety pays? That is the answer.

We have had some terrible disasters in West Virginia. I hope to God they have passed. Some of these disasters were due to the inherent hazards of mining, some of them were due to other things which I am not going to talk about. There is no reason for an explosion in any mine, whether it is gas or non-gas. I say that, knowing that we have mines in West Virginia producing six to seven and one-half million cubic feet in 24 hours of gas. If mines are properly ventilated, if they have adequate supervision, if they have proper care in assuring that the different things that you know or I know are enforced, explosions will be a thing of the past, and they should be a thing of the past. They have no place in coal mining. Our greatest trouble is the individual act. That is why we are concentrating on education.

We have, as I said, this first-aid movement and these safety clubs—that is, for the folks back in the mines. We are starting this year in the high schools of West Virginia a mining course. This course will be elective but it will give the boys back in the mines the fundamentals of mining. If they are not able to go to college, they don't have that wide gap that they would have if they did not receive this course. If they go to the mines then they are much better to go ahead and take up the duties as miner's sons.

We are starting in the New River field a mine foreman's training. I might say that our department is sponsoring these things. They are going to be carried out by the Department of Engineering at the University, and by training the forces which some companies have. I hope it will be a state-wide proposition and it is all thought out for one thing—safety and efficiency. We need it. You need it. We hope great results will come from it.

Men, I would like to talk longer. I will tell you that every state should have a State Safety Day. Every man that works in or about the mines or the industry for a year is entitled to that day to show to the world that he belongs to that army of safety, and we in West Virginia feel it is one of the greatest movements we have ever started. The towns become aroused, sections become aroused as to what it is all about. They go back to the mines much better. I tell you that \$900,000 has been saved to the coal companies, but we can't tell you the number of homes to which we have not had to go and tell the wives that their husbands had passed on. It is a serious proposition, more so in mining than anywhere else, especially where every man is dependent upon himself. He must be taught. We can't ask a man to do anything unless he is shown what, how to do it, and when to do it. If he is taught and is able to know the dangerous surroundings and able to protect himself, then we are doing something worth while.

I want to say that West Virginia does not have a branch of the National Safety Council and I am hopeful something will be organized in our State that will interest the mining people and bring in other industries so that life and limb might be saved.

Think this Safety Day over, give your men a chance. Nothing gave me greater satisfaction than what a lady told me on the Saturday night after that meeting. She said, "I have seen the army of men pass. I have seen every kind of a parade, but there was something impressive about this parade which causes men to give up a day. It seemed eternal—where men were taught the feeling for their fellow men. I was just filled up with emotion from the crowd when I saw those men

pass." When you get folks talking along that line, and realize that those men with those big thick fists from the mining district are going out and helping their fellow men in this army of commerce, you know that these men will be much safer from then on. When you have done this you can answer that "safety pays."

CHAIRMAN McDOWELL: I don't think there is any question about this part. That "Safety Pays" needs no further proof. I don't think there is a question as to the sincerity put forth in that subject by our friend, Mr. Lambie. They have done a considerable amount of worthwhile safety work in West Virginia that we in other states can look up to and feel that probably we need an awakening to do something of a like nature. I think it is a wonderful subject. I think it is a subject that you men should discuss. I would like to see it brought out very clearly. Let's have as many people express their opinions as possible.

A. H. TRESTRAIL (Pickands Mather & Co., Caspian, Mich.): I would like to ask the gentleman if this Safety Day is held on your regular Labor Day or whether you have a separate day for that purpose.

MR. LAMBIE: Safety Day activities are held usually on the second or third Saturday in September, a day apart from Labor Day, devoted to the State. This is the first year we did not have any appropriation from the State. We went out and solicited the money. However, the legislature of West Virginia appropriated \$5,000 to carry it. We hope it will continue.

J. T. RYAN (Mine Safety Appliance Co., Pittsburgh, Pa.): I had the pleasure of witnessing this State Safety Day. I want to say it was the most remarkable display of safety spirit that I have ever seen in my life. It is impossible to explain the interest that was displayed there on that day. I want to second Mr. Lambie's suggestion that other states follow that example established in West Virginia. It is really unexplainable—I just simply can't believe the interest that was displayed. Most of you have attended first-aid meets, and they are rather dry affairs, but in West Virginia they do things just a little different. They work in enough entertainment to make it interesting, not only for the teams competing, but for the spectators.

THEODORE MARVIN (The Explosives Engineer, Wilmington, Del.): If someone is interested (for instance Oklahoma wants to establish a safety day) according to your experience, what procedure would you suggest?

MR. LAMBIE: If the state wants to start a State Safety Day, the Governor of West Virginia will be only too pleased to send a man a month prior to the day to help that state. Next year, we expect a larger interest in the State Safety Day. The fuel companies, lead companies, chemical companies down through our section who haven't been in it yet, have stated that they will take part in the next year.

MR. MARVIN: If someone is interested, they can communicate with you and you will assist them, or through you?

MR. LAMBIE: Yes.

C. S. HURTER (E. I. du Pont de Nemours & Co., Wilmington, Del.): The Pittsburgh Limestone Co. instituted a Five Year No-Accident Club. A man who has been five years without an accident gets a badge. He joins automatically this Five Year No-Accident Club. Once or twice a year the company gives him a blow out. If he has an accident or is the cause of an accident to another man, he loses his badge and has to re-earn it. That has been very successful in the safety campaign of the Pittsburgh Limestone Co.

CHAIRMAN McDOWELL: I would like to hear from Mr. Arthur Crowfoot.

ARTHUR CROWFOOT (Phelps Dodge Corp., Morenci, Ariz.): I was very much interested in Mr. Lambie's talk. We found absolutely that safety does pay. I have no figures on dollars and cents in mind but in numerous branches which our companies have, we have gone month after month without a lost-time accident. We have a mining division and concentrating division, that is sheeting. In my

particular case, being superintendent of concentrating at Morenci, we have worked 87,365 man shifts without a lost-time accident. Our concentrator at Nacozari has gone for a good deal longer period than that. The concentrator in Nacozari went two years, with the exception of five days, without a lost-time accident. The greatest result that I see is that it has the men absolutely more contented in his work. Labor turnover is very greatly lessened and the men take a very keen interest in their work. Now, to the men that have gone a year without a lost-time accident, we present a watch fob. Any man in our branch who goes through a year without a lost-time accident receives one of these watch fobs.

Now, we have just revised our safety rule book. They were issued at the beginning of the month. Starting on October 15 we will examine every man in our employ regarding his knowledge of those rules. We expect every man to pass an examination on safety rules within a period we have set. There is no definite time, but we will say within the period of four or five months every man in our employ must pass the examination to show he understands every safety rule we have in force. We regard 80 per cent as a passing mark for all ordinary operators and for foremen we will increase that to 90 per cent. Those men that pass, we will present with a very good quality of belt with a silver buckle with the same design on it as the watch fob.

There is one question I would like to ask Mr. Lambie about the safety clubs. Are they composed entirely of men that are operators, or does the club include their families?

MR. LAMBIE: The membership of the safety clubs are men who are employed in the mines. Usually the president of the safety council is the mine superintendent.

W. H. FORBES (New England Fuel & Transportation Co., Great Town, West Va.): All from one particular mine?

MR. LAMBIE: That depends upon the number of men employed. We have 10 or 15 in some and 400 or 500 in others.

C. L. WILSON (Berwin-White Coal Mining Co., Philadelphia, Pa.): I would like to speak about one point in Mr. Lambie's talk this morning and that is the reaction this Safety Day has created in West Virginia. A large number of operators in West Virginia are not altogether sold on Safety Day. They believe it is a good thing but they have not yet got the spirit. It was my privilege to invite our Philadelphia office to West Virginia. I want to tell you very candidly they were converted to the West Virginia State Safety Day. They came back and told me it was one of the grandest things they ever witnessed and next year there would be no trouble to get across our budget for Safety Day.

T. T. READ (American Institute Mining and Met. Engineers, New York): I am turning over in my mind the splendid speech of our friend Mr. Lambie on the topic "Does Safety Pay?" Why in the world should we ask ourselves that? Perhaps it was intended to be whether certain things we do in the name of safety pays. I know that some people do raise the question as to whether the great amount of effort that is put in on certain safety campaigns really pays. I must confess that I am more and more convinced that the absolutely essential character in our human lives is in our attitude of mind. If you get people thinking and believing one way, they will do things. If you don't get them with you, they don't.

I am reminded that a few years ago, a distinguished gentleman came to New York. He packed Madison Square Garden. He didn't make any impression. It was because his message and his method did not produce any effect. The people came to see him just the way they would see a two-headed calf. They didn't do what he told them to do. We have to meet the same factor in our safety campaign. We have got to get people. They have got to get it demonstrated to them. The woman Mr. Lambie spoke about was converted in her heart. She believed she could do something. I think these State Safety Days is one thing

that will move people's emotions. I think when we all get people's minds and hearts to do something that is really worth while, we will produce results that pay.

WILLIAM GEORGE (Madeira Hill Co., Phillipsburg, Pa.): I just want to refer what Mr. Lambie said about reducing accidents. Four years ago we adopted a system what we call "educating the miner in taking care of his own hazards," and we fixed up a system of codes by which the assistant foreman marked daily the hazards coming under his observation. He instructed the miner how to take care of them. Since adopting that system we have reduced our accidents at the working base over 50 per cent in man day losses.

CHAIRMAN McDOWELL: I would like to go West and find out whether safety pays. I am going to call on Mr. Bochert.

W. C. BOCHERT (St. Joseph Lead Co., Bonne Terre, Mo.): In regard to the question whether or not safety pays, I am very glad to say it does. The St. Joseph Lead Co. about four years ago decided to establish a safety department that had the same rating as any other department. So the first thing for the safety department to do was to make that department pay. I think we have done that in two ways. In the first place, we have cut down very largely the number of accidents we have had in our mines. In the second place, the efficiency of our operations has been very materially increasing every year. Of course, I don't know how much that is due to safety but the safety department feels as though they are entitled to a certain amount of credit, because in our safety work we are trying to sell the idea that safety and efficiency go hand in hand and can be created and established through cooperation. We are getting that very nicely.

In listening to Mr. Lambie and his safety work, especially the safety contest, I would like to say that before I went to the St. Joe about six years ago they attempted to establish first-aid field meets. Several companies went in on that. I understand because of a poor selection of judges, the thing developed into a fizzle. No one has been eager for such a thing since. I think, however, the idea could be resold to the operators in the lead belt and the thing could be reestablished.

However, in our operations in the lead field, we are considerably different from the coal mines. Fortunately, we do not have the things that exist in the coal mines or in many of the metal mines. Our rock happens to be of a kind of material, mat limestone, that builds very easily. At the same time it is in unusual stopes. We have some stopes as high as 250 feet that have been mined out as much as 40 years ago. That rock is still there. The roof is as solid as it was 40 years ago. It is a very peculiar situation. It is fortunate for the safety department and for operators. With some of that ground, for example, a set of drills will last an entire week without sharpening. At the same time that limestone stands up year after year without trouble.

We have some ground that is very slaty. The roof has usual thin laminated layers. That is the ground that gives us the most trouble. About four years ago the companies in the lead belt had a large number of roof miners. The business of the roof miner was to take down the working layers safely and take care of that until quitting time. That accounted for many accidents because the roof miner wasn't on the job. We tried to sell the miner the idea that he is the best man to take care of his ground. At the present time we have very few roof miners and use only the roof miners as the assistant when there might be too much to take down. That system is working out satisfactorily. It was just a little hard to put it across.

In connection with prizes, we started out with the idea of selling our bosses—mining captains—on the idea of safety first. They were not entirely sold on safety. In order to make it interesting for the bosses we established the bonus system, whereby the shift boss gets one cent per shift for every man shift under his supervision. If he has a lost-time accident we charge him 50 cents a day for every man that is off the job. The reason for that is that the more man-shifts a

man works the more bonus he is able to make. That encourages the bosses to get the man back. We want him to encourage him to come back. But so the man won't come back too soon, and before he is ready to come back, we have a stringent method through our doctors organization, that each man must have a doctor's permit before he can come back on the job. So it is entirely up to the doctor to permit the man to come back to work.

Now as far as creating interest in safety, the premium method works good, also contests of various kinds. We conducted those just recently; one of our shift bosses, having an average of 55 men, completed a record of 30,000 shifts without a lost-time accident, and the company is buying each man in that crew a pair of safety shoes. One of the other things that has worked out nicely is the premium, and I might pass on to you men the pocket knife made of stainless steel with the man on one side of the handle and the inscription on the outside. We find that those men will work unusually hard for this little premium. We have found it the best thing to interest the men and keep them interested in safety.

In fact, we are not pushing our contests too hard for this reason: we find the men get too enthusiastic about it sometimes and will not always report their injuries. Very often we have a man that will neglect or will not report an injury and the first thing we know a serious infection develops. We have a system that very few mines of this country have; that is, that a man can go to work pretty much at whatever time he pleases and he can come home when he gets through with his work. We work almost entirely on the bonus system. If he wants to go to a picnic or some other place, he can start work at three in the afternoon. And when he finishes up his work, he can go home.

C. M. WAMPLER (Eagle Picher Lead Co.): I would like to ask the last speaker in regard to this one cent bonus system. Does the foreman get that one cent per man shift, regardless of whether he has any accidents during the month or not? And also whether in case he has a man hurt one day, but returns the next day, is there a 50 per cent reduction made in that case?

MR. BOCHERT: Last year we had several things to overcome in our bonus system. In the first place, we paid the shift boss a cent a shift for all of the shifts that came under his supervision. If a man is injured, the first day of accident does not count. We will give the foreman a day. So it is to his advantage to send that man to the doctors for all little injuries that arise. That is the idea of making the first day free; no penalty on the first day. It has worked out nicely.

Another thing; if a man, for instance, is injured on the last day of the month and the man is out five days the shift boss will lose five days of his bonus, with a penalty of five times 50 cents after the first day. In that case he would lose five days and he would lose two dollars in bonus.

Another thing we do. In case a man has a serious accident on the haulage and is out six months, we merely deduct that shift boss's bonus for that month and start him out with a clean slate again. We started to carry the bonus plan until the time was entirely cleared up, but in the interval the foreman lost—for instance, he lost six months before he got any bonus. He wouldn't take the interest. We consequently gave him a chance to start out with a clean slate at the beginning of each month. It costs the company a little more but it keeps the foreman on his toes constantly.

GEORGE MARTINSON (Picklands Mather & Co., Hibbing, Minn.): After 15 years of safety effort, I want to say there isn't any question in my mind or in the mind of my employers that safety pays. We have tried all of the stunts that men have spoken of and probably some others, too. I think the attitude of the employer—our employer—is shown by the fact that in 15 years there has never been any question about safety expenditures. The personnel of our department

is now six times as large as when the safety plan was originated. That answers as far as our mines are concerned.

CHAIRMAN McDOWELL: Does anyone else have any particular comment to make? I think we would like to hear from Mr. Brennan of Phelps Dodge Co.

W. D. BRENNAN (Phelps Dodge Corp., New York): We have tried to reduce in our own minds in cost per cent of tons of coal produced. In the course of the last four or five years, we have brought our costs away down as far as the compensation allows us to work, from five cents a ton for accident down to three and if continue with the showing that an intensive campaign has resulted in I hope that the cost can still be materially reduced. Safety does pay with us in dollars and cents; it has paid.

MR. MARVIN: So many of you got up and said "Does Safety Pay"? I think if you will notice the program, it says emphatically that safety pays; not "does it pay?" or "why it pays." The ones on the program committee were emphatic in believing that and in stating that safety does pay. I hope you will just look at the program. It is a positive suggestion to you that it does pay. I think the discussion has brought that out.

CHAIRMAN McDOWELL: We have just a few minutes on this particular paper and it might be well for us to confine ourselves probably to particular points of interest that will bring out that safety pays.

I notice that one coal mining company has sent three or four representatives to this meeting. They no doubt had a particular idea or interest in the meeting and especially in sending four representatives. I would like to hear from Mr. Lenhart, of the W. J. Rainey Coal Co.

F. S. LENHART (W. J. Rainey, Inc., Uniontown, Pa.): We have found that safety pays, looking at it from the point of view of the hard coal operator. It pays on the cost sheet. It also pays from the standpoint of humanity, we feel. We don't give any form of award to our officials for safety work, but we do reward them by sending them to the National Safety Congress each year. Those awards are figured, each plant is placed against his own safety record for the preceding year, his cost per ton of coal mined per man, and the plant that can reduce that cost the greatest percentage, is given the award.

Now, our Mount Reddy plant won the award this year. We have with us today the superintendent, the mine foreman, and the assistant foreman from another plant.

Our safety work is handled through our bulletin board in the first place. I might say we use the Elliott Bulletin Board. These boards are kept well lighted, and posters are changed every day. We endeavor to put the safety meetings home at the place. We hold the foreman responsible for all classes of accidents, no matter how they occur. It is up to him to instruct the workmen safely. If he is negligent, he is held responsible. Sometimes he is demoted; in cases, he has been discharged. We have what we call a general safety committee which is comprised of the general superintendent, the assistant general superintendent, the master mechanic, etc. We have a plant safety meeting or Safety Day. We hold safety meetings in each of our plants each month. Into those safety meetings the man who was injured during the previous month is called and asked to explain how the accident occurred and how it could be prevented in the future. In that way we get the man injured and the foreman in the meeting. Sometimes we get a better slant on how accidents occur. We feel we are having success in our work but that we have a good deal to do in the future.

CHAIRMAN McDOWELL: From what Mr. Lenhart said, I think it would be well for us to have Mr. Ainsley, the superintendent who is with Mr. Lenhart, explain how safety pays, how he does it.

DAVID AINSLEY (W. J. Rainey, Inc., Almontown, Pa.): Mr. Lenhart covered the group pretty thoroughly. Each foreman is responsible for his own section.

If he has an accident the mine foreman has to come along with the man, at the end of the month, to the meeting and it is brought out there. The thing is to place the blame on somebody. The man himself has a chance to speak first, explaining how the accident did happen. Therefore, we get the thing before the whole safety committee at that time. I think it is a very good thing. It places the blame where it belongs.

CHAIRMAN McDOWELL: Anyone else? Mr. Hensel?

H. G. HENSEL (Youngstown Sheet & Tube Co., Chicago, Ill.): Yes, safety pays. I think we all know that but we feel we would like to hear what other people are doing, how they are overcoming their problems, and that is the real reason for these meetings.

In the past year or year and a half we have tried at some of our properties a rather new stunt, that we call the "Daily Report of Unsafe Practices Corrected by Foremen." We have found that this report system has had a very good effect upon our accident record. It is the foreman's duty to make out that report every day whether he is correcting any practices or not and that report goes to the department superintendent. It then goes to the safety department, where it is chalked up on a card. These cards are filed with the foreman's name. On that card is not only his record of unsafe practices that he has corrected as reported, but a record of the accidents he has had in his department; and if eventually that foreman has a serious accident and he is called before his department superintendent, or the superintendent of the plant or mine, that record is then laid before the officials and they have a chance to judge whether this foreman has really been doing anything in safety, whether he has been trying to prevent accidents or whether he has been lax in his activities. That has had a wonderful effect upon the men.

The system was suggested by one of our foremen. He gave a talk in one of our safety meetings. He was scheduled with the superintendent to talk a week in advance and one of the main points he brought out was this: "We foremen are held responsible for our accidents but we are never given a chance to say what we are doing for safety, how we are trying to prevent accidents. Why can't we make a report of some kind to our superintendent as to what we are doing?" And then we started this system of giving them the opportunity. Finally, it spread to all of the departments in the Western Division of our company.

We find if a department superintendent at the end of the month receives his report from our department and that certain foremen are either not sending in reports or sending in blank reports he is soon called in to answer for it. For this reason, inspectors in the safety department are continually finding unsafe practices in that foreman's department and he says to this foreman, "If these men from the safety department can find unsafe practices by going through your department once a day, or perhaps once a week, what can you find there on the job your full eight or ten hours? What can the foremen on the other shifts find? You should be able to help on these things that are really causing our accidents."

We find in going through our cost sheets that safety pays, and it is true also that we are saving lives and limbs because fatalities are being cut out, and our serious accidents are being cut out, until we feel it will be impossible for us to stop the safety movement in any of our works and mines where it is now going along as it is. Of course, there is big room for improvement. We are urging all of our foremen and superintendents to give it more and more consideration and to give our men and foremen a chance to take part in it. I think you will find that if you give your men an opportunity either through a suggestion system or through a system of meetings held by the foremen to take part in the safety

movement that they will take more interest in it. They feel that it is a part of their job; that it is meant for them; that is, not something that the company is interested in alone, and they will be only too glad to give their suggestions for the correction of unsafe conditions and practices.

CHAIRMAN McDOWELL: We will close the discussion on this paper. We want to thank Mr. Lambie for his talk on the subject and all those who took an active part in the discussion.

We will now have the second talk scheduled for our program which is by Mr. H. S. Gilbertson, Director of Personnel, Lehigh Coal & Navigation Co., Lansford, Pa.

Training the Mine Foreman

By H. S. GILBERTSON

The Lehigh Coal and Navigation Company, Lansford, Pa.

I have been asked to speak about methods and results in mine foreman training. But it seems to me that before we get down to details, it is eminently desirable that we should decide what it is that we hope to accomplish by this sort of educational effort and what are the underlying conditions which have to be met, and possibly altered, as a condition precedent to success in foreman education. The answer to these questions will go a long way toward determining methods.

What every industrial concern really wants to bring about, I believe, is a condition under which management, supervisory forces and rank and file, will be thinking and acting in unison, where everyone in the plant will be facing the same way. This is effective organization.

Now there are a good many reasons why management, supervisors and men do not always think in unison. One of these which seems to play an unusually important role in the mining industry, or at least that portion of it with which I am familiar, is the traditional theory of organization. The mine foreman in times past was given almost complete responsibility for what went on underground. There were and still are some perfectly good reasons for this policy. But there never were any very good reasons for some of the implications which were drawn from it. Giving a man full responsibility does not necessarily or properly mean that he is not to be supervised, or that he is entitled to keep his superiors in the dark as to what he is doing, or to go his own gait regardless of the consequences outside his own jurisdiction. And yet, the situation in years gone by has been much like that in a good many organizations. The mine foreman was held responsible for "results." And "results" meant not so much low costs, nor good personal policies, not so much conservation of the mine and not so much safety, but rather, big production—tonnage.

The mine foreman of yesterday, and to some extent today, the man whom we hope to improve by training, is the product of this policy of the industry. Under the weight of very large responsibilities and not very much detailed supervision and still less positive guidance, he developed into a very resourceful and self-reliant man with strongly individualistic leanings. This is the element of great strength which the mine foreman possesses, possibly in greater degree than foremen of other industries. His is a bigger job than that of other foremen. Greater hazards, greater possibilities of damage to property and more acute and difficult labor problems are involved in his work.

In some important ways the tradition I have indicated and the mental habits in the foreman which it has created are a stumbling block in the way of improved organization procedure. Individual temperament is not always a safe guide in personnel and safety work. There is a certain amount of standardization desirable

in these things and consequently there must be a certain amount of sacrifice of personal point of view in subordination to a broader company policy.

Furthermore, the traditional plan of organization which I have described has tended to create a habit of secretiveness as to the methods employed, and as to what goes on generally in the mines. The general management of mining properties do not always have the information to which they are entitled, and in the interest of the business and of the foreman whom they should help.

Now, as the result of the great and direct emphasis on production and as a result of the lack of constant communication between foremen and management on matters of detail, it is not surprising that there were produced comparatively few men with the all-around characteristics that present ideals of foremanship call for. There were ever so many good producers, probably not so many good conservationists, probably still fewer cost analysts, and while most of these men were keenly interested in safety, there remained much to be learned as to the methods of arriving at this great objective.

Now it goes without saying, that all this is not so much a criticism of the foreman as it was of past management policies. Managements themselves have been secretive about their larger interests. They have not always let their work supervisors in on the great and interesting problems of the industry which may seem to lie mainly outside of the mine itself, but are very often problems that the foremen themselves have a large part in originating. The labor problem, for instance, in all its ramifications, is a management and personnel problem as well as an economic one, and yet we know that there is often a very incomplete understanding between the man who deals with the larger economic relations and the man who intimately knows the individuals who are affected.

And so foreman training is to my mind—and it is the policy adopted in our company—first of all a matter of understanding the position and characteristics of these strategic men and directing every effort toward overcoming their deficiencies. Fundamental to everything else are those deficiencies which arise from lack of information. A foreman should not be expected to do much toward reducing his costs if you simply keep telling him to get his costs down, or to get better production, if you merely hammer away at the idea of production, or to improve his safety record, if you merely talk safety in general terms.

We have tried to meet this need for a background of knowledge by opening lines of communication both ways, and it has seemed to us that first responsibility lies not with the foreman but with the management. For a number of years our foremen have been receiving analytical statements of costs which have enabled them to put their fingers upon the details which affect results in this direction. More lately we have inaugurated a policy of publicity which relates to practically everything directly and indirectly associated with the proper functioning of mine operation. This publicity relates less to technical mining matters than to questions involving personnel, and questions related to the economics of the industry, but there is scarcely a subject which even remotely bears upon operation which has not been discussed at one time or another. Our particular medium for this publicity is a monthly publication that goes not only to our operating supervisors, but to the English speaking miners and to the leaders in the mining community.

Of a more permanent nature is another publication of ours entitled "Mine Management Policies," directed more specifically to our foremen and their assistants. It is a little book of principles based upon specific conditions in our operations and defines the ideals and objectives of the management with respect to numerous considerations that have to do with operation. It deals with such economic factors as costs, production and profits, and with such personnel problems as selection, construction and discipline of men in the handling of their grievances, and such intangible but very real matters as industrial goodwill. And it may be

added there is a chapter on safety, which undertakes to go to the bottom of the subject, in a manner that I will describe more in detail presently.

We believe that men of the calibre of our mine foremen by reason of being exposed to information and analysis of matters of this kind will respond to the larger problems of the company. In the three or four years of our experimentation along this line, I believe that our confidence has not been misplaced. Specifically, we believe that we have done something to create that atmosphere of open-mindedness which the General Motors Corporation seems to regard as the chief cornerstone of its success.

Another quality which we hope to inculcate in our foremen and particularly the younger men who are coming up to fill these supervisory jobs, is a greater degree of exactitude. It is characteristic of the so-called practical man everywhere in contrast to the engineer that he is likely to be content with rough approximations of fact.

Thus, in the matter of safety. In our company textbook, the chapter on this subject tries to teach the foreman the cost of accidents; first, the obvious cost such as compensation insurance liabilities, loss of production, etc., then we lead him into the intangibles, such as the loss of morals, loss of confidence in the company. We impress upon him the importance of following through to its ultimate cause or causes, and particularly to the human cause if, as is usually the case, there happens to be one. And then, we emphasize the importance of the margin or factor of safety, that extra measure of precaution over and above what is obviously indicated.

In our course in Mine Management last winter we tried to instill some clear thinking on safety matters by breaking up procedure of accident prevention and investigation in three parts. In our first meeting we asked the members of the class to picture themselves as taking a safety observation trip through the mines, beginning at the top of the shaft and following through to the last working face. We asked the class to confine themselves absolutely in this particular conference to the barest statement possible concerning the actual danger points along the line of their trip. It was a difficult matter for some of the class to keep their minds on this particular phase of the subject; they would wander off immediately into discussion of causes and remedies, which was just what we wanted to avoid at that stage. But gradually it became clear what we wanted, and many of the members, I believe, saw the point of trying to do one thing at a time, and to keep the personal equation out of the investigation. In the second conference on safety, we dealt with specific measures for removing the danger points, and in the third conference we got down to the discussion of principles.

The old time training of the foreman militated against his becoming the most effective sort of an executive. The State Mine Laws, for example, which I suppose reflect the traditional thought about proper procedure in mine operation, seem to assume that a good foreman spends practically all of his time running around the mine. As a result of this tradition, many foremen are deficient in the quality of being able to delegate work, or being able to multiply their own eyes and legs so as to cover the mine at all times with supervision. We have put the matter to our foremen somewhat in this way:—"It is all very well for you to be on the job at a particular point where something unusual is happening, but what about the other 999 points in the mine where things are going on and you are not present?" We are, therefore, trying to get our foremen to build up their subordinates, pointing out to them that this is absolutely necessary, if the foreman's job is to be made into something bigger, more effective and more remunerative.

We are striving earnestly also to have our foreman acquire a balanced sense of values. As I pointed out a while back, the emphasis has been in the past mainly upon production and that is where it belongs, but production is only in an indirect sense a matter of pushing cars and other things along. In a mine, at least, it is

primarily a matter of completely setting the stage with proper maintenance conditions, proper equipment and service to the operating man, satisfactory morale, discipline, instruction, etc. When the foreman acquires a balanced sense of values which takes in not only production but costs, safety, etc., the great objective of production will automatically be taken care of far better than if the whole emphasis were put upon production.

And, of course, we lay a great deal of emphasis upon leadership. This, after all, is the secret of much of the success of American industry. The fact is that to a greater degree than in some countries, the whole man is put to work as a willing captive who knows something of the objectives for which he is working. Over one hundred and fifty years ago one of the highest officers in the army of Frederick the Great, the ancestor of our contemporary, William II of Germany, was brought over to America and put in charge of the conditioning of the American troops. He rendered a tremendous service to the American cause, but in speaking of the American soldier and contrasting what he was accustomed to in Germany, he wrote to a friend in his home country, "You say to your soldier, 'Do this,' and he doeth it. But I am obliged to say, 'This is the reason why you ought to do that,' and then he does it."

I suppose in view of the subject assigned to me and after this rather extended analysis, it really is necessary to say something about methods.

Our first attempt at foreman conferences followed a full year of publicity such as I have described. During the long strike of 1925-1926 we instituted discussion conferences at our several collieries, attendance at which was practically compulsory. The basis of these conferences was a uniform series of questions for the several operations dealing with practical mine management, rather than technical mining problems. Each conference was attended by the foreman and his assistants, with the superintendent acting as conference leader. They were held once in each two weeks and were supposed to take two hours. Some one acted as secretary of the meeting and sent in to the director of personnel the composite result of the thought of the group on each question. Later on, the reports from the several collieries were consolidated and sent out in mimeograph form to each man. The subjects treated included several phases of personnel, the handling of materials, several aspects of costs, and production.

The results obtained from this experiment varied at the different collieries and clearly reflected the different degrees of interest, intelligence and leadership among the foremen and their assistants in the several groups. In some instances, the men voluntarily doubled the time supposed to be given to the discussion. The reports turned up a lot of practical information which led to some important changes of procedure particularly in the employment office and in the handling of certain materials. Facts came to the surface which these men had been keeping to themselves; grievances they had been nursing and difficulties which they had been trying to solve locally but which needed outside assistance.

It did not seem desirable to repeat the experiment in just this form. In the second year we shifted from a compulsory to a voluntary basis and directed our attention to prospective mine executives, men holding the assistant mine foreman's papers, but still miners. This time we enlisted as conference leaders some of our best and most experienced foremen and mining men, department heads and others conversant with various phases of mine management and also one or two outsiders. Meetings were held once a week during the winter.

A number of the foremen and assistants, in addition to the conference leaders attended these meetings. The superintendents were quite regular and interested visitors and were constantly on the lookout for new material with which to man their organizations. As a matter of fact a number of the class were promoted to assistant mine foreman jobs as a result of their attendance in this course. Courses of this kind impart a good deal of valuable practical information but

their greatest value lies in provoking thought in the men who attend. In fact, the best discussion is that which always takes place out on the sidewalk after the meeting or at the colliery the next day or possibly weeks or months later. Many of these discussions have been reported to me and they attest the real earnestness of the men who engage in these.

One of the best testimonials to the value of the idea of these foreman conferences comes from one of our sub-storekeepers who has stated that: "One thing that impressed me was the fact that the men attending these sessions now realize that a vast understanding is necessary to capably manage a mine with all its attending problems, and that intense study and application is necessary if they are to merit promotion by properly fitting themselves for a supervisory capacity."

(Mr. Luke Barnett of Pittsburgh, Pa., impersonating a Slavish miner from the coal mining regions of Pennsylvania, offered criticisms of the exhibits of safety posters. After this, he entertained the meeting with humor.)

CHAIRMAN McDOWELL: We will now open our discussion. There are a great many here interested in this work and we are open for discussion. Who will start it?

Mr. Brennan, will you start it?

W. D. BRENNAN (Phelps Dodge Corp., New York): I am going to ask the gentlemen if they have made any special effort to educate the foremen, educate men to the position of foremen, bring them up along certain lines of making foremen of them?

MR. GILBERTSON: We have devoted more effort to that phase of it than to actually training the foremen we have. As we all get along in years we become less receptive to suggestion and we believe that there is a more abundant amount of hope of accomplishment among the more ambitious miners, particularly men who have the assistant foremen's papers and even training men who are actually on the job. Yes, we have given a good deal of attention to that.

MR. BRENNAN: Have you worked along the idea of taking the practical man or the engineer and what results, if any, have you got in bringing up the engineer to foreman or bringing up the practical man?

MR. GILBERTSON: We have given our attention to the practical man. We have mining conditions there that make it absolutely necessary for a man to spend a number of years in those particular mines. There are a variety of local conditions. A man must have much practical experience to become foreman, so our drift has been entirely to the practical man who has grown up in the mines, rather than to the engineer. We have never developed a practical mine foreman out of an engineer yet.

MR. BRENNAN: That's the point. My experience has been along the same lines. I have tried to bring up as foremen engineers in a number of cases, but to date I have not been nearly as successful as I have been able to take the practical miner and bring him up to the position of foreman; but I feel that with the mechanical loading that there is going to be a field where there is going to be possibly an opportunity to develop the engineer into a foreman's position.

CHAIRMAN McDOWELL: There is one thing brought out upon which we all have given considerable thought, and that is the point of bringing the engineer into these conferences. I think we might have further discussion on that. Will anyone volunteer to continue with the discussion?

F. S. LENHART (W. J. Rainey, Inc., Uniontown, Pa.): We are very much interested in foremanship conferences. We have valuable foremanship meetings in each plant each month. All of the men attend from the superintendent down. The men are given notice about a week in advance to what the subject will be. We discuss such subjects as getting out the work, making the job safe for

workers, reducing labor turnover and others along that line. We feel that we are getting quite a good deal of benefit out of these meetings, although it is very hard to put your finger on it just at the present time. We intend to keep them up.

MR. MARVIN: Mr. Nesbitt, who is acting safety engineer of the Tri-State District, conducts what really are foremanship training courses, majoring in safety. I think he could give you more help.

FRED. H. NESBITT (Tri-State Zinc & Lead Ore Products Association, Miami, Okla.): Two years ago we had some wonderful series of foremen's training conferences that were led by Mr. I. N. Anderson, and we have felt that they were a big help to us. Shortly after that we formed a foremen's accident prevention club and held night meetings. After a few meetings it got so they didn't come out, so we started this year holding monthly banquets or luncheons for the foremen. The first one, I think, had 135 in attendance; 98 of them were round foremen. In our district, we have 89 mining companies and something like 216 or 217 mines. These foremen were from all the different mines in the district. We are still continuing those meetings every month. We really think that they have done us a lot of good. With these foremen's meetings and our clinic work, we feel that our accidents this year have been more than cut in two and our fatalities this year have been only one-third of what they were last year.

CHAIRMAN McDOWELL: Is there anyone in the room who has specialized on foremanship conferences? Mr. Henrie?

H. C. HENRIE (Phelps Dodge Corp., Bisbee, Ariz.): Several years ago we went after our accident rate. The number of accidents had been decreased somewhat. We then ran into a situation where it seemed to be quite difficult to get a further reduction. We were able by means of foremanship conferences to get the foremen interested in the problem and make still further reductions.

Now the way those conferences were handled was that the mine superintendent held meetings twice a month with all his foremen, night foremen and shift foremen. Our accident record as to cause of accident was the basis for discussion. For instance, it was found the great majority of our accidents were occurring in operations centering around haulage. We were able to subdivide that further. But finally, we would center attention on some one specific hazard. Then each man present was asked his idea as to the correct method of performing that particular operation. For instance, we would start out, "What is the first thing to do?" We would get that man's version as to the first move that should be made and so on until we carried the operation through. In other words, analyze the operation.

After we had more or less of a standardized method for the operation in question, these standardized methods were typewritten, given to the individual boss and also posted in a conspicuous place or places throughout the mine. The men, after being instructed, were compelled to follow that operation and they were held responsible that the work was done in that manner. In that way you accomplished a two-fold purpose. You found the safe way of doing the job. You probably got a more efficient way than had been customary prior to that, and thirdly you had uniform practice, where before practice would vary in certain details in different parts of the mine and with different qualities.

To illustrate how the simple operation may involve considerable discussion, there are matters of loading a car from the chute. That was quite simple. When we got through there were 22 separate and distinct operations in loading a car. If everyone of those operations was performed in the proper way or in sequence your accident hazard should be reduced to a minimum. At first, it looked difficult in regard to getting this matter over to the day's-pay man. In that case this standard method of loading the car from the chute was posted on each loading chute, the man was instructed and then compelled to work in that manner. That's

just one example of what we have been able to accomplish through these foremanship conferences. They are still held regularly and have been a great factor with us in removing accident hazards and consequently in reducing the accident rate.

T. T. READ (American Inst. Mining and Met. Engineers, New York): May I say I happen to have another thought? Emerson said that in his opinion the great characters of modern industry were increasing voltage rather than amperage. What he meant was that the great development of modern times was not on schedule. Mr. Gilbertson said that by setting things up to some theory, production goes along naturally. I was reminded that back in the war times I had a good deal of contact with efficiency planners. The War College told the other people what to do and they did it. It can't be done that way now. You have to fertilize that planning and control down in your actual operating organization. You have something of the same thing in research.

The fundamental point about foremanship training is that you are going from that wrong step to do the thinking and planning assigned to a specific group and putting it back in the operating organization where it belongs. You are training those practical men so they will get out of their minds certain things because they have theories, they say. They will have theories just the same. They may be wrong. Train them so they can approach things in an engineering spirit and place in their minds a spirit of analysis which they may apply in getting it down to the men. This idea of increasing the voltage and reducing the amperage applies here; in other words, getting the work done with less waste effort.

CHAIRMAN McDOWELL: Unless there is some specific point to be brought out we will close this discussion. I really feel that the foremanship conferences mean a great deal. I have been particularly interested in that phase of training, whether it relates to safety operation or what not. For some time we've all done a certain amount of that work. It is just a matter of how we do it. I am rather of the opinion, regardless of how it is done, if we are doing it, we are doing a particularly good job.

On the Nominating Committee I have appointed Mr. H. I. Young. This was done several weeks ago. Also Mr. J. T. Ryan and Mr. H. C. Henrie. Mr. Young is not present. I will ask Mr. Henrie to make that report tomorrow—at tomorrow's meeting.

The Resolutions Committee. I will appoint on that committee, Mr. Hosler, Chairman; Mr. Henrie, and Mr. Berry.

ADJOURNMENT.

October 3, 1928

C. A. McDOWELL, Chairman
Safety and Personnel Manager, Pittsburgh Coal Company
Pittsburgh, Pa.

The second session was called to order at nine-forty o'clock by the chairman, Mr. C. A. McDowell.

CHAIRMAN McDOWELL: It was my privilege to attend one session of the Rocky Mountain Institute of Rock Springs this year and I was greatly interested in Mr. Miller's paper. There is one thing that is especially interesting to us. It is this: that the Rocky Mountain Institute was set aside one day to take care of National Safety Council work. That means that we have an opportunity, as Mr. Miller expressed it to me, of the Mining Section helping to put across this propaganda on that particular day, and I think it is worthy of our consideration that we keep that in mind. I would particularly bring it to the attention of the next chairman, that we keep that particular question for next year in mind and help them all we possibly can as far as the Mining Section is concerned to put across the program.

Our first talk this morning will be interesting. The speaker is Mr. Cleveland E. Dodge, Vice-President of Phelps Dodge Corp.

Educating the Miner in Safety

By CLEVELAND E. DODGE
Vice-President, Phelps Dodge Copper Company, New York City

One of the problems created by modern civilization and a growing population is the tendency toward an increasing number of accidents. It is a splendid thing for the country that there is in existence such an active organization as the National Safety Council to combat this evil. The problem is just as evident in the different industries as in other walks of life. Owing to the hazardous nature of much work in the mining industry the danger of accidents is especially pronounced. I am sure that there is no other field in which there is required more hard work and careful planning to avoid the occurrence of accidents.

The mining industry combines a large number of varied activities, including all types of regular underground and surface mining, the transportation of ores and materials and different kinds of metallurgical processes.

In underground mining the avoidance of accidents is especially difficult. The greatest number of fatal and serious accidents occur through falls of rock from roof or sides of the workings. Even when miners use every precaution in testing out newly opened up ground, it is apparently impossible to prevent some of these accidents. Constant vigilance, however, can do more than anything else to forestall trouble caused by bad ground and is the aim of every good mining organization.

Perhaps the most difficult feature in mining is due to the fact that conditions are changing constantly, wherever new ore is being developed and extracted, and it is at such points that the majority of the employees must be working. Supervision is difficult, especially in mines where the stopes or working places are situated away from the shafts and main levels. For instance, in some mines a shift boss may perhaps have only 30 men working under him, but it will take him all morning to get around to the points where the men are employed. In mines where the men are more concentrated, supervision and accident prevention as well are made much easier.

Surface mining is in most cases carried on by means of churn drills to break

the ground and steam or electric shovels to lift the broken rock to railroad cars. There is not the same risk as in underground mining from falls of rock, and of course supervision offers no special problem. There is danger usually from slides of broken rock caused by some of the material being constantly removed. In all types of mining one common cause of accidents is in connection with shooting or blasting. Constant care is required to avoid premature explosions or the drilling into unexploded pieces of dynamite.

A great deal more could be said in regard to occurrences of accidents in mines, but the above will serve to point out a few of the conditions which exist to make mining more hazardous than most other types of work.

After ore has been mined it has to be treated by concentrating, leaching, smelting, refining or in other similar process. Most serious accidents are likely to occur in smelting plants, where it is necessary to handle molten materials, but in other respects there is no great difference between metallurgical plants and most manufacturing works.

In a recent book on creative education, Professor Osborn of the American Museum of Natural History compares education in the Stone Age with that of today. In prehistoric times all education came through the handing down from parents to children the arts of hunting, war, agriculture and domestic duties. Especially in the northern climates existence was hard and there was plenty of incentive for children to learn everything that they could. Practical experience went hand in hand with the acquisition of knowledge. Life in our generation presents an entirely different picture. We buy our food and clothes in shops and receive the major part of our education from books. In comparison with today, when children have too much done for them by others, it is possible that the education of the cavemen of northern Europe was superior to ours.

Habits Most Easily Formed in Childhood

This condition has a direct bearing on safety work. The period when habits are most easily formed is during childhood. When we try to teach safety to grown men in our mines and industrial plants the results are often disappointing. The safety education being carried on in some places amongst school children appeals to me especially and I am sure will bear fruit later on in the prevention of accidents.

In the mining districts of Arizona and the southwest specialization in safety prevention was started only about fifteen years ago. The railroads were perhaps the first companies in that part of the country to provide special men for that purpose.

At first a mining company would have one employee to carry on publicity and educational work in regard to accidents. These duties were broadened out to include inspection of working places and conferences with foremen and bosses. Assistants and extra help were later given to the original "Safety First" man. Safety departments organized in this way succeeded in securing successful results, but eventually a point seemed to be reached where any further improvement was altogether too slow.

Several years ago our company found that its accident prevention work had reached this condition and that a new approach would be necessary to attain further improvement. At the same time we noticed that the United States Steel Corporation had been securing increasingly good results in their safety work and this led to a study of their methods and organization. We found that the secret of success of that corporation was in the interest taken by all the officials from Judge Gary down through heads of subsidiary companies and superintendents of plants. It became evident that our weakness was in placing the responsibility for safety on a few special men, rather than considering it as a major part of our operations in which the responsibility would fall on all operating officials.

We organized one committee for our whole company with our general manager in the west as chairman; also a committee for each separate branch or mining camp, with its manager as chairman, and in addition different committees representing departments or smaller divisions of work.

All of these committees have met regularly and maintained a real interest in trying to secure a better accident record. The department committees include a number of days' pay men who are chosen to serve for about three months when others take their places. By this means quite a number of men have been afforded an opportunity to serve as members of one of these committees. Besides regular meetings, inspection trips are arranged for the members on company time, when safety conditions are reported upon and suggestions for changes offered. A number of valuable improvements have grown out of these inspections. The management and supervisory force has steadily become more impressed with the benefit and importance of this work until now it is considered on the same level as the securing of efficiency and low costs or other results of a similar nature.

We have two company trophies, one based on frequency of accidents and the other on severity. Each is awarded annually to the branch holding the best record. There are other trophies also for similar departments of the different branches. Dinners and barbecues are provided for especially good records such as long periods without an accident.

Our different mines and plants have adopted goggles, hard-boiled hats and hard-toed shoes. It is impossible to estimate the number of eyes, heads and feet protected by these devices, but we know definitely that several lives have been saved. One Mexican breaking rock in connection with a new power line at Nacozari had his goggles broken by some flying object. Rather than take a chance, he walked six miles back to camp to procure a new pair before going on with his work. Although this case may be extreme, the spirit back of it is shared by a large majority of the employees. All men at our coal mines in New Mexico are compelled to wear hard-boiled hats and to use goggles when picking coal.

At several of our mines we have organized training schools for new men. Undoubtedly these men are a source of danger to others as well as being detrimental to general efficiency. When it is necessary to employ a number of new green men at the same time, we have on several occasions started them together in a separate part of the mine under the supervision of two or three experienced miners. By this means men unaccustomed to the work can be given special training for as long a period as necessary. These training schools have won the approval of others, as evidenced recently by a "Certificate of Merit" being given to our coal properties at Dawson, New Mexico, by the Joseph A. Holmes Safety Association. The award states that a portion of No. 6 Mine was set aside for the training of new men and during continuous operation for twenty months produced over 45,000 tons of coal with a total of three minor accidents involving only ten lost days.

Since the time when we reorganized our safety work, real improvement has been made, as indicated by the following results:

Combined Figures for Copper Mines, Including Copper Queen, Moctezuma and Morenci Branches of Phelps Dodge Corporation, and Old Dominion Company

Year	Number Lost Time Accidents	Rate per Thousand Shifts
1924.....	2,386	1.047
1925.....	1,394	.629
1926.....	499	.228
1927.....	263	.122
1928 (6 months).....	82	.072

**Coal Mines of Stag Canon Branch, Phelps Dodge
Corporation, Dawson, New Mexico**

Year	Number Lost Time Accidents	Rate per Thousand Shifts
1924.....	443	1.656
1925.....	382	1.490
1926.....	297	.829
1927.....	167	.550
1928 (6 months).....	64	.482

At both copper and coal mines the number of serious accidents has declined as well as the total number of lost time accidents. There are still occurrences of fatal accidents, but we find that these tend to decrease along with a cutting down of the number of total accidents. It is important to educate the employees to avoid all accidents, however slight.

It is interesting that our mines at Nacozari, in Sonora, Mexico, have won for the last two consecutive years our trophy given for the lowest number of lost time accidents. Their record has been as follows:

Year	Number Lost Time Accidents	Rate per Thousand Shifts
1926.....	86	.153
1927.....	37	.062

During the entire month of May, 1927, the 1,800 employees of all departments worked without a lost time accident. These results have been due entirely to the personal interest in safety of American and Mexican officials and bosses.

The avoidance of accidents and training of employees in observing safety rules is similar to any other problem in operating a mine or industrial plant. Success comes by means of individual interest, patience and persistency. The end is worthy of real effort upon the part of all concerned. As respect for safety is acquired by a larger proportion of the industrial workers in the country and by the population as a whole, it seems reasonable to believe that the safety movement with gather momentum with a corresponding decrease in suffering and economic waste.

In closing may I make a special plea to all officials of mining companies to take the responsibility of this work to heart and to exert themselves conscientiously in furthering the cause of safety.

CHAIRMAN McDOWELL: The paper is now open for discussion. Mr. Dodge will be glad to answer any question that anyone may want to ask.

C. S. HURTER (E. I. du Pont de Nemours & Co., Wilmington, Del.): I have not had much experience with Mexican labor but I have been in a number of Spanish and American mines. In view of what they accomplished in Nacozari and other places, where they have Mexican labor, I wish to state they have done a remarkable piece of work.

MR. DODGE: I might say Mr. Ayar, who is manager at Nacozari, and Mr. Lehman, the general superintendent, are here, if anyone would like to ask them any questions.

CHAIRMAN McDOWELL: We would like to have Mr. Ayar start this discussion.

FRANK AYAR (Phelps Dodge Corp., Morenci, Ariz.): I don't believe there is anything in particular I can add to the summary of the safety work which Mr. Dodge has given us. The only thing—that most impressive part of our safety work in Phelps Dodge Corp.—has been the point that Mr. Dodge mentioned; that it started at the top. The biggest secret is starting at the top and showing your men that you are absolutely serious all the way through in your safety campaign.

Now one thing at Nacozari and Morenci that has given us good results in particular, is this safety organization scheme. This gentleman speaks of the work of the Mexicans. I might say that we would stake the Mexican laborer, from a standpoint of safety, against anybody in the world. He is most susceptible to safety training. He welcomes it, if you approach him from the right angle.

We have thrown safety right into the hands of our men in every one of our departments. We have safety committees and lots of committees. We don't have just one committee for a mine. We have a committee in every division of the mine and these committees are not the bosses; that is, our inspection committees are the men and the men make independent inspections twice a month of the property. But these inspections are made at times agreed upon between the superintendent and the safety engineer so that everybody doesn't know just when it is going to be. Under this system, the man is absolutely free to say what he thinks. The safety engineer is the secretary of the inspection and he writes down every recommendation made throughout that division. So, when you get through we have gone right through our mine, or through our concentrate or smelt, everything that a workman has found wrong with it.

There not being any bosses in the inspection, the workmen don't hesitate for a second to say just what they think and we have never in any case failed to comply with the recommendations of our workmen if they have a trace of a chance of improving the safety in that division. Sometimes we have complied with them anyway, because we find that the average man gets a great kick out of seeing some operation that he has recommended put into effect. We have done—like all of the properties—lots of advertising. We feel that you can't do too much of it. We have gone the limit on safety inspection and protection.

Mr. Dodge said we have had—I think it will run well into hundreds of cases—men whose eyes have been saved by goggles, men whose lives have been saved by hard-boiled hats; and I might say that both at Nacozari and at the Morenci Branch of the Phelps Dodge Corporation not a man in the corporation can go down our mines without a hard hat. That includes the president of the Phelps Dodge Corp. and any other corporation, even if you go down there to look around. This is for the psychological effect upon the workmen.

In a letter which I sent out some time ago to our men—every now and then we send out personal letters and circulars—I made the statement that we were absolutely serious in this movement and our policy is not production first, it is not costs first, but it is safety first. A few days afterward, one of our men came around and said, "Mr. Ayar, just between you and me, do you really mean that—that cost is not first, production is not first, but that safety is first?" I said, "You are dead right, I mean it, and I challenge anybody in this organization to show us one case where we have failed to put safety ahead of cost and production." I think that until everybody does that you will never get the limit in safety work.

MR. DODGE: I would like to say in regard to Mr. Ayar putting safety first that I think it is true that in all our mines we found that through playing so much emphasis on safety it improves discipline and it incidentally helps efficiency. Mr. Ayar has his costs at Morenci and I think he will back me up. If you get in your safety and discipline, it helps all your operations. It helps both ways. It is not putting safety in at the expense of other things.

E. H. SUENDER (Madera Hill Co., Frackville, Pa.): In Mr. Dodge's statement of the number of lost time accidents from 1924 to 1928 showing that most remarkable reduction from 443 to 84, if I remember correctly that was in the mining end of the business. May I ask, as a matter of information, the approximate number of men involved in that particular part of the business?

MR. DODGE: About 900 men.

H. S. GILBERTSON (Lehigh Coal & Navigation Co., Lansford, Pa.): I would like to ask Mr. Dodge about the types of accidents which are most prevalent in the mines. I believe accidents from falling roof are the most prevalent forms of accident. If the mines are fortunate to have favorable roof conditions, the accident record would be less. In the copper mines, how big is the factor of falling roof?

MR. DODGE: The fall of roof is the biggest factor by far, especially in the severity of the accidents, and Mr. Ayar can probably answer that. I think the fall of roof is the cause of the majority of accidents anywhere.

MR. AYAR: I think at Nacozari it is true also. The ground is slippery, and sometimes 200 or 300 tons will come down and nobody can see by sounding the ground if anything is wrong at all. The first thing you know one of these big pyramids will drop out and that has been met by using lots of cribbing stock. I think we have got the fall of ground beaten there.

MR. DODGE: It is a little hard to generalize. What is true of one mine is not true of another. The falls of rock cause more difficulties than anything else because you have constant supervision and attention to give it. When you do get a bad fall it is generally a serious accident.

N. W. GREENSFELDER (Hercules Powder Co., Wilmington, Del.): I was interested in company trophies. The spirit of competition is a very potent thing in encouraging men to take a greater interest in safety. I would be interested in having Mr. Dodge tell whether that cooperation has had a tangible effect.

MR. DODGE: I think it has had a big effect. We have these trophies exhibited for a few days around at all the branches and it goes permanently to the branch that won for the previous year; it is put up in a place where anybody can see it. They take pride in the thing. Competition has an influence in anything.

We make use of the usual kind of signs and different features to try to get it up before the men. Yes, I think it has a very big effect in each of our departments.

R. N. HOSLER (Coal Mine Section, P. C. R. & I., Harrisburg, Pa.): If I am correct, Mr. Dodge refers in his paper to the fact that he set aside a portion of their mine for training of new men. I would be particularly interested in knowing the detail, just what they do there and many of the others will.

MR. DODGE: Could Mr. Brennan answer that?

W. D. BRENNAN (Phelps Dodge Corp., New York City): In our training school for miners, we found that the accidents among green men were large. We were getting a number of them. We took one pair of entries and as each man went through the employment department it was ascertained whether he had had any coal mining experience or not, or just what experience he had; and where we found the man had very little or no experience we sent him to this school. This year we had from 18 to 26 men usually under the supervision of one special instructor.

The general supervision of that part of the mine was carried on by the mine foreman or assistant in a general way. A special man spent his entire time educating these men. They went in under the ordinary conditions. They were in the machine operated portion of the mine and partly on the general retreat. As the man became more efficient, after he was shown the props and different kinds of work, he was given an opportunity to learn the driller retreat work which in our mine is rather dangerous as we have extremely bad top. The men in that department became familiar with the conditions under which they were working and learned the idea of the school and very soon took pride in trying to take care of themselves and to work up their production.

We found that as the man became proficient and we were ready to move him to another part of the mine or to another mine, in a great many cases he didn't like to leave. They liked the close supervision and the attention that they

had in this particular place. We used the word "school." It seemed to be a good word. It was operated in conjunction with the Vocational Department of the State of New Mexico. They found out what we were attempting to do and became interested and wanted to take part in it, so we arranged for them to do so, and to fill out reports for them and to work with them and at different instruction orders connected with the department. While they were not mining men they came up and visited and it created quite a little comment and interest throughout the entire State in that particular department.

We feel quite proud of the record we made, considering the conditions under which the men were required to work. At first the school operated in only one mine but we have broadened it out. Now we have several schools in the various other mines and before we started this school it was quite difficult to get the young fellows as they finished their high school courses to become interested and anxious to go underground. Their ambition in a great many cases has been to find some surface work or get out from the mines, not to go into the mines. But we notice now that quite a few of them come around after they have finished their high school courses and say they think they would like to go into the mine and would like to start in the school. We feel we are bringing back into the mines some of the younger generation. It seems we are developing pretty good miners as miners go today.

C. M. WAMPLER (Eagle Picher Lead Co.): I would like to ask whether the Phelps Dodge Corp. is doing anything to protect the men's feet?

MR. DODGE: In coal mining, we require a man to wear a hard boiled hat. Nobody can go there without a hard boiled hat.

We always require every man to wear goggles not only at the face when he is picking and when he is shoveling and all men working on tracks and any place where there is a possibility of flying material getting in their eyes. Those two are in effect now and have been for two years and the hard boiled cap a year.

The safety shoe—we have the rubber. About half the men wear rubber shoes, the other half leather. The best thing we have been able to find in the way of rubber shoes is not very good but the tip of the rubber shoe must be hard. The leather shoe has been quite a little experiment and quite a little trial and to date we haven't got a very good shoe, but the last batch we got in seems to be good so that now every man that shows up at the mine with a new pair of shoes is required to wear a shoe with a hard cap. We are not asking the men to throw away their old shoes but we are working along the line that everybody that goes in with a new pair of shoes has to have a shoe with a hard toe. We figure that in the course of three to six months everybody in the mine will be wearing shoes with hard caps.

Mr. Ayar could say something about copper mining and shoes. The last time he was in the office he had a shoe store.

MR. AYAR: We have been going into the shoe business quite seriously. There are different types of shoes with hard caps. At the present time over 80 per cent of our men at Morenci Branch of the Phelps Dodge Corp. have safety cap shoes. The safety cap shoe comes down over the end of the toe. We have had lots of cases where men's toes have been absolutely saved by the shoes. In fact, Mr. Crowfoot, superintendent of the concentrate, had a case where a casting dropped on a man's toe and the cap held but the pressure from the floor shoved up and it actually hurt his foot from below, but the cap held. Every now and then we have a man with his little toe hurt. We are demanding a shoe which goes all the way around, not only the cap, but all the way around and covers the little toe also.

I would like to say also that following up the shoe business we found that every now and then if something would drop on a man's instep, where we are

dulling rock through, he had no protection at that place. One of our men designed a spat with heavy strips that fastens on like a skate. It sets on the top of the shoe and fastens up around the man's instep, so we get the man's instep as well as all his toes protected.

E. H. SUENDER (Madeira Hill & Co., Frackville, Pa.): Does that interfere with a man's instep?

MR. AYAR: A little, but it is much better than injuring his instep. The men buy the shoes and the company furnishes the spats. They are kept in a tool room, checked in and out on every shift. I don't know what is inside of them. We have never had a case where it broke through the cap.

B. J. DRYER (Woodward Iron Co., Woodward, Ala.): I would like to ask the kind of goggles they use underground. Are they wire goggles or glass goggles?

MR. DODGE: In coal mining, we use wire altogether. In metal, some wire and some glass, mostly glass.

MR. AYAR: Mostly wire underground, although we are coming around more and more to glass.

MR. DRYER: We had trouble in our mines with glass.

MR. FRANK AYAR: In some cases, I might say, that there is a goggle that if you just unscrew the end of it you can put wire or glass in. If a man has trouble with his glass he can put in wire.

MR. DRYER: Dull finished wire?

MR. AYAR: Dull finished wire.

DANIEL HARRINGTON (U. S. Bureau of Mines, Washington, D. C.): If the good record that was announced by Mr. Dodge and inquired into by Mr. Suender, is in connection with the operation of the coal mines, I want to say to you people who are operating coal mines, that if the Phelps Dodge Corp. of Morenci and Nacozari can have a good safety record as far as falls of roof are concerned there isn't a man in the United States, in so far as my knowledge goes, that can't do the same thing; because if there is any place in the United States where they have rotten roof in coal mines it is at Dawson, N. M. I have had a fine chance to find out about it. I made an examination. Those who are interested in the school that was described by Mr. Brennan can get some published information about it from an article that was written by Mr. Grove of the United States Bureau of Mines and published as a report of investigations; and the paper was also presented before the Coal Mining Institute last year at Pittsburgh.

MR. SUENDER: This discussion leads me to believe that the Phelps Dodge Corp. has the safety movement really in their hearts and minds especially when they get to equip their miners with spats and all of their miners with goggles. I think they have done a real job on the miners' end because goggles are concerned all along the line and I would like to ask another question. Did they find in trying to get these men to wear goggles any opposition on the part of the labor unions?

MR. BRENNAN: We don't have any labor unions.

MR. DODGE: You can't jam an order through right away. For instance, the copper mines are very hot in places and you can't force men to wear hard boiled hats with the same degree you can in a cool mine because for years they have been going around without hats or with a light hat. You can't make up your mind and do it, irrespective of conditions. Naturally, we have been pretty slow about it. You have to start at it slowly and get the interest of the men and get their cooperation and then you will find all of a sudden most of the opposition breaks down and you can put through these customs which you couldn't do at first. It takes a good deal of study. That is where the interest of the management is also his interest. If you turn it over to somebody else, you are bound to make mistakes. Probably you won't get results. If you put it up to the management, he is going to study it and take all the different sides into account and make it possible where it wouldn't be otherwise.

F. S. LENHART (W. J. Rainey, Inc., Uniontown, Pa.): We are particularly interested in knowing how this goggle question is put over. Although all miners, loaders or diggers are required to put on screen goggles when they enter the mine, our experience has been that most of the time they wear the goggles on their caps instead of on their eyes. We have been unable to solve this question. If the gentlemen have any particular methods of solving this, we would certainly be glad to hear them.

C. M. WAMPLER (Eagle Picher Lead Co.): We found in the Tri-State District especially they were rather slow to adopt the goggles. At first we didn't think it could be done and it took at least two years to put it over properly. When we first put in goggles not over 20 per cent wore them. One of the main ways we found of putting it over was that we tried to fire some. Finally, we suggested to the foremen that if we had a man we thought we didn't care to keep anyway and if we were on the verge of letting him go, it would be a good chance to catch him not wearing goggles and we put it over in good shape.

Goggles Used Under a Variety of Conditions

A. H. TRESTRAIL (Picklands Mather & Co., Caspian, Mich.): I would like to ask those gentlemen if anyone had an accident due to the fact he couldn't see with the goggles?

MR. BRENNAN: No.

H. C. HENRIE (Phelps Dodge Corp., Bisbee, Ariz.): In answer to Mr. Trestail's question, I can recall several cases where the cause of the injury, the man claimed, was due to his sight being somewhat affected by the use of goggles. However, in all those cases the committee visiting the same working place under those conditions were unable to find any difference. That is to say, the man should be able to see properly. Then we had their eyes examined. In some cases we found instances of rather defective eyesight, which means that you have to have a corrective lens as well as your safety feature. You understand, men are examined when they go to work. They are required to take a physical examination, but in some cases a period of years has elapsed when their eyesight fails. That is one point to watch. We are coming to the point where we have to take into account possible defective eyesight.

CHAIRMAN McDOWELL: Gentlemen, we will have to close this discussion. Perhaps all of us have had it in our minds to ask Mr. Dodge whether he found the school added materially to the cost per ton mined? Second question, if so, does he find that the men who have been trained in the school are safe enough miners so it could drop the cost of accident that way?

MR. BRENNAN: I think possibly with the slight supervision there might have been a slight increase in cost per ton of the coal from that district, but I think that would be more than compensated by the increased production per man due to this supervision where we had this group of green men, so that in the end I wouldn't say there was any material increase in cost.

J. N. CARMODY (Coal Age, New York City): There are two vital points brought out, one being technique, the other leadership and management. I think any of us who have visited the Phelps Dodge properties as I have had the privilege of doing, realize that a very large part of the success is due to the leadership of the men who supervise the job, from Mr. Brennan down through the line. I had the privilege of visiting the mines underground. I even went to a dance attended by almost everybody in the town, and Bill Brennan danced with the finest looking girls. That's the kind of leadership that puts across this safety success. It is no small thing. It is a large thing. The boys and girls, men and women, are just as glad to see him there as is his own foreman. That is the quality of the thing that goes across.

CHAIRMAN McDOWELL: In relation to the shoes you were talking about. Our company has been making experiments in the last four months with a new type of bootee and it is especially new in many respects. So far we have found it to be successful. I have on record in ten or twelve pairs we have put out for experiment, instances where heavier objects than we would expect would fall on the toes and save those particular toes. This shoe is made with a cap that is a little larger than the cap on shoes that have been made in the past. To do that, it was necessary to increase the vamp of the shoe as they call it, which raises it slightly in front. It doesn't look so well but we find in the re-arrangement in the making of this particular bootee that the wearer finds no discomfort and we have on record now four or five pairs that have gone through three month periods and up to the present time are still going along strong. They were given to men that really had something to do and not men who probably didn't have so much to do—men like drivers who were jumping on cars and the like. The miner also wore the bootee.

One thing we stressed in the building of this shoe was a new bottom to this bootee, one in which it would not wear smooth in just a very short period as the present bootee on the market. We did that on account of men doing their work rapidly, jumping around on cars and the like, and we find in one case in particular where a bootee has gone three months. We had the man appear at our safety meeting just recently and show the bootee and explain it to the men—a foreigner, by the way—and it showed conclusively that we were going in the right direction.

After our experiment has been made, I am sure that we shall be glad to pass it along to others.

FRED. H. NESBITT (Tri-State Zinc and Lead Ore Products Association, Miami, Okla.): Are those rubber or leather boots?

CHAIRMAN McDOWELL: Both.

MR. NESBITT: Do you find any objection to that long extension to cap?

CHAIRMAN McDOWELL: It was necessary to revamp the entire shoe to put a longer toe cap on it. We did that on account of taking care of the last two toes. The other boot does not take care of the last two toes.

MR. NESBITT: Could we get the name of that company?

CHAIRMAN McDOWELL: Yes, I would be glad to give it to you. Gentlemen, I am turning the meeting over to our entertainment man, Mr. Ryan, for a few moments.

The Seventh Inning "Stretch" is Enjoyed

JOHN T. RYAN (Mine Safety Appliance Co., Pittsburgh, Pa.): The membership decided last year that they liked the idea of a seventh inning stretch or interruption in the program. We have been discussing various ways of arousing the safety interest. The New Jersey Zinc Company has a rather unusual method and we are going to give you a demonstration of how Ben Tillson, a former president or chairman of our Mining Section, does it. In fact, he is almost a perennial. He was chairman for six years. He will show where he gets most of his inspiration from.

(Mr. B. J. Tillson, New Jersey Zinc Co., Franklin, N. J., and his family band played for fifteen minutes.)

CHAIRMAN McDOWELL: We will go on with our program. The next paper on the program is to be presented by Mr. S. P. Howell, Explosives Engineer of the United States Bureau of Mines, Pittsburgh, Pa.

Safe Handling of Explosives Underground

By S. P. HOWELL

Explosives Engineer, U. S. Bureau of Mines, Pittsburgh, Pa.

My theme is the reduction to a minimum of accidents from explosives underground. The safest explosives and blasting accessories should be chosen for the work. Approved methods of using these explosives and blasting accessories should be adopted, and adequate supervision provided to see that these explosives and accessories are used and the methods adopted are enforced.

It will suffice to say from the statistical standpoint that for a 15 year period, 1911 to 1925, the average number of accidents from explosives underground in coal operation was 199 yearly fatalities. Of these, 135 were in coal mines and 64 in metal mines; or put on a percentage basis, 5.7 per cent of all coal mine fatalities were due directly to explosives underground, 12 per cent of all fatalities in metal mines were due directly to explosives underground; or 6.8 per cent of all the underground accidents of both mines.

So far as transporting and storing explosives underground, in coal mines, are concerned, permissible explosives are, by reason of the fact that their sensitiveness has been established by test, safer than either dynamite or black blasting powder. They are safer than dynamite because as a class they are less sensitive to blast and shock; and they are safer than the black blasting powder by reason of the fact that black blasting powder is so easily ignited and explodes so promptly thereafter.

One of the requirements for permissible explosives is of course not only their great safety against igniting gas and dust—a thing with which we are not concerned particularly just now—but also the fact that they must pass the pendulum-friction test. It is subjecting the explosive to the frictional impact of a wood fibre shoe on a steel anvil. It is a severe test. All permissible explosives must pass this test. They are the only class of explosives that are obliged to pass it before they may be offered for sale in the United States.

Safety in handling explosives can only be promoted and brought about underground by the use of the most dependable blasting supplies and the safest ones. Of these, we have the electric detonators whose legs are electrically short-circuited. We have the sturdy flexible shot-firing cable. We have permissible blasting units. We have carrying bags or carrying boxes which are electrically non-conductive and we have wooden accessories boxes for storage, wooden skewers and wooden tamping bars. I especially want to stress this matter of electrically short-circuiting the legs of detonators.

Electric detonators with the legs electrically short-circuited by shunts or by having the wires twisted together are used in many coal mines of the eastern United States. The universal adoption of this protected electric detonator in all coal mines would eliminate one cause of fatalities and accidents with explosives which is becoming more and more common.

The electric short-circuit is designed to protect the electric detonator from premature firing by electric current from such sources as power lines, lighting circuits, live shot-firing cables, stray currents and live terminal blasting units of the battery type.

The general use of cutting machines, the increasing use of loading machines, conveyors, and electric drills at working faces in coal mines, and the general firing of permissible explosives with electric detonators, means that sources of electric current are frequently in proximity to electric detonators. Constant vigilance is therefore necessary in the handling of electric detonators to protect them against all such sources of current, and the use of electric detonators with

electrically short-circuited legs is one means of reducing this cause of premature explosions.

Manufacturers now "short" all electric detonators having iron legs, and these are in general use in many coal mines where only single shot holes are fired. Except on special order, manufacturers do not "short" any electric detonators having copper wires; such detonators are commonly used in long holes or when firing two or more charges simultaneously. The cheaper iron-legged electric detonators are unsuitable for this service because of their much higher electrical resistance.

It is not uncommon for shot-firers and miners to remove the shunt or untwist the wires of "shorted" electric detonators long before connecting them to the shot-firing cable, or even before charging a hole, or before making a primer. This is done sometimes because they do not know why these devices are "shorted," and sometimes on the plea that it saves time. It is just as important that the "short" be maintained until the wires are connected to the shot-firing cable as it is that "shorted" wires be purchased for use. "Shorted" electric detonators sell at the same price as "unshorted" ones.

Operating officials of coal mines should consider the following suggestions:

1. Purchase electric detonators with electrically short-circuited legs.
2. Explain to shot-firers and miners who fire their own shots, why these devices are short-circuited and when to remove the "short."
3. Procure compliance with these instructions by adequate inspection and tactful discipline.

Another accessory to which consideration should be given is the shot-firing cable. I have found some very poor types of shot-firing cable, annunciator wire, cotton covered, etc. In my judgment the best shot-firing cable and one that is not too good from the standpoint of safety is one that has stranded wire so that it may be flexible, one that is rubber-covered so that it may be sturdy, one of a gauge not less than No. 18, preferably No. 16, and at least 100 feet long. When joints are made they must be well taped and staggered. When explosives are transported by miners they should be in boxes and bags electrically short-circuited and closed. I will later give an illustration of a method used by a certain mine which I think includes some very good features.

When explosives are delivered by the operator, they should in every case be in an insulated car. They should not be on a road that has current on the trolley line, and if it be black powder and must be hauled electrically, a measure of protection can be procured by the use of sturdy insulated couplings.

In the storage of explosives underground in coal mines, the boxes or bags should be put in locked wooden boxes and stored where it is dry; preferably in a rib 60 feet from the face in order to protect it from water, from theft, from flying particles that are blasted. Moreover, this box should be of such size that about one day's supply can be put in it. Nothing else should be stored in this box. It is especially bad practice to store detonators, electric detonators or carbide or metal tools in these boxes.

I have 16 rules for the safe handling of explosives underground. I will refer to some of them, maybe most of them, with comment.

"The permissible explosive (giving its name) shall be used for blasting coal in this mine." This isn't adequate. "Some permissible explosives only shall be used in this mine." It is desirable, even necessary, that the brand name be given so that there are not several different brands in one mine at one time.

"The permissible explosive (giving the brand name) shall be used for blasting rock in this mine." Sometimes it is necessary or desirable to have one for blasting coal and blasting rock in the mine but some coal mines have found it feasible to use one brand for blasting both coal and rock. This is the best practice.

There is a new class of permissibles—the gelatine class—which has a high density, high strength, eminently suitable for blasting rock. It is recommended for your use instead of dynamite.

The electrical detonators with six foot iron (or copper) legs, electrically short-circuited by twisting the ends of the wires (or by shunts) shall be used, and this "short" shall not be removed until the shot-firing cable is attached.

The shot-firing cable shall be rubber-covered, flexible and sturdy, of 16 (not less than 18) gauge stranded wire.

Permissible blasting units shall be used (specifying kind).

Bags or boxes for carrying explosives shall be of the electrical non-conducting type (specifying by name), and only explosives shall be carried in them.

Storage boxes for explosives shall be of dry one-inch lumber not larger than 20 cartridge capacity, provided with a cover and lock, and painted a distinctive color. The box shall be kept covered and locked at all times, except when the explosive is being handled.

Wooden skewers shall be used for punching holes in primers.

Wooden tamping bars shall be straight, at least one and one-fourth inches in diameter and in length about two feet more than the average depth of cut, undercut, overcut or shear.

An estimated supply of explosives for one day may be procured from the outside distributing station, and taken into the mine by a laborer; any unused portion shall be returned to the distributing station at the end of the shift. In case the miner carries his own explosives, the amount any employee has on hand in the mine at one time is automatically restricted.

Explosives shall not be transported on cages carrying men on man-trips, or on electrically hauled trips.

Where shot-firers are employed, electric detonators shall be carried by shot-firer only.

If electric detonators are carried by the miner who does the blasting his partner should carry the explosive.

Smoking and the carrying of matches or pocket lighters are prohibited in this mine. This rule should apply to all coal mines. Smoking is particularly vicious in a gassy mine or near explosives. The ignition of combustible materials, including explosives and electric detonators, is always a potentiality when smoking or matches are permitted underground, regardless of whether the mine is gassy or not. Smoking was one of the suspected causes of at least two gas explosions resulting in the death of 20 men, in gassy coal mines within the last year. The use of open lights in mines rated as non-gassy is a common excuse for permitting smoking underground. The fact is that open lights should not be permitted in coal mines.

Explosives or electric detonators shall not be taken underground in their original containers.

This rule is fully justified by the menace of a probable burning or explosion en masse of one or several boxes or cartons of these explosives. The toxic gases of burning or explosion may asphyxiate the men, explosion may cause fatalities directly, or may initiate a gas or dust explosion. Moreover, one pound of explosive can produce so many tons of coal or rock that no great quantity is used in the average coal mine daily.

All primers shall be made, all holes charged, the electrical short circuit of all electric detonator legs opened, and the shots fired by the shot-firer.

I will try to detail the example of a good practice in handling explosives underground in a closed light bituminous coal mine in the West Virginia territory where the miners take in their explosives in the morning in nice neat wooden boxes. The explosives are placed in this box at the distributing station by an attendant in quantities that the miner estimates to meet his daily supply, in no event exceed-

ing a certain number of sticks. He proceeds into the mine on a traveling way in which there are no trolley lines and that applies to both the main entry and butt entry. He crosses no track. He goes under no trolley lines enroute to his working place because there are overcasts over the roadways or ramps or steps. At the end of the shift or during the shift, the shot-firer comes around to fire the shots. The shot-firer carries electric detonators in a canvas roll containing 50 compartments, one electrical detonator in each compartment. This roll is carried in a leather pouch. The miner gives the shot-firer a check for the electric detonators which are used.

At the end of the shift, the miner returns the box with the explosives that are left, to the attendant at the distributing station, where the attendant checks up on that particular miner's box and if it is found that he has used, or the shot-firer has used, from this box six or eight sticks as determined in the amount the miner took out in the morning and returned at night, that number of sticks must correspond with what the shot-firer has on his record. Moreover, electric detonators of the shot-firer are checked up, because of the 50 which he takes in he must return either the unused electric detonators or the checks for them. I think this particular example of good practice illustrates a considerable number of good safety practices.

Of course, it is realized that this may not apply, and cannot apply, to all coal mines.

I recently investigated a coal mine which might illustrate good practice and bad practice—a non-gassy bituminous coal mine. In the afternoon an outside employee took a box; one of these insulated boxes properly made, had been used for about seven years and was in good condition, as I observed it. It was taken to the magazine. In it was placed 24 25-pound kegs of black blasting powder. It was then taken to the mine entrance. Now, it was customary at that mine, or at least their instructions were, that the two day-drivers should take in these explosives at the end of the day shift or after the day shift was out, that before they went into the mine they should pull the switch, cut the power off the trolley line, and they should haul this box on the truck by mule and distribute the powder.

What actually happened was that at six o'clock, for some unknown reason, they took the powder out of this box and put it in an ordinary car. When they got into the mine on a certain entry, they noticed that the trolley line was down and they beat it. They knew something was going to happen. Anyway, they knew the power was on the line. It was against the rules. In any event, the black blasting powder exploded and quickly burned both of these men, one 40 and the other 60 feet away. They died in 24 hours.

Now, the bad practices were: First, that they used black blasting powder at all. Second, if they did use black blasting powder, there wasn't any reason in the world why they should take it in in 25-pound kegs, giving to each miner a two weeks' supply to be stored underground and deteriorate there. In the third place, the powder should have been in an insulated box. In the fourth place, the power should not have been on the line. The reason the trolley line was down was that the coal had failed to support a plumb post which carried a cross bar to which the trolley line was secured. Now the good practice of course was that if they had to take black blasting powder or had to take it in those quantities that the rule was to have power off the line, and another was that they did not haul it in a motor haul trip but by mule.

Now we come to the metal mines. They differ of course from coal mines; that is, they do not have the gas or dust hazard to the same degree that the coal mines do, although that is to be given some consideration at special places; they use much larger quantities of explosives because their blasting is more difficult and their ground is tougher or harder. The commonly used explosive in metal mines is gelatin-dynamite. It is a very good explosive, has some excellent qualities; that

is, it has high density, concentrates your energy in the hole; it is plastic, you can put it in holes that point upward and it will stick there. It is water-resistant, therefore, you can use it in wet work; produces a small quantity of toxic gases, which is desirable for underground operations where you use explosives in such quantity.

But there is one characteristic which gelatin-dynamites have which I wish to stress. Gelatin-dynamites are insensitive to detonation. It is common in large charges, especially where the explosive may have aged somewhat, to fire them only by means of a No. 8 detonator or electric detonator. This is desirable and because of this characteristic it is commonly accepted that gelatin-dynamites are insensitive explosives.

But I didn't say gelatin-dynamites are insensitive. I said they are insensitive to detonation, which is and may be quite different to other types of insensitiveness.

Now, the other part, the other half of this characteristic, is that gelatin-dynamites are sensitive to frictional impact. Nine years ago I made some tests with a great variety of commonly used industrial explosives with the pendulum friction device, and of all such explosives the gelatin-dynamites were the most sensitive. Of course, the point that I want to make is simply this, that because they are insensitive to detonation, do not be fooled regarding their sensitiveness to frictional impact and thereby handle them with any less regard than you would otherwise. The fact is, they should be handled more carefully than any other commonly used industrial explosive.

I want to make a plea for the use of permissible explosives fired electrically and certain types of blasting in metal mines—blasting posts, mats in chutes or in blasting posts where you do or may encounter splintered wood or easily ignited wood. It seems obvious that if you use a permissible explosive which has a short flame, a cool flame, and if you eliminate the smoldering fuse, that you are going to reduce your fires in metal mines in such places.

Now, a fuse commonly cut and capped on the surface causes it to absorb moisture. It would be well to get it near its final state of use. Often 3,000 foot reels are capped with a crimper, placed in a container can, taken underground perhaps on the day shift. I see no great objection to that distributed to the different levels. I think it is an excellent method.

Before I get away, I want to stress this matter of electrical detonators whose legs are electrically short-circuited in metal mines the same as I did in coal mines. Safety in haulage in metal mines is largely a matter of moving it slowly, whether it is in a shaft, in a drift, in a stope or raise. It is well to take explosives in their original boxes, to handle them without the use of open lights. Permissible electrical cap lamps are suitable for use in metal mines to reduce the hazards of lights near open explosives. It is enough to recommend them for general use in metal mines.

I want to stress the matter of illumination of magazines underground. It can be done by self-contained electric lamps but I think that the keyless, vapor-proof bulb, installed in underground magazines; the wiring according to the Underwriters' Standard, with a switch outside the magazine and fuse outside the magazine, is a very good and safe practice.

Last, but not least, I want simply to refer to this matter of thawing explosives. Mr. Adams made reports for a great many years upon the details and causes of accidents in the last 15 years. "Thawing—no accidents in the United States." I don't believe we appreciate what that means and why it is so. In Europe they do not use the low-freezing explosives—the extra low-freezing explosives—to anywhere near the extent that they do in the United States, and manufacturers have provided you in every class and every grade of industrial explosive, a very low-freezing explosive and every factory can and does make these low-freezing explo-

sives. There is no reason for any operator to use any other kind of explosive in his work.

Say that blasting gelatin, of which but small quantities are used—I should say never underground—say that all explosives which are and should be made and bought, were of the extra low-freezing variety, if that is so we need never discuss how we shall build a thaw-house or how we shall heat our magazines. Heated magazines, or thaw-houses should be and almost are obsolete.

Now in talking about this subject I hope that I have raised some questions for discussion and indicated certain hazards and pointed out a means for correcting them. Surely I have not covered the entire subject. I have not mentioned all the hazards or all the means of combatting them by any means. I hope the discussion will elaborate on these things.

CHAIRMAN McDOWELL: The paper is now open for discussion and we will limit your discussion to 15 minutes. Let's see how much we can get out of this discussion in 15 minutes.

FRED. H. NESBITT (Tri-State Zinc and Lead Ore Products Assn., Miami, Okla.): Mr. Howell came down and spent three weeks with us two years ago at a time when we had been having a great many premature explosions from handling powder detonators and we got out a very nice bulletin on it that I suspect all of you have seen. Our fatalities in 1925 from handling explosives was six; in 1926, seven; and after Mr. Howell's visit, in the campaign we put on to make the boys realize that it could be handled safely we had only two and so far this year we have had only one. We give credit to the use of the shot tubes, as we call them—a paste board cylinder.

We have two types, one has a wooden block with a hole in it for the tamping bar spike. In the event we have blocking holes and cavey ground, lots of times you have to leave the shot back in the hole. We feel that through the use of these shot tubes and the campaign we put on, we were able to cut down our powder accident fatalities. We have never in the three years that we have used these shot tubes had any premature explosions at any place where they are using them. Unfortunately, the fatality we had this year was at a mine where they had been using these shot tubes and had discontinued it about six weeks before, because they had a ground boss and he didn't think they were necessary.

C. S. HURTER (E. I. du Pont de Nemours & Co., Wilmington, Del.): The thing I want to elaborate on is one which I had in my paper at Detroit two years ago. In addition to short-circuiting the leg wires of the explosive, I consider it of great importance to have the leads shorted at the point of application of the firing current until it comes to firing the shot. That was developed by Mr. Martin. He developed a fine firing switch. It is safe to use. One of the greatest difficulties in the past has been the carrying of powder. I have a sample of a smaller sack which was developed by us and the copper mines of Butte for the carrying of powder. In the past, the great danger was of the sticks dropping out along the line. The same was made so that it could be carried on the shoulder by straps. With this the powder is pretty well protected. I shall be glad to show the same to anyone who wants to see it.

A. H. TRESTRAIL (Pickands Mather & Co., Caspian, Mich.): I wonder if anybody has had any accidents attributed to fuses not burning at the same rate, or if any extensive, consistent tests have been made relative to whether or not all fuses are uniform in its burning rate?

C. M. WAMPLER (Eagle Picher Lead Co.): On that subject, I was recently called as a witness on a case where a man had lost his eye-sight and he claimed it was caused by fuses burning too fast. I mention I was a witness in the case, because I believe that anybody that thinks a fuse burns too fast—I mean the tip of the fuse—we use the metal—if he will write to the fuse makers and explain the thing, they will send a pamphlet on how fuses are made. It thoroughly con-

vinced me you can't have a fast fuse. I won't explain at this time how it is made. That thorough investigation convinced me it can't burn too fast. They also said it can't burn too slow, or you can't have a delayed fuse, but I am frank to say they haven't convinced me of that.

MR. BROWN: I have investigated several accidents which were alleged to have been caused by what is known as running fuse and we have made a great many tests with fuses and in conjunction with the manufacturers of the fuse we have been unable to make a fuse which will run as they say. You can increase the speed of a fuse a trifle by taking it and hammering it on a steel rail, softening it up, but you can't get it to run. We had a case in a tunnel over in Jersey. A man claimed the six-foot fuse burned in ten seconds. It is simply impossible to do it. They have tried to produce a fuse which will run and they have been unable to do it. They can't make a fuse that stops burning. Even the manufacturers say they will vary 5 per cent either way from normal; the 40 second, 30, 25 and 20 fuse will vary 5 per cent.

MR. HOWELL: One of the first papers the Bureau of Mines published was on the influence of pressure and temperature on the rate of burning of a fuse. That was a technical investigation. The fuse was subjected to various temperatures, the effect upon the speed noted. I think that by combining these in rather extreme ways—ways that were quite impossible to get practical work—it was possible to increase the speed of burning by as much as 50 per cent.

MR. BROWN: The speed is greatly increased when it is under confinement. We have tested every fuse that has been manufactured in this country and in some cases German fuses and Belgian fuses, for burning in air and burning under confinement. We find that with certain fuses, what we call "D Acceleration and burning speed," their speed jumped up as high 50 per cent. That will vary according to the nature of the fuse. With some of the lighter ones the acceleration is greater than in the double tape or triple tape and the higher fuses. The fuse burns fast in the bore and in the open. At higher elevations there is considerable difference. For instance, a fuse will burn slower at Denver than it will in New York.

MR. HOWELL: There are two things I have discovered in investigating accidents in the use of fuses: 1. That the average time burning of a fuse is faster the shorter the fuse you test—it is slower the longer the piece you test. When you light the fuse the gases are not under pressure. As it starts to burn, it burns slowly, then when it gets near the end, the last quarter or half an inch, it spits out. And the practical application of that is that in the metal mines if you use a twelve or eight foot fuse, that is the length of fuse you want to test to determine the speed of burning. Another thing, in lighting block hole shots or dokey shots, sometimes perhaps in rounds, they take a piece of fuse and use it as a light. In doing that they slit every inch or so and if your fuses in your round are six feet you take a six foot piece of fuse. Frequently, the assumption is made that the man lights this and gets away from the base while it is burning. In other words, he's got time equivalent to the burning of a six foot fuse. Since he lights that—that is the first length of fuse light—he is in the clear as long as he gets away while it is burning.

MR. BROWN: The manufacturers of explosives are now manufacturing what they call a warning fuse cap or fuse and the man uses this cap called torpedo and eliminates that first. When that explodes it is time to get out. He hears it.

C. L. WILSON (Berwind-White Coal Mining Co., Philadelphia, Pa.): I would like to ask Mr. Howell a question. When the miner returns his daily supply, would there be any objection, in a bituminous coal mine, to have that miner return that daily supply to a central daily supply magazine?

MR. HOWELL: In general, I don't like the use of a daily underground supply magazine in coal mines. One of the reasons, and, to my mind, the principal reason, to have supplies returned to the surface is that underground storage is a

severe annoyance. That brings up a detail of use that might be mentioned in this connection. The permissible explosives they use may be a cartridge and a half or a whole or a third. Consequently they are cutting their cartridges. They are having left at the end of a shift a half cartridge or a third or two-thirds. If that remains in the mine over night, it will deteriorate promptly. It ought to be used at least by the next day.

Now it has been suggested in some quarters that the manufacturers ought to make half cartridges. I suspect manufacturers will not react very favorably to that because it means more expense. These half cartridges, when they are cut, are usually covered with a dry paper and wrapped dry. They could be maintained in a permissible condition a long time. Sometimes these half cartridges cause partial misfires in bore holes. A half cartridge may be put in a bore hole and an inch of it may be very wet because that inch has been cut—that is the severed end of it. Now, for some reason or other when they put in half cartridges they always put the crimped end at the back and leave this deteriorated end to make the contact with the primer on the cartridge ahead of it.

In some places they have eliminated these partial misfires and are still able to use the cartridges; that is, placing the half cartridges with the deteriorated end at the very bottom. So you continuously have good explosive until the last half inch. If it didn't go, it doesn't make much difference as far as safety or efficiency was concerned.

MR. WILSON: When there are five or six mines returning their powder to the surface, it seems to me we are creating another situation there. If you distribute these explosives at night or have them distributed by the miners and get them from the central station there is quite a condition. What I am trying to explain is that we have our assistant foreman estimate the daily supply for the miner and he in turn distributes that powder at the central place at night and it is locked in a wooden box and closed in a non-combustible building. That evening he returns that powder to this centrally located magazine underground. In some cases there are three, four or five sticks of powder; in many cases, none. After making inspection of these underground magazines at night when the day shift has completed their work, it has been found in some cases there were only three or four dead ones or three or four sticks of powder.

We were trying to have the miner return the daily supply or unused daily supply at the surface and it created a little hazard that we were sorry for.

If the mines are two or three miles apart and all returning powder to one place, there would be too much of it. We decided to have them return it underground. I am wondering whether that is in contradiction of good safety practice?

MR. HOWELL: I don't think that under certain circumstances there would be any objection to your practice.

N. W. GREENSFELDER (Hercules Powder Co., Wilmington, Del.): One class of accidents Mr. Howell didn't speak about is accidents to children who pick up blasting caps, or miners who take them home and the children play with them afterward. The manufacturers of explosives have been giving study to that subject. A year ago they got up a motion picture, which is available to the mining industry, and it has been found effective. Certain companies have taken it, shown it throughout the schools, and we have definite evidence that it has prevented accidents to children.

CHAIRMAN McDOWELL: It has been very interesting to note that the two papers this morning have created considerable discussion.

At this time we desire to have the report of the Nominating Committee. As expressed to you, Mr. Young, chairman of that committee, is not present, but Mr. Henrie of the same committee will now make that report.

H. C. HENRIE (Phelps Dodge Corp., Bisbee, Ariz.): In the absence of Mr. Young, I shall read a report prepared by him and the committee.

Report of the Nominating Committee

Your committee, appointed for the purpose of nominating officers for the Mining Section of the National Safety Council for the year 1928 and 1929, are happy to recommend for the approval of the membership the following officers:

Chairman—George Martinson, of Pickands, Mather & Company, Hibbing, Minn.

Vice-Chairmen—A. W. Dickinson, of Union Pacific Coal Company, Rock Springs, Wyo.; J. P. Hodgson, of Phelps Dodge Corporation, Bisbee, Ariz.; F. C. Miller, of The Colorado Fuel and Iron Company, Trinidad, Colo.; R. N. Hosler, Pennsylvania Compensation Rating & Inspection Bureau, Harrisburg, Pa.

Secretary—Daniel Harrington, of United States Bureau of Mines, Washington, D. C.

It is the opinion of your committee that the Chairmen of the Standing Committees can best be chosen by the new officials. Therefore, we are not recommending Chairmen for the various Standing Committees at this time.

Signed: J. T. RYAN,
H. C. HENRIE,
H. I. YOUNG, Chairman.

CHAIRMAN McDOWELL: I thank the committee for their work in making these nominations. You have heard the report of the Nominating Committee. What is your pleasure?

(Motion was seconded and carried, that the secretary be empowered to cast a ballot for the entire slate.)

ADJOURNMENT

October 3, 1928

Luncheon Session

C. A. McDOWELL, Chairman
Safety and Personnel Manager, Pittsburgh Coal Company
Pittsburgh, Pa.

(Benjamin J. Tillson's (New Jersey Zinc Co., Franklin, N. J.) Band of 40 pieces played during the luncheon.)

The meeting was called to order at one o'clock by the chairman, Mr. C. A. McDowell.

CHAIRMAN McDOWELL: I think it is especially interesting that we should meet in a case of this kind. It is very inspirational for us to sit and listen and get that throb that works through us occasionally when we hear such music. As we look over that crowd we feel that Mr. Tillson has done a wonderful job and it should be inspiring to us in our own communities for work of that kind.

The speaker for the day needs no introduction. However, I really want to state that I have known this gentleman for sometime and I feel that if there is anyone at all who can give us an inspirational thought it is he. I therefore ask that Mr. J. M. Carmody, Editor of "Coal Age," speak to us for a few moments.

Address

By J. M. CARMODY
Editor of "Coal Age," New York City

About half past eleven I was leaving the Waldorf for my office, when Marvin said to me: "We want you to say a few words at the luncheon, and we want you to come back." I suggested to him there were several other fellows whom I named who could do a better job, but he said they may not be available. Ten minutes ago Jack Ryan said "You're elected."

It seems to me that the key note of the genuine safety movement was struck by Mr. Dodge when he said two things; first, that the safety movement with the Phelps Dodge Corporation started at the top and went from the top down through the organization; and then again he said (and what he said was supplemented by statements of Mr. Brennan and Mr. Henrie and Mr. Ayar) that they didn't force the thing through, that they took time to educate the men to a point where they had a desire to carry out safety instruction.

I have always said that safety rules, important as they are, are not enough; nor is the kind of forceful election that is sometimes taken to influence safety movements and methods; good as it is and important as it is, technique enough. The most important single thing that the safety movement needs, and the thing it is getting more and more year by year, is personality and leadership on the part of the men who are carrying out the program for the various companies.

As I look around here now, I find a splendid group of men—men whose personality stand out in this crowd and whose personality will necessarily stand out in a crowd of working men whom they are asking to do certain things for their own protection. The whole thing is psychological, more psychological than it is anything else.

The first important thing, it seems to me, is to establish confidence on the part of

the men in the man who is doing the job. I said upstairs this morning that that is the thing that struck me when I visited Dawson, N. M., about a year ago. I went there as a visitor with the Rocky Mountain Institute crowd. We saw Bill Brennan in action. He wasn't showing off. He was doing his job. He wasn't able to see everybody every minute and incidentally slipped away from the crowd, and I went down to see about something else. But the point is that everybody in that town not only knew him but they had confidence in him. When they had that party that night, at which everybody danced with everybody else, it was a hard job for any visitor to get a girl away from Brennan, particularly the good looking ones. That is the kind of thing that stands out. It is the thing necessary in every single community.

Now, personality, leadership, confidence—it means that men have to have more than a desire to do a good statistical job. Statistics are important in safety. It is absolutely necessary that they be of some fine sort that you can pick out exactly what the conditions are that are causing trouble and causing the difficulty; but they are not enough.

That was demonstrated to me particularly in Bluefield a week ago last Saturday. There was that great Safety Day. That originated in the brain and heart of Bob Lambie who brought together thousands of people and some 180 teams for competition. What did that mean for the State of West Virginia? It meant that the Safety Movement was brought to the attention of every man, woman and child in the State. It meant that the officials, from Governor Gore down, got an entirely new conception of the responsibility of the State to the Mine Safety Department and to the mine operators and to the mine workers.

It meant that the mine workers who came there in large numbers, driving long distances even after it had rained several days and made some of the roads rather difficult to pass—because I spent a week in an automobile going to Bluefield—it meant for those men that they realized that the things they were being told by their safety men, by the State inspectors, were not things that these men alone wanted them to do, but they were things that the whole State Department and government of the State were tremendously interested in. They were doing something for their own good.

I can't think of any other single thing that is quite so important as the expression of your personality, based on a generous understanding of the other fellow's desire largely not to do what he is asked to do first. After all, the thing that safety men must remember is that not only the working man, but every single one of us, builds up resistance when somebody asks us to do something that we haven't done before. It may be for our very best good, but there is something that goes clear back through probably a thousand generations that asks us to be a little skeptical about this thing that somebody asks us to buy, take or use. We have to break it down and we must not break it down by force. Some people say "Well if they don't do the job, ultimately you have to fire a man." Of course, that is the admission that you are not a good manager, that is an admission that you have given up in your desire to convert this man to a practice that is good for himself and good for the company.

Now sometimes it finds its expression through the development of bands in the communities, as you fellows well know, sometimes it finds its expression in the development of baseball teams. It finds itself more frequently than not in some sort of indirect approach to the man's confidence in yourself, to the man's desire to do the thing that is best for everybody to do. You have to build up in the man a desire to take pride in the organization as a whole that does a first class job.

I could talk a long time to you fellows and I would say many things. You know them better than I do. You are on the firing line all the time. I want to leave the single thought with you that is the most important single thing—the development of confidence.

I want to say one more thing. You have to dramatize safety. It hasn't always been done. It can be done. For instance, as I look around here right now I see among my own acquaintances fellows that have put drama here. Jack Ryan, the very name Jack Ryan, carries spirit and fire from the Atlantic to the Pacific. The name Bob Lambie has reached far beyond the borders of the State of West Virginia. With Bob Lambie, with Jack Ryan, and these other fellows, they have a great heart. Bob Lambie would sacrifice himself for everybody else. He doesn't do it for himself. He is so modest. If he weren't so modest, he would be better known, and he ought to be better known everywhere because the people outside of this country ought to know what kind of a man he is. So it goes with Dan Harrington, with Jack Berry; it goes with Forbes and many others. I can name many who are giving of themselves completely for the safety movement; and it comes back and washes back many, many times when it is properly dramatized to those men down in the mines whose lives they are protecting. It ought to be known outside the borders of this country, to the people of other countries, as well.

CHAIRMAN McDOWELL: It is a matter of great regret to us all that Mr. D. D. Muir, vice-president of the United States Fuel Company, who was to have talked to us at this hour, has not been able to be present. But the address Mr. Muir expected to make here will become a part of the record of this meeting.

Safety—A Common Denominator in Coal and Metal Mines

By DOWNIE D. MUIR, JR.

Vice-President and General Manager, United States Fuel Company,
Salt Lake City, Utah

As long as mines operate there will be accidents, and just so long it becomes the duty of every operator not only to use known precautions and preventatives but to use his ingenuity to devise new ones that will fit the particular case. There is not now nor will there ever be a fixed set of safety rules or regulations fitting all cases that will prove a 100 per cent eliminator. The problem of the operator is to approach that goal as near as possible from both humanitarian and economic viewpoints.

Safety in general is considered to mean freedom from danger or hazard and elimination of causes of such. Industries of today, largely mechanized, present far greater hazard to the worker than formerly, not from the standpoint of unit production but from exposure. Transferred underground, industry becomes more hazardous, many conditions existing there not found on the surface. The mine operator is beset with such additional danger for his employees as lack of light, fall of roof or rock, electrical apparatus of a necessity in near proximity to the work, use of explosives, and in coal mines the ever present fear of gas or coal dust explosion. By just this degree his problem calls for additional precaution and renders mining for an industry of its magnitude the most hazardous of all.

It is nearly impossible and thoroughly impractical to attempt listing all causes contributing to accidents. The majority may be, however, confined to relatively few, as follows:

Metal Mines

Falling rock	31.79%
Particles in eyes	13.66
Miscellaneous	8.84
Falling	6.99
Handling drills and other tools.....	6.10

Lifting or overstrain.....	5.30
Transportation system injuries.....	5.27
Falling timber.....	5.16
Struck by axe or pick.....	3.45
Injuries by nails.....	2.36
Cut or pinched by rock.....	2.36
Falling ground.....	1.90
Hands caught.....	1.82
Riding on locomotive or cars.....	1.28
Handling material.....	1.22
Acid water infection.....	.88
Carbide burns or explosions.....	.81
Blasting and handling explosives.....	.81
Total.....	100 %

The above constitutes a nine year record of a Utah metal mine employing in excess of 300 men.

Coal Mines

Mine explosions or fires.....	0.0 %
Fall of face or pillar coal.....	18.0
Falls of roof.....	21.5
Loading mine cars.....	15.0
Miscellaneous.....	11.0
Foreign body in eye.....	4.0
Mine cars and locomotive transportation.....	12.0
Handling tools, axes, bars, etc.....	3.5
Falling timber.....	3.5
Falling.....	3.5
Handling machinery (other than mining).....	3.0
Mining machines.....	2.0
Electricity.....	1.0
Nails, splinters, etc.....	1.0
Explosives.....	1.0
Total.....	100 %

The above is a three year record of three Utah coal mines employing in excess of 600 men. While conditions in these two types of mines differ widely from other mines in various sections of the United States, they are representative of Utah conditions and may be used as criteria for comparison of types of accidents in metal and coal mines.

By far the greatest hazard in both types of mines from standpoint of frequency is falling rock or coal. From standpoint of severity of injury and loss of time, this same hazard is the greatest offender, followed closely by falls of persons in case of metal mines and loading of cars in coal mines. Any similarity of hazard or severity ends at this point, as might be expected, due to widely different conditions.

The question comes to mind as to which type of mine is the more hazardous. Accident records for coal and metal mines are compiled so differently as to make accurate comparison difficult. The Bureau of Mines, however, after considerable effort, have compiled statistics which afford a comparable basis. For the years 1913 to 1925 inclusive, these figures show 4.38 fatalities in coal and 3.53 fatalities in metal mines per one thousand 300-day workers. The same figures for the year 1925 alone show 4.65 fatalities in coal mines and 2.99 fatalities in metal mines on the same basis.

In 1927 the Bureau of Mines, for the third consecutive year, conducted a safety contest among 250 mines and quarries. Among the bituminous division 45 mines reported. In the rating one Utah mine was fifth, another nineteenth and another forty-first. The average frequency rate for the 45, based on fatal, permanent and other lost time accidents per million man hours of exposure, was 97.32. The severity rate, based on number of days lost from accidents per one thousand man hours exposure, was 15.73. The three Utah mines referred to above belong to the United States Fuel Company, Salt Lake City, Utah. Their record for 1925 to 1927 inclusive, on same basis follows:

Records for Three United States Fuel Co. Mines

		No. 1	No. 2	No. 3
Frequency rate	1925	136.463	141.672	136.622
	1926	84.696	130.031	269.985
	1927	77.688	90.789	122.449
Severity rate	1925	81.559	16.894	28.153
	1926	1.671	17.315	123.440
	1927	.784	3.282	35.685
Average Employees	1927	280	249	96

The average frequency rate for 58 metal mines reporting was 63.90 and the severity rate 8.39. This again indicated the greater safety of metal mines. I firmly believe this to be the result of the naturally less hazardous physical conditions of the latter for there is no doubt that greater and more precautionary measures are exercised in coal mining than in metal mining. A comparison of the hazard between coal and metal mines on the basis of production is more difficult to obtain. The following figures were arrived at from such data as available on Utah operations:

Comparison of Coal and Metal Hazards

Year	Metal Mines	Coal Mines
	Frequency rate per 10,000 tons production	
1919	17.2	
1920	18.1	2.3
1921	18.2	2.6
1922	22.0	2.3
1923	24.2	2.3
1924	30.3	2.4
1925	22.5	1.6
1926	19.3	1.4
1927	15.6	1.1

These figures are contradictory to Bureau of Mines' figures, the exposure period of the worker per ton of coal produced being considerably less than per ton of ore produced in Utah. With high flat seams, Utah coal miner averages about 6.65 tons per eight hours; the metal miner approximately 1.3 tons for the same period. This is ratio of at least 5 tons of coal to 1 ton of ore for equal period of exposure. Even after applying this ratio to the preceding figures, frequency of accident per ton production per unit exposure is greater in metal mines. However, the only fair basis of comparison is on the unit exposure regardless of tons produced, which leads to conclusion that coal mines are the more hazardous. In both types of mines the danger of accident increases with increase in number of employees and greater extent of workings. There is no favoritism shown in the preceding comparisons, it being the endeavor of the writer to allow figures to speak for

themselves and also reduce hazards at both coal and metal mines under his supervision.

Utah coal is 40 to 50 per cent volatile matter, low ash, low moisture and in many instances has a high resin content. Mining of same produces a dust, one of the most highly inflammable and explosive known in the United States. Probably one third of the mines in the state have methane. Some contain oil seepage. Arid climate deprives mines of moisture. Seams vary from 6 to 30 feet in thickness, from flat to 10-12 degrees pitch. All in all a combination which, of a necessity, has placed majority of Utah coal mines if not first, well up in the ranks in conscientious endeavor to prevent accidents.

Metal mines of the state are mostly fissures in limestone or replacement of sedimentaries. The latter usually stand well and offer no unusual or extraordinary hazard not encountered elsewhere. The state mining code is a good one and well adhered to by operators. Comparatively the metal operator's task from a safety standpoint is rather less difficult than the coal operator's.

Utah coal mines in general are equipped with hospital facilities within easy reach. Some have a resident doctor at each camp, a first aid room at the pit mouth, and one a central hospital serving four mines.

No open lights are permitted underground, shot firing is done from the surface by independent line from surface to face. No employees are allowed in mine at time of firing and rock dusting is carried on well up to requirement. Rock dust barriers carrying as high as four tons of dust installed at frequent intervals. One mine is now rock dusting back entries. Mines are equipped with tight, solid-end cars. Haulage entries are graded—56 pound steel on main haulage ways. All precautions deemed essential for gaseous mines are taken whether gaseous or not, such as ventilation, rock dust, inert material on haulage ways, concrete overcasts, stoppings and safety record sign boards at pit mouth.

The larger mines maintain safety engineers who make regular inspections and reports, keep accident records, attend to helmet equipment and train rescue crews. Safety measures at some mines cost as high as 3.5 cents per ton production. The operators of these mines feel this to be one of their best investments.

Metal mines in general do not carry safety measures so far, the necessity not being there. They are equipped with hospitals and medical service, have oxygen helmets and trained crews. The use of helmets or hard hats is becoming more general and is decreasing not only severity of head injuries but number of accidents. Use of wire screen goggles of a comfortable pattern is increasing. Blasting powder in red wrappers, due to great visibility, has decreased to a marked extent drilling into missed holes. Strict enforcement of rule that all accidents, no matter how trivial, be reported and treated decreases infection. Containers for drill steel filled on surface not only gets steel to desired point but saves many fingers and bruised heads.

The personal equation of the employee is common to all employers and is more or less successfully handled in many ways. To secure an honest effort against carelessness, the Joplin idea of flags of various values for periods of non-injury is used. The Arizona idea of buttons has worked well. The use of signs at working points where a large number of men pass is good, but upon familiarity with same effect is lost. Welfare and safety associations which stir up and maintain interest do their share.

On the other hand, the employer is entitled to some consideration. The writer is a firm believer in the card system whereby applicant is given a card to the doctor for examination. If this discloses temporary or permanent defects which would incapacitate applicant for work at hand or jeopardize safety of other workers, he should not be employed. The practice of deducting from the payroll accrued premiums on accident policies of employees leads to abuses, especially where com-

pensation laws return high compensation, and should be avoided. Life insurance is entirely different.

The welfare of a mining camp is of paramount importance in matter of safety, although many operators fail to recognize this fact. Given a safe place to work, a decent place to live, schools for his children and some form of diversion for his leisure hours and you have a satisfied employee, who will be permanent. A large labor turn-over is directly responsible for many needless accidents through unfamiliarity with the mine and working conditions. The benefits of a permanent employee and the best class of labor are enjoyed to a greater degree by the coal operator by virtue of the fact that coal mines are longer lived than metal mines, justifying capital expenditure incidental to better camps and accommodations. There is undoubtedly a similarity in safety measures employed successfully in both types of mines, but if there be a common denominator it is constant vigilance, first, last and for all time to even the smallest hazard on part of employer and employee and the teaching of the latter that danger may be seen, recognized and avoided.

ADJOURNMENT

October 4, 1928

C. A. McDOWELL, Chairman
Safety and Personnel Manager, Pittsburgh Coal Company
Pittsburgh, Pa.

The meeting was called to order at nine-forty o'clock by the chairman, Mr. C. A. McDowell.

CHAIRMAN McDOWELL: The first paper we have on the program this morning will be delivered by Mr. E. H. Suender, General Manager, Maderia Hill Co., Frackville, Pa.

Management Believes in Accident Prevention

By E. H. SUENDER
General Manager, Anthracite Mines, Madeira, Hill & Company,
Frackville, Pa.

Judge Gary, Chairman of the Board of the United States Steel Corporation, says accident prevention is not only good morals and good ethics, but also good business. Industry cannot afford to accept this statement as anything but a fact.

Speaking for the Anthracite Industry, with its 158,000 employees, with an annual exposure to accidents of 340,000,000 man hours, and a yearly payroll of over \$300,000,000, and as a Member of a Committee representing the Industry on Accident Prevention and First Aid, I can unhesitatingly say that that management does believe in accident prevention.

Undoubtedly progressive managements and others have similar beliefs, but to believe in an ideal, and to put that belief to work, toward the consummation of the ideal, is quite a different matter.

Executives and managers of industry, and the personnel of their organizations believe in a great many things, but as weak humans, they permit their consciences to direct their activities, for the major portion of time, along channels that are only seemingly more important, although admittedly not so in the opinion of these very executives or managers, than the question of Accident Prevention.

The great majority of the personnel in industrial management believe in the universal necessity for better and better service; better and better quality of product; in the Golden Rule; in the Ten Commandments; in the Constitution of the United States, and in the Eighteenth Amendment, but in all probability, it's only the few who come anywhere near a perfect score in their endeavor to carry out these teachings, rules, laws and regulations.

Now, the point I am trying to make is, that in my observations, limited as they are, I find that while management and their staffs believe in accident prevention, many of them do not have this most important obligation to society, and factor in their production costs, close enough to their hearts and minds to sell it to their superintendents and foremen, much less than to the rank and file of workmen.

I do not concede that the accident prevention effort to conserve human life is being overdone, as some have argued—a fatal accident that could have been prevented by a proper precaution, is a charge that industry can never satisfy or eradicate. A serious accident, leaving the victim maimed, is a living example, in many cases, of the negligence of management. It can well be said that there are no repair parts for the human machine.

Industrial managers are, in a sense, the trustees of their employees, and as such, must be charged with any negligence on their part to conserve life and limb. For years industries, organizations and municipalities have been striving to reduce accident records. For the past fifteen or more years an organized effort to reduce

accidents has been made by many industries—the records confirm the effort. True, it seems in some instances that increased efforts are sometimes met with an increase of accidents—one can only conclude in such cases, that the record, in the absence of effort, would have been all the worse.

Society has erred and is erring today, in failing to educate the child, first in the simple safe practice of play, and finally through all the grades and colleges, constantly impressing upon him his own safety, as well as the obligation he owes to his fellowmen and industry, to do everything within his power to reduce to a minimum the toll that management and workmen are today, through neglect, imposing upon society, industry and the dependents of the gainfully employed. Service clubs in this country, and through the world are doing a splendid piece of work in an effort to improve service to humanity; further the interests of communities, sponsor the commendable movements for the good of all; they might well place more stress on this most important subject of reducing accidents.

In the matter of importance, accident prevention ranks well with ideals sought in the advancement of understanding, good will and International peace, that the Nations of the world are striving for.

The Annual Accident Toll

It is estimated that there occurs in the United States, about 85,000 fatal accidents annually, with a total of all accidents probably equalling 2,500,000 to 3,000,000, with a wage loss in excess of \$1,000,000,000, or about 3 per cent on the \$40,000,000,000 payroll in United States. Of the total fatalities from accidents in the United States, approximately 23,000 are street and highway accidents, 20,000 home accidents, 20,000 drownings, fires, fire arms, falls, electricity—the balance, or 22,000 is charged to industry. The cost to industry alone is estimated at \$5,000 for each fatality. Automobiles cause 25 deaths per 100,000 population in the United States, and this curve seems to be constantly increasing. Twenty-seven per cent of all accident fatalities in United States are motor vehicle accidents. Fifteen thousand lives are lost annually by burning accidents in the United States. Considering the task performed by industry, i.e. its tremendous productivity, it would seem, in a comparative way, that industrial managements are not only making progress, but have established a pretty good record, and yet, only a start has been made—the possibility of further improvements is tremendous. Over 250,000 eye injuries occur in the United States annually, and approximately 15,000 workmen lose their eyesight. It is estimated that 75 per cent of all accidents are preventable. Here is surely a field for real opportunity for management to create and maintain a safety atmosphere.

Forty per cent of all manufacturing in the United States employ from one to five wage earners; 28 per cent between six and 27 wage earners. These two groups employ 825,000 workers.

Low accident records go hand in hand with progressive organizations, efficiency in operation and increased productivity in the greater percentage of cases. The problem that confronts us is to persuade the tremendous number of small business establishments to take a proper interest in this important work. The merging of existing businesses, of similar kinds into larger corporations, with progressive leadership, therefore helps to lessen accidents. Since industries are being merged in part to effect economies, it is apparent that as competition increases and margins decrease, there is all the more necessity to effect mergers, and there is every indication that the next ten years will be a period of consolidations and mergers of industries that will far surpass any similar period heretofore on record. Of the first 1,000 industries listed in Poors Manual, 200 represent consolidations.

Industrial accidents are probably increasing in number, although lack of data makes it impossible to say whether accidents are increasing on the basis of expo-

sure, certainly they are decreasing on the basis of productivity. Increase of accidents and periods of increased industrial activities go hand in hand. The trend seems to point to greater production per man employed, less accidents per unit of production, but more accidents per man employed.

The principal factors that contribute so much to our long list of accidents may be summarized as follows:

- (1) Physical hazards.
- (2) Ignorance of employees in the detail of their work. This is especially true of new or unskilled workers.
- (3) The strain of worry, due to finances, sickness, strife or other family difficulties.
- (4) Ill health of employees.
- (5) Failure to properly warn or instruct the foreign language employee.
- (6) Gross carelessness of shiftless workers.
- (7) Fatigue among employees.
- (8) Employees taking chances.

It's a slipshod, haphazard industry or management that is making no effort to reduce accidents in any of these directions. Such are rendering service to neither customer, society or investor. That they can operate at a profit at all is to be regretted. It is encouraging to note that an ever increasing list of industries, organizations and associations, under wise leaderships, are appropriating large sums of money, and through management are insisting that correctives be applied to each and every factor that tends to conserve life and limb. It is estimated that compensation laws plus organized effort is saving the lives of at least eight persons per 100,000 population, or somewhere between 9,000 and 10,000 persons per year.

Among the progressive industries and managements, physical hazards either have been or are being removed. The exhibit on the roof garden of the Pennsylvania Hotel tells only part of the story. There we have translated into practice the thoughts, study and experience of an army of engineers, practical operating men and wise leadership in industry.

That many accidents occur because employees are ignorant of the ordinary hazards or details of employment, and because they are not properly warned, or instructed, particularly when they are first employed at new work, in unquestionable, and is proven by analysis, in numerous cases. Management is responsible.

That family strife, finances, sickness or other distracting difficulties has contributed its toll in accidents is uncontrovertible. Management can and should interest themselves in such matters, relieve the workmen of the strain, if possible, in order that he may give his proper attention to the detailed performance of his work.

It is argued by some authorities that ill health rather than carelessness is responsible for most of our accidents. I cannot join in that belief, but there isn't any question that the health of the individual is a real factor. Any good accomplished by industry or society, to raise the standard of health is therefore helpful. Industry, municipalities, state and federal government, and the great insurance companies, have done a splendid piece of work in this direction. The Metropolitan Life Insurance Company alone has accomplished remarkable results in its welfare department toward the prevention of diseases and the prolongation of life. The statistics of this company show a reduction of from 13 to 9 days lost per person, due to illness in the year 1909, as compared with 1927. It is estimated that 350,000,000 man-days are lost annually in the United States, due to illness, and that of the 500,000 persons who die each year in the United States, 50 per cent die from postponable deaths. Remembering that there are 42,000,000 persons gainfully employed, we can visualize the cost item to industry. Here is a vast field for work, and many industries and others have recognized it, and are busy combating it.

Accidents among the Non-English speaking classes are in excess of those in

similar occupations in other groups in the same industry. Certainly management cannot offer as an excuse that Non-English speaking employees cannot be properly warned or instructed, for that reason. There is a way to do it—no one knows better than management how to do it—and where the facts reveal that accidents are increased on that account, management must shoulder the responsibility.

That gross carelessness of shiftless workers is one of the real problems from an accident standpoint, is undoubtedly true. There are those who cannot be educated, instructed or warned. Discipline, and discipline only, will correct such carelessness. I know of no better way than to dispense with the services of such workmen. The worker who finds it difficult to secure employment, because of his careless habits, will probably be educated in time.

No foreman has the right to expect from an employee more than a fair day's work. It is gratifying to know that workmen are not being driven today, as might have been the case many years ago. No man should be forced to do a day's work which brings about fatigue to the point where he is more apt to be injured. It is just as sinful to expect a man to do more than a fair day's work, as it is to permit him to do less than a fair day's work. Horse sense on the part of any boss will correct the problem.

To my mind the hardest problem that confronts the foreman is to eliminate the taking of chances, and the gambling against injury while doing so. Here is where we find unusual accidents, the unlooked for occurrences.

Many people are by human nature venturesome, they take the shortest possible routes in the performance of a task. Note the speeding automobile on hill tops and curves, the flying switch on railroads and in mines, the miner in his desire to get his maximum tonnage, or yardage, for a given effort, the short cut fuse in firing shots, the miner's early return to the face of a mis-fire; the big game hunter in the wilds of Africa; the racing automobilist; the aviator in his plane flying through unknown conditions. The question is "How to combat it." Education, warning, instructions, discipline, acquiring the good will of employees, the foreman keeping everlastingly at it is the answer.

Accident records are best, all other things being equal, where the maximum of good will exists between the foreman and his men—and foremen must remember that the only way to purchase or acquire good will, is to give it away. A task can be done in one of two ways—safe or unsafe. The objective to be striven for by industry, is the performance of a job in a safe way, placing productivity secondly, rather than the converse.

Coming down to our individual problems in mining and preparing Anthracite; we do claim that accident prevention and safety practices were effective in the industry in an organized way probably as long as any other industry in the country. The hazards of the business necessitated this activity for many many years. The mines are regulated by State Mine Laws and are under the supervision of State Mine Inspectors—further improvements might well be made by coordination of State Mining Laws, establishing reasonable rules and regulations that can mutually be agreed upon between State authorities and progressive mining managements. Notwithstanding this State supervision and regulation, the record of fatal accidents per man employed, or per million tons produced, or per exposure of man hours is not altogether a cheery one, although progress is being constantly made in the face of the ever increasing hazard that the business of mining is confronted with. Because of the hazard, the industry with its 158,000 employees, must be prepared to meet every emergency, and is therefore equipped with emergency hospitals, mine rescue apparatus and first aid and mine rescue teams, until today the industry knows that trained men are immediately available in the event of accidents occurring on either the day or night shifts.

A recent survey, concerning the preparedness for emergency, discloses the fact that a large number of men are trained in mine rescue and first aid work. To

Mr. W. J. Richards, formerly President of the P. & R. C. & I. Company, belongs the credit for having started the First Aid movement in the Anthracite field in an organized way, as early as 1901. While all this has nothing to do with accident prevention, it has the effect, however, of impressing upon the rank and file the necessity to increase the maximum care on account of the hazards involved.

Mining, from an accident standpoint, is quite different from that of many manufacturing industries, and just as it is true that the unit cost in mining is constantly increasing with fixed labor and material unit costs, so the accident hazard for a fixed productivity and exposure of man hours is constantly increasing. It therefore follows, that just as the industry must expend large sums of money in improvements to maintain a somewhat uniform cost of the production unit, whereas in many other industries such expenditures bring about a lower cost of the production unit—so is it also necessary, that in order to prevent an increasing list of fatalities, and serious accidents per production unit, or exposure, increased efforts must be made to not only correct physical hazards, but every avenue that indicates a lessening of accidents must be traveled. This is one of the reasons why the business of coal mining has not made the maximum reduction in accidents that is found in some manufacturing establishments.

In the year 1926 the Anthracite Industry had 5.33 fatalities per million tons of production, as compared with 6.47 fatalities in 1925. In 1870 the rate was 13.47 fatalities per 1,000,000 tons produced. Anthracite in five year periods, 1870 to date, shows moderate continuous reductions from 13.47 to 5.80 fatalities per million tons, or from eight fatalities per one thousand 300 day employees, to 3.71 in 1926.

The encouraging factor is the substantial reduction made in the last 20 years. It was during this period that a tremendous construction program was carried on throughout the field, mechanization of hand operated jobs, introduction of electric haulage, undercutting, mechanical loading, complete electrification of collieries, the building of new modern preparation plants and the rebuilding of many more. All of this certainly added to the toll of accidents.

The United States Steel Corporation spends over \$1,000,000 annually for accident prevention work, and estimates the saving at 15 times that figure. In 20 years the United States Steel decreased its number of fatal accidents 61 per cent; many other corporations have similar enviable records—reduction ranging from 25 per cent to 75 per cent in fatalities alone, over a period of from 10 to 20 years.

One of the serious handicaps confronting a manager in an accident prevention program is the need of funds to correct an existing hazard. We will probably all concur in the belief that the progressive management of a profitable industry has a greater opportunity to put a program of accident prevention over than has the progressive management of an unprofitable industry, all other things being equal. It should not be so, but I am talking about the practical situation that the managers of industry are confronted with. Take the business of coal mining the world over, from a market standpoint, it is in trouble, and that means, of course, that except in spots it is being operated at too narrow a margin of profit, or without profit, or at a loss, and under such conditions management is certainly handicapped, in every direction, not excluding accident prevention work.

It can't be said that coal mining management, on the average, is less efficient than the management of other industries. It certainly can't be disproved that the highest type of management found in the coal mining business compares favorably with the highest type of management found in other industries. I mention this point because I believe that it is a factor in accident records, in coal and any other industry where such conditions prevail. I think, in the end, this problem will be solved—its solution is now under way.

We are living in a most competitive age. The severest of competition confronts most industries. Profits per unit of production are being reduced—the proportion of accident expense that investors bear is therefore being constantly increased.

Speed seems to be the order of today. Time saving seems to be a factor with all, but in spite of speed, in production, travel on ocean liner, railroads, automobiles or in the air, accident records as a whole, considering the work done, show constant improvements. Thanks to the organized efforts of progressive industrial managements, and the splendid efforts of the National Safety Council, who have been engaged in educating the public and the more derelict industrial managements, to assume their obligations to those whose capital is employed, and to their fellow-men, as well as to themselves.

Upon management devolves the responsibility to build the Safety Conscience among department heads, superintendents, foremen and bosses, who in turn will create the safety atmosphere in our mines and workshops. In the absence of this safety atmosphere we cannot hope to import the safety habit, so essential in the reduction of accidents, to our army of workers.

Any foreman, any boss, who at the finish of a day's work, cannot say that he personally corrected at least a few unsafe practices, that come to his attention during the day, or that he has done some act during the day in the interest of accident prevention, surely does not have the matter close enough to his heart, and isn't worthy of his hire.

The fact that the accident prevention movement is rolling on like an avalanche, gathering speed and volume in its journey, is sufficient evidence to show its worth to executives and managers of industries, small as well as large. The time has long since passed when anyone can doubt the possibility of controlling accidents, the record of industries engaged in this commendable work is the answer after all. Control of accidents is a challenge to management. It is solvable, and the managers that have solved the many seemingly impossible problems in industry are today engaged in working out this problem, and making splendid headway.

Our difficulty is not with the great majority of workers, but rather with the minority. I have the greatest confidence in the loyalty and integrity of the majority upon whom we can always depend for cooperation in such important work.

Looking at the task in a broad way, I think industry can conclude that they are making progress. It is difficult to note the progress from year to year, especially under the existing conditions, which are revolutionizing our industries.

Visualize this problem—in the last ten years, over 33 per cent increase of horsepower per person employed has been installed in United States. The growing new industries, require the training of millions of men in the performance of new tasks, the high speed of productivity, the high speed of travel everywhere, the movement of 1,000,000 cars of revenue freight per week on American railways, the generating and sale of 80,000,000,000 K.W.H. of energy annually, the production and operation of over 21,000,000 automobiles and trucks, the construction work, installation and maintenance of over 18,000,000 telephones, the raising and marketing of over 5,000,000,000 bushels of grain annually, the daily production of over 2,000,000 barrels of crude oil, the annual production of 35,000,000,000 feet of lumber, the tremendous building construction program, averaging over \$6,000,000,000 annually for the past three years, the annual production of over 600,000,000 tons of coal, and this represents but a part of labor's effort. Are we making progress? The answer is in the affirmative. One need but only compare the records of today with the records of many years back in any industry, anywhere.

May I cite a very interesting record, concerning accidents on the one hand on railroads 85 years ago, at about the beginning of railroad travel, as compared with travel in the air today by aeroplane. "According to the most recent announcement (1927), Imperial Airways in England carried 52,000 passengers over 2,500,000 miles without injury to a single passenger." In the London Times of June 14, 1842, we find this "In 1841 the number of passengers carried on the eight railway lines, numbered 10,508, the distance 3,562,338 miles yearly. In this time only 56 passengers were injured, of whom 22 were killed. Remembering that 85 years ago a speed of

30 miles an hour was considered dangerous, excessive, and greater speeds were unthought of, while today passenger trains are exceeding 60 miles an hour, automobiles are frequently operated at and over that rate, and have exceeded 200 miles an hour in races, aeroplanes, with cruising speeds of 65 miles an hour, in recent years have increased these speeds to 90 and then 180 miles an hour, and in races have exceeded 300 miles an hour.

Of course, management believes in accident prevention, and the records show it. The task is but started—the problem concerns all of us, and each must do his part. May I leave with you the words of Kipling: "It's not the ammunition nor the guns, but the everlasting team work of every bloomin' soul."

CHAIRMAN McDOWELL: I think that is an especially good paper for discussion. There are no doubt many in this room that can bring out particular points of interest for all of us. I am going to ask Mr. Leland of the Montezuma Copper Co. if he will start this discussion.

E. LELAND (Montezuma Copper Co., Nacozari, Son., Mex.): The employment of foreign labor is one point. Of course, with us, all our workmen are Spanish speaking. When we first started our safety campaign, we found that we had lots of foreigners, but they apparently knew enough Spanish to get by. When we came to put over a safety campaign we found they did not know enough Spanish to get by. In other words, we had to tell the story of safety to our men through our bosses in their language or in language they could understand, and in putting over safety we have simply followed out the principles that have been brought out in all of these talks, including safety from the management to the man.

Through our committees, we found all the members would be enthusiastic, but it wasn't taken to the man, so we had to carry the thing specifically to the man by impressing upon the bosses the necessity of having talks with men on the job. We started out calling contractors together on each level and explained to them the necessity of carrying out the safety idea to their men.

We followed that up with the safety talks in the stations, group talks, and finally the last thing has been to have examinations on safety rules. This started about a year ago. At the present time every employee of the company has successfully passed examination on safety rules. Approximately everyone, I should say. The first of October the rules went into effect that men accepting employment with us within a reasonable length of time (which we have set at 60 days), successfully pass examination on safety rules or they will not be retained in the employment of the company.

F. H. AMRAN (New York City): I happen to be in an insurance organization which is interested in the maintenance of accident prevention work, particularly in metal mines throughout the Middle West. I would like to ask if Mr. Leland's organization has a book of rules mentioning the fact that all workmen have to comply with the rules within a certain period and unless they do they are no longer maintained in the service?

MR. LELAND: Yes, we have a book of rules covering it. We call it "Operating Safety Rules." We base this examination on that section of the Rule Book pertaining to the class of work the man is employed in.

MR. AMRAN: Are those rules printed in English?

MR. LELAND: All in Spanish.

DANIEL HARRINGTON (United States Bureau of Mines, Washington, D. C.): Don't you have copies in English?

MR. LELAND: We have copies for the American speaking people.

MR. SUENDER: Are your efforts directed in the English language or in the particular language of that miner whom you want to reach?

MR. LELAND: Principally in the English language. In some rare cases in a foreign language. We have twice as large a population of foreign speaking

people, but a large percentage of them are Americanized sufficiently to understand the average talk of the mines.

CHAIRMAN McDOWELL: The subject of this paper is "The Management Believes in Accident Prevention." I am going to ask Mr. Adams if in the study of statistics brought to his attention whether it is his opinion that the management believes in accident prevention.

W. W. ADAMS (United States Bureau of Mines, Washington, D. C.): Management does believe in accident prevention. I think if it didn't we would not have any progress in safety work. I was interested in what Mr. Suender had to say regarding the interest of management in safety work and a part of his paper has records which indicated that the foreign speaking man had an accident rate no worse than the English in the same occupation. I am inclined to agree with that. I have not been able to find records along that point, however. I would like to ask where they can be obtained?

MR. SUENDER: I don't think I said just that. I said, "Accidents among the non-English speaking classes are in excess of those in similar occupations in other groups in the same industry. Certainly management cannot offer as an excuse that non-English speaking employees cannot be properly warned or instructed, for that reason." That's a general statement made about it. I think I could find the authority for the statement and we find a little of it in our mines.

H. D. MCGINNIES (Du Pont Co., Wilmington, Del.): I am very much interested in the foreign side of it. I am interested in the fact that our company takes an interest in the family side of it. I attend quite a lot of safety meetings throughout the country, and at those meetings I have to address them in their dialects. The sufferer, after all, in any accident is not the man himself as much as the family. I put it over at these meetings that they should talk safety at home and they should make the men promise on leaving home that they would do all possible to return to them just in as good shape as they left. I had one foreign fellow come up to me after a meeting and he said, "You know you make trouble for me last night?" "Why, what's the matter?" "I go home, the woman she give me hell. I have children. She say, 'Andy, anything happens to you, nobody wants to marry me with eight children.' She give me hell. She say, 'I go out work washing. Boss tell you something to do, you do. I don't know. Too much job for me raise this eight children.'"

That was the effect it had on this foreign born fellow and his family. I think management should take an interest in the family side of it.

GEORGE MARTINSON (Pickands, Mather & Co., Hibbing, Minn.): If the membership of the Mining Section of the National Safety Council is an indication of the interest of management in accident prevention, I think it should be answered in the negative. We have 246 members of the Mining Section in the entire country and there are many other mining organizations over the country. People are certainly interested here but there is a vast field which hasn't been touched.

CHAIRMAN McDOWELL: There's a whole lot of truth in that statement. Naturally, we would like to see as many as possible attend those meetings.

Is Mr. Cameron in the room? Maybe you can give us a few moments.

A. P. CAMERON (Westmoreland Coal Co., Irwin, Pa.): "Does the management believe in accident prevention?" That's the question, isn't it? I think that is really a silly question, on first thought. I think that the management that does not believe in accident prevention is not a coal management concern. That is our first duty, all the time, morning, noon and night. We try to stress that before any part of our organization. At our meetings, at our foremen's meetings, monthly, weekly and at the mines—that is the individual mines, monthly meetings—we talk it. We have the general meeting of our foremen, and accidents and how to prevent accidents is always our subject for discussion.

We have possibly a little different system of putting questions at our general

meetings. The boss of each mine is sent to some other mine and makes a careful analysis of all the defects he can find in the other fellow's mine. He's got to be careful because the other fellow will be back of him next month. The point is that we get the viewpoint of the other fellow. It raises a good deal of discussion in our meetings as to what one fellow thinks about accident prevention as against another.

Then we get a broad view of our mines in general. Of ten or fifteen mines we discuss one mine each month.

R. N. HOSLER (Coal Mine Section, P. C. R. & I., Harrisburg, Pa.): I don't think we could find a mining company in the United States whose management does not believe in accident prevention, but one of the shortcomings of human nature is that we don't always practice that which we believe, and I think Mr. Suender hit the nail on the head. I wish that more managers of mines might be here and with that stroke drive the nail clear to its seat. He said the one important single thing is that management must convey their belief in accident prevention down to their organization and unless they do that it will be of no avail. They simply have to put their beliefs into practice.

Mr. Adams and I spent a couple of hours yesterday afternoon together and we were looking at some figures; I'll give you just a little picture. We are so apt, I think, at times to not consider the seriousness of accidents. I think we had a record in these particular figures something like more than 50,000 non-compensation accidents under the Workmen's Compensation Act in Pennsylvania, for the bituminous mines only. From these figures as a basis, we deduced that the bituminous industry in Pennsylvania has an army of 500 men who were injured not sufficiently to be compensated under the Workmen's Compensation Act. Now picture to yourself what any one of your managers or you men could do with 500 men for a year and you will get some idea of the magnitude of this waste; and this one thought must be accompanied with the statement that every one of these accidents is a potential death.

A. H. TRESTRAIL (Pickands, Mather & Co., Caspian, Mich.): I would like to ask the gentleman that read the paper where the dividing line is between the management and the rest of the organization; or who, to the employee, is the manager?

MR. SUENDER: To my mind, the management makes contact with the employee, as a foreman, the assistant foreman or the boss. You can't blame him for not putting in the accident prevention program if somebody doesn't put it over for him. Just as I said, it is up to the management to build the accident prevention program in the minds of the foremen, the superintendents and department heads so they can create the atmosphere in the minds of the workmen. When the atmosphere is created the work is done.

I was interested in Mr. McGinnies' statement. I believe that one of the places where we do fall down is the failure on the part of the foreman to make a personal contact with the employee to the point where he takes an interest in that employee's family.

I had expected somebody was going to ask me that question or "How can that be done?" Well, it can be done at least on the part of the foreman to the point where he knows his man by name, where he knows something about his family, where he can inquire about the health of the family or the child that is in the hospital or the sick wife, and if the management can't do anything more than that they have done a lot there. We have worked out an experiment in one of our mines where there are some 1,200 employees; where we have a welfare worker, so called; where we have a nurse; where we take care of the child, see that the parents are properly instructed how to feed it; where the child before it is born and the child's mother are being looked after, the child being picked up through the kindergarten school; and finally into the girl and boy scout movements where we are endeavoring to interest men and boys in club work; where we sponsor

baseball, football, basketball; where we can say there is not a child in the community who should have its tonsils removed that hasn't had them removed; and where we can say the children have been taken care of so that diphtheria doesn't get into the mining village, and properly looking after it. I believe with Mr. McGinnies that is a big factor and that less attention is paid by all of us to it.

C. L. WILSON (Berwin-White Coal Mining Co., Philadelphia, Pa.): How much colored labor do you have?

MR. SUENDER: The percentage of colored labor in the anthracite is negligible, although there is a stray one here and there. Prior to the big slump in the bituminous field there were no colored people in the anthracite field. I don't suppose there is 1/10 of 1 per cent if there is that.

CHAIRMAN McDOWELL: I am going to deviate from my prearranged plan. You brought up the subject of the colored workman. I don't mind saying that when we mention the colored workman there is sometimes a smile as to the proficiency and efficiency of his work. About 28 per cent of our employees are colored. In my study for the last year, taking his work with the work of the white man, and this study is from month to month, it has proven to me conclusively from all angles that we do not have as many colored men injured in our mines as we do whites, regardless of all figures or any figuring we might do. It gives you a slant on the colored population especially in the Pittsburgh district.

As for welfare work, recently I employed a colored welfare worker for our colored people. He is doing a wonderful job. We went out and got a first-class man—a man that has had three years in Pitt, a man who has had five years in the largest colored Community House in Pittsburgh. The only thing I can say is that he is doing a wonderful piece of work. I think this is an especially worthwhile subject for discussion. I would like to have a few more questions asked about it, and I am particularly interested in the thought brought out by Mr. McGinnies. I do not think the management spends time enough with the family. We have men in this room who stressed that particular point very conclusively in their work. I am going to ask Mr. Berry for a few minutes to tell us something about the work he is doing.

J. V. BERRY (Bethlehem Mines Corp., Johnstown, Pa.): The work we have been doing in the last few years is through the general safety meetings. Last year we had 27 at different mining communities. After all, we have them open to the school children in the community. School is dismissed for that part of the program. In the evening we keep the school children out. It is open to all the men and women, the hall not being large enough to house them all. Last year we had 37,000 who attended twenty-seven meetings. The meetings averaged from 500 to the afternoon to as high as 700 in the evening. We find that this is a great way of putting over a safety movement in the home, through the men at the mines, through the children at the school, and through the women.

The other day we were asked whether we would have them this winter. The men were very much in favor of it.

We don't confine the meetings to safety. However, one of the main features is to have a good talk on safety. The men themselves put over the amusement. We have a sort of vaudeville and also a motion picture. The vaudeville entertainment is all home talent, taken from the men at the mines and the children at school. The teachers make up the entire entertainment.

We hold them on Washington's Birthday and on different days, while we put that on as a safety feature.

Another thing that we have been doing is to have teachers cooperate with us in having the children make up safety posters. It is surprising to see the things they will pick up around the mining camps and notice a hazard about the mine.

Another feature, through cooperation of the teachers, is the writing of an essay on some section of the Mining Laws and Rules which we have posted in and

about the mine. In doing that, of course, we didn't tell them anything about it, but they go around the mine, look at the bulletin boards and see what to write about. It is surprising to see how many did that in writing their essay of their different groups: We think that it is a good thing, and we have been doing that for the past three years. We expect to continue this winter.

That, however, is only one point of our safety work. We have, in addition to that, a committee called "Safety Committee No. 1," which investigates all lost time accidents. In addition to this committee, which is composed of a miner, a day man, a safety engineer, or the division mine inspector, which makes up part of that committee, there must be a report made—a detailed report of every phase of each accident—so that responsibility can be laid where it belongs. They have found that our foremen, superintendents, are all very much in favor of it and they cooperate very well with our committee. We feel that it has been the means of helping to reduce accidents.

CHAIRMAN McDOWELL: We have been favored by Miss A. R. Coombs. I would like to have Miss Coombs say a few words to us.

MISS A. R. COOMBS: There isn't anything I can say except to reiterate the interest of our organization in your safety work and to pledge ourselves to your work. I am sure you are more interested in hearing from the operators or operating men who are really doing the work, than anything that I might say.

SIDNEY HALL (New Jersey Zinc Co., Franklin, N. J.): The personal touch with the man is important. We have been in safety work for a good many years and we have gotten some results. We have tried various ways in safety meetings, so we find the personal touch of the foreman and the management with the men is doing more and has been doing more than anything else we have done. We put it up to the men themselves. The company does not believe in compulsion. We use hard-boiled hats, goggles, safety shoes, first-aid training and we make the first-aid men the permanent safety committee. That is, we really put it up to the men themselves. We find that that does more than anything else to help us in our safety work.

MR. WILSON: In connection with this personal touch, I would like to add the colored situation. We take a picture of the colored family, have a slide made of it, place it in the hands of moving picture operator every night we have a show at the movies. If he is a safe worker, we state so. If he is not a safe worker, we also tell the community this man has been found doing a certain thing. A little inscription left at the bottom says just what happened. In many cases we found the wives took a great interest in coming out to see their pictures. That creates a lot of interest around that mining community.

MR. SUENDER: I think that is effective work. I believe advertising pays. That kind of advertising can't be put over everywhere, but if it could I think we would make more progress.

MR. AMRAN: I referred just a little while ago to the mines of the National Lead Co. The record as to what has been accomplished and the reasons and causes were fully described in the *National Safety News* in the April number. I presume a number of the gentlemen present in this meeting saw that article. I think, without going into detail, accomplishment in their mine was due mainly to the fact that the management (by saying management, I mean from the president of the company down to the foreman) everyone is interested in the subject of safety and I think our safety committee meetings down there, which are held semi-monthly for each one of the various shifts, has accomplished possibly great results in this no-accident work.

Of course, we also have a very elaborate educational system. For instance, from our office we send a man twice a year, to stay at the mines about a week or ten days, and he does not only make his suggestions to the miners, but also he lectures in the various public schools in this region because the management very

wisely thinks that eventually all children will have to go in the mines themselves.

CHAIRMAN McDOWELL: I find it necessary to close this discussion.

We shall pass on to the next paper. Mr. Dan Harrington, our secretary.

Fires in Metal Mines—Causes, Prevention, and Methods of Handling

By DANIEL HARRINGTON

Chief Engineer, Safety Division, U. S. Bureau of Mines, Washington, D. C.

Before going into the subject, I think it would be advisable to give you at least some sort of idea why I, supposed to be a coal mining engineer, should try to talk about metal mine fires and probably make some drastic statements to you metal mining men. The reason is that for about eight years while I was in the Bureau of Mines field service, much of my time—in fact, most of it—was devoted to a study of metal mine ventilation.

In that study of metal mine ventilation I had a chance to go into metal mines in 24 or 25 states. In several cases I was present at or after the most destructive metal mine fires in loss of life in the history of the United States. I am going to list a few of them.

The first one was the Pennsylvania mine fire in Butte, Montana, in 1916, with 21 lives lost.

That was followed in the same year with the Yellow Jacket at Gold Hill, Nevada, where there were five lives lost.

In the next year, 1917, there was the North Butte fire in Butte, 163 lives lost, and in this I had a rather odd experience for several months before that fire. Dr. Lanza of the United States Public Health Service and I had been making a detailed study of that particular property and we knew it from A to Z. In fact, I think I was probably more familiar with that particular property than with almost any other mine I have ever been in in the United States, except some in which I had charge of operation.

I was present at the recovery work at the Argonaut fire in California in 1922, in which 47 lives were lost, and this year I went up to Northern Canada to the Hollinger fire in the Porcupine gold mining district where there were 39 lives lost. That is just a list of the mine fires in which, in each instance, several lives were lost.

In addition to that I have had a chance to be present at, and make reports on, metal mine fires in which there were no lives lost, in Arizona, Idaho, Wyoming, Colorado, Minnesota, and Michigan. So much for qualifying.

A few years ago, the Bureau of Mines issued a publication, in which I participated as co-author, giving some figures as to metal mine fires and giving some facts concerning the figures and fires. It developed that out of 114 fires of which we had fairly definite information before 1922 about 7 per cent of those fires or eight of them was caused by electricity. There were 191 fatalities from these eight fires out of a total of 533 for the 114 fires. A recent report by a Bureau of Mines engineer as to fires which have taken place in recent years—the previously mentioned tabulation and report being on fires before 1922—shows that of a list of 55 fires from 1917 to 1922, 12 were from open lights or flames, 6 from smoking, 22 from electricity, 2 from an open acetylene torch, 4 from friction and 9 from unknown causes.

Going back to the electrical hazard which I am going to stress throughout this paper, the figures before given for a long series of years before 1922 as to metal mine fires show that about 7 or 8 per cent were due to electricity. Figures for

the latter period from 1917 to 1928 show that 40 per cent were from electricity. That is something which I wish to call to your definite attention, you metal mining men. If I were going to speak on coal mining, I could bring the same cause to your attention as to coal mining because the same thing is applicable, although a large number of coal mining people deny it. The facts however are there.

Now as to causes: In the early years of metal mining up to about 1914 or 1915, the prime cause of metal mine fires was the candle. The miner would be given three or four candles to take underground to light his working place during a shift. As the candle would burn down to about an inch or an inch and a half in length, he would take another candle from his pocket, light the second candle, and throw aside the first one, very seldom taking any precaution toward extinguishing the flame. There were hundreds, literally hundreds of metal mine fires, caused by these discarded candles. Later on, the candle was superseded by the open acetylene light or carbide light. As we know, the carbide light was an enormous improvement over the candle, but the carbide light itself is by no means a safe light for either coal or metal mines.

As to instances in which the open light has been at fault, the North Butte fire with its 163 lives lost was caused by ignition of electrical cable which had not as yet been used for electricity. It was being taken into the mine and was wrecked in the shaft and the wrecked frayed insulation of it was set afire by an open acetylene lamp in the hands of an assistant foreman when he was trying to remove the wrecked cable from the shaft. The resulting fire and poisonous fumes spread down into the mine because it was a downcast shaft. When the fire got a good start, it converted the shaft from downcast to upcast and did it in short order, notwithstanding the fact the fan was working. They had a very efficient ventilation system also. Of about some 400 workers, 163 of them were trapped and killed. Only two of them, however—I want to stress this point also—only two of them—came in contact at all with flame. The rest of them were killed by fumes.

At the Hollinger fire in Canada, there have been a number of misconceptions in mining circles concerning the affair. It was caused, in my opinion, by an open light. Possibly the open light may have been a match from a smoker; more probably, it was due to a very reprehensible habit which persists in metal mines that in order to obtain information as to what may be the condition in a winze or a stope which is below or any open working below, the metal miner frequently lights a piece of paper and throws it into the opening, whatever it may be. To my mind, that is what occurred at Hollinger. It was either the throwing of a lighted piece of paper into the stope below or the throwing of a smoker's match; possibly it was the ignition of paper from explosives wrappings which were being dumped in the chute coming in contact with a carbide light of a worker.

There is another possibility as to Hollinger which should not be entirely ignored, and that is that the trolley locomotive system did not bond the rails and there is no question there were some very drastic electrical arcs at the rail sections when the trolley locomotives were being used and they were being used past the point at which this particular fire occurred.

Another point is the fact that there was a minimum amount of material burned. The total amount of material that burned in the Hollinger fire, to my mind, could be easily contained in this room. It probably could be contained in one-fifth of this room. Nevertheless, it resulted in the death of 39 men.

Here I am going to digress and call attention to an almost universal failing of metal mining men. We of the Bureau of Mines have made studies of metal mine ventilation in practically every district in the United States. In going into the mines, we call attention to what in our minds are fire hazards, and I have had metal mining men after metal mining men tell me I had wheels in my head because I called attention to the hazard of underground timbered shacks, of timber

bark, or timber piles, or piles of old timber which were being thrown aside, of manure, or of dumping explosives wrappings in abandoned raises or of dozens of similar hazards. They say, "We have been doing that for 10, 20, or 30 years and we have never had a fire." Gentlemen, that is what happened at Hollinger. It was a wet mine as mines go and any one who would tell those people there was a possibility of a fire would be laughed at. The facts are that there is hardly a metal mine in the United States that does not have a fire hazard. Why? What burns in a metal mine fire? Generally timber. How many of your mines do not have timber? The other things that burn in metal mine fires are oil and electrical insulation, explosives, etc.

Another thing which people do not realize is the hazard of the insulation on electrical wires which burns and which can transmit fire hundreds of feet, sometimes thousands of feet, yet it is practically neglected as a cause of possible fire or transmission of fire.

Then there is the matter of hay, manure, trash of various descriptions. Some mines have a fire hazard from carbonaceous shales or slate, which is particularly true in some of the regions up in Lake Superior. I think some gentlemen here can bear me out on that.

There is also the question of explosives—storage of explosives, the handling of explosives boxes, the handling of wrappers from explosives, of the sawdust in which the explosive is packed; this is a very fruitful cause of fire.

As a matter of fact, there was a fire in a metal mine not long ago in an explosive magazine which bade fair to be destructive. Fortunately the explosives burned and did not explode. There again I understand was an ignition from an open light or from a smoker.

Now as to smoking, generally speaking when a person goes in a mine and calls attention to the hazard of smoking, he is again pronounced a crank. "That's all bunk. There isn't any hazard. That has been done for five years or twenty years or thirty or forty years," and probably it is true. Nevertheless, there is not one year that goes by in the United States that there are not a half dozen to a dozen or more fires in metal mines caused by smoking. Gentlemen, the answer is up to you. If you are going to allow smoking in your mines, you are going to have fires. If you can not handle the hazard, you are going to handle fires. Generally speaking, when you put it up to the metal mining men that there should not be any smoking in the mine, they say it can't be done. That in my opinion is pure bunk. If you have the will to stop it, it can be stopped.

I have given you some things which can burn in a metal mine. I can not call attention to all of the things. Very few here do not have some of those things. It does not matter whether it is a wet or a dry mine, whether silver, copper, gold or whatever kind of material is mined, there are few, if any, mines, coal or metal, which do not have a fire hazard.

Another fallacy very prevalent among metal mining men about fires is that the only metal mine fires are in sulphide ore mines; because in silver, gold, and other mines, the metal generally is carried in quartz, which is non-combustible, it is figured that a fire is impossible. Of course, the quartz is non-combustible, but that is not true of much of the material you bring into the mine such as timber, explosives, hay, oil, insulated electric wires, etc., etc.

Going back to the causes again; open lights in the past have taken their toll. They are going to take their toll as long as used in mines. I indicated at the beginning that at the present time the hazard is becoming more and more due to electricity. What form of hazard is there in connection with electricity? A confidential memorandum was made out sometime ago and sent to the members of the Safety Division of the Bureau of Mines concerning fires, recent fires, which had occurred and giving their causes. This was not published because of the fact

that we secured some of the data confidentially and if it were published giving names, places and dates, we would get into trouble with our friends who gave us this information. I am not going to give out the names of the places, or the dates, but I am going to indicate what was given to us as the causes as follows:—

1. Some one, either on one of the levels or coming up in the cage threw a lighted cigarette butt away and this started the fire.

2. Timber in underground shaft gave way breaking the electric wires that were in the shaft and as shaft was very dry it is probable the timber was ignited by the wires.

3. A miner or some other person threw a lighted piece of paper down a chute, in going off shift, to see how much ore was in the chute. Fire resulted.

4. This fire started close to the fan motor on the south side of a shaft station and was caused by a carbide lamp on the hat of a miner coming in contact with canvas tubing, taking air from fan to raise where miners were at work.

5. Fire caused by overheated electric light globe (incandescent) coming in contact with some rope.

6. This fire was started close to a timber shaft presumably by a match thrown by a smoker.

7. Fire was caused by a spark from a short circuit in the hinge on a knife type trolley switch.

8. Caused by carelessness of a pumpman, burning newspapers on a concrete floor in a pump room, deliberately setting fire to material in a mine.

9. The bark on a timber cap piece probably caught fire by coming in contact with a carbide lamp on miner's cap.

10. Candle used for illumination was left burning by miner and caused fire.

11. Here is another one. The contact of a trolley wire with the cap of a set of timber in a wet drift, which was being crushed, caused this fire. Here is another point I want to call to your attention. You can talk until you are black in the face to most any metal mining man stating that he has fire hazards where he has damp ground or wet ground and he will tell you without any ifs, ands, and buts that you are crazy. Nevertheless we have definite records of very disastrous fires occurring in mines which are decidedly wet. Not long ago in a shaft being sunk in the aid of driving a tunnel for water purposes for a big city, there was encountered carbonaceous shale which throws off methane. The shaft was so wet the workers had to use rubber boots, "slickers," rubber caps and hats. The methane was ignited by an open light and came in contact with timber, and notwithstanding the fact water was pouring in the shaft, the timber was ignited and burned briskly. This fire is of recent origin—two days ago, in fact.

12. Fire was started by the contact of electricity with 12 inch by 12 inch timber.

13. Flame of a carbide lamp came in contact with a leg of a set of timber.

14. Probably due to defective electrical installation, installation in this case being wires.

15. Small transformer and a starting compensator ran hot setting fire to a wooden frame, which was burning when the fire was discovered.

16. Men were using an acetylene torch in a pocket of the shaft station and went away. Later on fire was found.

17. Here is a significant one. "It did not seem possible that a fire could occur in this shaft. The timbers burned, and the mine is wet." Two possible theories have been advanced. One is that a candle which was in use by a miner—a rather unusual thing in these days—was left in a dry place in the shaft station. The other theory is that the fire was caused by a short circuit in the electric power cable. I want again to call attention to the frequency of electric power ignitions.

18. The fire was caused by an overheated resistance on one of the electric tuggers used for slushing ore.

19. Fire was found in a raise 80 feet below the 300-foot level at a point where spent carbide was thrown.

20. Another case of throwing lighted powder wrappings into the raises to see how much dirt was left.

21. Fire was caused by sparks from a railroad locomotive setting fire to the wooden headframe on the surface. Hot embers from the headframe fell into the shaft and burned out the shaft. There is another thing about which our metal mining people are decidedly careless: having inflammable structures on the surface and little or no protection for the workers underground. There is no reason why these should not have been safeguarded by having concrete or steel frame and suitable door to be closed in case of fire. The cost is not prohibitive yet this precaution is not present in one-tenth of 1 per cent of the mines of the United States.

22. The open flame of the lamp of a man who hid some tools in a certain place where there was some dry lagging probably came in contact with timber.

23. It was determined that it started by a carelessly thrown cigarette, although there was a "no smoking rule" in the mine at the time. I want to call your attention to the fact that very frequently we find that there is a "no smoking rule" supposedly in effect in places in and around mines, and the man who most frequently violates it is the mine foreman or the shift boss.

24. Here is an odd one. It was stated that fire was caused by the rope on a slope running against the bearing on a roller heating the oil that was in the roller bearing. The burning oil set fire to the nearby ties. It was a destructive fire.

25. Another case. Fire started from a lighted carbide lamp which a powder man placed on a shelf under a large fuse box, setting fire to paper between the boards.

26. Several cases of fires, causes unknown.

27. Electric cable which was in conduit burned from the 21st to the 22nd level. Trolley wire had fallen, and not being sufficiently grounded to operate the circuit breaker at the shaft, it heated and caused the feeder wire to burn. There have been a number of instances where trolley wires have been down, set fire to cable, or set fire to the insulation on cables, and then the insulation carried fire to timber and caused fires.

28. Probably a match or burning tobacco from a pipe started this fire.

29. Current left on controller of a sinking hoist. Motor-hoist became overheated and timber foundation began to burn. Why have electrical machinery on timber foundations? It is almost universal for temporary installations underground but should not be.

30. Another case of electricity, but it does not give the details.

31. There is another class of ignition which comes in blasting, that is the use of fuse in connection with timber. There have been a considerable number of fires in metal mines where timber has been blasted, either blasting of cribs in top slicing work or in cut and fill work or in blasting of posts where the timber mat is following. There have been very severe and costly mine fires from this, although they have not resulted in very great loss of life.

32. One mining company was blasting some posts out to bring down the overlying material in a caving system and the timbers caught fire undoubtedly from the fuse and before they could finally get the thing under control they had to flood the entire mine, with an enormous loss to the company. The cause is apparent, though the answer is not quite so easy although we had been recommending the use of permissible explosives for blasting of timber; and where it can possibly be done, the blasting of timber electrically rather than through the use of fuse is advisable.

33. There have been fires in a few mines from the use of dynamite in large charges. In high sulphide ore, 40, 42 or 45 per cent sulphur, in some mines, there have been fires and explosions very much like we get in coal mines, from the ignition of these sulphides, where blasted in the ordinary manner with dynamite.

Here is a case where in my opinion coal mining methods will have to be used

if they are going to avoid occurrences of this description. That is water down the face thoroughly, keep the territory back of the face wet, as we try to do in many places in coal mines, and it may even come that our metal mining friends may have to go to our coal mining method of introducing rock-dust to prevent explosions in their sulphide drifts. I referred a few minutes ago to spontaneous fires. That has been a source of much trouble in some of the mines in the Lake Superior region and in some Western mines. The spontaneous fires in the Lake Superior District generally come from carbonaceous slates or shales and I understand there is some trouble there right now in some places from this cause. The spontaneous firing of oily waste thrown into the gob, especially in the backfill stopes, has resulted in a number of fires. It is poor practice. In the past there was much of a practice to throw manure into an old stope; this has caused a number of fires which have in some instances at least cost the company far more money than the removal of the manure would have cost. As a matter of fact, our metal mining companies are far more in danger from rubbish fires apparently than are our coal mining companies. Why that should be I do not know, but there seem to be more fires from that cause in metal mines than there are in coal mines.

A number of metal mines have sealed fires and very frequently these sealed fires break out anew, and it is almost incomprehensible how far a well defined metal fire can penetrate through what are supposedly solid walls. In one instance, the mining company is very much of the opinion that a fire which had an exceptionally good start—as a matter of fact burned for 20 years—finally penetrated through 75 feet of solid rock. The reason they give is that the rock was gradually heated to such extent that the temperature on the outside was brought up to the ignition point of timber in contact with the rock.

Now as to the fumes which come off mine fires; they certainly are of interest. The metal mining industry, unfortunately for it, is afflicted with a greater variety and more virulent type of fumes than is the coal mining industry, especially at the time of a mine fire. In coal mines, if we have a fire our dangerous fumes are ordinarily carbon monoxide which will "get you" quickly. If the fire is in concentrated form and burns out of the air all the oxygen, it leaves an atmosphere with a deficiency of oxygen and composed chiefly of carbon dioxide and nitrogen. If you leave those two out of consideration, there are practically no other fumes met in coal mining at fires or afterward.

In metal mine fires, on the other hand, there is, in some isolated instances H_2S or SO_2 . Metal mines at times of fire have carbon monoxide and carbon dioxide in proportions that are ordinarily greater—far greater—than at coal mine fires. In addition the metal mine fires very frequently have, strangely enough, given off methane, the very same gas with which you coal mining people have so much trouble. There are instances on record of sealed fires in metal mines causing surrounding ground to break the stoppings and men entering the mine to mend those stoppings, using the open type of lights, have ignited methane; in some instances these men were killed or had to be sent to the hospital. This was very mysterious for a while until we were finally able to get some samples of the gas and it analyzed regular old CH_4 . In addition to the CO_2 , CO , and sometimes methane, frequently the metal mine fire fighter is afflicted with SO_2 . Believe me, it is a nasty gas to handle. In some instances they are afflicted with H_2S . The SO_2 is like a rattle snake. It gives you warning. You can't go into it. You can't breathe it. You can't keep your eyes open. But the H_2S while it gives warning from its odor if it is in a mild, very mild concentration, when it gets into its heaviest concentration, gives very little odor and you are soon down, and when you are down you are out. In addition, metal mine fires very frequently have arsenic fumes; some of the copper ores are a combination of copper, iron and sulphur and arsenic. In the Butte district of Montana one of the main ores up there has such

a combination and when they have fires they have arsenic fumes, as well as CO, CO₂, SO₂, and sometimes H₂S and CH₄.

Then there are in some instances fumes of which I do not know the exact composition. We have never been able to get the data on them but we know that they must be dilute sulphuric acid or sulphurous acid because they have the effect of those fumes. These gases are formed in an unknown way but when they come they are absolutely deadly and have caused death.

Now, as to precautionary measures; I have tried to indicate in general what I think should be done toward prevention. There are a number of other things, which, in my opinion, should be done. Every metal mine should have a mechanical ventilation system; preferably the fans should be located on the surface. Fans should be so fixed that air current can be reversed if necessary. The reversal should be used only when necessary and under proper precautions. To make that reversal possible it is necessary to have a definite system of doors underground. The doors should be so placed that when the direction of air is reversed they will not open. That seems to be almost an impossible thing to get through the minds of people. They think you can place a door with a fan which is exhausting and the door will automatically remain closed when that fan is made a force unit. All they have to do is to use their heads and they can see that it is an impossibility; yet the matter of proper placing and construction of underground doors is handled correctly very seldom in metal mines.

Another thing which should be in metal mines—and I am not sure it does not apply to all coal mines also—is that there should be in place in every main air course either in itself or adjacent to it, a system of doors such that, by the closing of those doors, an entire course can be isolated from the rest of the mine or any part of it. At the Argonaut fire, they had a system of doors in place between their main intake and their main return, except that they had no door on the lowest level. All of the air went down through the main shaft or main incline to the lowest level and was then allowed to go through the mine and up to the surface. The men who were trapped—47 of them—came into the lowest level when the smoke came on them and they telephoned for the cage to go to the surface. They could not get it. The smoke finally drove them back where they were found two or three weeks later dead. If there had been a door in place on the lowest level those men could have shut it and it is entirely probable they would have been saved. That has been repeated in a number of metal mines. If there is a well planned and installed system of doors along the various shafts there need not be the usual heavy loss of life in metal mine fires.

As to ventilation, I accompanied the Bureau of Mines car to Ontario at the time of the Porcupine fire and about the only thing we did which amounted to anything was to show these people how to handle their ventilation in order to remove the smoke from the mine. Other than that we could have stayed at home. Metal mining people seem to feel that ventilation is abstruse. They can not touch it and do not touch it. Very seldom do they do a good job, even when they try to handle it.

Ordinarily, the metal mine people have little or no conception of what to do with ventilation, even if they have it. If they install mechanical ventilation in a metal mine and do not install it correctly and do not use it correctly, in a time of disaster it is a menace instead of an aid. That is a thing that should be brought home definitely. I have been in one metal mine where they had a system of ventilation of which they were proud. They had an intake or downcast shaft which was timbered, had any number of electric wires and electrical equipment along the various stations. The fan was pulling the air out of another shaft and the time interval from the time the air went down one shaft to the other was about ten minutes. That meant that if there was a fire in the top of the intake or downcast shaft that within ten minutes every man in the mine was trapped. The men

who were running that mine were exceptionally able men. They knew more about metal mining in a minute than I would in my life, yet they were continuing a wholesale death trap, which however they afterward corrected. My time has expired, yet I have failed to touch upon a considerable number of decidedly important points connected with fires in metal mines.

THEODORE MARVIN (The Explosives Engineer, Wilmington, Del.): I would like to condemn the practice which many metal mining companies have of leaving their paper wrappings and powder boxes underground. I think that anyone wishing to start the campaign for fewer mine fires can do a great deal I believe by eliminating that practice from their mining methods.

GEORGE MARTINSON (Pickands, Mather & Co., Hibbing, Minn.): I enjoyed Mr. Harrington's talk very much. I want to say that he told us about all the fires he attended. We had him in the Lake Superior Region. He knows more about it than any other man who visited our country. The statement that 40 per cent of the fires have been caused by electricity is interesting. I didn't realize it had grown to such proportions. I can see his figures are based on facts of the Bureau of Mines.

I don't know just how true his statement is that carbide is not a safe light. There have been suggestions made at various times at metal mines they ought to go into electricity. It may be Dan has particularly good reasons for that statement. I think he has.

Another interesting thing was the statement that permissible explosives might be used for blasting down rooms. Mr. Harrington said they are being used. We can't trace any fires to that particular cause, but to the fuse and other explosives setting fire to the rooms you have blasted, there might be possibilities there. I don't know whether it would be practical to get any special explosives for the job, but it might be. I am not familiar enough with it to know. It requires particular skill on the part of the company just the same as you are using dynamite.

FRANK AYAR (Phelps Dodge Corp., Morenci, Ariz.): I must say that I don't believe there is any talk we have enjoyed as much as Mr. Harrington's, because we have done quite a lot of safety work in the metal mines. Although we think we have done a lot of safety work, we are absolutely asleep when it comes to fire protection and prevention. I just want to give an example to show how much asleep we were at the Morenci plant of Phelps Dodge Corp. About twenty-six months ago we got the best electrical engineer we could find in that part of the country to make a survey of our electric hazards. This man made this survey absolutely independent of the mechanical organization and reported directly to the management, and we were dumbfounded when the survey was completed to find we had something like 2,500 or 2,600 electrical hazards in our company, which we thought was getting along pretty well from the standpoint of safety.

Well, we had copies of this report sent to every department and the report is a great thing. It is about thirty or forty pages, describing in detail each of these hazards; and now at each weekly meeting of our department heads and superintendents, we require that each department head tell us just how many of his particular hazards he has eliminated during the past week and what his total percentage eliminated to date is. I might say we have two departments that have eliminated every one of their hazards. Mr. Harrington spoke of the hazard of electrical conductors in mines. Just as a matter of information, we have in process of being driven from the several levels a separate raise all the way from the surface of our fourteenth level for no purpose except to carry these wires and get every power wire out of the shaft.

We have been quite fortunate in not having a fire caused by these wires. But I think the big thing in safety is not to wait until you have had an accident, nor to wait until you have had a fire, but to make believe that you have had one and take the same action you would take if you had a terrible disaster.

We have talked this morning about the subject, "Is Management Interested in Safety?" and if they are there is nothing they should tackle more thoroughly than fire hazards. Mr. Harrington mentioned the wet timber as being a hazard even though it is wet. It is our experience that the wet timber is a vastly greater hazard than any dry timber; and all through our haulage ways, everywhere we go under a cap with a trolley wire we have got a hazard. We have quite a problem. We haven't worked it out yet to know what to do to eliminate that hazard, but at the present time we are working along the lines of fireproof paint and if that doesn't work well, to actually put on some sort of an insulating coating on the timber. The paint would be much cheaper and if anybody knows of a fireproof paint which will not wash off with water we would be very much interested in getting information about what that paint is.

Another thing, in these fire analyses, you will find that almost every company interested in fire has got a great big poster up in their property or in their mines telling just what to do in case of fire. But my opinion is that not one in a hundred of those organizations will do what that poster says. I think that everybody ought to get together and make believe they have a fire in their company and summon every key man to a certain point and have those men tell exactly what they are going to do if they have a fire in a certain place. That takes everybody, from the manager of the company down through to the master mechanics and superintendents and everybody else. If you don't do that you are going to have terrible confusion when the fire comes. Then don't think you can emphasize too strongly the cleanliness of your mine—from chips, papers, etc.—because it is a terrible hazard.

One other point, in connection with electrical firing. That is one problem we have not been able to solve. We do quite a little firing with delayed action fuses. To date we can't find a single manufacturer who will guarantee that his delayed action fuse will not burn the powder. We have tested every fuse we can find and we find these even though they have double protectors over it fulminate, while the fire burns out through both of these cases. If somebody has a protector that they will guarantee, we would be interested in knowing what it is. I would like to know.

SIDNEY HALL (New Jersey Zinc Co., Franklin, N. J.): I think there is an answer to that side burning and side spitting and delay of the detonator cap through the development of liquid oxygen explosives. Liquid oxygen explosives are very easily ignited. In order to use them in some drift ground underground, it was necessary where they wanted to use a delayed electrical detonator to devise a special means for preventing that side ignition and I am sure that at least one company and maybe others have developed those satisfactorily. In fact, I was at the plant of one company when they were working with this, and as a test, the delayed detonator, or delayed action detonator, was embedded in gunpowder and it repeatedly passed that test.

MR. HARRINGTON: Before leaving this subject, I want to put before our coal mining friends a similar thought about this electrical hazard. They have escaped unscathed today. They might get their share of the medicine as well as the metal mining people. We have summed up in the safety division of the Bureau of Mines the causes of all of the explosions of which we have record for the fiscal year ending June 30, 1928, confined to the United States. This is for coal mines alone. We have a list of 29 with 341 fatalities. Of these, fourteen are definitely known to have been caused by electrical ignition, the total number of fatalities are as follows: Fourteen electrical explosions, 282 fatalities. Get that—282 out of the total of 341. Ten explosions from open lights with forty-eight fatalities; three from explosives with nine fatalities; and two unknown. I don't claim this is a complete list of all the explosions in the last year, but it is a complete list of all of them of which we have a record.

A. H. TRESTRAIL (Pickands, Mather & Co., Caspian, Mich.): I know of one case where the steel head frame was being taken down and they were burning out the rivets. We hadn't sufficiently covered the shaft and metal dropping down to timbers started a fire in the shaft. This happened previous to the noon hour. The men working on the shaft went to lunch and a workman discovered smoke coming out of the shaft. He turned the water down the shaft which drove the smoke through it first. As it happened the smoke was not intense enough to suffocate anyone and one man lost his life, whether it was heart failure or what we don't know. But in taking down head frames it would seem that covering the shaft would be a very important thing to watch out for.

CHAIRMAN McDOWELL: We are going to close the discussion. As members of the Mining Section, I am sure we are greatly honored to have in your presence this morning one who is vitally interested in work of this kind. This gentleman has been formerly Secretary of Agriculture of the United States. At this time we would appreciate having a few remarks from the Honorable Howard M. Gore, Governor of the State of West Virginia.

HON. HOWARD M. GORE: It is inspiring to me to come here and say a few words to you about the great humanitarian work of you men of the mines. Its far-reaching activities really give it the greatest force in the public good. For example, those of you who make your researches at your laboratories and your studies under practical conditions, frequently fail to get it in such shape so that it reaches the imagination and inspiration of the masses of the public.

In all public matters, like mine work or safety work, the work that carries with it probably as much poetry and as much of the human side of life and human interest in life as any other work, it is difficult to catch the public interest and imagination. Therefore, give it the proper standing in our schools, our laboratories in the industry itself, among the masses of the people, among your own political leaders.

Take for example in our own State. For a great many years the coal industry was a rather somber industry. That is, I mean to say, that it was a place for men to become soiled at their work, and then they hurried home from it. It was a place to make a living, and then to sort of get away from it. Our citizens in and around the border of the coal regions looked upon it as a somber place. But in our State under the direction of our mining division and our Chief Lambie, we undertook to put on a State Safety Day. You know, for example, here is one of the interesting things. One of the things this State Safety Day has done is to interest the public in the explosive power of coal dust.

We thought it was a great event, but this simple demonstration before the public eye aroused the interest of the public school child and of the workmen of the profession and all of those engaged in every line of endeavor.

Today in our State the public imagination has been stimulated to the point that the public and those engaged in other professions are also deeply interested in that rule of humanity where we save and conserve human life and human suffering, where the laws of economics and humanity meet perfectly.

I sometimes wonder if you in the profession get the idea that in addition to knowing these things, in addition to impressing upon the human family and mankind the necessity for being safe and for promoting safety, you don't get their imagination. It has been the habit of many people to take a chance and you have got to catch their interest, and by catching their interest we get, as we might say, the entire family of the public mind centered behind this work of safety and this work of improvement.

I don't know, men, really why I came here. When my chief suggested I come up and say a word to you, I hesitated. You know I am a farmer by profession. I hesitated, and then I thought this, that on this occasion I might be present and say to you that I doubt whether you quite value the great service that you are

rendering to humanity, and I am wondering if, as you gather from the four corners of the country here to study these problems, each of you to take back what you get from your neighbors' laboratory, your neighbors' study, whether you realize that we have made a uniformity of activity in the interest of the human family that each year expresses itself in a greater sum total of human happiness. God bless you and continue your good work.

CHAIRMAN McDOWELL: I think we should close this meeting and the Section for the last three days. First, I would like to know if the Resolutions Committee has anything to report?

Report of the Resolutions Committee

R. N. HOSLER (Coal Mine Section, P. C. R. & I., Harrisburg, Pa.): We have a resolution.

RESOLVED, That the sincere appreciation of the Mining Section of the National Council be conveyed to Mr. Benjamin F. Tillson, a member from Franklin, N. J., for the entertainment furnished this Section by his family orchestra and the boys' and girls' band.

Signed by Messrs. Hosler, Henrie and Berry for the Resolutions Committee.

I would like to say that I don't know if it is the custom to offer a resolution for service rendered by members of the Section, inasmuch as they are appreciated, but we feel that it was such an unusual pleasure in Mr. Tillson bringing his family over here and playing to us yesterday, together with the boys' and girls' band for our luncheon, that it should be recognized in the form of a resolution to be conveyed to him.

(Motion seconded and carried.)

CHAIRMAN McDOWELL: In closing, and in turning over the meeting to the next chairman, I want to take a minute or two of your time.

Report of the Chairman of the Mining Section

I have been especially interested in safety, personnel and community activities for a number of years, but more particularly have I been interested in this work since attending the annual meetings of the National Safety Council. I have endeavored to do all I possibly could to further the cause of the Council, especially the Mining Section, and I assure you that it has been a privilege to be Chairman during the past year of such a worthwhile institution. As Chairman it has appeared rather difficult at times to carry on the work of the Section on account of various circumstances, but I assure you that I have constantly endeavored to carry out the principles of the Section and to have the membership know that the standards set up in the past by our worthy executives were upheld to the highest degree possible during the past year.

We are all striving for the same objective and we should feel worthy of our responsibilities when selected as Chairman or for any other office in the Mining Section of the National Safety Council. We should strive willingly and be in perfect accord with the National Movement to bring about a most successful conclusion of that particular or collective effort.

There is no doubt in my mind that this work is going forward and forward until we have reached a definite goal and can feel that the work has not been in vain.

We become discouraged from time to time when our particular efforts are not as successful as we may have desired them to be. But this not discouragement to the minds of those who have been in the work for any length of time, but should rebound as a stimulating tonic towards closer concentration and greater

effort in those particular problems. Success will come to those who follow such principles.

I can look back over the year's work and see where, as Chairman, I could have performed the duties of my office probably more satisfactorily to the membership, and for not doing those particular things I feel that I owe the membership an apology.

The Chicago Office keeps one particularly busy and on the job at all times. The National Office has indeed a wonderful system. They sent out for this Section an eight piece mailing campaign that was indeed worthwhile. Some of it went out under the signature of your Chairman. I feel that it was of considerable interest to those who received it and that it will help materially to strengthen this safety movement. I received many congratulatory replies to these forms of membership appeal.

We have had exceptionally good meetings this year and I believe we have been interested every minute of the time. I thank the membership for the honor of being its Chairman for this year and assure you that it was a pleasure to work for you. The officers of the section, the chairmen of the committees and their associates were willing at all times to help in every way possible to make these meetings a success. I thank them all kindly for their help, and assure the membership that I will be willing at all times to help in my humble way to further the cause.

I desire at this time to have the new chairman for next year, Mr. Martinson, come forward and assume the duties of chairman.

Appointment of Committee Chairmen

GEORGE MARTINSON (Pickands, Mather & Co., Hibbing, Minn.): I want to tell you that I deeply appreciate the honor that is mine in being chairman of the Mining Section and in doing that I also want to tell you that I appreciate the responsibility that rests with me and the other officers of the Section. The standards that have been set by the previous administration are going to be hard to equal and much harder to beat. I have nothing more to say at this time, and I want to announce the committees that I have appointed to help in the work of the coming year:

Poster Committee: Chairman, Fred Nesbitt (Tri-State Lead & Zinc Producers Association, Picher, Okla.).

Membership Committee: C. A. McDowell (Pittsburgh Coal Co., Pittsburgh, Pa.).

Publicity: J. M. Carmody, (Coal Age, New York).

Slide Committee: H. G. Hensel (Youngstown Sheet & Tube Co., Chicago, Ill.).

Engineering Committee: Chairman, Dr. T. T. Read (A. I. M. & M. E., New York).

Statistics Committee: Rush N. Hosler (Coal Mine Section, P. C. R. & I., Harrisburg, Pa.).

News Letter Editor: Daniel Harrington (U. S. Bureau of Mines.)

Program Committee: Marvin and Jack Ryan.

Entertainment Committee: Jack Ryan.

Executive Committee: Mr. Yates (Home State Mining Co.), B. J. Tillson (New Jersey Zinc Co., Franklin, N. J.).

We want Jack Ryan to know that at the request of the chairman, we ask him to continue in his capacity as chairman of the Entertainment Committee. He has done splendid work this year. I know his efforts will be better next year.

MR. HARRINGTON: I note from the new chairman's appointments that I am supposed to continue as editor of the *News Letter*. Gentlemen, I would like to call your attention to the fact that unless you people supply information to be put in that monthly *News Letter* the only thing you are going to get is stuff from me.

You are going to take my ~~fibes~~ and that's all you will get. Unless you want that cant, you want to shoot stuff which is yours, rather than receive stuff which comes from me only?

MR. ADAMS: I was in Chicago recently and called at the office of the National Safety Council. While there I saw Mr. Keefer and Mr. Burns, who as you know prepared this yearly summary of accident statistics, which is based on reports from various sections of the Safety Council. It does not show a very good representation from the Mining Section. We in the Bureau of Mines have for several years been in what we call the National Safety Competition that is based upon very detailed information which comes to us from 250 mines and quarries. It offers just the type of information that Mr. Keefer and Mr. Burns are anxious to get for the mining industry, but many of the members of the Mining Section are not represented in those yearly compilations. I have promised the Council I would be glad to supply them with all of the data we can as early in the year as they need to have it in order to prepare their yearly summary covering all of the sections or all of the sections of the Council. I want to invite all of the people in the Mining Section here to cooperate. It does not involve very much labor on the part of the companies that are participating. I shall be glad to furnish the details by correspondence to anyone who participate.

CHAIRMAN MARTINSON: That is an important matter to the Mining Section and the mining industry. I wish it were possible for the various companies to cooperate with the Bureau of Mines in this work.

MR. HARRINGTON: It seems to me that a few moments in description of what needs to be done there should be given here. It really means practically nothing in the way of additional work to you people. All that is required practically is that you supply to the Bureau of Mines a carbon copy of the accident report which you are already obligated to hand in most states to your inspector. That is practically it. The man-hour exposure is the only additional work. It entails practically no additional work. It really adds one carbon copy of your accident report.

MR. ADAMS: How many companies represented here are now taking part in that contest? That could be answered by the raising of the hands here. I don't know by looking at them.

CHAIRMAN MARTINSON: Isn't it true, Mr. Adams, some people are furnishing you reports who are not entered in the contest? Quite a number?

MR. ADAMS: As many are furnishing reports that are not in the contest, as are in the contest, and they have various reasons for not wanting to be formally enrolled, yet we would be mighty glad to have the formal enrollment.

MR. HARRINGTON: You don't need to be afraid, if you have a particularly bad record, that it is going to be spread throughout the United States. No names of companies are given out, the names of the companies or the individual companies entering into this are not given out to the public. You can't tell whether the records are east, south, north or west.

CHAIRMAN MARTINSON: Can we get a raising of hands now? All who are in the contest raise their hands?

(Four raise their hands.)

All who are not in the contest and not furnishing reports raise their hands.

(Four raise their hands.)

ADJOURNMENT

SEVENTEENTH ANNUAL SAFETY CONGRESS
NATIONAL SAFETY COUNCIL

Packers and Tanners Section

New Section Officers

Chairman—EDWARD E. DREWS, Safety Engineer, Libby, McNeill and Libby, Chicago.

Secretary—HUBERT L. CLOVER, Safety Supervisor, International Shoe Co., St. Louis, Mo.

Poster and Slide Committee Chairman—FRED SCHWARZE, Pfister and Vogel Leather Company, Milwaukee, Wis.

Membership Committee Chairman—WILLIAM C. COREY, Delaware Leather Co., Wilmington, Del.

Program Committee Chairman—S. R. JENSEN, Armour and Company, Chicago.

Publicity and Statistics Committee Chairman—DEAN MONEYSMAKER, Disability Department, International Shoe Company, St. Louis, Mo.

Executive Committee: The Officers and

N. L. BRAINARD, Swift and Company, Chicago.

J. M. EATON, Libby, McNeill and Libby, Chicago.

Retiring Officers

Chairman, WILLIAM CAMPBELL, Graton and Knight Company, Worcester, Mass.; *Vice-Chairman*, O. C. STERN, Plankinton Packing Company, Milwaukee, Wis.; *Secretary*, EDWARD E. DREWS, Libby, McNeill and Libby, Chicago, Ill.; *Poster and Slide Committee Chairman*, FRED SCHWARZE, Pfister and Vogel Leather Company, Milwaukee, Wis.; *Membership Committee Chairman*, WILLIAM C. COREY, Delaware Leather Company, Wilmington, Del.; *Program Committee Chairman*, F. A. HONNELL, Wilson and Company, Chicago, Ill.; *Engineering Committee Chairman*, S. R. JENSEN, Armour and Company, Chicago, Ill.; *Statistics Committee Chairman*, DEAN MONEYSMAKER, International Shoe Company, St. Louis, Mo. *Executive Committee: THE OFFICERS AND* N. L. October 2, 1928

WILLIAM CAMPBELL, Chairman

Safety Engineer, Graton & Knight Company, Worcester, Mass.

The first session of the Packers and Tanners Section at the Seventeenth Annual Safety Congress was called to order at nine-thirty o'clock by the chairman, William Campbell, Graton & Knight Company, Worcester, Mass.

CHAIRMAN CAMPBELL: Members of the Packers and Tanners Section, the first on the program this morning is a round table discussion on methods of preventing

the outstanding accidents of the packing and tanning industries. Mr. McLean, we'd like to have a few remarks by you on that.

Methods of Preventing the Outstanding Accidents of the Packing and Tanning Industries

By D. D. McLEAN

Supervising Engineer, The Travelers Insurance Company, Hartford, Conn.

In the United States today there are over two thousand plants engaged in packing or manufacturing meat products and there are several hundred thousand persons employed by them. In addition to the edible substances that are shipped all over the world innumerable by-products are made from what was formerly considered waste material and the disposal of which was a source of considerable expense to the packers. For this economical condition of affairs credit is due largely to the efforts of chemists who have made possible the utilization of practically every part of the slaughtered animal including the offal.

According to the last industrial census of the United States Department of Commerce, the leather industry, of which the tanning industry is the origin, is the third greatest manufacturing industry in this country and there are over a quarter of a million persons engaged in it.

Nothing, therefore, needs to be said as to the tremendous importance of these two industries in their relation to the happiness and prosperity of our Country nor as to the high place they occupy in the industrial firmament.

In considering the methods of preventing the outstanding accidents of these two industries it is necessary to refer to them (the industries) separately and, as the subject is of exceedingly wide scope it is obvious that it cannot here be dealt with exhaustively nor is it necessary or desirable that we should attempt it.

The method by means of which we propose to approach the subject is to follow as closely as possible the regular course of the processes involved and to notice the more important accident hazards as they arise in the progress of the work.

Methods of Killing Animals

Let us look at the Packing Industry first. In a packing house, the animals are separated into three general divisions, one of which include sheep, lambs, and calves; another hogs, and the third cows and steers (which are collectively known as beeves). The methods of slaughtering and cutting up the different animals vary somewhat, and for that reason each group is usually handled in a separate building or department.

- Removing the Hides

The department in which animals are slaughtered is called "the killing floor" and after the animals have been killed the work of removing the skins and hides calls for considerable skill. The floors are usually slippery where this work is done and there is danger that the man may slip and fall if he loses his grip on the skins which he is pulling off. The workman should never hold a knife in his hand while removing a hide in this way but should put it in his pouch or lay it down in some safe place. The hides should not be allowed to accumulate but should be taken away as fast as practicable and the floors should be kept reasonably clean.

In this department the slipping hazard must necessarily be faced. This is the origin of many painful injuries. This hazard can be mitigated by surfacing the floor of the department with an abrasive material at the time of its original construction or by roughening its surface. Further, the wearing of boots by the

butchers and other operators in this department, soled with non-skid material, will do much to reduce the slipping dangers and the results occurring therefrom. This hazard cannot, apparently, be altogether removed and its elimination is an outstanding problem.

Slaughtering Hogs

In the hog and sheep slaughter departments the principal danger in the shackling or hooking pens occurs when the conveyor wheels with chains attached are returned along the overhead rails from the floor above or from some other point, by gravity. In some plants single-grooved-wheel trolleys are used and these often attain considerable speed during the return journey and sometimes they jump the track. In such cases severe injuries are likely to occur if there are persons near by, especially if one of the conveyor wheels, while carrying a heavy animal, should fall upon a man. Guard rails or other effective devices should be provided to prevent accidents of this sort, particularly at curves and at the end of the rail. A better plan consists in the installation of a two-grooved-wheel trolley. It is almost impossible for such a trolley to jump the track, even though it attains a swinging, jerky motion. The chains and shackles should be inspected frequently and carefully, and any that are found defective should be discarded at once.

In the subsequent operations in connection with the slaughtering of hogs, the carcasses are moved along by means of overhead trolley to scalding vats, which are simply long wooden troughs containing water heated to about 140 degrees Fahrenheit. The workmen in this room have long wooden paddles or poles with which they push the carcasses about in the water. The humidity in this room is excessive in the summer months, owing to the vapor that constantly rises from the hot water, and considerable water is unavoidably spilled or splattered upon the floor. Suitable ventilating apparatus should be installed to improve the atmospheric conditions in the room and the floors should be so constructed that the water will drain off quickly and thoroughly. In modern plants heated air is forced into the room in cold weather to prevent fog. It is particularly important for the health of the employees, especially during cold weather, that their working clothes be changed for warm, dry garments before leaving the plant.

The progress of the carcass now brings it in contact with various workmen in succession, each one of whom has some special operation to perform in the work of cutting up the animals. The injuries resulting from this work consist mainly of accidental cuts from the knives which the men have to use. It is the general opinion that dull knives are more dangerous than sharp ones. If a knife is sharp, the work can be done with little effort but if it is done with a dull knife considerable pressure must be exerted; and in case the knife should slip this extra pressure would be likely to make more serious any accidental cut that might follow.

The trolleys in large plants are usually operated by an endless chain which gives each workman sufficient time to perform the particular task that is assigned to him. In determining the speed at which the trolley shall be operated, consideration should be given to the fact that the men cannot work as skillfully nor as rapidly toward the end of the day as they can when starting fresh in the morning. The difference in productive capacity may be slight but it is likely to be sufficient to cause an increased number of accidents if the rate of production is based upon the output obtained under the most favorable conditions. Moreover, some men are naturally slower of movement than others and would be at a serious disadvantage with respect to their safety if they had to work constantly at top speed in order to keep pace with the more rapid workers. For the safety of all the men, therefore, the speed of the trolley should be such that the slowest man in the group can perform his part of the work without undue haste and in this way local congestion and confusion will be avoided.

The men engaged in splitting, cutting, trimming, and scraping the hogs usually

stand on platforms elevated from three to four feet above the floor. Strong substantial railings should, therefore, be installed upon them to prevent the men from falling off and the platform should be well covered. Modern equipment for scraping hogs consists of a machine having a set of revolving beaters made of leather strips and steel knuckles.

The hogs are passed through this machine and the greater part of the hair is scraped off. Singeing the fine hair from the hogs is done by means of a gas torch and while using a torch the man should be careful to avoid burning himself and other workmen near him.

Killing Cattle

Although the killing of cattle is done in a somewhat different way from that used in killing sheep, calves, and hogs, and though it is, performed in another part of the plant, the hazards are very similar to those confronted by the workers in the smaller animal departments and the accidents, therefore, in the beef killing departments are similar to those on the other killing floors. The accidents occurring here, however, are likely to be more serious because the animals handled are larger and, therefore, the knives, cleavers, and other implements must be of a larger and heavier pattern.

A serious hazard in the beef killing department is in the danger that arises when the muscles of the dead animal contract unexpectedly. An instructive case of an accident of this kind is that of a skilled workman who had been employed for more than ten years as a butcher and who had an artery cut by his own knife. He was engaged in the usual course of his work when, without any warning, the muscles of the animal he was working on contracted suddenly and sent his knife flying. Unfortunately the knife struck his arm and injured it so badly that amputation was necessary in order to save the man's life. This danger of muscle contraction is ever present in the handling of freshly killed animals and cases of it are frequent in meat packing plants.

New workmen particularly should be carefully instructed with regard to this danger and all employees should be reminded of it from time to time and be warned to keep their knives in safe positions.

Mechanical and Hand Implements

The mechanical hoists located above the killing floor must be inspected, oiled, and repaired from time to time.

Suitable platforms should be provided to facilitate this work and they should be well constructed and rigidly fastened; moreover, substantial guard rails should be installed along the entire length of such runways or platforms.

Accidents may occur in the cutting and trimming department and are mainly due to the use of knives, saws, steels, and machinery. The steels should be equipped with satisfactory stop guards. A guard of this kind may be cast as part of the handle but very good guards can be made by fitting these steels with leather discs cut from discarded belting. With protection of either of these kinds the workman may sharpen his knives without fear of having them slip and cut him.

The meat saws (called *hand* saws) are also a prolific source of accidents because the workmen often become careless and saw their own fingers. Many of these accidents may be prevented by attaching finger stops or hand stops or rests to the saw blade. One of these should be rigidly secured to each side of the blade and may consist of a light metal plate with a curved bottom extending out from the blade a distance of about half an inch. This guard should be about 4 inches long. When guards of this kind are properly used it is not necessary for the workman to get his fingers under the saw blade.

Other saws used in the cutting and trimming department are the band saw and the circular cross-cut saw, both of which should be guarded. The band saw should have both driving wheels completely boxed and the cross-cut saw should have a movable guard arranged in such a way that a workman cannot bring his hands in contact with the saw blade while properly performing this work. Under no circumstances should workmen be allowed to clean saws or other dangerous devices while the machines are in motion.

The belly roller is one of the few machines used in the cutting and trimming department. The entrance point of the first roller should be so guarded that it will be impossible for the operator to get his hands caught. This is highly important because the table is usually greasy and slippery. The side chains and sprockets that drive the roller should be guarded as well as the main driving chain and sprockets.

Undoubtedly the greatest hazard in the cutting and trimming department is due to the condition of the floors. In some plants scraps of fat and meat are *constantly* falling on the floor, thus creating conditions that are likely to result in falls with the possibility of cuts from the knives, saws, and other tools that are commonly used. There is no need to allow scraps to remain under foot in this way and in the best plants of today it is a very rare thing to find a single piece of such material on the floors. It is wasteful as well as dangerous to be slack in this respect and the flooring should be kept clean at all times even if it becomes necessary to engage extra workmen for this express purpose. One source of wetness is from pickle dripping out of trucks.

Cooked Meat Department

In those plant where cooked and minced meat products are manufactured dangers to the hands are encountered in the operation of chopping, mincing and grinding machines; the knives and cutters of which should as far as practical be enclosed in substantial covers and the operators should be furnished with wooden paddles in all cases where it is necessary in feeding the machines to push the meat with the knives.

Pressure Cooking Vessels and Rendering Tanks

In packing establishments where cooked meats are manufactured, cooking kettles of various designs and usually constructed of copper and operated under steam pressure are used. Definite knowledge of the safe condition of these vessels should be aimed at. Their structural data should be known and the pressures under which they are working should be kept as close to the usual factor of five as is possible. They should be examined and tested by a hydrostatic pressure at regular intervals—annually—and records of these inspections and tests should be kept.

In establishments where fertilizer is manufactured from the otherwise waste material, large rendering tanks operated under steam pressure, there is a hazard of explosion. These vessels are usually made of boiler plate steel, are constructed of truncated cylinders, riveted and stayed together, and are subjected to bursting and collapsing strain. Their construction should be based on the most careful calculations and the best workmanship and should operate at a factor of safety of not less than five, and they should be provided with safety relief valve and pressure gauge. Because of the acids and corrosive vapors in and given off by the material cooked therein, they are subject to very rapid plate corrosion and deterioration. They should, therefore, be carefully inspected at regular intervals of not more than six months by a competent engineer or boiler inspector and upon detection of serious plate wastage they should either have their working pressure reduced or substantial repairs made to them. Records of inspections and results

discovered therefrom should be kept by the safety department of the plant and their conditions always carefully watched and studied.

These suggestions apply to all other vessels operated under steam, air or gas pressure in the processes incident to the industry, and definite knowledge and check of structural data and conditions should be kept. In and about plants of this kind there are usually air pressure tanks and in connection with the refrigerating apparatus there is oftentimes an ammonia receiver operated under very high pressure.

We mention these things because it has been our experience that even in the best regulated plants the executives and the Safety Department know very little, if anything, about them in respect to their safe conditions but they carry precisely the same explosion element as a steam boiler. Many states now have laws requiring the regular inspection of steam boilers, but very few have laws requiring the regular inspection of unfired pressure vessels.

Shipping Department

The shipping department is one of the largest of the meat packing plant. All of the products are packed in boxes, barrels, cartons, and other packages. Accidents are frequently due to carelessness on the part of the workmen. The danger from projecting nails is a prominent one and everything possible should be done to eliminate it. Nails should never be left projecting from boards, barrels, or boxes. Care should be taken to stack boxes and barrels in a safe way because careless methods of piling are likely to result in serious accidents. Truckmen should avoid overloading their hand trucks or stacking the boxes up too high on them.

A large proportion of the accidents in meat packing plants are caused, as we have said, by the knives, meat saws, cleavers, and other implements that are constantly used. Many of these accidents are due to carelessness or haste. In this industry sharp knives and heavy cleavers of a wide variety of shapes and classes are used literally by armies of men—long thin knives, short heavy knives, knives that curve up and knives that curve down, crescent-shaped knives with handles at both ends, knives of every possible size, weight, and form, all sharpened to razor keenness; and it has been well and truly said that "the knife question is undoubtedly the greatest safety problem in the packing industry."

Much can be done in the provision of safeguards on the knives themselves and in the use of gloves and cuffs and aprons as protective devices on the person of the workers. Unguarded knives should not be permitted; the use of guarded knives should be strictly enforced upon the workers so that accidents to the fingers, hands, wrists, and forearm may be as far as possible eliminated.

Occupational Hazards—the Tanning Industry—Anthrax

The handling of animal and cattle hides, pelts and fleeces in the tanning industry exposes the workers to a number of inherent dangers to life and health and, prominent among these is the disease known as anthrax. This disease is caused by a certain microscopic organism known as the anthrax bacillus which enters the animal or the human being in some way or other and then grows and multiplies in great numbers, thriving and developing at the expense of the tissues of the body, and at the same time producing substances that poison the entire system of the victim.

Infection may be acquired either externally or internally. Most commonly, the anthrax bacillus gains admission through some abrasion of the skin, such as a scratch, cut, or newly-opened pimple. The parts of the body that are most often affected are those that are uncovered, as the neck, face, arms and hands.

Less commonly infection is got by inhaling, or swallowing the germs. This is

much more dangerous than external infection and it usually results fatally in a very short time.

There are many measures that can be adopted for reducing this danger and there has grown up considerable literature on the subject. The following is a list of typical recommendations for the mitigation of this hazard.

Typical Recommendations for Prevention of Anthrax

1. Foreign skins should be segregated or physically separated from domestic skins in storage sheds by partitions constructed to facilitate the separation. Apartments emptied of hides should be ventilated or disinfected with a solution of phenol or carbolic acid immediately upon being emptied.
2. Waste, scrap, hair, and other debris should be washed from the floors daily. This practice can be exercised at the noon hour or between shifts.
3. Departments of the plant where dust from the skins may be a factor in distributing anthrax germs should be ventilated to dust collectors or reservoirs. This debris should be burned at regular intervals.
4. Tanneries working on raw foreign skins should thoroughly soak them no less than forty-eight hours in a one to one thousand bichloride of mercury solution (one pound of mercuric chloride to one thousand pounds of water), to which has been added enough formic acid to make a 2 per cent solution of acid.
5. In case of anthrax being contracted by employees from hides in any department of the plant, the department that is suspected of containing the contagion should be fumigated by the gas generated from the mixture of formaldehyde and potassium permanganate. At the time of this fumigation no employees should be allowed in or about the department.
6. Machines for buffing, kneading, willowing, burnishing or heckling skins should be provided with a dust exhaust system.
7. If there is accumulation of dust in any department of the plant where skins are buffed, dehaired, skived, etc., the ceilings and the walls should be disinfected by the use of carbolic acid, formaldehyde, or a solution of mercuric chloride.

Personal Sanitation

8. The eating of lunches in the plant in proximity to skins that are being processed should be prohibited.
9. Separate rooms or partitions should separate the lunch rooms from other departments of the plant.
10. It should be a rule that previous to eating lunches the employees should be required to wash hands thoroughly, and if there is a suspicion of anthrax contagion, or if the employees have been handling foreign skins a wash containing 2 per cent of mercuric chloride solution should be used, and the hands rinsed after with water.
11. Employees having pimples, skin abrasions or cuts should report to the office immediately for first aid administration, or to physician in charge of the medical services of the plant.
12. Aprons, boots, and long-sleeved gloves should be furnished the employees handling the skins previous to their being subjected to dehairing solutions.
13. Employees engaged in carrying hides on their shoulders should have their necks fully protected from coming in contact with skins. Hides should be transported on trucks if practicable.
14. Overalls, aprons, and other miscellaneous clothing worn by employees handling hides should be disinfected at regular intervals.

Handling Chrome and Acid, etc.

In preparing the hides for the dehairing process and in the process of tanning, various acids and dilutions are used in the soaking and tan vats. Among these may be mentioned lime, disulphide of arsenic, tannin or tannic acid, chromium, soda ash and caustic soda, hydrochloric and sulphuric acid, etc.; danger to hands, eyes and other parts of the body arises from this source and acid burns are a common kind of injury in many tanneries. Chrome sores are also of frequent occurrence.

The workers exposed to or handling these acids and dilutions should be provided with rubber gloves, aprons and suitable footwear and they should be made to wear them at all times when engaged in these duties. Also, as a preventive, the workmen should be provided with ointment for treating their hands before starting work so that if acid by any chance gets into their gloves, ill effects are less likely to occur.

In addition to these personal precautions, acid carboys should always be mounted on suitable inclinators before any pouring is done from them. Great care should be exercised at all times while handling carboys of acid, especially while unloading to see that stoppers are firmly set and that no danger of the acid spurting exists.

Skin Eruptions and Diseases

Unless the precautions suggested are carefully carried out the occurrence of eruptions and diseases of the skin will certainly result and the hands, fingers and arms of the workers will become foci of ulcers, eczema and other painful infections leading to incapacitation, and loss of time.

Poisonous Fumes; Fire; Explosion

In those tanneries in which patent leathers of various descriptions are manufactured the degreasing and other processes involve the use of large quantities of petroleum naphtha, wood alcohol, amyl-acetate and nitro-cellulose. These solvents not only give off poisonous fumes which are capable of producing very ulterior effects on the health of the men, which may bring on incapacitation, but they are highly flammable and explosive. It is imperative in such establishments that ventilation be of the most adequate kind and that all possible sources of ignition be effectively guarded against. All electric wiring should be run in tight metal conduit; all switches should be of the safety enclosed type and should preferably be located outside of the rooms in which these volatile liquids are used; all electric light bulbs should be of the keyless socket type, enclosed in vapor proof gloves. No open lights of any kind should be permitted and the workers should be forbidden smoking or the carrying of matches.

Vats and Tanks

The soaking and tanning of hides is done in vats and tanks which have their tops level with the floor. Danger of slipping and falling into these receptacles is inherent to the industry. The manner in which this hazard can be reduced naturally suggests that the tanks be covered or that they be railed along their edges. If covers are used they should be of 2 inch plankings well fitted into recesses along the edges of the vats. If railings are used they should be substantial, double barred, with the top bar 42 inches high above the floor level, and they should be securely fastened in place.

Floors

Because of the natural wet process of tanning and the quantities of oils and grease used in the stuffing operation etc., the floors of a tannery are always subject

to wet and slippery conditions. Here, as in the packing industry, the hazard of slipping must be faced and accidents due to falling are common. Several remedies are available. First, of course, every effort should be made to prevent unnecessary slopping of water and tanning liquids and the spilling of oil and grease. Careful workmen should be able to help these conditions very materially. Second, wooden floors can be treated with a sprinkling of ground feldspar or powdered resin. Third, oily or greasy conditions can be remedied by the application of caustic solution or air slaked lime. Fourth, employees should be provided with footwear of non-skid type and made to wear them.

Machine Hazards

There are many machines used in the handling and working of hides and leather; a good proportion of these have points of operation with cutting, pinching or squeezing action. The hands and fingers of the operators are subject to amputation or mutilation unless these machines are properly guarded and it should never be lost sight of that, if a machine of this class goes unguarded, it is only a question of time, when some unfortunate workman will lose a hand or an arm or parts thereof. Each machine should therefore be carefully studied and an automatic guard device provided to prevent the hands of the operator from being inserted into the pinch or shear point.

Embossing Presses

It is quite impossible, in this paper, to consider all of the machine hazards in the tanning industry. The embossing press, however, is possibly the most dangerous machine used in this business and has been the cause of many amputated hands and fingers. This machine should always be fitted with an automatic guard, both on the "operating" and "off take" sides, designed in such a manner as to close the feed and off-take apertures prior to the engagement of the dies or plates. Wherever the nature of the work will admit of it, a fixed guard, which reduces these apertures to an opening of not more than three-eighths of an inch, is the better arrangement. This latter arrangement is also better than a two hand operating device, which requires the use of both hands of the operator, to set the machine in motion, thus taking his hands away from the point of operation.

The Human Hazard

The workers in these two industries are made up of many nationalities. Those of foreign birth predominate. It has been estimated that 60 to 70 per cent of them are from the European countries. They are necessarily of strong and robust physique, capable of withstanding the heavy duties which fall upon them. The average wage in the packing industry at the present time is about \$28 per week while that in the tanning industry is about \$26 per week. The general level of intelligence makes skilled, understanding, sympathetic and disciplinary supervision imperative, if the best results are to be attained in accident prevention. It is in this field that the causes and remedies for industrial accidents, more than in any other, are to be found.

It has been known for a number of years that physical hazards are becoming less and less a real factor in safety; and recent authoritative research, through the analysis of 75,000 accident cases, the study of actuarial records and engineering reports, it has been found that 98 per cent of all industrial accidents are preventable. Further, this research has demonstrated that 10 per cent only have their origin in plant physical and mechanical causes and that 88 per cent of all industrial accidents are preventable through the enforcement of proper supervision.

The results of this research have been made the subject of a most interesting paper "The Origin of Accidents" by Mr. H. W. Heinrich, Assistant Superintendent of The Travelers, Engineering and Inspection Division, copies of which are here for distribution and more of which can be had upon request.

Success in Accident Prevention

Success in accident prevention, as in any other field of human endeavor, requires that we shall establish and follow a definite plan for its attainment; it cannot be secured by inconstant or haphazard methods. Such a plan involves and necessitates—First, the sympathetic and active personal interest and participation of the executive forces—Second, the definite imposition of responsibility for the prevention of accidents upon the supervisory staff and strict accountability for each and every case of injury—Third, the education and discipline of employees—and Fourth, the energetic elimination of physical accident causes.

"The salvaging of human life" as Professor H. A. Overstreet points out in his excellent book, *Influencing Human Behavior*, "consists not simply in having high ideals; it consists as much in knowing *how*. We need, in short, to know how to interest our fellows; how to arouse their expectations; how to build up habits of favorable response; how to lead and adjust and control."

These remarks cannot apply more aptly to any man than to the safety supervisor of an industrial plant, for he, above all else, must be a skilled artist in human nature and in the enterprise of life.

MR. CROMWELL: There are a few things I want to bring out. In the first place, we represent one of the biggest tanning industries in the United States. In April of this year we had one anthrax case. That occurred about two or three months ago, and in looking up this case we find that the whole family is subject to all kinds of infections, so that probably answers the question right there. We had one of the man's brothers working in the beam house, and on looking up his past record I found that he had an infection about every few weeks, so that shows that the man was predisposed to infection.

Another thing, the Interstate Commerce Commission and the United States Board of Health require you to fumigate all hides coming from outside the United States, so that you can't get away from the fumigation process. They also require you to fumigate the car that the hides come in, and fumigate your hide house after you remove the hides from it, and everything connected with it, and you must burn all ropes, tags, and other materials that come on hides immediately they are taken off the hide, so that there is no chance of the anthrax getting through in case it should come to your plant.

Probably our worthy brother isn't familiar enough with the tanning industry, but I believe you should have divided it, probably, into Upper, Sole, probably Belting, and Harness Leather, because the accidents for each one of those types of leather are entirely different from the others. They'd probably have the same beam house quotations, but after that they would be different practically all the way through the various departments; and of course the accidents common to Upper are not common to Sole, and the accidents common to Sole are probably not common to Harness Leather, or Belting; so you see, in taking the industry as a whole, there are many things to be taken into consideration.

Speaking of health in the various plants, I am here to tell you right now we have some plants in which we haven't taken in but one or two employees in 28 years, so it shows it is a pretty healthy place to work.

Now, in reference to acids, I want to tell you men that I don't think we have a plant where acids are not entirely mechanically handled, and the man does not come in contact with them in any way. They are handled directly from

the car to the big tank outside, and under air pressure are distributed to the various departments and piped to the various receptacles where they are used. All the man has to do is turn his valve from the main container, draw his supply, shut off the tank, and shoot it into the container. So he doesn't come in contact with it in any way. Of course that equipment has to be replaced probably every four, five, or six months, depending upon how much acid is used.

In reference to limes and lime burns, we had one lime burn about two weeks ago. It is the first one we have had in some time, but that was due to a fellow being plain foolish. He walked into a vat of lime soaps in a beam house, and it went over the top of his boots. He was an ignorant chap and didn't change his boots; in fact, he wore the same pair for three or four days. At the end of the fourth or fifth day, he came to the office and said his feet began to hurt him. If he had reported it right away he wouldn't have lost any time. In case any of you men have lime burns, Johnson & Johnson puts out the best remedy. It can't be beaten. As to chrome sores, it is a very good remedy for those, so we don't have any chrome sores any more.

One thing I think he should have mentioned, is masks for men handling lime and various powder extracts. There is no getting away from that. If you don't, you are going to have lime burns on the nose, and injuries to the nose and lungs from different types of powders. It will make a man have hay fever, or something like that, even though it won't be serious.

Now, as to smoking around the plants, there isn't a plant where we permit smoking any place. If they want to smoke, they must get at least a hundred feet away from the building, and they generally go to the fire room and sit around the outside to smoke for a few minutes.

Now, as to vat accidents,—he mentioned the vat accidents. It depends upon the type of tannery whether you have covers or not. It depends upon whether you use the rocker system, or the open, or closed system. In the last few weeks we have inaugurated a new system whereby every time a vat is opened or emptied of leather, as soon as the men finish pulling the last piece of leather out of the vat, they immediately put up a guard far enough away so that if a man backs up to the vat he will be warned before he slips over, or falls into it.

CHAIRMAN CAMPBELL: Was that in the tan yard or beam house?

MR. CROMWELL: In the tan yard.

CHAIRMAN CAMPBELL: What about your vats in the beam house?

MR. CROMWELL: Generally they are full of hides and you can't do anything about those. I am speaking of yard vats. On the beam house vats you only have, as a rule, four or five men working around them, so that you rarely have a man fall in.

I mentioned about three years ago, to the Congress, where we had a green man working in there, and a carload of hides was going by, and he jumped and took in seven with him.

As to slipping about the various departments, I don't believe you can get away from it. This gentleman mentioned abrasive materials. I don't think you can use them. I think it is out of the question. We have tried every kind of a floor that you can think of, and the only floor that will last is a good wood floor. It should be washed down at very frequent intervals. Now there is another thing you can use, which I think will reduce accidents, and that is the ordinary paving brick laid in cement. We are doing that in some of our scrub houses, where very hot water is going through, and it seems to split up the fibres of the wood and you get a lot of splinters. We are using paving brick laid in cement, and I think that is about the best there is, but then, where they are wearing rubber boots, you will still have the slipping.

Now he mentioned the three-inch clearance on the Sheridan Press—I think it was the Sheridan Press from the description of it. You can only use that on Upper Leather. You can't use it on Sole Leather. In the first place, you have the hip bulges, and you couldn't possibly get a piece of that through there. It wouldn't clear. If you did try to run it through the guard would scratch it up and you'd have a second or a third grade piece of leather. You must have at least 2½-inch clearance on all your guards.

CHAIRMAN CAMPBELL: Mr. Cromwell, if you should put Sole Leather or Bat Leather through, you'd have to raise up your guard so high it wouldn't do you any good. You can only use a ¾-inch guard where you are using a fine Upper Leather or Kid Leather, where you lay it flat on the table.

MR. CROMWELL: Yes. Now you mentioned the time of day that accidents happen. I went over a period of four years, over all our accidents, and I find that the greatest number of accidents happened at eleven or eleven-fifteen in the morning, and that the greatest in the afternoon was around three o'clock.

Now there is one type of accident in our industry that he has not brought out, which is the worst, and which we can't do anything for. That is injury to fingers and thumbs through rotor accidents. We have them every week, and in Pennsylvania particularly, the Pennsylvania State Department of Labor and Industry has camped all over us for the last three or four years about it. There is nothing you can do for it. There are no two pieces of leather that are wetted—and we always have to wet leather down before we roll them—there are no two pieces that will take the same amount of water. Now you may apply the unit to one side of leather and it will soak it up, and apply it to another side, and it will only soak half of it up. Now the first piece of leather going under the roller pawl may roll fine, and the second piece may jerk the man's hand under.

CHAIRMAN CAMPBELL: Mr. Cromwell, would you call that the tanning industry, where you use the roller plan?

MR. CROMWELL: Oh yes, sure. We roll all side leather and sole leather.

CHAIRMAN CAMPBELL: We designate that as curing it.

MR. CROMWELL: "Curing" is generally applied, as I always understood the term, more to harness leather than it does to sole leather.

CHAIRMAN CAMPBELL: That is the reason we haven't so many in this Section, because we call it the Packers and Tanners. All sole leather has to be rolled, and that is called the Finishing department.

MR. CROMWELL: Well, it is the same thing. It belongs to the tanning industry. You have to finish your leather before you can sell it, so naturally it has been classified as one of the departments of the tanning industry.

D. D. McLEAN (The Travelers Insurance Co., Hartford, Conn.): Mr. Chairman, I just want to say that it would have been utterly impossible for me to cover every phase of these two industries in my talk or paper. My function, of course, is simply to generate thoughts in the minds of you gentlemen here, in order that you might do more of the talking than I did; and I do think that up to now it certainly has been successful in producing the effect. Discussion has been aroused; and I just wanted to say this, that I think Mr. Cromwell certainly has got hold of the intelligent way in which this thing was intended to be propounded. I generated thoughts in his mind. Don't you get the idea? I am not here to tell it all to you, because, it would be utterly impossible. I could fill volumes, possibly, if I followed out research enough.

CHAIRMAN CAMPBELL: I think Mr. McLean did quite a lot of good. He got Mr. Cromwell to say something that we haven't heard for quite a long time. But now in regard to this lime. You say you had only one lime accident inside of a year, Mr. Cromwell. You had only one lime accident inside a year?

MR. CROMWELL: No. We have had more than that. We have had, I suppose, maybe five this year. They weren't serious.

CHAIRMAN CAMPBELL: You are pretty lucky. We have one every week.

MR. CROMWELL: If I may take another minute of your time, I might say, on this lime question, if you will watch your men's clothing in the beam house—I know it's an awful job—but if you get after your beam house foreman and talk to him like a real friend, I believe you will get away from the lime question. The way I got under their skin, so to speak—two weeks ago an employee of ours who had met with an accident died and left a wife and five children. Of course it was rather difficult for the family to get along; and every time anything like that happens, if you will get your foremen together and don't be afraid to mention names, but just point these facts out to them, it makes them stop and think and realize the condition that their families would be in if anything happened to them. I think you can get more cooperation from them by going after them from that angle than any other.

If you will have your foremen look after the clothes, and thoroughly impress upon the men not to work in the beam house with any holes in their clothes, any holes in their rubber aprons, or any holes in their rubber gloves or rubber mittens, I think you will get away from your lime burns entirely. As I say, we have had only this one serious one this year. We get lime burns in between the fingers, where there is possibly some perspiration and some lime dust has gathered in there. A man does not lose any time from that. He may have a sore hand for a half a day or so, but he gets some of that Johnson & Johnson preparation and that is the end of it.

Now there is another thing that the worthy brother brought up, in speaking of clothing, about disinfecting. I don't believe that is possible. That is all I'll say on that.

CHAIRMAN CAMPBELL: Any more questions to be asked of Mr. McLean?

FRED SCHWARZE (Pfister & Vogel Leather Co., Milwaukee, Wis.): Mr. McLean has aroused a thought in my mind, likewise. In so far as the time of the day is concerned, our survey has indicated that there are accidents in the morning, afternoon, and at night. Any time. Any place. They just happen. If they didn't, they wouldn't be accidents. They would be forestalled. I think the sentiment that is expressed here today is by those who represent the greater majority, in so far as the volume of business done in the packing and tanning industry is concerned, and probably the minority in the number of plants or establishments that are in effect in the country today. I believe that the type of plant that is represented here is the best type of plant, where the owners have taken an interest in the human side of the question and have provided a good many measures which are lacking in the smaller plants, and to which the insurance element, so to speak, has access. Probably in the larger industries, the liability insurance is carried by the larger establishment on the so-called self-insurance basis. However, there is a parallel between the exposure in the small and large establishment.

In so far as anthrax is concerned, in the operation of six plants over a period of eighteen years, we have not had one single case of anthrax—anthrax infection, I mean. Whether we have had the anthrax bacilli come into the establishments is an unknown fact. I could probably say that the anthrax germ has come in, but through some good streak of fortune there has been no hard luck following on its trail.

In so far as the bichloride treatment is concerned, we only consider that a tentative treatment. In fact, we know that the anthrax spore, so to speak, is immune to the bichloride solution and that only boiling in an excess of 160 degrees Fahrenheit will terminate the potential hazard of an anthrax spore.

As regards the furnishing of rubber gloves, boots, footwear, etc., that is good housekeeping, and means of prevention that will afford itself in the long run.

As to the industrial disease liability of rheumatism in connection with the packing and tanning industries, I would hate to have to ask Mr. McLean, or even

better medical authorities, to qualify that statement. I have sat in on legal and medical discussions, and in the presenting of testimony in cases, where that question has always remained unanswered. The fact is that some people, under the most favorable conditions of living, some people that never get within a mile of a tannery, have rheumatism. The extraction of teeth, tonsils, and everything else, does not cure them, but in some cases an ulster does. The opinions are based more or less on an hypothesis, although I will admit this, that the tanning and other wet industries are blamed in the minds of the laymen and a good many professional men, unjustly, for contributing to the disability account of rheumatism.

As regards the lime burns to hands, we make a so-called "hand inspection," also an inspection of rubber gloves and rubber boots, furnish the squirting barrel without cost, only as to the deposit to be made, to maintain control.

I gained from both Mr. Cromwell's and the chairman's comments that the beam house vats in their establishments generally are not covered. Am I correct?

CHAIRMAN CAMPBELL: Yes, in the beam house.

MR. SCHWARZE: Our practice is just the opposite. In fact, our beam house layouts are rather crowded, and we use our vat tops for trucking and handling. I don't know of an open vat that is maintained open after the stock has been abstracted or replaced. We close them up, and maintain guards around them while the stock is being lifted or placed into these vats.

In the matter of slipping hazards, we have found that emery abrasive and a proper mixture of cement gives a fairly good protection against slipping. In wet places, we have also always had a brick and cement construction. Both have materially minimized the hazard. I will not say that they will eliminate slipping hazards, but they appreciably minimize it.

As regards the $\frac{3}{8}$ -inch setting of the guard on an embosser press—did I understand $\frac{3}{8}$ -inch setting?

MR. CROMWELL: $\frac{3}{8}$ -inch aperture.

MR. SCHWARZE: I would say an aperture of that dimension is impractical, although an aperture of greater dimension, possibly as high as an inch and a half, and to avoid risk the form of entrance is very effective. We have been operating an average of a dozen of that type of press for a period of twenty years. In the first three or four years we had a lot of serious accidents. In the last five years, we have had only one minor accident from operating with different types of guards. We have developed a guard for a sole leather press that has a swinging feature to it, and permits a minimum of 2 inches and a maximum of 3 inches clearance.

MR. MCLEAN: Mr. Chairman, in my paper, referring to the safeguarding of the plant operation on an embossing press, or on any other machine where there is a pinching, squeezing, or cutting action, I referred to three different types of guards that can be used. Now first of all, you can use a $\frac{3}{8}$ -inch aperture or opening. I mention that because in the industrial standards adopted by the various states you can use an aperture of $\frac{3}{8}$ of an inch, which will permit the operation of that machine. Or you can use an automatic safety device that has for its purpose the ejecting of the hands of the operator away from the point of operation as the die begins to descend; or you can use a two-hand device to set the machine in motion, necessitating the taking away of the hands of the operator from the point of operation.

Now I understand that you can't use a $\frac{3}{8}$ -inch aperture in every circumstance in the packing or the tanning industry, or in any other industry, as far as that is concerned; but where you can use a $\frac{3}{8}$ -inch aperture, you will be given credit on your rating schedule for a fully guarded machine. The point of operation of the machine, in states where schedule rating is in operation, is a machine that carries a charge with it on the premium, or the premium rate. In some instances it is a flat charge as high as \$15, for instance, for an unguarded circular saw, under the

schedule in Pennsylvania—\$15 for every saw that is not actually guarded. The premium is increased from that flat rate. The same with other machines, by decreasing in terms of charge or cost. A punch press, for instance, gets a flat charge of \$12, unguarded. Now if you can fix that press up so you can use a $\frac{3}{8}$ -inch aperture, fine! Now it wouldn't be any use of me explaining a larger aperture which would be admitted, or which would get you any credit for a fully-guarded machine. I come down to what is the standard requirement. Now, if you can't use that, why then, of course, you must resort to either the automatic guard or the two-handled device. That is the reason I used the arbitrary figure of $\frac{3}{8}$ of an inch.

MR. CROMWELL: You were speaking of a $\frac{3}{8}$ -inch guard. What you can do is this. You can move your guard far enough away from your machine and have an aperture of $2\frac{1}{2}$ inches. He can also run his hand under that, but it will be about that far (indicating) away from the machine, which prevents putting his hands around the side of the enclosure. We have done that in lots of cases where the man can't possibly get into the machine.

MR. MCLEAN: That is a very good device.

MR. CROMWELL: We use it in practically every plant we have, especially on rings, where our experience was very sad when we first started to use them. There are men about the plant today with scars all over them from that.

MR. MCLEAN: Bearing out the point I mentioned in my paper, that unless the machine is guarded it is simply a question of time. Now in referring to safeguards, I naturally adhere to standard requirements that are to be found in the various schedule rating formulae. But that isn't to say that if you can devise a guard from a job study of the machine itself that is equally effective though not of standard pattern, you are not to use it. By all means, let us use our own genius in devising these guards, and if we can modify or amplify in any direction, in order to save a man's hand, or to save a man's life, why let's do it. I mention that because of what you explained you have done in this particular instance.

MR. CROMWELL: There is one thing about anthrax; a solution put out by the Philadelphia Chemical Company, which you can get your local hospital to stock. It is good for about eight months, and you can get a supply large enough to take care of any of your needs, and it will only cost you about six dollars. The local hospital will stock it and store it in the refrigerator until the time limit has expired, and then replace it and charge you for the original amount.

MR. SCHWARZE: We've carried it for fifteen years.

MR. CROMWELL: It's very good stuff.

MR. SCHWARZE: I'd like to ask, Mr. Chairman—he referred to the arbitrary standard of $\frac{3}{8}$ of an inch. Is the regulating body very arbitrary about maintaining the $\frac{3}{8}$ standard?

MR. MCLEAN: It all depends in what state you are operating, but I do believe—in fact, I know—that if the employer can show to the governing body on the question of standards that he has a guard equivalent to the one that comes under the standard, why by all means they allow him credit. As a matter of fact, according to my duties as an insurance inspecting engineer, among the things that I undertake to do (and all our men undertake to do) is to see that creditable guards are given the deductions they are entitled to. The engineer can often help you in producing the evidence, the right kind of evidence, in the right form, before the board of the governing body in order to convince them that you are entitled to credit.

CHAIRMAN CAMPBELL: Mr. McLean, I have been working forty-four years in the tanning industry and have never seen a case of anthrax yet. Like Mr. Schwarze, I don't know what it is.

MR. MCLEAN: Well, that is mighty fine. You know anthrax is like many other highly dangerous conditions in industry. It is known to be fatal unless it is adequately taken care of, and consequently the employer or manufacturer, as well as

his supervising staff, and, in many cases, also the worker in the industry, is so conscious of the danger that he heeds every possible precaution, both required by legislative enactment and by common sense. Where we know a thing to be dangerous, we certainly take every precaution to prevent such accidents.

As a digression, let us look at the coal mining industry in Pennsylvania. In the bituminous fields, the roof is known to be good. In the anthracite field, in Eastern Pennsylvania, the roof is known to be bad, and yet, in the bituminous fields where the roof is known to be good, you have more accidents from falls than you do in the anthracite region, where it is known to be bad, because naturally they are on their toes all the time to stop the accidents.

MR. CROMWELL: What kind of hides do you work, Mr. Campbell, domestic or foreign?

CHAIRMAN CAMPBELL: A good deal of foreign, but we are getting the cheapest we can, the same as the Central Leather.

MR. CROMWELL: That would answer your anthrax question.

CHAIRMAN CAMPBELL: We don't use much foreign hides, and we haven't much anthrax. You get anthrax more in goat skins and sheep skins than in heavy hides.

Mr. McLean, you have been talking about safeguarding machinery. Here's a machine (handing Mr. McLean a photograph) that was safeguarded automatically, done by the maker before it was put in, and here are the results (handing Mr. McLean two additional photographs). I'll show you the full pictures. Pass them along. That is a de-hairing machine. You will see what happened if you look at these pictures.

MR. CROMWELL: He was lucky to get away with an arm at all.

MR. SCHWARZE: Mr. Chairman, following up what Mr. Cromwell said on anthrax. About four years ago we had the hoof-and-mouth epidemic in the South. We were receiving hides on bordering area territory, and, to put it that way, we possibly did receive some indirectly out of the infected area before the quarantine was set up, but in justice to the men exposed to the handling of these hides, we checked up every man who was absent, no matter what the reason was, unless he had been definitely excused, and we did not find a single case of infection.

CHAIRMAN CAMPBELL: I have a little note here that I have just picked up now. We are talking about safety here and the preventing of accidents, but I think "Safety goes where it is invited, and it stays where it is well-treated." That means that your foreman is the keynote of all the departments. The safety inspector or the safety engineer may be all right as an executive, but it is the foreman that should look after these men, and be given all the credit for the no lost-time accidents.

Any further questions to be asked? Well, we have twenty minutes more. If you'd rather stay here than go outside, why we can have a little more discussion, Mr. McLean.

MR. MCLEAN: I think it is up to the gentlemen representing the industries.

CHAIRMAN CAMPBELL: Mr. Schwarze, do you haul your hides out of the beam house by hand or machinery?

MR. SCHWARZE: By hand, and in some cases we reel out with a toggle—we have an endless set-up of hides toggled together and run the first ones out by hand over a reel, and then they are conveyed to a distant vat or point of working.

CHAIRMAN CAMPBELL: Well, we run them over by electricity. We don't need to have them guarded, because the big electric wheel is on the vat all the time.

MR. SCHWARZE: I suppose if you spill the contents, you have a basket right there?

CHAIRMAN CAMPBELL: Yes, but it is cement vats we have—all wide open, and no guards, because they are full all the time and you can't get around them.

MR. CROMWELL: You don't need them.

CHAIRMAN CAMPBELL: Not where they are full all the time, lying flat, and then this machine is on the place where we are going to take it, the fleshing machine. No. 7 Vat is emptied on the seventh day, Monday, generally; the hides then going to the de-hairing machine, and from that to the fleshing machine. We have overhead cranes to handle what has gone through the fleshing machine. As it comes from the knife, it goes down into the pit, and the pit has three big buckets, and that fleshing goes in that and is lifted up by electric motor and shoved right along into the fleshing house.

MR. SCHWARZE: We contemplate a similar arrangement in our new buildings, but our old buildings do not permit that type of handling.

MR. CROMWELL: You don't have any residue there at all. When you stop at night, everything is clean, except possibly a few pieces hooked around some part of your equipment.

MR. SCHWARZE: Mr. Chairman, how are we going to combat the outstanding conditions leading to accidents in our industry? Mr. McLean's paper carried us along a certain line of discussion. I think there is ample time and opportunity to take up some of these vital issues. In trying to determine which part of the industry, in the lower tanneries, not in the sole leather industry, sole or upper leather industry, which part of the industry furnished the greater hazards, I feel that, generally speaking, it is in the lower tannery, particularly in the beam house, where the hazard is practically on an even basis, exposure of cylinder type of machines and roller type of machines, with the pinching hazards equal in any kind of tanning. I believe that a discussion of this kind may bring out some information of benefit to us all, here, so I recommend that at this time we discuss the hazards in the beam house.

CHAIRMAN CAMPBELL: Mr. Schwarze, regarding the beam house, where we have men who have worked there as long as thirty or thirty-five years, it occurs that when a machine gets old, there is something going to happen. Well, generally, it is rheumatism, see?

MR. SCHWARZE: On the Machine?

CHAIRMAN CAMPBELL: The old man is the machine, and it is getting played-out after thirty-five years of working in the wet and dampness. It was a good machine to do it that long. Even your de-hairing machine will get rusty and you have to throw it out before thirty-five years. But the man will stay there for thirty-five years before you throw him out. So he begins to get decrepit. Now what does it? I have heard some people say here that the tannery is a safe place to work, and there is no rheumatism. Mr. McClellan said that. We have an old man who has been working there twenty-five or thirty years, and of course if they get rheumatism that means compensation, you see. If a man goes out with rheumatism, it means, sometimes, he will be out for six months, and when it isn't rheumatism, they call it lumbago.

MR. CROMWELL: I think, if I might make a suggestion, the only accidents we have in our beam house are knife cuts from trimming fleshings off the edge of the hides. Once in a while, even though sawdust is used and everything else, the knife will slip, and just cut the tip of his finger, or the side of his thumb.

MR. McLEAN: I don't want to seem to be taking more time in this discussion than I have any right to, but the question that you raised with regard to the man becoming decrepit and suffering a physical deformity from having been engaged for thirty-five years in a particular kind of work that he was doing in a tannery—that kind of thing is only amenable to adequate medical supervision in a plant. Now industrial medicine is a growing science. It takes a special and particular study on the part of the medical man and the physician to know what the growing incompetencies of working men are likely to be, due to the kind of work that they have to do; so that as Safety grows older and becomes more and more intelligent, and as the gospel of safety becomes more widespread, preventive medi-

cine, as an ally to the physical accident prevention campaign of the industries of our country will become more and more efficient, and will spread its influence and save men from such deformities as you mentioned, and from the diseases that they are subject to as a result of their life work.

That good thing has been done already—a good deal has been done already. Anthrax is one of the occupational diseases that has got to be faced in the tanning industry, and has been, practically most of it, conquered by the efforts of the industrial physicians, by industrial men; and only through that medium, Mr. Chairman, will the things that you speak of be eliminated, and all the toilers in industry be saved.

Now I might take that a little further. The greatest thing that each and every one of us has to deal with in connection with accident prevention in your establishments is not so much the machinery or the physical conditions under which laborers must perform their work, but it is the human element that you have to deal with. I said in my paper that you must not only have ideals that are high, but you must have the knowledge "how." You must know how to interest your fellows. You must know how to build up habits of favorable response.

I don't believe that in your industries you are lacking in knowledge how, mechanically or physically, to prevent the accidents. You know practically everything that you ought to know, in a physical way, to prevent injuries to your workmen; but you still have accidents. Why is this? Isn't it because the human element naturally enters into the situation?

You say to a foreman, "Here is a man who got hurt in your department. What have you done to prevent that?" He replies: "Well, I told him not to do the job in that way. I told him the right way in which to do it." And Mr. Foreman naturally thinks that he has gone as far as he can go. But he hasn't. As a foreman, it is as much his job to stop accidents, and the incidental costs that arise therefrom, as it is to keep up the production in his department.

Now, not all foremen are fully conscious of their obligation in accident prevention. The foreman is the key man of the situation. He has got, not only to show the men in his department how to work, how to work safely, but he must impress his personality upon those men who are working for him in such a way that they wouldn't dare to do the thing in the improper or in the unsafe way. And in so far as a foreman has an accident in his department, he fails.

Now I do not mean that he is culpable, or negligent, or anything like that, but he has this responsibility, whether or not he is conscious of it, whether or not he has fully accepted it. That responsibility is there, and if a man in his department is hurt, he has failed as a foreman. There is something lacking in him, and were I a foreman in a department in industry I would feel that I had failed if any one of my men was hurt, or if I were having a recurrence of accidents.

Doesn't every one of us here do something every day in a certain way because we know our superiors require us to do that thing in that certain way? Of course we do. Every day of my life I am doing things as best I know how, in the way that I am required to by my superiors. Why? Because they have impressed their personalities, spiritually, upon me. They have sold themselves to me. They have made me realize that this is the right way to do it, and they want me to do the thing in that way. And consequently, being good foremen, as they are, I do the thing in the right way.

Now that is the thing we have got to get over to the foremen, that unless they stop accidents, unless they get to those men who are working for them and show them the right way to do the thing, and keep them up to requirements in that respect, and not just throw the thing aside after once telling them—you can't expect to tell a man a thing once and expect him to know all about it. You must keep on telling him; and, gentlemen, in this paper, "The Origin of Accidents," by Mr. Heinrich, you get a new thought on accident prevention, a

new point of departure. You have got to be seeking out new ways of reaching down to the fellow in the ranks whom we want to save, and it is only by impressing ourselves first, as safety workers, and getting the message over to the foreman, the key man, backed up, of course, by the personal interest and personal participation of the man who pays the bills at the top—only in this way are we ever going to make accident prevention the high and the noble thing that it can be made.

It is not ignoble now, unquestionably, but it has higher things ahead of it, as soon as we get these thoughts thoroughly impressed upon our own minds and upon the minds of those who have charge of toilers in industry. I want to give these copies of "The Origin of Accidents," by H. W. Heinrich, assistant superintendent, Engineering and Inspection Division, The Travelers Insurance Co. Take them and read them as opportunity offers.

MR. SCHWARZE: Mr. Chairman, I'd like to come back on Mr. Cromwell's statement regarding the beam house. Do I understand you correctly, that you have your machines all satisfactorily guarded in the beam house, and that you have no other accidents besides cutting accidents?

MR. CROMWELL: We had only one other accident, as I recall, last year, where we were working extraordinary hides, and since then we have guarded the machines so that accident can't happen in any plant we have; and that was two men working on both sides of the machine. They threw the hide into the machine, and as they did so, the shank or the post hit the operating lever, and one of the operators broke his arm. That is the only accident I can recall in the beam house, at the present time, outside of cutting.

MR. SCHWARZE: How do you guard your pinching hazard on the top?

MR. CROMWELL: We haven't had any trouble on that at all.

MR. SCHWARZE: There is a danger of a man being caught as the feed roller turns inward.

MR. CROMWELL: No, there's not much chance of that. We have two bars in front of the machine, one located about that high (indicating), another that high (again indicating), so in case any man slips, or anything like that, he can put out his hand and catch himself.

MR. SCHWARZE: Doesn't that interfere with throwing in the hide?

MR. CROMWELL: No, this is located—I can't tell you the clearance on the top roll now, but it is enough so that the man couldn't get caught between the two of them, yet enough to protect the man from being hit, because he can probably put his arm against it and grab it.

There is another thing to watch in the beam house, which some foremen believe, and which some do not. We have bridges for all our men to stand on. By a "bridge" I mean a platform raised about six or eight inches off the floor, and these platforms are supposed to be covered with two-inch planking, and as a man works there he will naturally wear two holes in those planks—not holes, but depressions.

Now, some foremen insist upon replacing those planks immediately upon the wearing of the depression in the plank. Another foreman wouldn't allow you to replace any, because he says the depression gives a man a toe-hold, and more of a chance of regaining his former position if he does slip; whereas, if it were smooth, he probably would fall to the floor. There is a divided opinion on that. Every place I have been and seen these worn spots, I have made them replace them, because I think it is the right thing to do, but outside of that I do not know of any other hazard there.

MR. SCHWARZE: In connection with the bridges that you mentioned, we found it good practice to make them of cement.

ADJOURNMENT

October 3, 1928

WILLIAM CAMPBELL, Chairman**Safety Engineer, Graton & Knight Company, Worcester, Mass.**

The second session was called to order at nine forty-five o'clock by the chairman, W. Campbell (Graton & Knight Co., Worcester, Mass.).

CHAIRMAN CAMPBELL: The first on our program this morning, gentlemen, is "Routine in the Handling of an Injury Case," by A. B. Drummond, Industrial Relations Department, Wilson & Company, Chicago.

The Routine of Handling Injuries

By A. B. DRUMMOND**Industrial Relations Department, Wilson & Company, Chicago, Ill.**

As a matter of convenience and follow through, I am going to treat the subject assigned to me under three general headings—Safety, Medical, and Compensation.

Safety, in my estimation, is the Alpha and Omega in the routine of handling injuries. Constructive safety begins with the injury, as usually it discloses that something is wrong with men, methods or materials. By focusing attention on the causes, it gives us the experience necessary to carry on accident prevention with greater efficiency.

The natural and, at the same time, the imperative thing to do when an injury occurs, is to get the injured party into the hands of the medical department—for examination as to the extent of injury and determination as to proper treatment required; so that the necessary surgical care can be rendered and the healing process started without undue delay.

During the time of examination and treatment it is essential that the surgeon draw out from the injured person a full and complete first hand story of the accident and its causes. If a proper confidence in the medical department has been built up, this description could be secured easily and freely, and will form an accurate basis for further investigation as is deemed necessary. Careful attention should be paid to the physical conditions and characteristics of the patient with a view to making notations on any and all points that might have a bearing on future handling.

All this information should be written immediately on the surgeon's report (made in duplicate) one copy to be retained in the medical department for their file; the original being sent to the department handling compensation. It has been found desirable to have a printed form, to be filled in duplicate, notifying the department and a foreman's report covering the accident from his viewpoint. The duplicate copy, pinned to the original copy of surgeon's report which is sent to the compensation department, would seem to be a check against failure to return foreman's report promptly.

The foreman's report should stress two important points—"How did the accident occur?" and "What can be done to prevent a recurrence?"—together with other information that is deemed necessary and advisable.

The compensation department should check carefully on the surgeon's report and the foreman's report, noting all discrepancies, and make such further inquiries as are necessary to make the stories match and present a clear and complete picture of the facts.

Roughly speaking, injuries might be classed under three general headings: 1st, Those injuries which require only the original treatment and dressing (or subsequent dressings) and do not involve stoppage of work; 2nd, Those cases which

are returnable to work but can return to the medical department for treatment; 3rd, Those cases which require confinement to the home or hospital. The first two classes should be assigned a definite time to return for treatments and a record kept to check against failure to return as suggested. The third class should be followed through by the medical department for treatment as required. A progress report should be made out after each treatment, visit or dressing so that the compensation department is properly advised as to the situation in each individual case.

In cases where the recovery from the injury is delayed beyond the point where a full recovery can be normally expected, such additional tests and examinations should be made to positively determine that there are no contributing causes—other than the injury itself for failure to respond to the usual treatments indicated.

Somewhat the same procedure should be followed in those cases where it is suspected that malingering is delaying the recovery unnecessarily.

The compensation department—with these various reports before them, together with such personal investigations as may be required—should be able to handle those cases, which are of a partial permanent nature, or involve specific losses, or those compensable cases which are returnable to work after a period of treatment, with the proper knowledge of each situation. Usually, this should be a matter of simple computation.

The laws governing the payment of compensation to injured employees vary to a considerable extent in the different states. Some states make it necessary that hernias, for instance, be of such a nature as to cause stoppage of work completely and be due entirely to the work in which the injured person was engaged. Other states insist on the payment of compensation for this class of injury when the nature of the work may or may not have exaggerated or aggravated a previous existing condition.

Other causes under some state laws throw the entire burden upon the employees, while other states are more liberal in their interpretations. Each set of circumstances must be considered as a separate matter, as to what is or is not compensable, depending upon the laws of the state in which you are operating or in which state your employees may be when injured.

Working in conjunction with the medical and compensation departments, the safety department should check carefully on the records of injuries and causes and take such immediate action as may be possible to correct the accident producing causes.

It is recommended that a plant safety committee, composed of both supervisors and workers be organized, and to this body should be brought the composite record of injuries and causes. As a means of enlisting the active cooperation of the plant personnel and spreading the gospel of accident prevention this system has proven its worth.

Regular inspection trips should be planned for the committee and the results of each trip should be sent to the superintendent of the plant in order that a complete follow-up may be had. If your operations cover more than one plant, the accident records and accident prevention records should be compiled jointly, so that each location will have the advantage of the experience gathered.

Much more could be said as to the value of records and statistics in carrying on safety work and the information to be gained by careful checking through the accident reports which are constantly passing over our desks. But as the subject assigned to me was the "Routine of Handling Injuries" and it is my understanding that speakers to follow me will cover these points, I feel it would be unfair to those men who have spent time in preparing their talks to steal their thunder.

CHAIRMAN CAMPBELL: I think Mr. Drummond has brought out the handling of injuries very clearly, because we do just the same thing in Graton & Knight Com-

N. L. BRAINARD (Swift & Co., Chicago, Ill.): I have one question I'd like to ask at this time. We sometimes find cases, and I think others will have the same experience, where the doctor will, after the injured man has been examined, pass it as a no lost-time accident. In the doctor's opinion, the man should go back on the job; but occasionally a man will think otherwise, and he does not go back on the job. What is your procedure in such cases, Mr. Drummond, just for a matter of information.

MR. DRUMMOND: There isn't any set procedure, Mr. Brainard. I call to mind a case recently where a man claimed that he had a pain and was not able to return to work. The case was taken up before the Industrial Commission, and all the medical advice that we could possibly get, either from the standpoint of his own doctor or that of the Commission's doctor, or our own doctor, would show no apparent reason or cause for pain; but we couldn't disprove the fact that the man did have pain. He showed very clearly, by his actions and reactions that something was wrong, but nobody could say that there was a certain definite reason for this man suffering pain in his heel. Of course we all realize there are a number of bones in the heel. It may be that something was disjointed, which was not revealed by X-ray or any other test. But we paid on the case, because he claimed absolutely that he had pain, yet no doctor could show why he had pain.

There will be constant disagreement with your doctors. Some men will say that they are not able to go to work, and the doctors will say they are.

MR. BRAINARD: That is the type of case I had more in mind, particularly the type of compensations not involved for maybe three or four days, but they are a source of a good deal of—

MR. DRUMMOND: After an amputation, the doctor may decide the man is able to go to work. The man may claim the end of his finger is a little bit tender and he is unable to go back. It is a fact that has to be tested in each individual case.

MR. BRAINARD: I have in mind cases where a man has possibly been to the doctor's office to receive treatment, and is then told he can go back to the job and finish out the day, but he doesn't come back until the next day. I think such cases present a problem in the routine of handling; as far as the doctor's office record is concerned, that man has gone back to work.

MR. DRUMMOND: Well, of course there is also the other side of it, that we may return a man back to work with what would ordinarily be a simple scratch or cut, which may develop into a serious infection later, or a claim of pain due to an infection which would have to be proved or disproved. It has to be based on the facts in each case.

MR. BRAINARD: The method we follow is to check up those cases the next day.

MR. DRUMMOND: I believe I said, Mr. Brainard, that in those cases where the recovery is not during the time we could normally expect it, in cases of that sort such further tests and examinations as are necessary may be made to determine just what were the causes aside from the injury itself. That may even go as far as tests, or whatnot, to find out definitely just what the reason for the delay of recovery is.

MR. BRAINARD: It is largely a matter of detail or routine, but it has caused a good deal of controversy between the plant foremen and the doctor's office; for the reason that the plant foremen criticize the medical department for marking men "no lost time," and then the man does lose time. They do not seem to understand that the doctors are not infallible.

MR. DRUMMOND: Well, you have the first examination charts and your periodic examination charts, which, if the man has been in your employ some time, ought to be very helpful in figuring a man's reaction on each special case. Some fellows, of course, are free bleeders. Other fellows can almost have their hides taken off without bleeding. It is the same thing on nerve reaction. Some fellows can stand the gaff pretty well, while other fellows faint at a mere scratch. Some of them

are fellows you wouldn't expect to do that, husky chaps, and if they get a little scratch, they just topple over. On the other hand, you will find some little fellows, about four feet three, who stand up under an awful pain. I'm just drawing a picture from one extreme to the other. I don't know whether that answered you, Mr. Brainard. It is a different situation each time. I think that is a matter, largely, of the skill of the men in your medical department, backed up by periodic reports on examination which are made purely for rehabilitation purposes; and you can pretty definitely determine the situation if you have a picture of the man's background, physically and socially. You know about how he lives, and what his complaints have been prior to this time, and how he reacts to them. Some fellows, of course, will indicate straight through that they are going to be fellows difficult to handle under any situation, and yet they may have a class of skill that makes them desirable to employ, in spite of that.

FRED SCHWARZE (Pfister & Vogel Leather Co., Milwaukee, Wis.): How do you control your injured employee—an employee temporarily disabled? How do you control him from getting back to the foreman and going in on production work?

MR. DRUMMOND: You mean a man going back?

MR. SCHWARZE: Without being qualified to the foreman as being able to go back to work.

MR. DRUMMOND: The medical department decides when he should return.

MR. SCHWARZE: Yes, they make a written qualification, but in the meantime he loses control of that man.

MR. DRUMMOND: That absolutely passes to the hands of the medical department, and they, in cooperation with the production department, usually handle the matter of when the man should go back to work. In the case Mr. Brainard brings out, that doesn't quite fit in with that schedule.

I have seen cases where somebody has built up an enviable record for no lost-time accidents. I recall, about a year ago, being in a shop where they had built up a record of 429 days without a single lost-time accident; and I was really amazed that that thing was possible in the kind of work that these particular people were doing. When I was going through the shop I noticed a fellow with one arm bandaged heavily, sweeping the floor with a broom. Now that man, as a matter of fact, had three fingers amputated on one hand, but in order to keep the record going the foreman put the man back on the job. He was able to work with the broom in one hand, and it was not lost time. But by the time that was worked through the Compensation Department it was determined that it was lost time, although the record would mount to that point before it was discovered. When you build up a record of 429 days without a lost-time accident, you are going to be mighty jealous of it!

MR. SCHWARZE: Are you inclined to give the employee the benefit of the doubt when he maintains subjective symptoms—he claims a pain existing, and there is no proof of it?

MR. DRUMMOND: There is no set rule on that. It depends entirely on the man himself, his background, and things of that sort. In this particular case that we brought up before the Board, there was no medical authority to prove that that man had any reason for having pain, but they couldn't prove that he didn't have pain.

O. F. W. CROMWELL (United States Leather Co., Ridgway, Pa.): Mr. Drummond, don't you think it is a good plan, where you have a dispute, to pay another physician a couple of dollars more, or three dollars, to check up on both sides? I do that right along.

MR. DRUMMOND: I think I said that in cases of recovery beyond the point of normal recovery, such further examinations are made as are necessary in order to determine just what the causes are. I made that as a broad statement. In any cases of dispute, it is always well to back yourselves up with the best opinion that

you can get. While of course we feel that our medical department is as good as any medical department, in all our plants, yet we feel that we should have two, or three, or four, as the case may be, independent examinations and reports to back up their report. We are fortified a whole lot better. We don't stop at our medical department in cases of that sort. One opinion isn't worth very much; that is, in a case that involves some money. Mr. Schwarze was telling me about some cases he had to bring up in the supreme court, amounting to something like \$12,000, in which case it is money well spent, and of course we'd be prepared to do the same sort of thing.

CHAIRMAN CAMPBELL: Mr. Drummond, we had an accident in our place, where a man had a rib broken, so he said. The doctor took him to our own hospital and put the X-ray on him, but there was no rib broken. He belonged to five different societies. He had five other doctors to go to see, and all five would say that his rib was broken. We had to pay him the compensation, and he was out seven weeks.

MR. DRUMMOND: I recall a minor case similar to that. We recently paid on a case in dispute, backed up by the testimony of the man's own doctor, who had also certified him to three or four different organizations who paid weekly indemnities. About two or three weeks later we understood there was a case in the police court, where this fellow and the doctor had a fist fight over the disposition of the spoils.

DR. J. R. FRENCH (Golden State Hospital, Los Angeles, Calif.): Perhaps I can add something to Mr. Drummond's statement as to the class of case the gentleman mentioned, about the difference of opinion between the doctors and the patient. Sometimes the patient has an idea that he has pain. Now that idea is simulated for one of two purposes, either with the idea of gaining compensation from three or four societies, or a false interpretation of the existing symptoms. Now, we classify those cases into true malingerers and false malingerers. The false malingerer is the one that I just mentioned, that misinterprets existing symptoms. He may have pain in his heel, and he feels that if he uses that foot that he is doing himself a great bodily injury. That case is a difficult one to handle, and it can only be handled through the salesmanship of your physician.

Your physician has to be more than a physician. He has to be a salesman. He has got to sell that man the idea that he is able to return to work, and his being able to return to work is for his own good. The doctor who takes the stand of representing the company—or if the patient feels that the doctor is representing the company and is trying to get him back to work to save the company money—there is a certain amount of resistance developed in that man. That mental resistance is going to be present, and the more you examine him, the greater momentum your case is going to gain, because that man is going to stand up before the commission, and he develops a group of subjective symptoms that even the commission, or any one else, can't determine, and the commission takes the man's word for it, and you are penalized. Now that case, if handled in the beginning, and the man were sold the idea that he should return to work, for his own good—why you take some of the big cases, and they would amount to nothing if handled properly in the beginning.

Now, in the other type, where the man is attempting to get money under false pretenses; as a rule he is not difficult to handle, because, if you make an early investigation—there is one of the things the doctor can do for you. The doctor has to sign the reports for an application into these various organizations. Now, if the doctor will just bear in mind, instead of merely writing them out, and will just get right down into it and start his sales talk, he can terminate the disability. So it is really a matter of psychology. The doctor has to be more than a physician. He has to be a salesman and sell the man the idea that he is able to return to work, and complete his records accordingly. In that way, some of these cases, as I say, that start out innocently, do not grow into a great big snow ball.

MR. DRUMMOND: Mr. Chairman, again I will say that I really covered that. If the proper confidence has been built up in your medical department, so that the men recognize that the doctor is more than a physician, that he is really a friend—if you might call it that—he is sympathetic, or should be, that he is glad to see the fellow come into the office, not just because he is injured, but just on account of his personality; but his attitude should be, as you say, not that of a high-pressure salesman, but a sympathetic salesman—and if he can make the man understand that his entire purpose is not hurrying him back to the job, but one of complete rehabilitation, and let him understand that he is not dealing with anybody except a friend. Only in that way can a confidence be built up in the medical department, and if that degree of confidence has been built up, and all your other things covered, in the way of investigations and reports, up to the time they come before your Compensation Department, I say, again, that most of your compensation should be a matter of simple computation.

CHAIRMAN CAMPBELL: Any more questions to be asked?

MR. SCHWARZE: There's a question I'd like to ask Mr. Drummond, how he finds his organization being willing to take care of permanent or partially disabled employees, men who have suffered the loss of a hand or arm, or leg—some permanent injury of that kind. Do you have to make allowance in your production records for the inefficiencies of such a man, compared to a normal man?

Rehabilitation a Duty

MR. DRUMMOND: Well, a physician industrially can not be any different from what he was during the last war. As a matter of fact, the attitude of the physician was to rehabilitate and put the man back into fighting shape. As to those who were maimed, other arrangements had to be made. So it is industrially. If a man is injured to the point of no longer being able to perform the functions he performed before, it does not mean that he is entirely barred from employment, but such employment can be found for him as is in line with what he can still do. That is an unfortunate way of looking at it, but it is the fact. If a man is required to have his full faculties, all his arms, limbs, eyes, etc., on a particular job, that does not mean that we can't fit a man for some other job, not necessarily paying less money, but one requiring a different degree of skill. I remember that during the war we made a survey, anticipating a lot of loss of eyes in conjunction with the Red Cross organization. We figured, from the experience of previous wars, that there would be a lot more wrecks than did come back. We were fooled on that, and I'm glad we were. We found it was possible for a man with only one arm, no eyes, and no legs, to perform an operation in our plant. That thing was carefully rooted all the way through. There wasn't a single job that was not surveyed for the possibilities of putting handicapped men on the job. We still have that information, and we are using it. It seems almost impossible to believe that men without any eyes, no hearing, only one arm, and no legs, could perform an operation satisfactorily, but it can be done.

MR. SCHWARZE: In conjunction with that, the person would earn a living wage?

MR. DRUMMOND: Yes. Of course that would mean some additional assistance. The man would have to be placed on the job, but he could perform that function—necessarily on a chain operation, when the stuff would be brought to him.

MR. SCHWARZE: His production cost would not exceed that of a normal man?

MR. DRUMMOND: No.

CHAIRMAN CAMPBELL: Any more questions to be asked?

MR. DRUMMOND: I want to say that at the time the survey was made, it was also made on the basis of time study—just to cover your point, Mr. Schwarze.

Report of the Nominating Committee

CHAIRMAN CAMPBELL: I might add that the nominating committee is ready with its report:

The chairman of the nominating committee, Mr. McClellan, has appointed a full organization to serve for the incoming year:

Chairman, E. E. Drews, Libby, McNeill & Libby, Chicago, Ill.

Secretary, Herbert L. Clover, International Shoe Co., St. Louis, Mo.

Chairman Poster and Slide Committee, Fred Schwarze, Pfister & Vogel Leather Co., Milwaukee, Wis.

Chairman Membership Committee, Wm. Corey, Delaware Leather Co., Wilmington, Del.

Chairman Publicity Committee, Charles Boncholt, Hammond Standish & Co., Detroit, Mich.

Chairman Program Committee, S. R. Jensen, Armour & Company, Chicago, Ill.

Chairman Statistics Committee, Dean Money maker, International Shoe Co., St. Louis, Mo.

Executive Committee, The Officers and N. L. Brainard, Swift & Company, Chicago, Ill.; J. M. Eaton, Libby, McNeill & Libby, Chicago, Ill.

LOUIS BARR (Armour & Co., Kansas City, Kansas): I move that those committee nominations be accepted.

(The motion was seconded and carried.)

CHAIRMAN CAMPBELL: Well, these gentlemen are elected for the incoming year.

Now, the next thing on the program is "Accident Statistics—How to Compile and Use Them to Get Results," by E. Drews, safety engineer of Libby, McNeill & Libby.

Accident Statistics

By EDWARD DREWS

Safety Engineer, Libby, McNeill & Libby, Chicago

The first casualty in the history of mankind of which there is any record, appears to have taken place in early bible times, when Abel lost his life at the hands of his brother Cain.

We, as children at our mother's knee, have often heard this little story, also the story of Cain's reply. "Am I my brother's keeper," when the Lord questioned him as to the whereabouts of Abel.

In our impressionistic childish minds, we immediately decided that Cain was an onery sort of a cuss to feel that way about his own brother, and I believe, we still think so.

We are now grown up, yet as we look about in the hustle and bustle of our busy lives, we still see altogether too much of the spirit of "Am I my brother's keeper?"

The spirit of Libby, McNeill & Libby in regards to Safety is to always help and teach others, and this requires nothing more than team work and cooperation.

I believe it has been discussed on several occasions that it is not good policy to rely upon the foreman in putting safety over in their departments, and also that the reporting of accident statistics was not of much benefit.

I am going to try to give you a little outline of the manner in which we function with regard to Safety Work.

We are not by any means 100 per cent perfect, but our records show a marked

improvement each year. Considerable amount of Safety Work has been done by Libby, McNeill & Libby as far back as the organization of the National Safety Council, but it was not until the year of 1926 that a record of accidents was kept, listing them by departments. Also itemizing them as Minor, Major, Neglected, Infected Cases, Lost Time, and Causes.

Although we have been members of the National Safety Council almost since the time it was organized, and have held Safety Meetings regularly, there never had been a monthly report of accidents made to our foremen. It was somewhat of a surprise to many of our foremen when they received a copy of the first report in 1926, and naturally it created considerable thought.

A report is received daily in our safety department from our doctor's office, listing all accident cases handled. This report is segregated by departments, and a copy sent to each foreman, which gives him a record of the previous day's accidents that occurred in his department, and this report should agree with his records. The neglected and infected cases shown on this report are underlined in red. If a foreman finds a neglected or infected case on his report, he immediately calls the employee into his office and requests an explanation why he or she did not report to the doctor's office at the time of the accident.

All employees receive instructions at the time of hiring that they must report to the doctor's office every accident or near accident to themselves at once. If this is not complied with it means dismissal.

This system of compulsory reporting by each employee produces very good results in getting them to receive medical attention.

A comparative statement is made of all safety records for the previous month and the previous year. These reports are read at our regular safety first meetings.

Personal investigation is made of all serious cases, and I am subject to call day or night by our doctor's office. The foreman of the department in which the accident occurred is also called into the doctor's office so that a thorough understanding is arrived at as to how the accident occurred, and steps are taken so that there will not be a recurrence.

Every foreman, sub-foreman, and department head is held responsible for safety work in his department. He must give a satisfactory explanation on all accidents—equally as well as keeping his production up to standard.

I do not want to give the impression that we demand our foremen to do their duty in safety work. The interest that our foremen have in safety work is entirely voluntary and better results are obtained.

Our Chicago plant consists of thirty departments. The largest is our can factory, manufacturing lard pails and all our cans for canned meats.

Approximately 100,000,000 food containers were manufactured during the year 1927, using 27,500,000 pounds of tin plate. You can readily visualize the hazards connected with this one department. 70 per cent of our minor accidents are tin cuts.

The canning department is next in size—packing 75,000,000 cans of food products annually.

The Beef Cutting, Freezers, Curing Cellars, Labelling Rooms, Box Factory, Smoked Beef, Dried Beef, Extract, Shipping Departments, Mince Meat, and Mechanical Departments follow in size respectively.

The average number of employees for the year 1926 was 1692 persons, with a total of 4,712,026 working hours. During this period we had 12 permanent disability cases, and 174 temporary disability cases. Comparing these figures with the year 1927 which shows an average of 1632 persons and a total of 4,267,312 working hours. During this year we had six permanent disability cases, and 160 temporary disability cases. You will note there was a 50 per cent decrease in the permanent disability in the year 1927 over 1926. We believe the constant drive for safety guards protecting dangerous hazards has accomplished this decrease.

Major cases described as fractures, broken bones, severed tendons, dismemberment, hernia, etc., have also shown considerable decrease in the last three years. Our record shows for the year 1926-38, for 1927-31, and for the first eight months of 1928-11.

Reports of minor accidents are constantly increasing. This is due to the fact that we encourage our help to go to the doctor's office for immediate attention no matter how small the cut or bruise might be.

A complete record of lost time and the value of same in dollars and cents is kept. Lost time is where an employee who has been injured in any way loses one hour or more of his time while away from the factory.

Comparative figures for the last three years show

1926—196 employees lost 15,151½ hours equal to \$7,630.66

1927—168 employees lost 10,247 hours equal to \$5,063.22

And for the first eight months of 1928 we show 72 employees lost 6365½ hours, total value, \$3087.10.

As we have stated previously our total number of cases treated in the doctor's office have considerably increased, while the lost time in hours and dollars has shown a steady decline during the same period. This decrease is of great importance, not only to the employee, but also to the employer.

Reports covering neglected and infected cases for the last three years show

For 1926—520 neglected, and 218 infected

1927—506 neglected, and 190 infected

First 8 months of 1928—206 neglected, and 67 infected

This report also looks very favorable and we look for a substantial decrease during the year of 1928.

We do not conduct periodical campaigns or safety rallies. Our policy is a continuous, steady application practice in safety work, meeting once a month or oftener. Every one is encouraged to do at least one good turn in safety work each day.

In November 1926 we installed in our Chicago plant a system which we term "Self Inspection System." This is one of the most valuable forms of inspection. The department foreman in charge of each floor or department inspects this department and makes a personal report to his department superintendent, who in turn makes a written report to the Department of Safety. This makes for close cooperation between the safety department and the operating departments. Better results can be obtained from these inspections than by having one or two men cover the entire plant. It gives a better opportunity to keep in touch with all departments at one time.

Before we installed this "Self Inspection System" we found that the foreman and operatives were relying more and more on the work of the safety organization instead of applying safety to their own duties and gaining safety responsibilities therefrom.

Our Chicago plant conducts a Foremen's School. The foremen meet one day a week for one hour, after working hours. A general discussion is encouraged and suggestions are requested covering safety, insurance, sales, piece work, employment and general plant policies.

In conclusion, it is my belief that a reduction of accidents to employees, or loss of time through injury, can only be obtained through close cooperation by every individual.

CHAIRMAN CAMPBELL: Any questions to be asked of the speaker?

N. W. PIERCE (Raritan Copper Works, Perth Amboy, N. J.): My name is Pierce, from the Raritan Copper Works, Perth Amboy, New Jersey. I realize that our industry isn't parallel with the packers and tanners, but I believe that this accident prevention problem is common to all of us. I came in here particularly to hear this paper on "Accident Statistics and How to Compile Them." I read,

from time to time, or glance over, long periods of time without lost-time accidents, sometimes for two or three years, a firm employing several thousand men. We have about 1,000 employees in our plant, a comparatively small plant. We think we have a pretty effective safety organization, but we never have been able to go one calendar month without a lost-time accident.

It is true that certain departments in our plant have gone long periods of time. I have one department that has gone pretty nearly six years without a lost-time accident, but I am talking about the plant as a whole, and I am particularly interested in finding out what a lost-time accident is. We are using the National Safety Council method, but I heard, in one of the meetings yesterday, an interpretation that this meant until the man could be returned to work, no matter what the work was. Now we don't put a man on watching, nor give him a broom to push around the plant. We figure when he is able to return to the job on which he was injured that he has recovered, and we have to figure the time lost until he can return to that job. I'd be very interested in hearing what the experience of some of these other gentlemen is along that particular line.

CHAIRMAN CAMPBELL: There are a good many concerns, you know, that have different kinds of jobs to give a man when he is injured. In my own firm, if a man is working on a wet job and he gets the point of his finger torn off by the machine—the same as this gentleman said—if there is some grit in him and he doesn't want to lose any time, and he doesn't belong to the organizations which give him compensation, we take him in and give him something easy to do. Therefore we avoid the lost-time accident.

MR. DRUMMOND: I can realize absolutely what this gentleman is up against, for the simple reason that when a person is drawing up statistics he draws them up for a certain purpose, and unless we know how they are arrived at, sometimes they don't mean what we think they should. There is a variance, of course, in how people handicap themselves.

For instance, I was very much interested in what you said, that you considered a lost-time accident one in which the man did not return to the job on which he was working at the time of injury. How could that always be possible, depending upon the extent of injury? Further, take your Interstate Commission. They have set up a certain set of rules as regards what should be considered a lost-time accident, which is entirely different, I believe, from what most of you here figure on, so far as your own plants are concerned. Mr. Drews made a statement of what he considers a lost-time accident. In figuring ours up, we figure anything over the day on which the injury occurs. Mr. Drews said "over one hour." I think the Interstate Commission is three days—I may be wrong on that, but I think it is.

You can readily see that where we assess ourselves on anything over the day on which the accident occurred we'd be reporting lost-time accidents, and the railroad company would not be reporting any, with a three-day leeway. On the other hand, Mr. Drews is reporting everything over one hour. Statistics don't mean a thing unless you know who drew them up. I believe it is a shame we don't put them on the same basis. As it is, he feels as though he hasn't done a darned thing. I don't think you should feel that way. You should get back of the system used, and I think you'd be a good deal heartened when you got through. After all, none of us is really bad.

CHAIRMAN CAMPBELL: Any more questions to be asked?

MR. DRUMMOND: Just one thing, Mr. Chairman. We have found that, instead of calling people together for a common agreement in regard to an accident, as Mr. Drews mentioned in his paper, we get a separate report from each fellow, —and we get that in written form—and then we have our meeting afterward. Sometimes we find some discrepancies that might be ironed out in the discussion,

that show up on the reports, and the written report has a marked effect, especially when it comes to cases of treatment by your medical department before your industrial commission board. The spoken word doesn't hold up like a written record will, so we have gone absolutely on the written record. We want it down in black and white what the fellow thinks at the time. We don't want to give him a day or so to change the story.

MR. BRAINARD: Just one word on statistics. While they are very interesting as a matter of comparison, they are of no real value to us unless we use them as a measure of the progress we are making. If we simply make statistics that we have gone so many days with so many days lost per 1,000 days worked, or something of that kind, it means nothing unless they are made on a basis whereby they are a true measure of the progress we are making in accident prevention; and such statistics, I think, are of value; but unless we do, when we are making the statistics, as accident prevention people, make them for our own guidance, and not to make a record, they are absolutely of no value. We are simply kidding ourselves if we get up statistics and do not use them to show just what is occurring. The statistics which we use are made from the records of the casualty company, showing the type of injury which is causing the greater number of accidents at our plants—the type causing the greatest amount of compensation, and the number of days lost—and I will say that we have been somewhat surprised when we got the statistics kept in that manner.

For instance, one might think, in the packing business, that we are going to have the greater number of lost-time accidents as a result of knife cuts, counting days lost, and severity, etc., but our statistics show at the end of the year that we have a greater number of accidents as the result of handling objects—handling objects classified in three different ways; first, handling of heavy objects, strains due to hauling, lifting or handling; second, handling of sharp objects, that is, other than knives, etc., and third, the handling of hand trucks and carts, etc., which result in a greater number of accidents, even in the packing business, than we get from knife cuts. And the same is borne out by the statistics throughout. We find, by a careful analysis of that kind where the accidents are occurring, and what type of accidents are causing the greatest degree of disability, and to that extent, I think, our statistics are valuable, but as to showing that we can go so many days without a lost-time accident, we are simply kidding ourselves.

MR. SCHWARZE (Pfister & Vogel Leather Co., Milwaukee, Wis.): I'd love to ask Mr. Drews regarding compensating foremen for attendance at foremen's meetings after working hours. Do you pay them extra in addition to salary?

E. E. DREWS (Libby, McNeill & Libby, Chicago, Ill.): No, sir; we do not.

MR. BRAINARD: I presume the foremen are on steady time, anyway?

MR. DREWS: Most of them are. I might say that fifty per cent of our foremen attend such meetings on steady time.

MR. DRUMMOND: I think Mr. Schwarze is bringing out whether it wouldn't be better to have the meetings on company time, or the time that belongs to the man, regardless of steady time or not.

MR. SCHWARZE: Do you get 100 per cent attendance, Mr. Drews?

MR. DREWS: We have about 80 per cent attendance at our meetings, and possibly 10 per cent of the balance are probably at work and can't leave the jobs, probably working after the time that we call the meetings.

MR. SCHWARZE: Do you feel that 80 per cent represents the wholehearted cooperative spirit?

MR. DREWS: There are at least one or two persons from each department present, either the sub-foreman or regular foreman is present.

CHAIRMAN CAMPBELL: On their own time?

MR. DREWS: On their own time, yes, sir.

MR. DRUMMOND: Is that immediately after closing time?

MR. DREWS: About ten minutes after the whistle.

CHAIRMAN CAMPBELL: We have tried that, and had nobody there.

MR. DRUMMOND: It is just a question depending upon your organization. Personally, we feel that those meetings should be held on company time, and that is when we hold them.

MR. BRAINARD: Ours has been about 50-50. We start the meetings about thirty minutes prior to closing time, the meetings that we have been holding, partly of plant foremen and partly of what we call the safety men in the organization, but we have been able to stimulate the meeting by a good moving picture for the first fifteen minutes. Some of those pictures have been safety films, pertaining, some of them, to the National Safety Council—not particularly in relation to our business, there are none that I know of—but they are of a general nature, and they are very good, and some which are educational films, but they stimulate the interest, we have found.

CHAIRMAN CAMPBELL: We have had good results for three or four months by having the meeting at noon time, for instance, while the men were having their lunch the safety talk was going on, and we had very good results from that.

MR. DRUMMOND: That is possible only where you have one general eating place. A meal is a wonderful stimulant.

O. F. W. CROMWELL (United States Leather Co., Ridgway, Pa.): How much of a lunch hour do you have?

MR. BRAINARD: We have thirty minutes.

MR. CROMWELL: If you have an hour, you can start in about twenty minutes to one and have the meeting last until half past one, for best results.

MR. BRAINARD: We are able to hold, sometimes, a short inspirational meeting, but it must be short.

MR. DRUMMOND: And you must confine it to one particular subject.

CHAIRMAN CAMPBELL: Any further questions to be asked on this subject?

Now the next on the program is "Anticipating Hazards," by N. L. Brainard, Director, Social Service Department, Swift & Co., Chicago, Ill.

Anticipating Hazards

By N. L. BRAINARD

Director, Social Service Department, Swift & Co., Chicago, Ill.

I have been asked to talk on a phase of accident prevention under the title, "Anticipating Hazards." The committee has added an explanatory clause, "A review of methods of making sure that accidents that have never happened will not happen," which may sound inconsistent. The thought is that conditions sometimes exist which are the setting for a bad accident and that this latent peril should be properly dealt with by prior action and the unforeseen mishap prevented.

This is nothing more nor less than "accident prevention." There are, however, hazards which should be anticipated in the sense that they should be foreseen or forestalled. Special reference is had to placing the responsibility for hunting out hidden and obscure conditions and finding the corrective measures before the accident has occurred, or seeing a risk which may be in plain sight and has never been recognized because it has not been seen from the right viewpoint.

Avoidance of the unseen danger and escape from such unforeseen accidents or disasters comes more by discovery than by protective measures and a review of methods can do no more than suggest some general lines of action. Many of the accidents which should never happen are unusual, something of a nature which

has not occurred before and may never occur again. The danger which exists is not likely to come to light in a routine check up by the plant safety committee or safety supervisor. The greatest menace in such hazards comes from the tendency to take things for granted. It is difficult to meet and overcome the argument that the thing has been done for years without an accident. The fact that accidents which have never happened do happen means that we cannot permit the old to prevail simply because of long usage.

Hiring and Adaptation

Investigation of an accident or an occurrence which might have resulted in a disaster may disclose that a mistake has been made in the placing of men. One of the means of anticipating a casualty, then, is that the employment office give consideration to the fitness of the man for the job. The employment offered must be in accordance with the capacity of the man. There are jobs which require men of particular aptitude; the right man for the right place.

Instructing New Men

Experience shows that a large percentage of lost time accidents and resulting costs results from accidents in occupations and operations not ordinarily considered hazardous, yet owing to lack of instruction, the workman did not know how to do the job safely; and this also means efficiently. It must not be taken for granted by the superintendent or foreman that a man hired for a common job needs little or no instruction other than to keep moving. The instructions should be competent and sufficiently cover the nature of the work and how it is to be performed. It is important to teach employees safe methods of loading and unloading, piling or taking down piled material, and any common hazards of the job.

A man may be hired who says he is a butcher. The man who hires him don't know just how much of a butcher he is, and in sizing him up the way he does his work with reference to safety should be given first consideration. The foreman knows the ways in which an employee may get hurt and should teach safety personally to the new man.

Cautioning Men

The time to discipline a man should be determined by the circumstances. A workman is not always hurt the first time he makes a misstep, but there is some question as to how far we should go before we resort to severe discipline. If he has been instructed in the beginning and doesn't go according to instructions, it is possible he did not understand them. He should again be cautioned and if he still disregards the warning, he should be penalized.

Some foremen do not think of safety as regards men, their concern is for the material and machines used. When told that the company wants safety on the job, he shows his idea of safety by spiking a scaffold so hard that it is necessary to destroy the material in order to dismantle the scaffold. The foreman should take the new worker in hand and in a friendly way, without letting him forget who is boss, train him to work safely.

Introducing New Methods

A great deal of work is more or less routine and is done in a matter of fact sort of way. In such operations a workman has his mind pretty well made up as to how he is going to proceed on a job. If a suggestion looking toward safety in any way changes this routine, it is likely to be received indifferently, if at all, unless there is an appeal to the practical side of the employee. It is always best to

get his cooperation by such an appeal than to say, "Thou shalt," or "Thou shalt not."

When introducing new methods or processes the safety element should not be overlooked. It is not always apparent what the hazards are until the accident occurs.

It is not always possible to convince superintendents, foremen, or workmen that there is danger in a particular operation until an accident has occurred. Unfortunately we do not always get such hazards guarded or preventive means taken until we accumulate some costly experience.

Lay Out

The matter of lay out is important. Frequently new machines or new processes involving change in location of equipment are made in old buildings. Such changes are made with a view to improvement from a production or a cost standpoint. As a result the safety factor is not given full consideration in the lay out. Work may be carried on under cramped conditions. Congestion will result and where there is congestion, there will be an accident.

Temporary Hook Ups

Temporary hook ups should have the special attention of the engineering department and safety supervisor. Some of the most serious hazards may be produced here. Included in this category are portable electric fixtures which are plugged into sockets on the wall; and rigging a job, where material is lifted by crane—the lashing of a load. Machinery is sometimes placed temporarily and later complete and permanent installation is made. The responsibility for being positively sure that temporary hook ups are not hazards must be lodged with some one thoroughly competent and dependable.

Near Accidents

There are many near accidents that almost result in personal injury and which should admonish us. If we have a number of minor accidents, not lost time accidents, but near accidents which might have resulted seriously, we are going to have personal injury accidents that will be serious. Grave consideration should be given to near accidents to learn what warning there may be in them or what possibility of a bad casualty. When there has been a bad accident, it is often found there has been a counterpart in a near accident, which if analyzed would have given a clue to a more serious occurrence.

Frequently after an accident has happened, it is said, "I knew it was going to happen because so and so was doing such and such." It is just as important to make a "preventive investigation" and place the responsibility for a near accident as it is to go into the causes of an accident which has resulted in personal injury. The possible cause of an accident should be located without the accident happening first and having the responsibility fixed. Accident investigations should deal with those near accidents that discover bad practices as a preventive measure and instructions given for their correction.

When an accident has occurred with a serious injury or a fatality resulting, we are greatly moved and an investigation is made to determine what the conditions or practices were that led up to the mishap. There are also accidents sometimes where there is an escape from death or serious injury which border on the miraculous.

For instance, the clothing of an employee working around an ice crusher caught in a revolving shaft and there was the beginning of what is usually a shocking fatality. The man realized his danger in a flash and caught hold of a cross timber

which was so placed that he could brace himself and hold on firmly. He was a powerful man and was able to save himself from being wrapped around the shaft. All his clothing was stripped from him and he was taken to the doctor's office in an overcoat belonging to another man. The only injuries were superficial abrasions of his back, arms, and hips. His nerves were badly shaken but he was at work the next day.

We should be warned by an occurrence of this kind to as great a degree as we are when the outcome is not so fortunate, so that action will be taken to guard against a recurrence at this particular place and a check made to make sure that similar conditions or practices do not obtain elsewhere.

Horse Play

There is another practice which should be most emphatically condemned and that is horse play which is more or less frequently the cause of a serious accident. The responsibility can usually be placed on several men, and if those men after having been given a fair chance to stop the practice do not heed the warning, they should be dismissed.

Machine Accidents

Accidents arising in connection with the operation of machinery average of greater severity than those due to other causes. For this reason machine hazards should receive a liberal share of attention. The biggest problem is education with reference to hazards wherever we may find them and putting into practice what has been learned. Accidents are not the fault of the machine but the result of poor practice.

It is probably more difficult to inspect safety equipment made for special purposes than it is on equipment which is standard and common to all such as buildings, elevators, and boilers. There are such things, however, as belts running so that they jump off the pulley, gear teeth becoming worn so that there is a possibility of breakage and so on. These are apt to be inspected rather casually by some mechanic. It pays from a financial and a safety standpoint to have them looked after by some one thoroughly competent who would do the job regularly.

Forewarned is forearmed and every plant should be given the experience of all the others. The warning from such occurrences should not go unheeded. We get out letters concerning unusual accidents of the kind we are considering here, those that have never happened. Some of these are of a nature that might occur anywhere and they teach a lesson that is very general: that is that we should study and analyze every accident, as each one has its individual lesson. And this is true no matter how similar they are to something which has occurred.

Each packing plant uses machines and carries on operations which are common to all, and they have similar hazards. Both the packing and tanning businesses have hazards that are common to all industries. Whether they exist or not may never be known until you have an accident. When we hear of an accident which has occurred at another plant, we may pick up something concerning a risk that exists unknown in our own plant. Sometimes we have to learn by experience to go ahead in accident prevention work, but we try to avoid the necessity of having an accident if we can profit by the experience of another.

The following are from letters which have been sent out as warnings and are presented here not only as illustrating hazards that we should anticipate but they carry suggestions of value to the others:

These instances that I cite may suggest a bad accident record, but the incidents are taken from records covering quite a period of years, involving over twenty-five packing plants.

"A young man employed as a clerk met with an accident by falling into the hot water tank in an ice manufacturing plant. He had a ten o'clock start and was not employed at the ice plant but went there seeking another employee whom he desired to see.

"This man wore glasses and the morning was damp and chilly and the room was full of steam and vapor. No doubt this had something to do with his walking into the tank. He inquired of a workman who directed him to the part of the building where the man he wanted was pulling ice. He started in that direction but seemed to lose his bearings in the heavy steam in the room and turned slightly to the left, stepping into the hot water tank where the ice cans are dipped to remove the ice.

"There is a safety device over the hot water tanks but the particular device was not working. The young man was painfully scalded and was taken to a hospital where throughout the day he seemed to be getting along well, but in the night he became worse and in the morning was in a very critical condition. He died at four o'clock that afternoon."

Safety Tags for Use of Mechanics

"A machinist with his helper were repairing belts close to the ceiling in the Hog Killing Department, directly over the hog scraper. The helper was standing on a rod that is part of the hog scraper. The machinist left him, and as he walked out of the department, another workman saw him and took it for granted that he was through with the job.

"It was this workman's duty to test the hog killing machinery to see that it was in order for the day. He turned on the power, causing the rod the machinist helper was standing on to move, carrying him along for a considerable distance, throwing him against the framework of the machine, severely injuring him across the abdomen.

"The investigation showed that the starting switch controlling this machinery had not been tagged by the machinist before starting to make the repairs, and it is this feature of the incident that we wish to call to your attention. It suggests the need of checking up on the use of these tags occasionally, and we believe it would be well for your Safety Inspector or Safety Committee to report on this at regular intervals."

Elevator Accidents

"The operation of elevators presents one of the most serious hazards we have to meet. Even when the elevator is properly built and all parts adequately guarded, a large number of accidents, many of them fatal, occur on elevators as a result of careless operation. Nearly all elevator accidents could be easily prevented.

"In a fatal accident which occurred at one of our plants, the regular operator left his elevator, leaving the door open. While he was gone a trucker stepped on to the elevator with his truck. Then a checker came on and, the elevator man not responding to the bell, the checker attempted to run the elevator but was unable to do so. Another dock laborer, who was passing, stepped on to the elevator, turned on the switch, and the elevator immediately started up. The trucker became excited, attempted to jump off, and was caught between the floor of the elevator and the top edge of the shaft opening.

"This is a striking example of what can happen when the rules governing the operation of elevators are violated. This was brought to the attention of the mechanical force, as well as foreman, safety supervisor, and safety committee."

"A fatal accident occurred at one of our plants in which an employee was crushed while passing between two cars.

"A string of cars had been placed upon a switch track with an opening of about

four feet left between the cars at one point. While the deceased and a companion were carrying provision racks from another track to the wash room, passing through this opening between the cars, a switching crew came in to move some of the cars. It had not been the practice to place track flags at the end of the cars on either track. Just as the coupling was made the victim of the accident was passing through the opening and was caught between the couplers.

"This was brought to the attention of foremen, the Safety Committee, and safety supervisor, who were impressed with the need of taking every possible precaution, particularly with reference to passing between, over, or under cars. Each manager was asked to look into the practice at his plant with reference to placing flags so that switching crews would know when employees are working in or around cars or passing between them, making it necessary to remove the flag before coupling on to cars."

Insecure Scaffolding

A millwright with the assistance of other employees of the gang, was raising a 12 inch eye-beam up into place. Not being able to lift the beam without some additional scaffolding, a truck was used for the men to stand on. While lifting the beam the truck slipped with the result the injured man was thrown to the floor and the eye beam came down crushing one arm, necessitating amputation at the elbow. A permanent stable piece of scaffolding should have been used in raising the eye beam.

Fatal Accident Resulting from Infected Wound

An accidental death was reported as the result of a neglected wound. The case is a striking example of the risk there is in failing to secure prompt and adequate care for a seemingly insignificant wound. The occurrence seems to have been quite commonplace; something of a nature that *might* occur anywhere.

A workman ran a piece of bone from frozen meat into his thumb. The accident occurred about 4:00 p. m., and had he gone immediately to the plant nurse, he could have received attention at once. Instead he delayed until after changing his clothes to go home. The doctor's office was then closed and the wound did not receive medical attention until the next day. Infection had set in and the blood poisoning had progressed so far that death resulted five days later.

Tractor Accident

Disregard for standing instructions and a foreman's indifference toward safety precautions recently resulted in a serious accident.

The driver of a gasoline tractor started his machine, at the same time making a left turn. As the tractor man made this start another employee jumped on the tractor to ride allowing his foot to hang over the side. In making the turn this man's foot was crushed between the tractor and a wooden retaining wall. It was necessary to amputate the injured foot.

Investigation showed that both men were familiar with the instructions about men not riding on tractors. There was a rush of work at the time, however, and the driver was intent on handling the orders and did not pay attention to the other workmen or observe the usual precautions.

Summing up, we must study the accident experience and hazards at our own plants as well as similar information from every available source. The information and the facilities for its application must be made available to plant managers, superintendents, foremen, safety supervisors, and Safety Committee. The individual workman must be properly placed and properly educated, as well as being provided with safeguards, safe working conditions and methods.

FRED SCHWARZE (Pfister & Vogel Leather Co., Milwaukee, Wis.): I'd like to ask Mr. Brainard what the general disciplinary methods are for the violation of safety rules.

MR. BRAINARD: The degree of discipline should be determined, somewhat, by the circumstances.

MR. SCHWARZE: How do you dispose of the cases? Do you have a trial board?

MR. BRAINARD: We don't have a trial board. We have a safety committee, which operates, probably, in a good many respects, the same as a trial board. They make an investigation and determine the circumstances, and if disciplinary measures are necessary, they make a recommendation to that effect. But as I said in the beginning, the first thing to check up, I think, is whether or not the man was properly instructed. Sometimes it is pure carelessness, but if it occurs more than once there is only one thing to do, and that is to get rid of the man. These accidents that I have recited, I think the record will indicate that almost all of them were due to carelessness, not due to lack of safeguards, nor due to lack of instructions. You get right down to the biggest problem of all in accident prevention, and that is education, instilling in the man habits of careful working.

A. B. DRUMMOND (Wilson & Co., Chicago, Ill.): Mr. Chairman, Mr. Brainard brought out, in a way, the thing I tried to stress in my own report, and that is the value of reports. For instance, I can remember a case where a man had been sweeping up a floor under a large generator. The generator pit was about eighteen feet deep. In pushing the broom, or, rather, pulling it backwards, he went down at a spot not properly protected by a rail. Why he wasn't killed, I don't know. He should have been, under the circumstances, but when he went to the doctor's office all he had were some superficial bruises. His clothing was torn a bit, but he returned to work after treatment. Now, if your reports are not filled out completely, that sort of thing is lost sight of. You will probably have a report from the doctor that there was a superficial wound on the dorsal tendon or the muscles of the right hand—the dorsal muscles and deltoids might have been ripped—but the man returned to work. The doctor's report, however, should bring out the full detailed story of how that thing happened. It is quite possible that the foreman will not be in touch with the situation personally, and it may seem a bit out of order to say that when you send this printed slip to the foreman, notifying him, that you are taking a step that should not be taken, but it is possible that he does not know that that accident has happened. It draws it to his attention, and he makes out his report.

Now, in so far as compensation goes, the man may be returned to work. It may take two or three treatments to put him into shape. But following through on your reports, and getting it down in black and white, absolutely makes the stories jibe, so everybody understands exactly how it happened, and you can follow straight through, as in Mr. Brainard's paper on "Anticipating Hazards," which you could not do if you had only the surgeon's report of what the extent of the injury was, not the story of how it happened. I think that by focusing your attention on the reports being completely filled out, by the time the people concerned get them, they know just the situation in each case.

DR. J. R. FRENCH (Golden State Hospital, Los Angeles, Cal.): I'd like to make one suggestion relative to the foremen's reports, which perhaps would help them out a great deal. I don't think that the foremen are properly instructed relative to making out reports. The foremen are very apt to take the man's statement of what occurred, and, as I mentioned to you a few moments ago, lots of times some little insignificant thing will work itself up to a great big case, that you have a hard time settling. What I mean is this: A case was called to my attention, the other day, where a foreman's report came in about a man who was lifting and strained his wrist. Now this was purely subjective. The man went to the foreman and told him he was lifting, and strained his wrist. When he got to

the doctor's office, careful investigation revealed the fact that the lifting he was doing was nothing more than what had been taking place every day. It was no accident, but he noticed pain when he was lifting. Now, on a careful examination, it was determined that that man was suffering from an acute arthritis, probably, in this particular instance, of a specific origin.

Now that was a case in which his employment was not responsible for his disability. In other words, his disability did not arise out of the course of his employment, but his employment was the occasion of his disability, the cause of which was independent of his employment. Now that can very easily slip in unless your doctor catches it and works it out, but I think a great deal can be done by training the foremen, in making out their reports, not to take the man's statement for everything that exists, but to investigate and put down the facts.

MR. DRUMMOND: We have found that usually the story that is given, if the doctor has been properly sympathetic and built up the confidence in his employees that he should have, we usually find that the statement of the man at the time of the injury is mighty accurate. Now there may be cases such as you called to mind, of an arthritis condition, called to the man's attention by some strain in the course of his work, but the cause itself not being due to the employment. Ordinarily, however, the condition will be revealed by the medical report. I was merely following through on the basis of the value of those reports from the standpoint of disclosing, or, rather, anticipating hazards, and rather than just merely taking a report that would cover the medical side of it, with nothing on there to indicate just what had happened; that is what you would get if your doctor were merely filling out a report from the medical standpoint alone. But where they have been trained to get the story, and get it on a friendly basis, we have found that usually they are mighty accurate, much more close to the real causes of the injury than the foreman's report would be, because he has a lot of jobs. He is pushed for production, and the problem of how many men he is going to need tomorrow, and how many next week—pushed mighty hard.

DR. FRENCH: The point I was making is that many times the man believes that he strained his wrist. He is not falsifying. He believes that he strained his wrist then and there, but you have to get into it very carefully to determine that he did not.

MR. DRUMMOND: You have a multiplicity of reports. You have one from the medical department, one from the foreman, and the two, of course, have to jibe.

DR. FRENCH: The point I was making is that the foreman many times just writes out his report that the man strained himself. The foreman should take a little more pains.

MR. DRUMMOND: Oh, there's no question as to that.

DR. FRENCH: And give the facts. I am referring particularly to a case where a man was lifting a quarter of beef. It was no accident, but he noticed pain when lifting that quarter of beef. The foreman reported that he strained his back, which was not the case. Now, the mere fact of going before your Industrial Board with a report from the foreman that the man did strain his back sometimes causes lots of trouble.

MR. DRUMMOND: Of course that is a matter for our trial board. Those matters are pushed in that.

MR. BRAINARD: Such reports are only taken on their face value. The foreman sometimes lacks ability to express himself. He doesn't know. The common expression for him is to say that the man sprained his back, and probably nine out of ten would say "strained his back." He does not know how or why, but that is the easy way for him to describe the incident. We can not give very much value to the foreman's report. I think the foreman should inform himself on conditions, and after the investigation has been made and it has been determined, then the foreman might be informed for his future guidance; but as far

as giving any too much weight to the foreman's report, it can not be done, because he is not in a position to say. He may report as to physical conditions which brought about the accident, but as to the nature of the accident or the injury itself, he can't say.

MR. SCHWARZE: Mr. Chairman, we answered that situation. To allow ourselves an opening, we use the word "claim." "The foreman claims," "the man claims." We don't definitely accept the statement. We set it up as a claim, merely as a statement, but not as a fact.

MR. BRAINARD: We say "the man says so-and-so."

MR. DRUMMOND: That is the way our report is drawn up, excepting in two questions. One is, "How did the accident occur?" and most of them say it was not an accident. The other question is, "What can we do to prevent a recurrence?" When this thing has been going on for fifteen or twenty years, with apparently no rest, you will find that most of us are inclined to put our best foot forward. Most of those figures are a post-mortem or an alibi, because they know they are going to be held responsible for conditions. In that case, they back up anything the medical departments say. Those are two vital questions on the foreman's report.

MR. SCHWARZE: We find out in qualified diagnosis that the investigation will either prove or disprove that particular claim, and we feel it is our first duty to try to assist the employee in proving his claim. If he can't prove it, it is naturally disproved.

MR. BRAINARD: I think that there you stated something. We should not take an antagonistic attitude toward the man who has the injury. In our company it is one of the duties of the Welfare Department to act according to the claim. We are there to represent the man, primarily, to look out for his interests, and to see that he gets all that is coming to him, not only in the way of compensation, but other things. We have some rather stiff battles, once in a while, to see that the man himself is properly represented. We have what is known in these plants as "Plant Conference Boards," with employees' representation, and where those organizations are functioning, as they are pretty generally, a man is pretty sure to have his case very thoroughly aired, and all of those facts brought out. Those cases, even in cases of personal injury, accidents and disability cases, are brought into the assembly, plant assembly, and the whole committee of workmen review them and pass on them.

MR. DRUMMOND: I think perhaps we have been misunderstood from the standpoint of what angle we are handling these claims. We are handling this matter from the standpoint of the safety in connection with it, and not the cost of the compensation. After all is said and done, compensation is really the small part of the economic loss of an accident occurrence. I have in mind the case, some years back, where the general manager's office was facing out on a large yard where the men came in and went out from work. A man had his leg broken, and I know, absolutely, that there were 300 people there around that man, who lingered on the ground for a half an hour apiece. You can imagine what that cost in time, from stoppage of work, and all the other things that mount up. Those are the hidden losses that we really do not anticipate, and our whole attitude is to eliminate those losses and at the same time not lose sight of the fact that the man shall get something he is entitled to. I'd like to get that clear. Our discussion is not a matter of holding down the compensation.

CHAIRMAN CAMPBELL: Mr. Drummond, a man came to our hospital limping, with a stick. He could hardly walk. The doctor happened to be in, and put him on the table. The cords of his hip were all out of order. They were all jumbled together. He claimed that coming up the stairs he had slipped. The doctor said, "That is too bad. We'll have to take you to the hospital." They got an ambulance

and sent him to the hospital. He was in there about three weeks. It was more serious than the doctor thought it was. By and by, a couple of fellows came in and told the doctor he had been playing baseball, while he had said he had done it on the stairs coming in. But we had to pay the compensation, just the same.

MR. SCHWARZE: Mr. Drummond brought out a point as regarding the attitude of the personnel men, or the medical men, in safeguarding the injured employee's interests. I think the matter of time lost, departmental or plant standing in the campaign, be it what it may, from the standpoint of a measuring-stick basis, is the last thing considered. If that is the first thing considered after an accident, forget about it. I think it is a matter of cause, effect, and remedy—remedy first. Our policy is this, that any physician, or surgeon, or group of medical men, that are placed at the disposal of an injured employee, shall treat him the same, as a private patient, and absolutely lose sight of the business connection. In that way we shall reduce the eventual disability period, and we shall cultivate a better feeling, cultivate the confidence, and the mere facts will be very easily determined. Now, no matter how serious a case is, if it is regular—by that I mean that the facts are right before you, and there are no altercations, no disputes—you can settle for a case of permanent disability which may run into \$40,000.

But when you don't have the facts, as in the case that Mr. Campbell brought out, of a man coming in and alleging an accident—we have had a good many of those minor accidents, those Monday morning accidents, those "day after" accidents, reporting at eight o'clock the following morning that a cinder or foreign object got into the eye the day before, and the man felt that first aid was not available on account of the lateness of the day—those cases, though trifling in their origin, may lead to major cases. How are you handicapped, and what do you do to control those delinquent notices?

MR. DRUMMOND: I think, Mr. Schwarze, you answered that question a short while back, when you said that all the claims put forward are a question, first of proof, and then of disproof. In other words, if a man had claimed an accident while in the employ of the company, unless he was working in an isolated location, all by himself, it ought to be either possible to substantiate the claim by some one who knew of it, or saw it, or disprove it on the same basis.

MR. SCHWARZE: I have in mind a case where no witnesses are available, yet it borders on probability and possibly on fact, that the man received a foreign object into his eye at that particular time and place, and that he was there at that time and place. The fact is that he may have received that during the week-end, away from work.

MR. DRUMMOND: Well, as Mr. Brainard said, those are cases which must be handled depending upon the situation surrounding each case. Now I have in mind one case where a man claimed he had received an injury as a result of stepping into a hole. He did step into the hole, but after we had taken the man to the hospital, we found his automobile standing outside of the employees' gate, and in that automobile was a chain fall. He had received the injury, all right, in stepping into a hole, but he had been taking a chain fall out of the plant, to use for his own purpose, or not to return it—I am not sure which—but the disclosing evidence was revealed in the chain fall that lay in his automobile after he was taken to the hospital. The hole he stepped into was outside the gate.

Summing it all up, I think first an endeavor should be made to prove the man's claim, and if that can't be done, the reverse is true. There isn't any routine that could be set up for that, because each one of those things is revealed in a different way. Sometimes it is just a matter of hunch.

O. F. W. CROMWELL (United States Leather Co., Ridgway, Pa.): A thorough investigation should bring out all the facts in connection with the accident.

ADJOURNMENT

SEVENTEENTH ANNUAL SAFETY CONGRESS
NATIONAL SAFETY COUNCIL

Paper and Pulp Section

New Section Officers

General Chairman—KENNETH L. FAIST, Champion Coated Paper Company, Hamilton, Ohio.

Secretary—D. D. THIRKIELD, The Sorg-Oglesby-Smith Paper Company, Middletown, Ohio.

Vice-Chairman for Canada—A. P. COSTIGANE, Ontario Pulp and Paper Makers' Safety Association, Toronto, Ont., Canada.

Vice-Chairman for South—G. W. PHILLIPS, The Champion Fibre Company, Canton, N. C.

Vice-Chairman for Extreme South—W. G. JENNINGS, Bogalusa Paper Company, Inc., Bogalusa, La.

Vice-Chairman for Middle West—M. G. HOYMAN, Kimberly-Clark Company, Neenah, Wis.

Vice-Chairman for East—N. F. BARTLETT, Hollingsworth and Vose Company, Boston, Mass.

Vice-Chairman for Paper Box Manufacturers—H. C. SACKETT, Alton Box Board and Paper Company, Alton, Ill.

News Letter Editor—W. J. PEACOCK, Northern Paper Mills, Green Bay, Wis.

Engineering Representative—R. M. ALTMAN, Marathon Paper Mills Company, Rothschild, Wis.

Regional Directors:

Maine—ALVIN RECORD, International Paper Company, Chisholm, Maine.

Massachusetts—A. S. WILSON, American Writing Paper Company, Holyoke, Mass.

Michigan—C. E. TORRANCE, Bryant Paper Co., Kalamazoo, Mich.

New Hampshire—J. J. TELLINGTON, Brown Company, Berlin, N. H.

New York—SAMUEL PRUYN, Finch, Pruyn and Company, Inc., Glens Falls, N. Y.

Ohio—ERNEST AUGUSTUS, The Mead Pulp and Paper Company, Chillicothe, Ohio.

Pennsylvania—EMILIE I. RAUB, Dill and Collins Company, Philadelphia, Pa.

Wisconsin Valley—F. H. ROSEBUSH, Nekoosa-Edwards Paper Co., Port Edwards, Wis.

Fox River Valley—W. F. ASHE, Thilmany Pulp and Paper Company, Kaukauna, Wis.

Poster and Slide Committee Chairman—AMEIL UMBERHAM, Fort Howard Paper Company, Green Bay, Wis.

Membership and Publicity Committee Chairman—EARL E. GRANT, The Crystal Tissue Company, Middletown, Ohio.

Contest Committee Chairman—A. SCOTT DOWD, "The Paper Industry," Chicago, Ill.
Health Research Committee Chairman—J. J. PLYZAK, Consolidated Water Power and Paper Company, Wisconsin Rapids, Wis.

Retiring Officers

Chairman, W. J. PEACOCK, Northern Paper Mills, Green Bay, Wis.; **Secretary**, N. H. BERGSTROM, Bergstrom Paper Company, Neenah, Wis.; **Vice-Chairman for Canada**, A. P. COSTIGANE, Ontario Pulp and Paper Makers' Safety Association, Toronto, Ont., Canada; **Vice-Chairman for South**, G. W. PHILLIPS, The Champion Fibre Company, Canton, N. C.; **Vice-Chairman for Middle West**, M. G. HOTMAN, Kimberly-Clark Company, Neenah, Wis.; **Vice-Chairman for East**, W. A. GLEASON, Hammermill Paper Company, Erie, Pa.; **Vice-Chairman for Paper Box Manufacturers**, H. C. SACKETT, Alton Box Board and Paper Company, Alton, Ill.; **Engineering Representative**, R. M. ALTMAN, Marathon Paper Mills Company, Rothschild, Wis.; **Poster Committee Chairman**, AMEL UMBERHAM, Fort Howard Paper Company, Green Bay, Wis.; **Membership Committee Chairman**, J. H. SLATER, Escanaba Paper Company, Escanaba, Mich.; **Publicity Committee Chairman**, D. D. TURNKIELD, Sorg-Oglesby-Smith Paper Company, Middletown, Ohio; **Statistics Committee Chairman**, E. E. GRANT, The Crystal Tissue Company, Middletown, Ohio; **Contest Committee Chairman**, A. SCOTT DOWD, The Paper Industry, Chicago, Ill.; **Committee on Health Research Chairman**, J. J. PLYZAK, Consolidated Water Power and Paper Company, Wisconsin Rapids, Wis. **Regional Directors**: *Maine*—ALVIN RECORD, International Paper Company, Chisholm, Me.; *Massachusetts*—N. F. BARTLETT, Hollingsworth and Vose Company, Boston, Mass.; *Michigan*—C. E. TORRANCE, Bryant Paper Co., Kalamazoo, Mich.; *New York*—C. H. O'CONNELL, International Paper Company, New York City; *Ohio*—KENNETH L. FAIST, Champion Coated Paper Co., Hamilton, Ohio; *Pennsylvania*—E. J. GAYNER, Scott Paper Company, Chester, Pa.; *Wisconsin Valley*—F. H. ROSEBUSH, Nekoosa-Edwards Paper Company, Port Edwards, Wis.; *Fox River Valley*—W. F. ASHE, Thilmany Pulp and Paper Company, Kaukauna, Wis.

October 1, 1928

W. J. PEACOCK, Chairman

Head, Department of Personnel, Northern Paper Mills, Green Bay, Wis.

The first session of the Paper and Pulp Section at the Seventeenth Annual Safety Congress, was called to order at one o'clock by the chairman, W. J. Peacock, Head, Department of Personnel, Northern Paper Mills, Green Bay, Wis.

CHAIRMAN PEACOCK: The program this afternoon is somewhat in the nature of an experiment. Those of you who have attended former meetings of the section will remember that at the close, usually on Thursday morning, we have held an informal conference confined strictly to the affairs of the section as such, and have had trouble in getting men interested in other features of the congress, to give that additional morning. Because of the importance of matters that belong to the section, I asked the cooperation of the Program Chairman in getting this informal meeting the first thing.

But first, it is the custom here to get acquainted. What I hope will be accomplished through getting acquainted will be something of group acquaintance, also something of regional feeling. As I call the different paper-making states will the members of these groups stand up and give your names, please. Now, those from

Wisconsin, from a long way off, there won't be many of them so we will dispose of them first. Get up and give your name, please.

(Representative groups from Michigan, Minnesota, Illinois, Ohio, Louisiana, Pennsylvania, New York, Massachusetts, Maine, New Hampshire, New Jersey, and Canada were then called on by Chairman Peacock.)

Report of the Chairman

By W. J. PEACOCK

Head, Department of Personnel, Northern Paper Mills, Green Bay, Wis.

During my three terms in office, it has been possible to get things said by others in ways that afford pride enough in being sponsor. This year, however, the Council has asked me to make a report covering the activities of the section, and I accept that task eagerly in the hope of passing on to the section some of the valuable impressions that have come to me.

At the outset I want to bear my testimony that holding office in the section has been a schooling in organized safety methods which I might never have received otherwise. For every hour of service I have given the Paper and Pulp Section I have received a week's wages in group vision and national outlook. I never began to utilize the services of the Council to the fullest degree until I was called upon to extend those services to fellowmembers, while the importance of my own job at home never appealed to me as strongly, taken alone, as it did after I began to see points in which my interests merge with the interests of 700 other plants.

I want to take time, then, to help the entire section to appreciate that profitable field in which the things that are "ours" enhance the importance of everything that may be called "mine." In somewhat the same respect that we are better men in proportion as we are worthy Americans, it can be said that a paper manufacturer is on the line to personal success in proportion as he participates in the vision and achievements of the industry as a whole. In three sessions to follow, you are to be handed the results of the work of others for the good of your own mills. This afternoon I ask you to think of yourselves as fellow-workers in a group which makes our individual efforts profitable.

One of the most useful tasks to me in connection with the chairmanship came the first month of my term in 1925. *The Annals of The American Academy of Political and Social Science* wrote asking for a chapter on "Safety in the Paper Industry."

The time limit given me was one month. Getting together historical data consumed most of the time. The article had to be written rapidly, mostly at night, with revisions by telegraph. Looking back now, I regret that so important a piece of work had to be done in a hurry; yet, coming as it did, the necessity for studying the records of the section was a valuable initiation into a section which has always been doing things.

For instance, in 1925 we might have thought we were originating the *News-Letter*. I discovered that in 1918 under the chairmanship of G. E. Williamson the *News-Letter* had been employed to stimulate interest in the affairs of the section. Imagine my respect for history to read E. P. Gleason in the transactions of the first meeting of the section advocating the safety contest as a method of creating safe habits. Like other safety men, I had been stirred by the discovery that the human element rather than machine causes, accounts for the majority of industrial accidents. The proceedings show that starting with the first program and repeatedly thereafter our leaders have emphasized the point that accidents are due to inexperience, ignorance and other human causes. What the American Engineering

Council finally worked out to a scientific conclusion, namely, that safety and increased production go together was stated with emphasis in 1915 by President H. W. Stokes, of the York Haven Paper Company.

I mention these things as showing the sort of leadership the section has had from its organization. To some of you present, this may be your first National Safety Congress. A banquet of 3,500 persons, a Council of 4,600 members, 3,000 of them member-companies, representing 153 industries—these are vast concepts. This Congress is, as the bulletin of the Massachusetts Safety Council puts it, "The most important convention of its kind in the world." We are proud of the fact that the Council itself only multiplies the spirit of the Paper and Pulp Section. The founders of this section were present formerly at the organization of the National Safety Council and contributed to its vision. We are fortunate that Shattuck, Williamson, Lundrigan, Turner, Costigane, Gleason, Wilson, Altman, and Phillips, men capable of growing themselves, have remained with us as pace-makers.

Organization Days of the Section

The Paper and Pulp Section was organized in 1915, four years after the National Safety Council came into existence. Philadelphia was host to the Congress that year and 25 of the 30 persons present were from eastern companies. The attendance and program had been worked up by S. F. Shattuck, of Kimberly-Clark Company, G. E. Williamson of Strathmore Paper Company, and R. B. Robertson of Champion Fibre Company. Thirty-six member companies had signed up and Mr. Shattuck was elected first chairman. During the year following, the membership increased to ninety-two companies, but Chairman Shattuck, with vision that still characterizes the industry, reported "five hundred or six hundred companies who have not yet found their place in the fold." Today, with two hundred four member companies, controlling about 400 or 500 mills, we are still far below Mr. Shattuck's dream.

I should like to cull items from year to year with the double purpose of appreciating our past chairmen and of visualizing their plans for the section.

Some of us have felt that we might make a leap in progress if we could only hold a session of the section in connection with the American Paper and Pulp Association. In February, 1917, that experiment was tried out for us by Chairman Williamson and we note the impression that the attendance and response did not justify the effort. Apparently safety interest centers in actual operatives. The most successful meetings depended upon men and management. At any rate the annual meetings were not displaced by the New York experiment and the following fall found a regular session in connection with the National Safety Congress.

At the 1917 meeting we note a suggestion from the secretary, A. G. Poundsford, that all the members of the Safe Practices Committee be appointed from one locality in order that numerous face-to-face meetings might be held. Mr. Poundsford was very early putting his finger on the geographical problem of our section, extending shoestring fashion from Maine to Ohio, and up into Minnesota, with flapping ends in the south and on the Pacific Coast and a strong side coil in Canada. Some of you present today probably have not attended a national congress since the last time the meeting was held in the east. The same thing is true of western mills. How to sustain interest, how to avoid loss of useful men, more especially, how to carry the influence of the National Safety Council every year into every region of our industry has become a live problem.

In the report of the 1917 meeting we run across some names with a familiar sound—G. W. Phillips, A. P. Costigane, John Lundrigan. In 1918 we find a few more—C. E. Jackson, Amiel Umberham, Franz H. Rosebush, R. M. Altman, pace-makers today in the section. At the 1918 meeting, also, we note the beginning of

another experience succeeding meetings have encountered. It was reported that while twenty-five new companies had joined during the year, ten former members had cancelled. Also, we note that the meeting in St. Louis, an out-of-the-way city for paper makers, attracted only thirty-two persons representing fifteen mills. However, Mr. Williamson, for the second time chairman, reported that the business of preventing accidents had begun in earnest. Frequency statistics showed an improvement of 31.1 over the preceding year.

The year 1919 was significant as seeing the start of our Safe Practices Pamphlet. Mr. A. P. Costigane, eminent as a safety engineer, was at the helm that year and R. M. Altman was pressed into service as the head of the committee which was to work together under the sponsorship of the National Safety Council in the drafting of a Paper and Pulp Safety Code. Mr. Altman, Mr. Costigane and Mr. Williamson, associated with other outstanding safety men five years later gave the industry a Code which was published as Bulletin No. 410 Bureau of Labor Statistics, U. S. Department of Labor, and was approved by the American Engineering Standards Committee.

Be it noted in passing that whatever safety literature may be on the shelves of paper mills, this code is our leading authority. If the section had accomplished nothing more in its history, the Code would justify all the money and time spent in its proceedings.

The congress returned to Milwaukee in 1920, the city of its birth, and R. M. Altman was elected chairman; during his chairmanship the section responded to the call of the Council for statistical data on accidents.

Forty-five mills voluntarily began reporting annually. In succeeding years the number of mills reporting increased to fifty-five, sixty-six, ninety-nine, one hundred thirty-three, one hundred eighty-six. This is a service which becomes exceedingly valuable in connection with studies of accident experience upon which our rates are based. What happens in the industry as a whole determines the premiums of each of us, and what can be done to reduce premiums of each of us depends upon the concerted effort of all of us.

Boston entertained the congress in 1921 and G. E. Williamson of Strathmore Company was again drafted for the chairmanship. Safety Bulletins, printed and distributed by the Council, but originating in the members' plants, came up for discussion. Amiel Umberham, chairman of the bulletin committee, reported that seven member companies had cooperated in the production of twenty-six bulletins.

Mr. Williamson followed with a request to all member companies to submit their ideas in the shape of photographs or drawings. At this meeting, evidence of the active cooperation of the American Paper and Pulp Association was furnished by Mr. Oliver M. Porter, Secretary, in plans for a membership drive. The time was inopportune, however, the period of readjustment having begun, and only nine new members responded to the appeal. Nevertheless the plans suggested by Mr. Porter for securing new members should be dug up again and the resources of the American Paper and Pulp Association employed to the fullest extent.

During the last nine years we have received one hundred seven new members and have suffered seventy-four cancellations. Apparently our sales problem is two-fold; to sell a new member the value of concerted safety work and to keep him sold. But more about that later.

What "prospects" for membership have we in the industry?

Without checking the figures, the following illustrations will bear consideration. In the United States there are six hundred fifty-six companies operating eight hundred sixty-eight paper mills and three hundred twenty-five pulp mills. In Canada there are ninety-five companies operating seventy-two paper mills and one hundred thirteen pulp mills.

By states, companies, and membership, figures are as follows:

State	Companies	Mills	Members
New York.....	127	138	45
Maine	23	29	11
Pennsylvania	60	63	10
New Jersey.....	37	40	5
Massachusetts	66	67	23
Connecticut	34	39	2
Michigan	41	41	11
Illinois	27	27	11
Indiana	23	---	1
Wisconsin	47	---	42
Ohio	51	---	11
Minnesota	10	---	4
Vermont	14	---	---
Virginia	10	---	2
W. Va.....	8	---	2
Delaware	6	---	1
Louisiana	9	---	5
Maryland	11	---	---
New Hampshire.....	22	---	3

There is no mystery about these figures. All of the mills of the industry, large or small, would profitably enjoy membership in this section. So far, half of the mills of the states have been reached. The question is: How can the section, dependent upon voluntary service, organize its efforts so that a larger proportion of our mills may be enrolled?

Coming back to our story: The next year, 1922, saw W. A. Gleason as chairman in the Congress assembled at Detroit. Mr. Gleason reporting on membership matters, stated that mills forced to cancel on account of business conditions had given assurance of their faith in the section and of their purpose to resume membership at the earliest moment. Nine new members had been gained, and the bulletin committee reported a new method of securing poster material. The National Safety Council had begun sending out a staff photographer to pose subjects suggested by interested members. The committee got together in one place and studied out a list of desirable ideas which were posed in various plants. We note at this meeting that much interest centered around methods of training foremen in safety matters. The foreman began to figure as the key to accident prevention.

The 1923 Congress met in Buffalo with an attendance of sixty delegates representing twenty-nine member companies showing interest in a program related to health conditions and their bearing on accidents. Such matters as eyesight, hernia, specific diseases, high blood pressure are to be considered when men are put on the pay roll. Physical examinations pay for themselves from the standpoint of management and men. Safety was discussed in a large way by Dr. Hugh P. Baker, secretary of the American Paper and Pulp Association. He pointed out that the industry itself needs the watchful care of all whose livelihood is derived therefrom.

Protection of raw materials, assurance of a market for our product, provision for educated labor and protection against the inroads of European competition were pointed out as calling for widening vision.

At this meeting, the section applied itself to the discussion of the new Code, a preliminary draft of which was furnished for criticism. The committee was continued and given encouragement to complete their important venture.

The next year, 1924, saw G. W. Phillips, of Champion Fibre Company, a veteran safety man, in the chair and a congress in Louisville, Ky. Here was a test of the pulling power of the section. Louisville is well out of the line of paper-mill locations but for all of that nineteen mills and interested organizations, including the U. S. Bureau of Standards and several state industrial departments, sent

thirty-two delegates to continue the discussion of the Code, now recognized as the most important task before the section. The Code, in mimeographed form was presented with parts covering the Yard, the Pulp Mill, Rag and old Paper Preparation, Acid Making, Chemical Processes of Making Pulp, Preparation of Pulp for the Machines, the Machine Room, the Finishing Department. It was decided that in form and substance the Yard and the Sulphite Divisions were fairly well taken care of. The committee, with John M. Sandel of the Council staff as chief editor, was encouraged to continue the task.

Cleveland, approximately at the center of our industry, claimed the 1925 congress, and M. G. Hoyman, safety man for Kimberly-Clark Company, the same company which furnished the first chairman, presided. At the preceding congress the section had decided that it is best to have the officers come from one region making it possible for several face-to-face executive meetings.

Mr. Hoyman is an indefatigable worker and under his inspiration a *News-Letter* was started. An intermill contest was held during the month of August sponsored by *The Paper Industry* with forty-one contestants. The cup was won by Nekoosa-Edwards, one of the charter mills of both the National Safety Council and the Paper and Pulp section, and some idea of the interest aroused will be gained from the fact that sixteen mills, all with perfect records, came to Cleveland with strong hopes of carrying home the trophy. Fortunately an equalization factor was worked out by the Council and the entire sixteen mills were given standing according to the hazards and difficulties overcome.

The contest immediately appeared as a unifying activity between congress meetings, and *The Paper Industry* was persuaded to continue the contest idea. To maintain interest and especially to help mills to train their men in safe working habits, the forthcoming contest was slated for a period of six months. Mr. Hoyman, experienced in inter-mill contests, pleaded for an entrance list of not less than fifty mills and was rewarded by a registration of seventy-two mills. It is only fair to state at this time that the wide-spread publicity given the section by its annual contests is due to the inspiration of Mr. Hoyman who with Mr. Edward B. Fritz, publisher of *The Paper Industry*, actually made a plan work which the section had talked of for years.

As a postscript, it should be charged also to the enthusiasm of Hoyman that another Wisconsin man was chosen as his successor in office.

In connection with the Cleveland meeting, a special conference was called of officers and committeemen new and old. The Chairman-elect, W. J. Peacock, of the Northern Paper Mills, Green Bay, Wisconsin, afterwards stating the program which this conference advocated mentioned the need for recovering the presence and counsel of former officers in an effort to build a section mid-year program that would interest members apart from the incidental stimulus of annual meetings. The contest feature, stimulated by a regular news-letter and by magazine publicity, appeared like an activity around which the service to members could be concentrated.

At the Cleveland Congress announcement was made by the Council of a decision to specialize during 1926 on regional conferences to bring the inspiration of the Safety Movement to the plants of its members.

This was welcome news and the new officers, all from one region, decided to ask for such a conference in Wisconsin. Whether by compliment to the chairman or by his own designs, the record is that such a conference was held in Green Bay, the chairman's home town. Under the guidance of the National Safety Council, this first conference was held in December of 1925, two months after the Cleveland congress, having the sponsorship of the American Pulp and Paper Superintendents' Association, the Engineering section, the Public Utilities section and the Wood-working section of the National Safety Council, the Industrial Commission of Wisconsin and the Chamber of Commerce, of Green Bay. The attendance in a

one-day program was six hundred seventy-four, good enough for a beginning, but what interests us is that one hundred forty-five of this number came from thirty paper mills and allied industries accustomed to attending our section programs. The attendance at the Cleveland meeting, drawing from thirteen states and Canada was forty-three delegates representing twenty-six member companies. Here was a regional meeting, in the heart of a paper and pulp state, costing members a nominal \$3.00 and traveling expenses per man, which tied all attendance records of the parent section. The Fox River Safety Conference became an annual event and one of its immediate results was ten new members for the section.

In the past a fortunate few were able to follow the section wherever it went, to Milwaukee, to Philadelphia, Detroit, New York, Louisville, Boston, Buffalo, and Cleveland, but the majority attendance each year came from the mills of the vicinity. Enthusiasm lags in the member who cannot feel the pulse of the section oftener than once in three years. No wonder we had seventy-four cancellations in nine years. There was too little to hold members.

At the 1926 congress in Detroit the Wisconsin experience was sold to the section and from those present selections were made of eight Regional Directors, each to be in effect chairman in his own state, all being expected to radiate the influence and service of the section.

As a result during the following year conferences in which this section had some active part were set up in Appleton, Wisconsin, Erie, Pa., and Grand Rapids, Mich., with a combined paper and pulp mill attendance for the year far greater than any meeting of the parent section. 1926 saw, too, an increased interest in the Cup Contest. There were as many mills with a perfect record each month as figured in the perfect column of August, 1925. In addition to the winner, the Neenah Mill of the Kimberly-Clark Company, six mills were given certificates for outstanding records, and such was the sportsmanship engendered by the contest that ninety-nine mills, an increase of thirty-three over the past high-water mark, sent their accident statistics to the Council. The activities of the year also served to increase interest in the annual meeting. Forty-one member companies sent seventy-three representatives to Detroit.

From now on the history of the section between congresses includes activities calling for more attention than the former programs. Midyear service enlisted the talents of many participants. Bob Altman and a patient committee completed their Code and had the satisfaction of seeing it published with the Government imprint. The contest became a monthly feature in the *National Safety News* and *The Paper Industry*. Our trade papers featured safety items and certain contributions of our programs appeared in print so often that they were practically broadcast throughout the industry.

The twelfth annual meeting of the section met with the sixteenth safety congress in Chicago and brought eighty delegates from thirteen states and two provinces of Canada, representing forty-seven mills. Our Regional Directors, eight in number, reported participation of the Paper and Pulp section in regional safety conferences in Boston and Worcester, Mass., in Erie, Pa., at Blue Ridge, N. C., at Grand Rapids, Mich., and at Sheboygan, Wis. Two cities in Wisconsin reported foremen's safety schools as a direct outgrowth of the Fox River Conference. One hundred thirty-three mills contributed their accident experience for 1926, an increase of thirty-four mills over the previous year. One hundred nineteen mills entered the 1926 contest and one hundred seven stayed to the finish. The severity rate for the one hundred seven mills was .63 and frequency 33.01. The severity rate of the first annual contest in 1925 was 1.746. The average number of mills with a perfect score for the contest was 37. Sixteen new members enrolled and nine transferred to our section from others. We closed the year with two hundred one members.

During the year our Regional Directors contributed an important set of articles

for the *National Safety News*, secured entrants for the contest, helped to build programs in five conferences, encouraged mills to send in statistics, produced posters, gave considerable voluntary service to neighboring mills, and attended to the reporting of programs in the magazines of the industry. It is interesting to note the different ways in which Regional Directors, new to the game, found and made their own contacts.

It requires no imagination to see the possibilities for increased service to members as these Directors continue to originate plans for their own states.

The present year, 1927-28, saw the foundation of three more annual regional conferences to serve paper mills as the result of the work of our regional directors. Ohio mills, to the number of seventeen, only two less than attended the Congress at Louisville, met and formed a region last November. Mr. Faist will tell us more about this Region.

Another Region, in the Valley of the Wisconsin River, under the leadership of Walter L. Mead, held its first conference also in November of 1927. Two hundred fifty paper and pulp men from twenty-five mills is the inspiring story.

At Blue Ridge, N. C., our veteran director, G. W. Phillips, in connection with the Y. M. C. A. is working up a conference in which safety matters play an important part.

The Michigan region, under the leadership of C. E. Torrance, of Bryant Paper Co., Kalamazoo, with only eleven members to draw upon, held a meeting in connection with the Michigan safety conference. Only four mills sent representatives but they received the worth of their money. Mr. Torrance is a valuable leader and with forty-one mills in the state, we hope he will feel that the beginning was worth while.

Under the encouragement of eight regional directors, our contest in 1928 enrolled one hundred twenty-four mills, an increase of five over 1927. Eight of these mills, we are told, completed the entire six months without a lost-time accident. The contest has been an improvement over that of 1927 in the totals achieved. I do not wish to steal the thunder of forthcoming reports, but a reduction of frequency among a hundred mills to the tune of 15.2, of severity 17.9 per cent makes one feel that the section, twelve years in training, is arriving at its stride.

I must forbear further comment on the things our regional directors have started. They will have something to say for themselves. What I have tried to accomplish in this sketch has been the development of a leading section from small beginnings, all the while under the inspiration of men of vision, all the while accumulating resources in experience, in members and esprit de corps.

But lest we think we have mastered our task, let us consider the facts pointed out to the industrial world by the American Engineering Council after an investigation covering over a year.

We are encouraged by the findings of the engineers that organized safety work is profitable in high degree. The correlation between Safety and Production is 0.84. To put it in picturesque form. Fourteen thousand plants were investigated to discover whether the safest factory is the most efficient factory. Eighty-four times out of a hundred that was the case, making the most convincing proof of the worth of safety work ever produced.

Our statistics in the Paper and Pulp industry indicate that the rule applies. Safety does pay. It pays so certainly that a plant is blind which does not organize against accidents. We have one hundred eighty-six plants aware of the facts sufficiently to be willing to turn in their statistics. How about some six hundred plants who do not report?

How can we get to their attention certain other findings of the American Engineering Council: That production in the industry increased thirty-four per cent from 1914 to 1925, forty and seven tenths per cent for each person employed. There has been an increase in the intensity of modern production. Accidents have

decreased on the average in proportion to the goods produced but production has become vast and accidents, on the whole are more numerous than formerly. Why?

Mr. Albert W. Whitney, speaking for the engineers, gives us the reasons. Machinery is displacing comparatively safe hand-working methods and machinery produces more accidents of greater severity. Automatic machinery has its influx of injuries due to repairs, always difficult to organize. Speed means increased exposure to danger and God only knows where the speed mania in industry will stop.

In the paper industry the cost of accidents is spread over our entire seven hundred eighty-three mills. I mean to say that premium costs are founded upon our united experience. We have had a demonstration of what can be done by united effort. Accidents can be put in the category of preventable waste and can be made to look foolish. Four times the number of mills reporting in 1920 reduced severity averages from 2.60 to 1.57 and frequency from 46.34 to 27.42. We might have expected the original forty-five mills to make an improvement of this kind in seven years but the influence of the section has been such that new members have brought new blood to the fight. Witness the St. Croix mill in 1928 going the entire six months without an accident, and a score of other new members falling into stride within a year or two. The methods of the section and the backing offered make it highly probable that any new mill will reap with the rest of us.

The vision I want to give you is of a section organized into regions, each with a director keen for results. We have eight regions now. We might start as many more with profit to the industry. The machinery is at our command for doing a significant piece of work, more significant by far than anything we have done heretofore. There are men amongst us who like to attempt big things. My suggestion is that we consider men and methods and possible regions and take up the task of realizing the hopes of the men who have gone before us.

Continuing, gentlemen, will you remember that in this first meeting we are trying to think in terms of the group as a whole. I am asking you to bring your individual contribution to that thing which makes this other thing possible for us, the strengthening of this section. Let's keep that in mind.

CHAIRMAN PEACOCK: We were to have an informal report on conditions in Maine, by Mr. Alvin Record, Supervisor of Safety, International Paper Co., Chisholm, Me. Mr. Record is our regional director from Maine and he writes me he is unable to be here, so I will read for him the report he sends to us.

What Has Been Done in Our Region During the Past Year?

By ALVIN F. RECORD

Maine Regional Director; Supervisor of Safety, International Paper Company, Chisholm, Me.

The States of Maine and New Hampshire comprise that part of the Pulp & Paper Section of the National Safety Council known as the "Maine Regional Section." In these states are 61 paper mills; 26 ground wood mills; 20 sulphite mills, and four soda pulp mills; or a total of 111 paper producing units out of a total of 1,149 in these United States, or approximately 10 per cent.

While much has been accomplished by individual manufacturing concerns and by insurance companies carrying liability insurance, and a start made in a few communities by such organizations as the Kiwanis and Rotary clubs along lines of public safety, this region seems to have lagged behind somewhat in real organized safety and accident prevention methods. No determined efforts have ever

been made to interest the public at large and direct attention to this increasingly important phase of industrial life and general welfare.

Efforts put forth by individual manufacturing concerns have been productive of amazing results. The State of Maine boasts of a progressive concern, the St. Croix Paper Company of Woodland, employing nearly 500 men who passed through the first six months of the current year without a lost time accident. These people should be among the leaders if not the leading competitor for the Class "B" cup offered by the National Safety Council. The Riley Mill of the International Paper Company located at Riley, with 70 employees has been since March 17, 1926, without a lost time accident; in fact nearly two years of this period without having to call a doctor to give surgical attention to any of its employees. These, as well as others, have made outstanding records which are the result of intensive efforts to interest employees and managements in this humanitarian work.

It has appeared for some time to many interested in a small way in accident prevention work, that the time was ripe for a state wide safety get-together to stimulate interest in and draw attention of the general public to the possibilities along lines of safety and accident prevention.

With this end in view, a general safety meeting was called—the first of its kind in the State of Maine—for August 11, under the sponsorship of the Maine State Department of Labor; Maine Automobile Association; Associated Industries of Maine, together with the Maine Regional Section of the pulp and paper division of the National Safety Council. However, through the advice of G. E. Burns, of this section, on account of the national convention coming on so soon, it was decided to postpone the meeting until November 15. Programs are now out for this event which will be held in the House of Representatives at the State House in Augusta. A very interesting and profitable program is assured with such speakers as Governor Brewster, Mr. Lundrigan of the International Paper Company; Mr. Beals, Labor Commissioner; Judge Cleaves, Secretary, Associated Industries of Maine; Mr. MacBrayne, Manager of the Mass. Safety Council; Mr. Geo. Burns of the Council and Nat. F. Bartlett of Hollingsworth & Vose Company of Boston.

The opening session is called for 9:30 a. m. Dinner will be served at the Augusta house nearby to all registrants, and the afternoon session starting at 2:30 p. m. A very cordial invitation is extended to all those interested in accident prevention in this section to be present and help us make the meeting a real success.

CHAIRMAN PEACOCK: According to Mr. Record's report, our section has a regional director starting the first regional meeting of its kind in the State of Maine. I hope all the men from Maine and New Hampshire who can possibly do so, will attend and assist in making this conference a great success.

I wonder if you will tell us something, Mr. Parant, about the enterprise of the safety movement as it begins to get out into the State of Maine as a whole?

L. J. PARANT (St. Croix Paper Company, Woodland, Me.): I don't know as I can say very much on what is taking place at the present time, except that the meeting is planned for the 17th of November, I believe, at Augusta. Mr. Record has asked me to act as chairman of that meeting. There hasn't been very much real work done toward planning the meeting as yet, but this morning I ran into Governor Brewster, and he spoke to me about the meeting. Now, the Governor of the State of Maine is interested in it and I feel we are going to have a very large attendance and a very interesting meeting.

CHAIRMAN PEACOCK: The next speaker on the same subject, for the State of Massachusetts, is Mr. N. F. Bartlett:

N. F. BARTLETT (Hollingsworth & Vose Co., Boston, Mass.): In Massachusetts, gentlemen, I am positively optimistic. I know what has been done in Massa-

chusetts by coming in contact with several of the large safety directors, men who have been imbued with the spirit and know what they are talking about.

A lot of you are conversant with the fact that in Massachusetts we are of a modest and retiring disposition. Immediately upon receipt of the letter to give this five minute report as regional director of Massachusetts, I corresponded with most of the paper mills, and received replies which were very, very gratifying. For instance, approximately 15 to 20 mills have reported that they have never had such a promising year, that their lost-time accidents had diminished greatly. Take Mr. Rogers, of Bird & Son. He reported to me that in one department of that large manufacturing industry, employing 225 men, they had not had a lost-time accident since October 11th, 1927. I also received a very gratifying and optimistic report from my good friend Mr. Wyman of the Strathmore Paper Company, at Mittineague, Mass. Mr. Wilson, of the American Writing Paper Company, Inc. of Holyoke, Mass., also reports progress and, in all modesty, I can say that the mill where I am employed have a very gratifying report for the first six months, one they are a little proud of.

I figure this way, that if young fellows can go into an industry and bring our lost-time accidents down, as we are doing in Massachusetts, from we will say, 40, 50, 60, 70 per cent in a year, the section as a whole will note improvement.

I would like to see the National Safety Council, the Paper and Pulp Section, provide a secretary who could go around to the different mills, in Wisconsin, in Maine, in New Jersey, where we see we have so many mills and only such a small percentage of membership, and sell to them the membership of the National Safety Council.

I know that the spirit of safety in the industries has taken a firm grip. Take the Massachusetts Safety Council, made up of various organizations, of all kinds of organizations, and they have every week in the John Hancock Mutual Life Insurance Building, in Boston, a meeting at which able speakers are secured who give to those present valuable information that they have had from actual experience. These meetings are doing much to stimulate the interest in diversified industries in Massachusetts and in closing, I am confident, in my position in Massachusetts, that I can report to this Congress and to you members present that Massachusetts has grasped the safety movement in earnest and the results of its efforts will be manifested in the days to come.

CHAIRMAN PEACOCK: You notice that Nat Bartlett is working out his problem in connection with an organization already on the ground.

We were to have, next, a report by C. E. Torrance, the regional director from Michigan. Mr. Torrance is unable to be here and I will present a report based upon information given me in a letter he wrote me.

Mr. Torrance, who is superintendent of planning and personnel, Bryant Paper Company, Kalamazoo, Michigan, reports that he circulated the 41 mills of the state in the interest of an All-Michigan Congress, to be held in May of 1928, in connection with which the Paper & Pulp Mills were to hold a sectional meeting of their own. While only four mills responded with representation at the two day sessions, the quality of the program and the interest manifested on the part of those present justified this beginning activity. Mr. Torrance compliments the Michigan Mutual Liability Company of Detroit for their participation in the meeting and their efforts in stumping the state on behalf of the attendance.

From his own mills, those of the Bryant Paper Company, Mr. Torrance had some striking reactions. Five mills were given an accident survey in 1927 and a thorough organization was set up. A large amount of guarding was effected, superintendents of the plants were called together by the management of the Bryant Company and were given strict responsibility for all accidents within their divisions. A safety committee was organized in each of the five mills, with divisional foremen as members, the superintendent as chairman and Mr. Torrance

himself, superintendent of Planning and Personnel, as secretary. Accidents were reported and analyzed and plans were made on the basis of facts discovered. The result in these five plants was a reduction of fifty-five and a half per cent in lost days during the first seven months of 1928, as compared with the same period of 1927.

Mr. Torrance reports that the problem of machine workers going barefooted was met with a strict order to wear shoes. Superintendents were firm in their insistence upon the order and counsel was afforded the men as to proper type of shoes, leather-soled and leather-heeled shoes being favored as against rubber.

I am sure that we can say the report of Mr. Torrance is received with satisfaction by this section, as indicating that a promising beginning has been made.

(Mr. Torrance was unanimously requested to serve in the capacity of regional director in Michigan for another year.)

CHAIRMAN PEACOCK: Next, we would like to hear from our New York regional director, Mr. C. H. O'Connell, Supervisor of Safety, International Paper Co., New York City. Let me say for Mr. O'Connell that his main task as regional director this year has been here in New York City. We have asked him to serve us in the setting up of matters relating to the Congress. He has been a member of the local committee and we have him to thank for a great deal that has been enjoyed.

C. H. O'CONNELL: I haven't done a great deal. As a matter of fact, I visited twelve mills, all over New York and part of Canada, and a good deal of my time is taken up by travel. However, I tried to do what I could before this meeting. I can't report much activity for the section except that of our own company. We have five mills in New York State. Our accident experience has improved a great deal during the year. In one of the mills where they had probably 300 lost time days last year, I don't believe they have had 25 this year. I think the biggest thing that we have done, and it doesn't originate with me, is the introduction of the safety movement in the schools. In two of our mills in New York State, with the assistance of the Metropolitan Life Insurance Company, we have introduced the teaching of safety in connection with the schools. This is correlated with the subject matter they have from the first grade up to the High School. I believe that is a good idea. It is nothing new but it will do a whole lot toward safety when these children get to be of working age.

CHAIRMAN PEACOCK: From Ohio we are to hear from Mr. Kenneth L. Faist, regional director, Safety Director of the Champion Coated Paper Co., Hamilton, Ohio.

"What Has Been Done in Safety in Your Region During the Past Year?"

By KENNETH L. FAIST

Safety Director, Champion Coated Paper Company, Hamilton, Ohio

In our region, or State, the Ohio Industrial Commission with Mr. Thomas Kearns, superintendent, inaugurated a state safety conference in November, 1927, and incidentally plans are under way for a still larger one on the 13, 14 and 15 of this November. It would be impossible to give enough credit to Mr. Kearns and the commission for their endeavors along these lines as this conference was second to none but the National Safety Council Congresses each year. Last November there were a dozen or more sections represented and a large number of paper mills in our own section.

In the pulp and paper section the first speaker, Mr. Roland Jones of the Surety Manufacturing Company, Chicago, Ill., had as his subjects, "Why Make Standard

Guards and What Can You Accomplish by Guarding?" Mr. Jones gave us insight into the part standard guarding plays in accident prevention. Mr. Jones brought out what real safeguarding of machines, etc., is, not just a makeshift to get by with if lucky, but real guards that are fool proof. Correct designing, said Mr. Jones, saves in two ways: correct designing saves by conservation of floor space. Pipe rail guards oftentimes take up quite a great deal of space where a guard properly designed would give you this additional space as added room for aiseways, etc. Mr. Jones referred to a case where an excellent looking guard was built costing in the neighborhood of \$200 but the State code on standards had been ignored resulting in the State Inspector condemning same and it had to be rebuilt.

Provisions must be made for oilers, maintenance men, etc., to get at the particular equipment with ease and speed and yet with the utmost degree of safety.

Guards must be tailor-made. Big brother's pants on little Junior gives an appearance so that you can't tell if he is coming or going. Some guards incorrectly designed give practically the same impression.

A real live discussion followed this splendid address.

We were more than fortunate in the first meeting of the Pulp and Paper Section to have as one of the principal speakers none other than our own "Bill" Peacock. Mr. Peacock's subject was "The other 75 per cent." His first words to quote direct were:

"I want to tell you fellows of Ohio that you have got a bigger thing here today, I won't say the number of mills represented but certainly in the number of men, than we had in Detroit in 1922. Ohio has a bigger thing here starting, than we had in the National Safety Council six years ago. Mr. Peacock laid special stress on the potential accident. The pipe that is hanging overhead ready to fall on someone, anyone at anytime. That is an accident even though no one has as yet been mangled or cut. These accidents cost hundreds of dollars, even though we may be lucky and have no one injured."

I am not going to take up a whole lot of your time in telling you what "Bill" said as further remarks would be futile, but recommend, if possible, you get a copy of the proceedings and read it word for word carefully. Hundreds of splendid points brought out in his own unique way of putting it across.

Officers in the Ohio Division

After the meeting the section went on record as a permanent organization and elected the following officers:

Chairman—K. L. Faist, C. C. Pa. Co.

Vice-chairman—Mr. Hiers, Ohio Boxboard Co., Rittman, Ohio.

Secretary—D. D. Thirkield, Sorg-Ogglesby-Smith Paper Co., Middletown, Ohio.

On March 16, 1928, there was held at the Anthony Wayne Hotel at Hamilton, Ohio, a Paper and Pulp Safety Conference. This Conference was exceptionally well attended considering the fact it was the first. I believe, that has been attempted in our section.

The program consisted of:

1st Welcome address, Dr. Mark Millikin, councilman, City of Hamilton.

2nd Address by Mr. Thomas P. Kearns, Superintendent, Industries Commission, State of Ohio.

Mr. Kearns' talk inspired all present.

Mr. Kearns pointed to making April, 1928, a no-accident month. This was done but the results did not come up to expectations by all mills. This month, i.e., October, is the second no-accident month to be tried this year. The April issue of the Paper Industry carried an account of the Conference and the high lights of Mr. Kearns' address.

During his discussion Mr. Kearns gave some very interesting data relative to the causes and rating of accidents—(This is Ohio only.)

Cause	Frequency	Severity
Machinery	1	3
Handling of objects.....	2	2
Stepping on or bumping into.....	3	5
Falls of persons.....	4	1
Handling tools	5	6
Falling objects	6	4

The National Safety Council, as per usual, came readily to our assistance with Mr. E. W. Corn who had everyone on their toes. If anyone here has not heard Mr. Corn and ever gets that chance don't fail to make use of the opportunity. It will more than pay you. I'll leave that to Mr. Augustus or Mr. Grant or anyone else here that heard him at Hamilton.

Mr. Corn's talk was divided into three basic points: Recognition of the Hazard, Mental Alertness and Dexterity and Watch Where You Go.

After Mr. Corn had been deluged with questions and remarks the meeting adjourned for dinner after which a short entertainment in sleight of hand by Mr. George Steiner, back tender, The Champion Coated Paper Company, Hamilton, Ohio, brought forth quite a lot of merriment.

Mr. Charles C. Barthe, Safety Engineer, Industrial Commission of Ohio, followed with an excellent address on Safety and Hygiene.

Discussion followed and all agreed that a great deal of inspiration had been received from the Conference. A total of 51 were in attendance and ranged from executives to safety committeemen.

Generally taking everything together, it was a very profitable afternoon and evening to all and believe all of us in attendance went back with renewed vigor to tackle our various safety problems.

The greatest values perhaps received in Conferences of this kind are ideas, interchanged which often result in things of value to all of us.

Incidentally one of our members here, Mr. Augustus of Mead Pulp & Paper Co. called at our plant before noon with Mr. F. S. Pope and Mr. Lawrence Bonner of the same organization. During the short trip (as our time was short) Mr. Bonner became interested in a calender roll scraper (details of which you perhaps noted in the National Safety News). According to information later received, believe these scrapers are being used in all the Mead Mills. I am calling your attention to this item merely to show that these get together meetings, etc., are very profitable in many ways besides the actual value of the meetings themselves.

Other visitors were interested in the problem of machine room men wearing shoes. It is compulsory in our plant for every employee to wear shoes. Am looking forward to the time when this will be an adopted rule in all Paper Mills.

Will say in closing, Ohio is heartily in accordance with any activities along the safety lines and we don't expect to let any other State in the Union show us up.

The Report from Pennsylvania

CHAIRMAN PEACOCK: In Pennsylvania, the section laid heavy hands on Mr. Ed. J. Gayner, assistant factory manager, of the Scott Paper Company, Chester, not realizing that his time was very much limited in these matters of safety. We are glad to have Mr. Gayner here and he will tell us how he sees things at this time.

ED. J. GAYNER: Two years ago I attended a National Safety Council meeting similar to this, in Detroit. At that time, as we still are, our company was seeking or rather groping for some solution to these industrial accidents that we had been

having and continue to have, although I can say that we have them in less numbers and of less severity today than we have ever had, accidents that were caused not by the lack of guards or by the failure to use guards, but what I term just plain dumbness. However, after that meeting, getting back into my usual line of work, which is production, I took an interest in safety and was appointed by the management as chairman of our safety committee. We don't have a full-time safety engineer. We conduct all of our safety work through this safety committee, composed of members of the organization. Just a few months ago, Mr. Peacock wrote me, saying that I had been unanimously elected regional director of Pennsylvania. I didn't feel I had the time to devote to this important job. However, my polite refusal of the election did not work, Mr. Peacock and different members of the Safety Council continued to send me literature under the title of regional director of Pennsylvania, so I wrote Mr. Peacock that I would do anything that I could do.

There is one matter that I think is deserving a report and I don't think it ought to be confined to the region of Pennsylvania. At Mr. Peacock's suggestion, I wrote to members of the organizations that supply paper mill machinery and equipment with the thought in mind that the initial safety work should start with them. My attempt was to get them present at this meeting with a view to their becoming a permanent part of this organization. I had some very interesting replies, in which several companies agreed to have men here.

I might mention some of these companies so you will have some idea of those that replied: E. C. Adkins & Company, Samuel Langston Company, Noble & Wood Machine Company, Valley Iron Works, Beloyd Iron Works, Hudson & Sharp, Cameron Machine Company, and Diehl Valve Steam Turbine Company. I wrote to twenty-three or twenty-four companies and didn't even receive an answer from the others. If we can get these machine builders and the engineering departments of these supply companies interested in guarding the machinery as it comes into the plant, we will have accomplished something or, at least, by-pass a lot of work that has to be done after the machinery gets there. Incidentally, we will save a lot of money. Now, as for the work that has been done in the way of group meetings, so far as I know nothing has been done. I do feel that I am somewhat of a wolf in a herd of sheep. My first job is entirely production and, of course, I am keenly interested in the safety end of production work and anything that I can do in the future, that will not interfere with my regular operation, I will certainly be glad to do.

The Report from the Wisconsin Valley

CHAIRMAN PEACOCK: This is a practical service Mr. Gayner has given us in calling to the attention of manufacturers of equipment the advisability of meeting with the rest of us to talk over problems of guarding.

From Wisconsin Valley we are to hear from Mr. Franz H. Rosebush, regional director, who serves as Director of Industrial Relations, Nekoosa-Edwards Paper Co., Port Edwards, Wis.

FRANZ H. ROSEBUSH: Your chairman has indicated that we held a regional meeting in the Wisconsin River Valley last November. We had about three hundred members there, a combination of the paper mills of the Wisconsin Valley and the wood-working industry of the Wisconsin Valley. It was my pleasure to be a member of the committee which set up a regional meeting in the Rock River Valley at Janesville and after that, there was a meeting provided for, which will occur next spring at Rockford, Illinois. I mention that so that you can see that the influence of these meetings is going down the valley and extending from the pulp and paper industry over into the other industries, as the meeting at Rockford will probably take in many others besides the pulp and paper industry.

There is just a word I would like to say in regard to the regional meetings. The object you and I have in attending these congress meetings is to get something to carry back to our own mills. At the regional meetings we have held we have insisted that our foremen, our machine tenders, as many as possible, should attend and catch the enthusiasm that we fellows who come to the congress take back with us, and some mills had twenty-five to thirty men as delegates. The thing I would like to urge is that you broadcast to the man who is doing the labor, who handles the tools, the lessons imparted here, by means of the regional meeting.

CHAIRMAN PEACOCK: Before we call on Bill Ashe, who will be the last speaker, I want to give Mr. Lundrigan a moment for a comment that has occurred to him.

JOHN T. LUNDRIGAN (International Paper Co., New York City): I am wondering if we haven't got beyond the day of requiring so much service of the volunteer, who is willing to give it, and get right back to the proposition that I thought pretty well agreed on a couple of years ago, that we ought to have a paid representative, explaining to members who are tardy in becoming a part of this section and pointing out to those who are using it as the first source of economy when they have to retrench, withdraw their membership in the Association, having, for instance, a man of the experience and knowledge and interest of our Chairman, to personally visit the non-members, to periodically, or as opportunity offers, visit those who are already members. Now, it seems to me that we ought to think ourselves between now and Wednesday, whether or not we are willing to go back to those of our own companies who have to furnish the sinews of war or to the Council itself or make some arrangement for a division of payment and hire some competent individual to take up this burden that we are trying to do. I consider it necessary if we are to progress much further than we have without making sacrifices in our own plants.

Now I believe that is a very serious question of policy, that this particular section of the National Safety Council ought to take some pretty definite action on at this meeting. That is all I have to say at this time, because as I said before, I don't intend to make a speech, but I did want to leave with you a thought which is with me a conviction.

F. H. ROSEBUSH (Nekoosha-Edwards Paper Co., Port Edwards, Wis.): It occurs to me that we ought to take it up with the officers of the National Safety Council a little bit and discuss with them on what basis such a man would be employed, whether or not he be a member of the staff of the National Safety Council and how much they would be willing to set aside for the expense involved and other details before we go too far in a business way of passing such a motion.

B. D. ROGERS (Bird & Son, Inc., East Walpole, Mass.): I heartily agree with Mr. Lundrigan. I was going to ask practically the same questions as Mr. Rosebush asked. If this is the proper place to ask it, I am wondering what has been done along this line before, which our chairman mentioned today.

CHAIRMAN PEACOCK: It would take a long while to go into this matter now. I see no place for any extended discussion, as the program has been made out. If you are willing to remain, some of you, Thursday morning, I am sure we can get Mr. Cameron to explain to us just what our problem is.

MR. ROSEBUSH: I move that this be laid on the table, to come up under item 6 on Wednesday morning, so that there will be something definite done with it.

(The motion was seconded and unanimously carried.)

CHAIRMAN PEACOCK: Our last speaker will be Mr. Bill Ashe, regional director for The Fox River Valley, Wisconsin.

W. F. ASHE (Thilmany Pulp & Paper Co., Kaukauna, Wis.): We had our regional conference this year, with four main sections, pulp and paper, wood-working, metal working and public utilities. In all of these regional conferences, from the first held at Green Bay, the second held at Appleton, the third at

Sheboygan and the fourth at Oshkosh, attention was given to the side of the public in the safety movement, with always one or two speakers to represent the public and the public generally has been invited to the evening session and the afternoon session, the morning session being devoted entirely to sectional meetings. The comment of one manufacturer in our state I think is significant of the feeling of all of us. He is the general manager of a metal working plant and perhaps the largest employer in our section. He said, "The regional meeting is the cheapest and most effective safety that we have got up to date." He said, "We send from forty to sixty foremen to that meeting and it costs us less than the cost of sending a single delegate to the National Safety Congress."

Foremen's Schools Throughout the Fox River Valley

In addition to the regional conferences, there have been started throughout the Fox River Valley, foremen's schools. These run for six weeks during the winter, one night a week. The average enrollment, I think, will run about 350 per city. Those are rather general meetings, with speakers picked from both our own locality and brought from a distance. These schools are run by vocational schools, the community and with the very efficient cooperation of our State Industrial Commission. These have been of great value to us: Last year they were held at Fond du Lac, Oshkosh, Appleton, Green Bay and Sheboygan. Next week there will be schools at Neenah and Menasha. Out of these have come a very fine appreciation of the importance of safety to our foremen.

CHAIRMAN PEACOCK: It is very interesting to see Bill Ashe organize one of these meetings. He begins to plan, not for a meeting, but for definite results. When we first talked about the necessity for getting enough men together to pay expenses, Bill came through with the suggestion, "That simply means a quota from each mill."

"About fifty men from The Northern; twenty-five men from Thilmany Pulp & Paper Company. Hoyman, that mans about forty from Kimberly-Clark." And so on. You can have a wonderful meeting when you have the quota idea. And, at \$3.00 a head, plus the day's wages, about all it costs per man, the more you send the greater the benefit and enthusiasm you will have returned to your plants."

ADJOURNMENT.

October 2, 1928

W. J. PEACOCK, Chairman

Head, Department of Personnel, Northern Paper Mills, Green Bay, Wis.

The second session was called to order at nine-thirty o'clock by the chairman, W. J. Peacock.

CHAIRMAN PEACOCK: I would like this morning to introduce to you the vice-chairmen of the section. First, Vice-Chairman for South, G. W. Phillips, Supt. of Safety, Champion Fibre Co., Canton, N. C.; for Middle-West, M. G. Hoyman, Supt. of Service, Kimberly-Clark Co., Neenah, Wis.; Vice-Chairman for East, W. A. Gleason, Safety Director, Hammermill Paper Company, Erie, Pa.

I am sorry to say that the other three officers are not here, Vice-Chairman for Canada, A. P. Costigane, of the Ontario Pulp and Paper Maker's Safety Association, Toronto; Vice-Chairman for Paper Box Manufacturers, H. C. Sackett of the Alton Box Board & Paper Co., Alton, Ill., and Secretary N. H. Bergstrom, Bergstrom Paper Co., Neenah, Wis.

Mr. Phillips is doing a significant piece of work in the field of industrial relations in cooperation with the Y. M. C. A. Mr. Gleason is serving us in this meeting as chairman of the Nominating Committee.

Now, gentlemen, I want to ask your indulgence in bringing to focus the suggestion made by Mr. Lundrigan yesterday regarding a permanent secretary for the section. I ask permission to appoint as a committee to bring back to us tomorrow some idea of what can be done. On this committee I will name Mr. B. D. Rogers, Bird & Son, Inc., East Walpole, Mass., and F. H. Rosebush, of the Nekoosa-Edwards Paper Co., Port Edwards, Wis. I am now going to ask the chairman of our Program Committee, F. H. Rosebush, to take charge of his own program for the rest of the session.

ACTING CHAIRMAN ROSEBUSH: Mr. Peacock introduced the vice-chairmen and it rather seems to me that it would have been the proper thing for one of them to take the chair this morning. The Program Committee held two meetings and we set up three different programs. Those were mailed out to some twelve members of the section, largely the regional directors and vice-chairmen, and they were asked to indicate which program they preferred. We did that with the idea of getting the sentiment of as many people as possible in the setting up of this program and, as chairman of the Program Committee, in making this statement this morning I say that this is your program.

The first speaker is Mr. W. F. Ashe, Employment Manager of the Thilmany Paper Company, Kaukauna, Wis.

The Relative Importance of the Plant Safety Department

By W. F. ASHE

Employment Manager, Thilmany Pulp & Paper Company, Kaukauna, Wis.

I never made a safety speech in my life, but last summer, sitting up in a hotel in Oshkosh with friends Rosebush, Bill Peacock, Hoyman and some others, I made some fool crack or other; and one of them said, "Well, let's have a speech from you for the New York Safety Congress." I thought it would be kind of easy and I looked around for all sorts of things, just like the rest of you fellows who got down here just because you wanted to come to New York in October. Some of you got away with it without having to make a speech, but like every fellow who has to make a speech I looked around to see where I could steal it and I found a safety speech in the most amazing place!

There's a book that has a more or less authentic story of people, two thousand years ago, who met all sorts of human problems, and in that I found a dandy story on safety organization. I was going to bring the book here and read that speech but knowing that Bill Peacock was formerly a minister, I was kind of afraid to bring it. I found that speech in the Eighteenth Chapter of Exodus.

That's a book some of you are not acquainted with, but the story is there and it goes something like this: Moses had led the children of Israel out of Egypt and after some years, when they had gotten a good ways out, Moses' daddy-in-law came to visit them and spent the day with them. Moses wanted to put up quite a show for his daddy-in-law—just like some of our safety men like to do with our big boss, and Moses was as busy as a one-armed paperhanger with the hives all day. He thought he was impressing the old man a lot. The old man's name was Jethro, if you've forgotten.

Jethro watched him all day and at night called him aside and said, "Boy, what's all this that you are so busy about; what keeps you eternally at this thing, keeping all these people standing around here?"

And Moses said, "Well, I've got to judge these people. They don't know anything; I've got to show them everything. I've got to settle their disputes because they've been in slavery and they just don't know anything." Jethro said, "The thing that you are doing is not good; you are wearing yourself out and the worst of it is you are wearing your people out, because they have to stand around and wait for you to do these things for them. No good; you're not getting anywhere." He said, "The thing for you to do is to get busy and get yourself a bunch of foremen. You want a superintendent over a thousand; you want a foreman over your hundred; you want a sub-foreman over your fifty and you want a straw boss over your ten men; and in all things that come up, let these men do this job." And then he said, and here is the meat of the whole cocoanut, "You hold yourself and the people God-ward; you furnish the inspiration; you furnish the leadership. Let these people do all the things they are able to do and you hold yourself free for only those big things."

I imagine Moses, being human like the rest of us, figured, "Well, there goes my job. If I can't be the big thing around here, I haven't got any job." But he was wise enough to do what Jethro said and for the first time he had leisure to think about his job.

I think there is a pretty good analogy there for the whole safety game. I look around and see chaps who don't know anything at all about it, hustling around and through the mills, trying to tell this fellow and that fellow and the other fellow to play safe. He can't do anything because, in the first place, he doesn't know what safe practice is; he has never been through the game, doesn't know anything about it, and right there, in his own hands, is Jethro's organization all ready for him. All he has to do is steal it.

You are organized for production, you are organized for maintenance, and all you've got to do, it seems to me, to get some line of safety is to say that we will have production with safety, we will have conservation with safety and we will have maintenance with safety and the birds who are running those crews know a heap more about just how to get that safety in it than you or I.

There is no place for a "safety department." There is place only for leadership and inspiration. You will say that we have to teach our foremen how to do the jobs safely. We don't. We have to get our foremen to the point where they will teach us how the job can be done safely. When we get them there, some of us safety men are going to learn a lot about safety.

You say, "That will take the safety man's job away?" No, it will be the first time he has ever had a job he can do. How is he going to do it? I'm not going to tell you that. There are other speakers here on this program to give you that.

We will never get a safe mill as long as that safety is in the hands of one man, never in the world. Now you will say this is a pretty big job for a safety man to get those things done. I have heard lots of fellows say, "The management of my mill is not interested in safety." Of course that's all bunk. There isn't any management of any mill that is not interested in safety. They may not bubble over with enthusiasm about your ideas of safety. Probably they are right about that. A lot of us have injected a heap of bunk into the thing and we have fussed around just like Moses did, trying to impress the boss, and you know he is a little bit difficult to impress.

You may say you haven't any authority. I don't believe the authority given to a man is worth thinking about. I believe that you fellows, a good many of you, will agree with me that that foreman in the mill is most valuable to you who hasn't very much authority and takes a lot. The authority that you take is the authority that is most useful in the mill. You may say, "If a foreman took authority in our mill, he'd probably get canned." No he wouldn't, not if he uses his head. Bear in mind that a man who steals authority, also takes responsibility, he shoulders responsibility and I don't believe there is a management anywhere who isn't looking for just that kind of a man. Looking for him as a safety man? Sure. A safety man has to be willing to take responsibility and say, even to a superintendent, that that particular practice can't go on because it's unsafe. "Well," you say, "our superintendent would sure hit the roof." Of course he will. But if you have behind you the knowledge and can show him definitely that that is an unsafe practice and give him an inkling of a way in which he can make it a safe practice, that superintendent is going to line up with you and go along.

I think the safety man has got to take the responsibility and the authority for saying that such and such a fellow is an unsafe man, both for himself and his fellow workmen. I think you fellows have all had men that you knew, if you kept them there, were bound to have an accident. I had a curious thing come up a couple of years ago. I had to discharge a fellow and he happened to be the father-in-law of the man who worked as secretary for our president. The president called me to one side and said, "Here, I think you are pretty hard-boiled about this. I don't believe you ought to discharge that fellow; he can't work anywhere else, and I think it's pretty rough to let him out. I think you ought to take him back. "Why certainly we'll take him back," I said, "if you will take the responsibility." "What do you mean, take the responsibility?" he asked. "Well," I said, "if we have him back here, we will probably kill him. We've just escaped doing it four times," and I described the circumstances. I said, "Sure I'll be glad to take him back; I like the fellow first-rate. You take the responsibility and I'll take him back and put him to work." He said, "Ashe, how would you like to go to hell?"

We have one job, all of us, and that is running a paper or pulp mill, taking raw material, working it through our process and selling it for a profit if possible. I hope that day will come, when safety is just as much a production and maintenance problem as anything we have got today.

Jethro said, "You be to the people God-ward." I say to us all, as safety men, "Let us be to our foremen the inspiration, the leadership, the backing up, that will allow them to do the job that every last one of them wants to do. Maybe he doesn't know he wants to do it, but he doesn't want to run his department in an unsafe way. There isn't any man anywhere who wants to kill or hurt his men. All right, let's capitalize on that, build on that, encourage them to build on that particular kind of thing until they run us out of a job. I have an idea if we are able to do that, we can find another job in that plant and I don't think we will have to look very hard."

Are we big enough to do it? Frankly, men, I think we are. I think that the

safety men in general who have been chosen to do this sort of thing average pretty well up with the others. So let us build ourselves up, not by asking for authority but by the fact that we put as much into the game as there is in it. Read, study, build, work, until we've gotten into a place of leadership to these men below us and give back the credit to them for the things they do.

ACTING CHAIRMAN ROSEBUSH: Knowing Mr. Ashe as we do in Wisconsin, we came down here prepared to defend ourselves against what he said. You remember, he said there is no place for a safety department, as such, in the organization, and then he proceeded to tell you how his own safety department functions in certain cases. Now, you may want to ask him questions as to how to link those two things up.

CHAIRMAN PEACOCK: I want to take the liberty, as a former minister, of asking Mr. Ashe what version of the Holy Scriptures he used in these quotations this morning?

MR. ASHE: In answer to that, Mr. Peacock, may I refer you to the answer that the president of our company gave me.

ACTING CHAIRMAN ROSEBUSH: What do you think about the statement Mr. Ashe made that the foreman or safety man sometimes would be out of a job, in regard to safety, that he would be all caught up on safety work?

MR. ASHE: I didn't say that. I said that there might come a time when there would be no such place as an individual safety man or safety department; in other words, when safety becomes incorporated in the entire process of manufacturing.

N. F. BARTLETT (Hollingsworth & Vose Co., Boston, Mass.): I would like to repeat a version of Scripture for Mr. Ashe and Bill Peacock. Don't you know in the Bible we read how Job asked the Lord to look after his safety?

J. J. TELLINGTON (Brown Co., Berlin, N. H.): I would like to ask Mr. Ashe how he handles the problem of the worker in his mill who is unsafe and continues to be unsafe—just what he does before he lets him out, that is, before he discharges him finally?

MR. ASHE: We try every means to make him a safe man. Perhaps he is in the wrong department. Perhaps the type of thing that he is fitted for is not the thing that he is doing. There are some men who can't work with machinery. Some fellows can't work in groups. I will say frankly that very often we find there is no place in the mill for some men and we suggest they go get themselves a job clerking in a store.

ACTING CHAIRMAN ROSEBUSH: We will pass on to the next paper on our program, to be presented by Mr. O'Connell, Safety Engineer of the International Paper Company of New York City.

Some Outstanding Hazards in Paper Mills and Their Control

By CLARENCE H. O'CONNELL

Safety Engineer, International Paper Company, New York City

Outstanding hazards in Pulp and Paper Mills have been and are still so numerous that it has taken years of study and endeavor to get them even under partial control. The unfortunate feature is that a great part of the experience gained and corrective measures employed have been brought about at the expense of much physical and mental suffering by human beings.

The hazards dealt with in this paper certainly are outstanding since in nearly every operation mentioned, one or more lives are lost.

In mills where wood is received in its raw state, prepared and stored, the dangers

incidental to its handling are greater than many realize. Thirteen-foot logs traveling up an inclined log haul where at any time a log may be disengaged from the hooks and tumble backwards, can only be guarded against by having sufficient clearance at the sides and at bottom of the incline for men to jump away should this occur.

Saws revolving at a tremendous speed require expert handling and inspection to guarantee freedom from breakage. In addition, there should be swinging guards in front of saws to protect sawyers in case a stick flies back.

Men guiding the wood into chutes where a jam often occurs, necessitates rapid and careful handling to keep things moving and at the same time avoid injury from flying blocks. We believe that men selected for this work should be given particular attention and instruction by the foreman at this operation. It requires a man to be alert and to move rapidly and we know this type of workman is also liable to be daring and a chance taker.

Conveyors, no matter at what speed they travel, are dangerous when, as often occurs, a workman takes the short cut and climbs over a moving chain. Signs forbidding this practice help, but there must also be continual watchfulness exercised by the gang boss.

Wood being unloaded from cars presents a continuous hazard by the fact that in no way can control be exercised to the point when a stick will not occasionally drop from the tier to the car floor; and, in this case, when wood is not piled but dumped into the cars, the hazard is much greater.

It is not unlikely that the loading of cars in this manner besides being hazardous at the unloading point, is false economy. Time is saved, of course, in loading, but the unloading is a very slow process. Not more than one man can work in the car door and he is obliged to be continuously jumping back and forth to avoid injury.

When an accident does occur here, it is usually one or more broken toes, possibly a fracture further up in the foot. What is believed to be a partial remedy is the wearing of safety shoes or metal toe guards. It is certain that either will afford some protection from foot injuries.

When it is necessary to take the wood from piles of 20,000 cords or less, every precaution is necessary to do the work in a safe manner. As the pile is being dug into from the bottom, an overhang shows above, and in warm weather this will usually take care of itself by gravity, but in every instance when wood falls from a height in bulk, workmen must be continuously put on guard to avoid being hit. In winter, the situation is further complicated by frozen piles, wood is hard to dislodge and gradually the pile assumes a dugout appearance at the bottom with jutting ledges above. It has been the practice, too much so, for men to climb the pile and attempt to break portions of it down by throwing sticks from a certain distance toward the edge. Due to the uneven formation, this is always hazardous for when the pile starts to break there is no telling how far back the slide will reach. In recent years the use of a heavy metal drag to rake the face of the piles has worked out pretty well. This device, sometimes an old ship anchor, can be rigged with cables to operate by electric or steam power and by its use a few times a day, sufficient wood is dragged down to keep a force of men working.

Electrical Hazards

The recent complete electrification of paper mills introduces a hazard that to the layman is little understood and to the electrical operator or repair man, a constant source of danger. Experience has shown that all electrical workers expose themselves at times to this danger, new employees due to inexperience, older ones to overconfidence and habits acquired during years of experience when perhaps they were just lucky. How often we hear an electrical worker recite an experience

where he absorbed 550 volts and was only jarred or stunned for a moment. The fact that he did survive a near accident of this sort is no proof that death will not result from even less voltage, depending on the physical condition of the victim, and the tools and appurtenances with which he is in immediate contact.

Without any knowledge of electrical power or its application, we do know that electric railways, public utilities and manufacturers of electrical equipment where apparatus is subject to severe tests, operate successfully and with comparative safety. We know also that this could not have been accomplished without intensive study as to safety standards and safe practices and the application of rules which will insure safety if followed.

Therefore, we who have this problem as only a part of our process, should endeavor to minimize the hazards we have. First, by thorough instruction of electrical workers, continuous inspection of equipment and surely the provision of safety equipment, rubber mats, gloves, fuse pullers, rubber blankets, etc.

Safety meetings of electrical workers apart from regular plant Safety Committee Meetings are recommended. Although rules cover ordinary causes of electrical accidents, it is important that all hands get together at regular intervals, perhaps because of changing conditions and equipment, but at any rate to create and maintain the tendency to think and act in terms of safety.

What cannot safely be dispensed with among any group of electrical workers is a well trained first aid team. Among safety men, the knowledge of this requirement is as old as the hills, yet, lapses in training do occur, changes in personnel perhaps may reduce its efficiency and when the crash comes with a man's life hanging in the balance, regrets and alibis are of no value.

What is of extreme importance in connection with electrically controlled machinery, both for electricians and others, is the use of danger tags on controls whenever it is necessary for a workman to make repairs or in any way expose himself to the possibility of being caught by parts while in motion.

There is to contend with, also, repairs and construction work around exposed current carrying parts, being done by others than electricians. The fullest protection should be given to workmen exposed to this hazard and should take the form of supervision by a foreman or expert who knows whether or not power is off and the clearance necessary for safety when the work approaches live circuits.

We have to also consider the operator of machinery who knows nothing of electricity beyond throwing in or pulling out a switch. This means the lathe operator in a machine shop or perhaps a conveyorman in a chipper building. Our job is not to give him a course in electrical power operation but to teach him a few things he must not do.

There have been occasions in our own experience where men were burned to death in tanks No. 1 because of the failure of the operating steam valves. There is no escape in a case of this kind when such a volume of steam will practically cook a man in a few seconds.

When steam is delivered under pressure to digester, or bleaching tank, where it is sometimes necessary for employees to go for inspection, repairs or cleaning, a safety valve should be installed between the operating and main supply valves, so located as to be easy of access and plainly marked "Safety Valve." Whenever there is occasion for a workman to enter this tank or vat, he should personally see that the safety valve shuts off the steam and is properly tagged by him.

The broke beater, while a very innocent and harmless looking piece of equipment, as generally viewed, is really a potential hazard. Less now than in the past because of more care being exercised in its handling, following fatal accidents in nearly every section of the country where paper mills operate.

Unless employees are carefully instructed, cautioned and watched, they have a tendency to lean too far over while feeding beaters, thus exposing themselves to the danger of being drawn in with the broke. And, not only will they lean toward

the point of danger but will even climb into a beater to relieve congestion or plugged conditions of the stock by treading it down. Any practice of this nature becomes highly dangerous the second the man's feet leave the floor. The control of this hazard can be obtained only through continuous education and instruction by the supervising force.

Belts.—The operation of taking off and putting on belts has been the cause of a great many accidents through employees undertaking to do this while machinery was in motion. When necessary to perform work of this kind driving machinery or power should be stopped, and where it is necessary to slow down or start up to do the required operation, the power should be regulated by a competent man, separate from the man actually handling the belt. It is true, too, that regular belt inspection for condition and repairs when machinery is down, will do away with the necessity for much belt handling during operating hours.

Machine Felts.—In nearly every paper mill accidents occur while washing felts, particularly so on the larger paper machines. Inasmuch as this operation is necessarily performed with the clothing on the machine, it is important that safe running boards, and, when possible, hand rails should be provided. If the running board cannot be used while the machine is operating but can be installed while the felts are being washed, a properly fitted removable board should be provided and used.

It is also important that every employee who performs work of this character be instructed how it can be done with the least possible hazard. Such instruction should be coupled with the actual work. One of the important features should consist of instructing the employee handling a running felt to keep his hands as far as possible away from the inrunning bite or nip between the felt and felt roll. In other words, wherever it is not absolutely necessary to do otherwise, the location of the operator's hands on the felt should be as far as possible away from the point where it meets the felt roll.

Paper machine winders are a constant source of danger on account of their speed and the inrunning nip, together with makeshift devices which winder operators sometimes use. The practice of using rope on winder shafts to prevent rolls slipping is unnecessary as well as unsafe, and should be discouraged. There is a tendency, also, in starting a reel to use a cloth or a piece of broke to drip water on the reel. The danger of this is that hanging cloth or broke may be drawn between the reel and the movement is so rapid that the workman's hand is usually drawn in with it. For this purpose it is recommended that sponges be used as they are so compact and suit the purpose even better than either cloth or broke.

When the reel is started the nip should be protected so that if a man stumbles and falls toward the winder he cannot drive his hand into it. A good practical guard consists of reinforced wire mesh in an angle iron frame about a foot wide and extending the width of the machine, installed to suit the particular type of winder on which it is to be used.

We know that today mills generally are well guarded to comply with state or province labor regulations if nothing more. There remains, however, the human factor; lack of proper instruction, mental lapses and want of cooperation between departments or individuals, not intentionally, perhaps, but nevertheless a primary cause of numerous accidents.

The control of any condition of this sort rests with the Plant Safety Committee to devise ways and means for betterment and for the Department Heads and Foremen to translate into action whatever plan is adopted for correction.

ACTING CHAIRMAN ROSEBUSH: There may be questions that you would like to ask, suggestions, experiences that you have had in your own paper mills.

W. H. JENNINGS (Bogalusa Paper Co., Bogalusa, La.): With reference to putting the rope on the rewinder, is there anybody in the house can give me

some idea of a collar ever devised to fit on that shaft when you start the roll? Now, we use the rope and during the course of a year, we have a number of men who lose a part of a thumb and down in the South, the paper mills are something new and we have had to build up our staff through local people to a great extent and we have had a lot of trouble with that rope on our rewinder. I wonder if the gentleman can give me some idea of a collar of some kind.

MR. O'CONNELL: There has been a collar made for that very purpose. We use it in our mills.

B. D. ROGERS (Bird & Son, Inc., E. Walpole, Mass.): We used to have some accidents to thumbs and fingers on rewinders. Our paper is fairly heavy paper and we use a gum paper in putting it on the shaft.

ERNEST AUGUSTUS (Mead Pulp & Paper Co., Chillicothe, O.): There is one hazard that is quite common in paper mills, that is your calender stack. Now, you can put a guard on the nip of your calender stack but you can't keep a fellow from getting his hands up in there, and on the machine stack, you can't put a guard over the nip in certain instances. How are you going to protect that?

MR. O'CONNELL: Isn't it possible to use air so the operator's hand won't approach the nip within six or eight inches?

MR. AUGUSTUS: Well, if the operator will do it. But we had a fellow just a month ago, pulling an armful of broke out between the first and second stacks. In some way, this caught the armful of broke and pulled five fingers of his two hands before he could do anything. We couldn't put a guard over there to keep that fellow from being drawn up; he had hold of it in such a way that he couldn't let go of the broke quick enough.

MR. O'CONNELL: That is on the front side? Yes, I don't know how you could overcome that, except by education.

MR. ROGERS: We had a very similar case and it was a wonder the man didn't lose his arm and he just plugged it in time as his arm stopped right at the nip, but we have since put in that guardway across the stack.

MR. O'CONNELL: I didn't mention the calender stack; I meant the paper machine winder.

MR. ROGERS: I thought you put a guard across the stack?

MR. O'CONNELL: Across the winder.

MR. ROGERS: We have a guard on our bottom nip so that in pulling broke out, the paper can still go between the stack but it won't go up in the nip and pull him in.

ED. J. GAYNOR (Scott Paper Co., Chester, Pa.): We had quite a little trouble in our calender stacks with fellows getting their fingers in there. Of course their arms wouldn't go through. We run a little sheet. We don't do much calendering, but the way we finally solved the problem was to instruct one man on the crew very definitely how to put the paper through the calenders and take the broke out and that's the only man who dares go near the calenders.

ACTING CHAIRMAN ROSEBUSH: What kind of paper do you use?

MR. GAYNOR: Twelve-and-a-half pound sheet, very lightly calendered, and it only goes through one nip.

H. A. FISHER (Bird & Son, Inc., E. Walpole, Mass.): We have had quite a few accidents where the men have lost the ends of their fingers by getting caught in the calender stacks and on a visit this summer that I made to another mill, I found where the end of the paper goes into the calender stack, about six inches long of, well, a piece of a broom handle will do, rounded off, and we are doing that now and we don't expect we are going to have any more accidents that way.

ACTING CHAIRMAN ROSEBUSH: Of course that means a matter of educating the man to use that stick. Someone else might say, "What happens if he mislays the stick?"

FRANCIS WOODCOCK (Hercules Powder Co., Brunswick, Ga.): I was very much interested in Mr. O'Connell's article, particularly that part relating to the handling of wood out of cars and the fracture of feet and toes. I would like to ask him what method he uses in inducing the men to wear safety shoes?

MR. O'CONNELL: To be frank with you, we haven't had a great deal of success in the wearing of safety shoes.

MR. WOODCOCK: Do you have the steel slippers?

MR. O'CONNELL: Yes. We find them satisfactory, except where a man has to jump around very much. If he remains on one level, they are quite safe but on uneven surfaces, not so good.

J. J. COFFEY (Pennsylvania Department of Labor and Industry, Philadelphia, Pa.): I came here to learn something about these calender stacks, because it is quite a serious proposition with us in Pennsylvania, in the number of people that have been caught.

W. A. GLEASON (Hammermill Paper Co., Erie, Pa.): That seems to be the general question before the Department of Labor and Industry and I know our district supervisor, Mr. Carey, is very much interested. We have the calender stack guarded by a simple angle arm placed in front of the nip, possibly about an inch and a half away from the exact nip and when the man puts the paper down there, his hand goes against this angle arm or guard and it doesn't interfere.

MR. COFFEY: I suggested such a guard and they all told me it would never do.

ACTING CHAIRMAN ROSEBUSH: Mr. Augustus asked that question when he inquired about the interference with the air pipe. Can anybody answer that?

MR. GLEASON: I think possibly he was talking about the calender on the paper machine. We have what we call the super-calender. The air pipe on our machine is only at each corner of the machine, one from each side, and in addition to that, we have this angle guard. On your paper machines, your doctor will answer as your guard. Now is that clear—on the paper machine, the doctor board answers as your guard. On the super-calender machine, we have this angle iron guard.

ACTING CHAIRMAN ROSEBUSH: Fine, but it doesn't answer Mr. Augustus' question as to how to guard the nip where the air pipes are used. Some of them have five or six air pipes in front of the nip.

MR. GLEASON: We only have two and our doctor board answers as our guard.

MR. COFFEY: Yet we know of accidents where they have the doctor board, so while it may decrease the accidents, it doesn't eliminate them.

MR. FISHER: There are some cases where we used the angle irons but on our paper machines we make a very heavy sheet, something around twenty-five to thirty-one thousandths, and it would be impossible; in fact, we found the angle iron was a detriment to us, there was more danger and in fact the men couldn't get the paper to the calender stack with a heavy paper like that.

CHAIRMAN W. J. PEACOCK: Mr. Faist has an invention that eliminates a lot of hazard on calender rolls.

KENNETH L. FAIST (Champion Coated Paper Co., Hamilton, Ohio): The majority of our accidents, we found, are due to scraping rolls. We were averaging five or six accidents at least, per month, on the super-calenders and they were due to scraping rolls. They used a piece of steel or anything they could get hold of to scrape a roll, to get all the marks off the roll. We made a small device that was in the May issue, I believe, of the *National Safety News* and you can get a copy of that or a copy of the blue print. We still use the blade in scraping the roll, but it has a handle protected by two wings. In case the blade should happen to get in the nip it will pull the blade right out from the handle but your hand is always covered.

ACTING CHAIRMAN ROSEBUSH: Has this question been satisfactorily answered for those who raised it?

MR. COFFEY: This gentleman back here states that on the heavy paper they found the angle iron was not practical. Now, that's just the point these people brought up with me, and by the way, Mr. Gleason, it was through me that Mr. Carey called on you.

MR. AUGUSTUS: I would like to ask Mr. Gleason for a further explanation on the calender stack of his paper machine. When the thing runs over 450 to 500 feet per minute, how are you going to get the paper behind that angle iron without wasting a lot of paper?

MR. GAYNOR: We have tried all manner of guards and angle irons. We have gone so far as to put a guard away from the calender, so the man could not get his hand in the calender. Our sheets run 755 feet a minute on one of the machines that have calenders, and we have found the only thing we could do was to insist that nobody but the back tender put the sheet through the calenders. I think the biggest job that we have in safety is just that matter of education; there are a lot of places that we can't guard against and that is just one of them but it is just a matter of education, to follow up and see that the proper methods are used.

F. L. IRVIN (St. Croix Paper Co., Woodland, Me.): We are represented here today by a practical papermaker, Mr. Coons. We would like to have him tell us about his work on calendering.

FLOYD S. COONS (St. Croix Paper Co., Woodland, Me.): I am working on a newspaper machine, running about 750 feet a minute. We take care of that by the process of air. The paper is blown through the stack and the broke is taken care of by going through broke holes, so the attendant doesn't have to touch the paper at all.

L. J. PARANT (St. Croix Paper Co., Woodland, Me.): Let me add something to Mr. Coons' statement. We reduced the hazard around the stack very materially by first cutting the slot into the floor on each side of the stack, to let the broke go down to the basement. Then we used the Warren doctor, which was another good move. The next move was the adoption of the air, which has reduced all hazards around the stack.

SAMUEL PRUYN (Finch-Pruyn Co., Inc., Glens Falls, N. Y.): I can vouch for what he says. We manufacture news print paper running about 750 feet a minute. During the last ten years we have never had an accident around our stack.

MR. FAIST: I think part of us are talking about one calender and the other part on another subject, that is the super-calender and the calender on the paper machine. The majority of our trouble has been on the super-calender, not the one on the machine. It is true that education has a lot to do with it. As long as a man takes the paper and feeds the paper in through the nip with his fist, there is little or no danger, however, when you have a green man on there ever so often, he will take his hand and run it in and eventually he will have his fingers in it. I would like to ask Mr. Gleason if he uses the angle iron on his super-calender.

MR. GLEASON: Yes. We have used it for years.

GEORGE E. AMES (Falulah Paper Co., Fitchburg, Mass.): We have tried out the angle iron on one calender and the operators immediately said it slowed them up, so that production didn't go well, and finally, on their promise to be careful, we took it off again. Now, I want to ask a question. If you find that is the experience of men from different mills and find the angle iron is not the correct thing, and the men object to it, how are you going to put it over?

ACTING CHAIRMAN ROSEBUSH: Increase your bonus.

A. S. WILSON (American Writing Paper Co., Holyoke, Mass.): Our Board of Commissioners down there is very much interested in these guards, especially

at the point of operation, and I was much interested in the angle iron discussion here. Our people have been able to work with it for some time. We got one of our local machine shops to devise what I think, on the whole, unless you are running some heavy board, works out very good and is adjustable, very inexpensive, and we are having success with it. But in our coarse mills we have had to move that guard back. I would be glad to give anybody interested the address of the manufacturer. It fits right into the hole and you can see your scratches, your marks on your rolls and see that they are scrubbed and cleaned with the guard on. It is not a hundred per cent guard and I don't believe they make them for us on all grades and weights of paper, but that guard is good for the finer mills. You can take it back half an inch when you are running your heavier sheets.

ACTING CHAIRMAN ROSEBUSH: Now, Mr. Augustus raised this question of wearing shoes around the paper machines and I am sure that there are a lot of folks here who are interested in that question. Who has the answer?

MR. GLEASON: Answering that in a short way, we put in cement floors in the paper machine rooms.

ACTING CHAIRMAN ROSEBUSH: Well, I'll give you our answer to it. At the Nekoosa-Edwards Paper Company, the question was repeatedly brought up. We had had accidents where men were barefooted on a cement floor and it was brought out that it never had been insisted upon by the management and the superintendents. So we said, "All right, we'll insist upon it," and within a week we had the problem entirely solved.

F. H. FISHER (Bird & Son, Inc., E. Walpole, Mass.): Bird & Son insist that the men wear shoes. All the time I have been going through the mill I don't believe I have ever seen a man without shoes.

ACTING CHAIRMAN ROSEBUSH: As a matter of curiosity, how many men representing mills here have operatives barefooted? Seven of you.

W. F. ASHE (Thilmány Pulp & Paper Co., Kaukauna, Wis.): Those of you who raised your hands, how many of you consider it is an unsafe practice? All of you? Then why don't you stop it?

J. J. TELLINGTON (Brown Co., Berlin, N. H.): It does seem strange but it is a fact nevertheless; we have no accidents and the papermakers go barefooted.

ACTING CHAIRMAN ROSEBUSH: Have your men persuaded you that they can do better work barefooted than they can with their shoes on?

MR. TELLINGTON: There has been nothing done about this. Our machines are running on a standard and everything seems to be O. K.

W. J. BRENNAN (St. Croix Paper Co., Woodland, Me.): In discussing this last point, there will be a conflict there immediately on first-aid treatments and dressings to feet. You can imagine what will happen if you drag a cotton bandage through a general machine room. First-aid is immediately handicapped if you permit those men to drag a clean dressing through the dirt. Our policy, and it seems a logical one, forbids it. A warning by bulletin, a rule issued from the papermaking department, a suspension on the first violation, which always hurts, and discharge on the second.

EARL E. GRANT (Crystal Tissue Co., Middletown, Ohio): From the standpoint of public health and hygiene, we don't allow our men to go barefooted because statistics show that about fifty per cent of the people have ring worm between the toes so from a first-aid standpoint we have to prohibit that.

CHAIRMAN PEACOCK: We have had a suggestion from our mill manager, Mr. W. A. Kelly, that has gone a long way in helping us to enforce our rule requiring men to wear shoes. When we put in a locker room with shower baths and other facilities for the comfort and health of our men, he ordered that we put in foot baths. We have three of them, designed to stand about 16 or 18 inches from the

floor, hot and cold water, and a stool. As a result we have a lot less foot discomfort.

GEORGE E. AMES (Falulah Paper Co., Fitchburg, Mass.): Our men wear shoes in all departments; but for all that, in the first six months of this year, we have had five fractured toe accidents. The feet don't seem any larger than the ordinary man's but they seem to be in the way when they are handling anything. It is usually a case of dropping things on their feet. I want to ask a question here as to what the experience of these men has been on shoes that are specially designed and reenforced around the toes, and whether any of your employees use them?

ACTING CHAIRMAN ROSEBUSH: Do you mean around the paper machines?

MR. AMES: In any section of the mills.

N. F. BARTLETT (Hollingsworth & Vose Co., Boston, Mass.): About six months ago we had a representative from a shoe firm, a safety-first shoe company, so I wrote a letter to each superintendent at our mills and sent out a sample of the shoes which were given to me by the salesman. That shoe was sent around the mill and shown to every employee and they were asked if they would like the privilege of purchasing that shoe—the cost was small and it was a good looking shoe, the toe strong and firm, and we sold a lot of shoes to the men. Now, Mr. Ames, if I can help you on that, you and I being neighbors, I would be glad to do it.

Hazards of Going Barefooted

A. S. WILSON (American Writing Paper Co., Holyoke, Mass.): I can't forget about five years ago, just about when I started with the American Writing people, the question of going barefooted came up then. We are getting away from it now, the superintendent has insisted on it, and they are going around with their shoes on. I think at times the men who perhaps go barefooted in the paper machine rooms, if you don't follow them up they will go down in the repair shop and they don't put their shoes on and they get splinters in, pick up a nail in the finishing room, and there is a lot of our trouble in that way.

ACTING CHAIRMAN ROSEBUSH: We watched our men both barefooted and wearing shoes and the superintendents were convinced that the men could wash up quicker and didn't have to pay as much attention to where they stepped and the way they went at the work when they had their shoes on.

MR. FISHER: Our men don't wear any stockings in their shoes. Just simply put their shoes on. And I wouldn't recommend rubber heels or soles for men in the paper machine rooms because the floor, as a rule, is wet and a little oil on that wet floor will flop a man mighty quick.

MR. AUGUSTUS: I would like to ask those fellows who require the men to wear shoes, whether they require them to wear them while washing up?

MR. FISHER: Always in Bird & Son mills.

ACTING CHAIRMAN ROSEBUSH: Always with us, too.

MR. GLEASON: Immediately when we have a wash up job, the men change from shoes to boots.

JACOB RECORD (St. Croix Paper Co., Woodland, Me.): I have been about forty years in the mills and looking after and around the paper machines. I agree with Mr. F. H. Fisher. No rubber soles. Have leather soles on your shoes. A leather sole is the safest, if you have got to wear a shoe.

ACTING CHAIRMAN ROSEBUSH: I am sure that if Mr. Costigane of Ontario had been here this morning, he would have enjoyed this discussion because it was his suggestion that we have a topic of that kind. The next speaker is Dr. J. G. Cunningham, of Ontario.

Health Promotion in Conjunction With Safety

By DR. J. G. CUNNINGHAM

Director of Industrial Hygiene, Ontario Department of Health,
Toronto, Canada

Sickness and accidents caused by industry have claimed considerable attention from industrial executives. General sickness among employees, although common to the community at large and not primarily the responsibility of industry, is receiving more and more consideration by industry, irrespective of its cause, on account of its influence on the workman and his work. This has brought those responsible for safety and health closer together mainly through problems presented in employment—workers with some disabilities are unsafe in certain occupations. They are indications that ill health influences accidents in ways much less obvious than this. So that the supervision of health in industry, apart from its importance in the reduction of absence and other benefits associated with the control of sickness, has a definite bearing on the number of accidents incurred.

Sickness and accident control have passed through parallel stages. Efforts toward the maintenance of health were first directed against nuisances with a purely external influence analogous to the machine-guarding stage in accident prevention, both important as far as they go. Then followed the period of general health education which still continues and cannot be underrated, having its counterpart in the efforts made in the last few years to encourage industrial workers to think in terms of safety, i. e., the application of what has been learned regarding the principles underlying health and safety. In health matters, not only in industry but in the community at large, an increasing amount of attention has been given to the health of the individual, this often taking the form of clinics of various kinds, all actuated by the idea that health education to be applied most effectively must be directed to individual needs and cannot have more than passing significance unless related to the condition of the individual as determined upon physical examination. Hygienic advice given at this time has been shown repeatedly to be of real value in that it is accepted and acted upon.

Reduction of the amount of sickness in industry by attention directed to the *individual* was at first confined to those exposed to specific poisons wherein mechanical safeguards and physical examination were used. Notably, in this country in many plants this has been extended in the effort to prevent general sickness among all workers. The grouping of large numbers of people together day after day makes it possible to bring medical diagnostic service conveniently within their reach so that they use it at the time when it is of most benefit, i. e., when the first indications of illness arise. The individual too frequently is not conscious of a pathological process in his body until considerable damage has been done and knows nothing of it until physical examination has revealed it. It is on this latter account that periodic examination is even more important than examination on employment. The rapidity with which the physical character of the same industrial group will change is sometimes very striking and by means of physical examination these changes will frequently be detected at an earlier stage than when complete reliance is placed upon complaints of ill health.

This second safeguard for the early detection of illness, i. e., complaints of ill health presupposes, easily accessible and good medical facilities for diagnosis and the worker's complete confidence in them. Experience shows that under these circumstances, the health problems presented by workmen for assistance extend far beyond purely medical considerations.

It is a common experience of industrial nurses that some unfavorable situation at home or at work seems to be the major factor in lowering resistance to disease

and that the situation only comes to light when circumstances of a minor or serious illness are investigated.

It is generally recognized that the causes of sickness and accident are many and varied so that any effort to control them often involves looking beyond the plant, to the workman's home. This is not resented when workmen have been convinced that the only motive is the reduction of sickness and accident.

This attention to individual needs, as practiced with respect to sickness has already furnished examples of the importance of the same procedure in reference to accidents. Physical examination of workmen limited to the discovery of the presence of hernia, varicose veins and gross heart lesions, is common. It is very incomplete. However, this attention to the physical condition of the individual in accident control is a step in the right direction and is in line with the indications furnished by the work of the Industrial Fatigue Research Board pointing to the existence of individual susceptibility to accidents. Certain persons having no gross defect, such as epilepsy, blindness, deafness or abnormally low reactions are, nevertheless, whether for physiological or psychological reasons, poor accident risks. At present, they can be identified only after the event by knowing their history with respect to major and minor accidents at home and at work. Progress is now being made in work which it is hoped will enable these susceptibles to be recognized at the time they are assigned to their work. One would expect such a condition to be materially influenced by general health. Some of the conclusions of the Board bearing on this interesting point are that—

(1) Persons of the same age and experience under similar conditions will show widely differing accident experience.

(2) To a considerable extent those who suffer industrial accidents also suffer home accidents.

(3) There is no definite relation between multiple accidents and ordinary environmental factors. This suggests that accidents might arise out of some inherent quality in the individual and would seem to warrant the idea that those who have three or four minor accidents should be removed from dangerous processes.

General sickness and industrial accident experience among industrial workers present some common characteristics. Uniformity in deaths from the predominating types of illness extends to the number of cases and even to the amount of lost time from year to year. Similarly, in industrial accidents this uniformity in deaths extends to the number of cases of over seven days' duration and even to the liability of various parts of the body to sustain injury. The accident record of the pulp and paper mills in Ontario shows that each part of the body mainly affected sustained injury with almost the same frequency for each year from 1922 to 1926, inclusive.

The total number of accidents and illnesses is greatly influenced by a comparatively small proportion of the numbers employed. The inexperienced and the young suffer both more accidents and more sickness. Environmental conditions influence both, either directly to produce accidents and sickness, or indirectly to put the individual in a condition where he readily succumbs to these. Susceptibility to some diseases can be determined, i. e., smallpox, diphtheria and scarlet fever. It is now suggested that certain individuals are inherently liable to accidents.

Further it has been determined that while there is no relation between the number of accidents and the amount of time lost from sickness, there is a small but constant relation between the number of accidents and the number of visits to the first aid room for minor sickness—the latter is a truer index of the number of cases presenting some maladjustment somewhere.

This again emphasizes the importance of correcting minor complaints of illness, which are generally the expression of minor derangements, rather than a minor indication of a more serious illness. The correction of these minor derangements

leaves the individual practically as well as he was before their accumulation is likely to result in incapacitating illness. The minor accident may similarly be the first manifestation of some condition easily corrected if recognized, but which, left alone, will accumulate in its effects, resulting in some more serious condition. A relation has been shown to exist between serious and minor accidents in most groups studied.

There is much to be learned regarding the problems in the control of sickness and accident and the indications are decidedly that the whole question cannot be dealt with en masse, but that each individual case requires separate attention, and, further, that the control of ill health desirable for itself is also desirable for the prevention of accidents. When incapacity from illness and accidents has arisen, facilities for the maintenance of health should be used to insure the best treatment which includes maximum restoration of function. The importance to industry of the patient's early return to work and the outside physician's duty in respect to his safe return to work frequently seem to be in conflict. This situation arises from the casual relation too frequently existing between the physician and industry. To delay return to work following illness or accident is not the best treatment and is decidedly uneconomical, but return to "light work" can mean nothing unless the employer is prepared to provide it and the physician is sufficiently familiar with the plant to be able to indicate what work the man could do.

When the period of active treatment is completed, whether it is a lung or a leg that is affected, this work should be such as to require the use of the injured part in therapeutic doses until function is restored. In the prevention of illness, with its influence on accidents, or the reduction of disability and unemployment associated with these conditions, those responsible for employment and safety will receive assistance from consultation with the physician, provided he is one who appreciates what incapacity for work means to employer and employee.

ACTING CHAIRMAN ROSEBUSH: I wonder if any of you have questions that you would like to ask Dr Cunningham.

J. T. LEAVENS (Standard Accident Insurance Co., Detroit, Mich.): About a year ago, I was transferred into a territory which includes about fifteen paper mills. This was due to high accident frequency. In my first inspection of my mill, I suggested a physical examination for all employees. The officials of the companies were very much in favor of it but the employees themselves were against it for the reason that they thought a physical examination might throw them out of employment. I would like to have the doctor's advice, if possible, as to the proportion of accidents that can be charged to a man's physical condition, insofar as the number of industrial accidents are concerned.

DR. CUNNINGHAM: The number of accidents affected by gross conditions of health or gross disability, or the number of accidents that may be influenced by minor ill health, may be quite considerable. I am sorry that I can't give you anything more definite.

ERNEST AUGUSTUS (Mead Pulp and Paper Co., Chillicothe, O.): Dr. Cunningham made mention of the relation between the number of accidents and the number of minor illnesses reported to the first-aid hospital. For the past three years we have been trying out a little scheme—I don't know whether it is original with us or not—but we have between twelve and fourteen hundred minor illnesses, ailments, etc., reported to our first-aid hospital every month, a record of which is made on our hospital day sheet. Then we take that hospital day sheet and transfer information to an individual card for each employee in the plant showing the date, nature of the illness or injury or whatever it might be on which first-aid is given, and the approximate cost, if any, of the dressings and if the man lost time, the amount of time and compensation.

Now, at the end of the year, or any time during the year, it is surprising what you can find from those records. You will find that possibly you have a certain

employee in a certain department who is continually coming in for headaches, or maybe he has colds frequently or something of that sort. Then, once in a while, that fellow has an injury, it may be lost-time or it may not; and then the personnel manager or superintendent or foreman goes over that record—we have it arranged so that if a man comes in a certain number of times for a particular ailment or particular type of injury, a little flag is put on his card—then you can go down through those cards and pick them out, study those cards, and frequently you will find the man is on the wrong job. His ill health is due to the wrong job and frequently he stops coming to the hospital when he is transferred.

We have been using that for three years and have found a number of instances where men, injured to the extent of losing time, could be traced right back to some physical ailment or certain peculiar condition surrounding that job to which he might not be adapted. Then we transferred him.

We do not have periodical health examination; we examine everybody when they come in and they must pass the examination before they can be employed. After they are in we don't tell them to be examined again, but from the information on these cards, if we find a big preponderance of accidents on his record, we call him in; maybe he is not aware of the fact that he has been having a lot of colds or stomach ache or minor accidents of a particular type; and then the doctor consults with him and advises him to go to his own family physician and have a medical examination or get treatment for what he thinks is wrong with him. Frequently the men have acted on that advice and kept their jobs where, otherwise, they might either have been injured or we would have had to discharge them because of being unsatisfactory.

ACTING CHAIRMAN ROSEBUSH: Tomorrow morning we are going to have Dr. Hourigan, physician of the Larkin Company, who I believe is present today, to take that theme right up there—"How to Administer First-Aid in the Small and the Large Plant."

DR. P. H. HOURIGAN (Larkin Co., Buffalo, N. Y.): I would like to say something on this health activity in the industry as referred to accidents and referred especially to efficiency and to compensation costs. You can easily trace from experience the connection between bad teeth, infected tonsils, infected nose and inflammation of the muscles, inflammation of the nerves, inflammation of the joints. Now those things, of course, weaken the man and a weakened man in a group of men is easily likely to be the factor that causes an accident.

And the other thing, along the line of knowing your men through a physical examination, is the special factor of eyes. It is well known that 40 per cent of people, working people, are badly in need of glasses. They can't see what they are doing, and if they can't see what they are doing, they are going to make mistakes, they are going to shove their fingers in and get them caught and 40 per cent means that they are badly in need of glasses.

Now, there was a thought in my mind when they were talking about the wet floors and the bare feet. Such a condition should not be permitted, without special precaution against ringworm, as mentioned here this morning. It is a common thing and I wonder if a physical examination of your employees wouldn't show that those men who go around with bad feet, haven't ringworm? That means cracked feet, sore feet, soft corns, etc. Then along the other line of following up your health conditions, we often run across people with bad physical condition.

Only last week in our plant a man wanted to return to work. He came in to me first some six weeks ago, not feeling well, out of breath, wasn't moving so fast. Physical examination showed a bad heart and he was laid off. After being home six weeks he wanted to come back to work. His condition wasn't good and we found he had not been taking care of himself, he was walking around more than he should and after a couple weeks more he told us he had seen his doctor and he said he was all right. We checked up a little more thoroughly and found

the employee had not gone to the doctor at all and he was bad enough, three days afterward, to drop dead in his home. He might have dropped dead on your job, he might have been the cause of a big accident.

Now, we meet those things and help to solve them and we prevent actually a great many accidents. Another important thing, I think, is the matter of handling your health problem with your sick insurance or benefits, and sick benefits also have operation benefits attached to them. You will find that necessity of many people is the dominant thing in their claims for compensation as a result of accident in your industry. Check up on your knowledge of those people and relieve their necessity and it will often reduce the number of your accidents, that is, in minor cases, because you have the relief in operation of a sick benefit.

ACTING CHAIRMAN ROSEBUSH: I would just like to mention a specific instance of what Dr. Hourigan is talking about. We had a man raking flumes. His boss came out and passed him and then heard some kind of a splash and looked around and the man had disappeared. Of course, at once he commenced to search for him and saw his foot sticking out of water right next to the flume. He called to his helper and they pulled him out and revived the man. At first it appeared as though there had been an accident, as though the pole or something had caught and he had lost his footing and gone in there. Some two weeks later he was downstairs near the hydro-electric wheel and toppled over on the bench; and then we became more suspicious than we had been before and sent him to the clinic at Rochester and found out that for a long time the man had been suffering from a tumor of the brain. Fortunately, we have our own sick and accident off-duty insurance, which does the same thing that Mr. Augustus told you his reports do.

B. D. ROGERS (Bird & Son, Inc., E. Walpole, Mass.): I just wanted to speak about a similar thing to that which the doctor brought out on the benefit associations. Safety and health are equally important in our program and we have found that a reduction in the amount of time lost from sickness has been reduced perhaps by half in ten years with a corresponding reduction in accidents. Now, that may be little Bill Peacock's corollary on efficiency and accidents, but I do believe sincerely with the other speakers that bad health is the origin of a lot of accidents. One way that we have benefited our employees and brought about better health is through our benefit associations and the employees are doing it themselves.

About ten years ago we selected for our different plants the best doctors in those communities and any member of the association was allowed to go to those doctors free of charge and the doctor would send the bill to the association and we soon began to find that there was less time lost due to sickness than before. I think that it was shown over a period of ten or twelve years that the amount that we saved in benefits has more than paid for the physicians' services. The member of the association goes to see the doctor and it is entirely confidential. He has no hesitancy about it, he can go to see the doctor when he begins to feel sick and not when he is sick in bed and has to send for a doctor. They don't lose any time at all in availing themselves of that privilege. The majority of our Benefit Association cases are office calls, and I think that in itself has proved to us that our Benefit Association is a mighty good scheme.

A. S. KLOSS (Hercules Powder Co., Brunswick, Ga.): May I ask the doctor what he considers the length of time between the original examination and the re-examination should be? In other words, how often in general should you re-examine the employee?

DR. CUNNINGHAM: I don't think there is anything particularly gained by having regular periods. The thing should depend entirely on what you find in the first examination, the kind of work the individual is doing, what degree of hazard he is exposed to.

ADJOURNMENT

mills, helping to set up regional conferences, organizing the contest and, in fact, all the activities of the section, but the main problem is something like ten thousand dollars a year which must come from the paper mills. It certainly wouldn't come from the National Safety Council. I am rather interested in this suggestion of our honored Director of the National Safety Council, that he could go out and raise the money. Now, the man he happens to have in mind is my own boss. Well, my own boss is not going to put ten thousand dollars a year in this thing. Your boss is not. The Paper and Pulp Section is not making money hand over fist like the Petroleum people are. All of these things have to be taken into account. I want you to face this matter, gentlemen; it has been on my mind for several years and because of the difficulties involved, those of us on your official staff have tried to help you organize efficiently such voluntary service as might be available. Now maybe we are helping you to decide this thing beforehand.

MR. ROGERS: Another thing that Mr. Rosebush and I discussed was the possibility of linking up in some way with the National Paper and Pulp Association. At the present time they have a technical association and a cost association. Most of us probably belong to those different associations. There may be some way that we can go back to our plants and talk to our managers who are members of the technical association, and get them to put up this money, or a part of it. It seems to me it is right along this line of work and they are, as I say, a very big organization, with headquarters here in New York.

MR. ROSEBUSH: There is one other point that I would like to make in regard to this representative. I think any scheme that looks toward having such a representative ought to be based on the idea of having it somewhat permanent. I think it ought to have three to five years of trial anyway. It would not be fair to take a man for one year and make an experiment of it for that period of time. I don't think it would be fair to the man nor fair to the section, and any scheme we might adopt for putting a paid representative in the field ought to have in it a three-year to five-year period of time so that it could be given a fair trial, and the man who undertakes the work ought to have a chance to show what can be done.

CHAIRMAN PEACOCK: Has anyone any further light to throw on this question at this time?

W. F. ASHE (Thilmany Pulp & Paper Co., Kaukauna, Wis.): I don't believe the main question in this thing is the question of money at all. Personally, I am not convinced that this is the thing we want to do if we had the money. It seems to me that the main talk about getting a paid representative has been with the idea that he could do the work that the volunteer fellows are doing now. He can't. He can't at all take the place of the fellows who volunteer to do it in this section. Neither can he expect the cooperation that the volunteers get. He will have no particular status in any mill, he will have the entire country to cover and I think we would be inclined to say, "Let George do it," if we had a paid man. I wonder if that is what we want to do? I wonder if we are not better to be a rather loose organization, working cooperatively, rather than an organization in which we have a paid secretary who comes around and tells us what to do. He can't tell us what to do. It isn't likely that the men here would tell him what to do, either, and I think he would have a rather odd sort of position. Personally I am not convinced that that is the answer for us at all.

CHAIRMAN PEACOCK: Let me inject another question in your minds, start you thinking. You remember, two years ago at the Cleveland meeting that Mr. Lundrigan exposed the fallacy of a six-thousand day penalty for a death case. He showed us that fatal accidents bring us an actual average penalty, based upon the facts, of less than four years, and that if we continue suggesting to the world that the actual damage involved is something like twenty years (continuing the figure of six thousand days) after a while we will have to meet that in the form

of actual premiums to meet increased compensation. He made the suggestion that we take a thousand days in our section as the charge for a death case and permanent injuries in proportion. Now, in our contest we are reporting on that basis—a thousand days for death cases. Mr. Lundrigan raised an objection to translating the reports of our sections, contests and mills, individual mills, into this six thousand day basis for reporting in general in keeping with the other sections of the National Safety Council. I am going to ask you whether you feel the time has come for the Pulp and Paper Section to direct the National Safety Council in the reporting of our statistics to use the thousand day basis instead of the six thousand day basis. Think it over during the day. Mr. Lundrigan may have a motion to make to that effect. We are now ready for our program and Mr. B. D. Rogers, of Bird & Sons, Inc., East Walpole, Mass., will act as chairman for the program.

ACTING CHAIRMAN ROGERS: In one of our plants, where we have 225 employees that have gone since the eleventh day of last October without a lost-time accident—about a year ago we put in a new lighting system there, a very thorough and efficient one—and I believe that lighting has had a lot to do in that plant to reduce our accidents to the minimum. Today we have with us a man who is going to give us some fundamental facts in regard to lighting, and it gives me great pleasure to introduce Mr. W. T. Blackwell, General Lighting Representative of the Public Service Corp., of Newark, New Jersey.

The Importance of Lighting and Its Relation to Safety

By W. H. BLACKWELL

**General Lighting Representative, Public Service Corporation of New Jersey
Newark, N. J.**

In casting about some time ago for an apt quotation to use in connection with the annual report of my activities with my company, I came across a quotation from the Bible which seems to be not only apt, but also most appropriate for this occasion: "And have no fellowship with the unfruitful works of darkness, but rather reprove them. But all things that are reprov'd are made manifest by the light—for whatsoever doth make manifest is light." Ephesians 5:11-13.

Now, the importance of lighting and its relation to safety is, as I indicated a few minutes ago, one of the hardest things that we have to prove. We know, axiomatically, that a person can't perform his duties properly unless he can see. You can't walk the streets unless they are lighted. We know intuitively that accidents result through lack of illumination but what percentage of accidents are caused by the lack of illumination, is where we stumble.

We endeavored to get some data on that subject, and the difficulty is that the accident reports do not split up the classifications sufficiently to enable us to get to the cause of the accident.

I would like to illustrate in this way. Suppose in the aisle of an industrial plant someone had carelessly left an industrial truck with the tongue extending across the aisle. Assuming further that that plant was poorly lighted, a man working on a lathe, which had local lighting of rather a bright order, started to walk down the aisle. He tripped over the truck and injured himself in some manner. You people and the casualty companies in general, record that as a tripping accident. Now, is it? What was the underlying cause? Take the same thing with stairways. A man falls down the stairs. Did he slip due to improper tread on the stairs, or was it due to lack of light?

Mr. Williams, in his chapter on Hoover's "Waste in Industry," states that from five to six per cent reduction in accidents may be obtained through the use of

guards and other protective mediums, but a very much larger percentage of reduction might be obtained in the less obvious causes of accident, such as inadequate illumination, dangerous manufacturing practices, etc. I want to plea with you gentlemen investigating and reporting on the causes of your accidents to find out really what causes them.

Now, to revert to my text, it seems to me "The unfruitful works of darkness" is a good name for accidents. They are unfruitful and they are works of darkness, many of them. It seems to me that the remedy is rather clear. We don't expect you to be a specialist in every form of engineering that might enter into the prevention of accidents, but engineering advice is obtainable and I would no more suggest to you men that you lay out, or have your plant maintenance man, or even your engineer, lay out the lighting in your factory than I would suggest that you try to fill your own teeth. Every man to his own task.

Now, because people are familiar with light, everyone feels confident to pass judgement on the amount of light, the direction of light, the color of light; and I might say that is one of our great difficulties, because everybody feels he is an illuminating engineer. You go in a factory and endeavor to talk to the man about it, and he says, "There is nothing like that here." "How do you know there isn't?" we ask. "Why; I can tell that with my eyes," they say. I am accustomed to dealing with this subject and I can't tell you now, within five hundred per cent, how much light there is on this sheet of paper at the present moment. The eye, without the aid of an instrument, is absolutely undependable when it comes to judging illumination.

Now, this intangible thing, light, with which we are all so familiar—nobody knows how mankind became acquainted with it, possibly through lightning striking a dead tree, the tree burning and then pre-historic man learned that it gave not only light but heat and that his food possibly tasted better when subjected to the heat of the fire, and so on as we went through the ages. But it is interesting, just as an historical back-flash as it were, to know that up until 1879 light was produced in one way, simply by burning things, oils, fats, torches and what not. The caves in Europe, which are of the Stone Age, show that the people were familiar with light. Since 1879, light of course has been produced differently, by the incandescent lamp, and I think I am not wrong in saying that the industrial progress of this country has been largely due to our ability to extend the hours of usefulness into the night, which has enabled us to increase production and has enabled the country to progress.

I can't understand, when I go into factory after factory and see the lighting conditions there, what the superintendent or manager thinks about when he goes through his own plant. How can he shut his eyes to the conditions that exist? It is beyond me to explain, but it seems to me that there is the cause of the whole trouble there is the thing that we have got to overcome. It can be overcome only by education.

There have been efforts made by the American Illuminating Society to get the casualty companies to offer a reduction in rates in those factories where they have improved illumination, as is done in fire insurance where the introduction of sprinklers and other fire fighting means brings about a reduction in premiums. I remember, some four or five years ago, I was in a paper mill down in the South, and in order to prevent the theft of lamps from the sockets in the plant, the plant electrician had wired the whole mill with what we call high tension lighting. I can't imagine a more ridiculous thing to do, with wet floors, where a man could easily become grounded, and then to use high voltage; and what was the reason? Simply to save the theft of lamps by jeopardizing the lives of the workmen there, because his equipment wasn't any too good.

Now, those things are ill-advised, those are the actions of people who don't understand and for that reason I am urging that when you do take up the ques-

tion of lighting your mill, get an illuminating engineer. All of the illuminating companies furnish absolutely dependable advice, the utilities also or, if you prefer, there are consulting engineers who can give you such advice.

Now I am going to quote Mr. Simpson's letter to me. I wrote him and asked him what he thought of the subject and he came back and said, "I think particular attention should be paid to the motive-power side of the machine, also to the low head room, slippery foot space and low, dark passageways in basements." I know they are based upon his experience, that they are prolific causes of accidents, those locations and those conditions.

Three years ago, in Newark, N. J., I became interested in the safety council work there, and in talking the matter over with Mr. Roseman, the manager, I suggested to him that a lighting committee should be organized. The first plan of action that we adopted was a course of lectures for factory executives, casualty insurance engineers and inspectors and other men in executive positions. The lectures covered six evenings and we had an average attendance of about eighty people. That was followed, the following year, by a second course where our average attendance ran to about 125. At the request of 35 or 40 of the men who had been taking the course, we ran a post-graduate course, as we called it, of six lectures covering three evenings. At that course we had 100 per cent attendance which showed the interest. These men, gentlemen, were not illuminating engineers; they were safety engineers largely, connected with the large plants in Newark. I commend that practice, even if it is not possible for your local safety council to undertake such a thing.

Now this organization I have has its counterpart in many other communities and you may be able to draw on them. In other words, the utility, maintenance and service organizations have lighting departments for the use of their customers in order that their customers may use their commodity and get the best of results. In short, if you were in my territory, you could call upon my department. I could go through your mills, make a survey, prepare plans and specifications, have one of my men supervise the work when your contractor was putting it in and then test the installation after being installed, to see that you have the right amount of light in each location of your plant, as required by the work.

Of the five senses there is no question but that sight is the most valuable. And yet it is the most abused. One of the commonest complaints that I have about the average plant is bare lamps. No one can work in front of a bare incandescent lamp, a few feet from his head, without suffering some permanent injury to the eye. The conditions in factories from glare are not only bad but many men enter industry with injured eyes, due to poor lighting in schools. We are getting after that just as fast as we can.

Statistics show that the average child of nine years is far-sighted, and yet the same child at the age of fourteen is near-sighted. There is an increase of over 60 per cent of near-sightedness just during that period of from nine to fourteen, from which it is apparent that as the difficulties of the curriculum require closer application the child's eyes are injured. Mr. Simpson has some very interesting cases which he has run down where a boy has been unable to carry on his school work, dropped from school, gone into the factory and then, through defective vision, has become permanently maimed. Now, if for no other reason than for conservation of vision, you should at least put reflectors over your lamps, even though you may not get the intensity of illumination that we consider productive illumination.

The state has taken recognition of this; the State of Wisconsin, in the preface to their "Code of Lighting Factories, Mills and other Work Places," has stated why the State regulates factory lighting. At the present time there are eleven states in the Union which have factory lighting codes, where mandatory illumination is specified for various locations and classes of work. These codes also

show in the agenda what they call "recommended value." I would like to read this Wisconsin preface because I think it is good: "Why the State Regulates Factory Lighting."

"Insufficient and improperly applied illumination is a prolific cause of industrial accidents. In the past few years numerous investigators, studying the causes of accidents, have found that the accident rate in plants with poor lighting is higher than similar plants which are well illuminated. Factories which have installed improved lighting have experienced reductions in their accidents which are very gratifying. Of even greater importance, poor lighting impairs vision. Because diminution of eyesight from this cause is gradual, it may take the individual years to become aware of it. This makes it all the more important to guard against the insidious effects of dim illumination, of glaring light sources shining in the eyes, of flickering light, of sharp shadows, of glare reflected from polished parts of the work. To conserve the eyesight of the working class is a distinct economic gain to the state, but regardless of that, humanitarian considerations demand it. Finally, inadequate illumination decreases the production of the industries of the state, and to that extent, the wealth of its people. Factory managers, who have installed improved illumination, are unanimous in the conviction that better lighting increases production and decreases spoilage."

That is put out by the Industrial Commission of Wisconsin. Now, many plants in this matter of conservation of vision, are practicing a periodic eye inspection.

Prior to going with the Public Service Company, I was with the Westinghouse Lamp Company. The process of making an incandescent lamp is partly mechanical but largely manual and very close work, requiring the deft fingers of a woman. You are all familiar with the little wire that is wound around on hooks inside of the incandescent lamp. Sometimes that wire is much finer than the hair of a woman's head. I recall that we had trouble in Milwaukee with constant sickness, the girls who did this winding being absent frequently and the cause seemed to be headaches all the time.

I went out there and what did I find? That the tables on which these girls worked were covered with white oilcloth and they had a piece of clean, white paper in front of them and they would hold up this little glass rod with these hooks in and wind that fine wire around there and then they had an electric weld which welded that to the wires that came in through the glass. The cause of the trouble was not difficult to find. It was because they had a large powerful lamp right up over their heads. The light struck the white oilcloth and came up to their eyes at an unaccustomed angle, at an angle to which the eye was not adapted. I reversed the procedure completely. I had the tops of the tables painted a dead black, then sent out and got some cheap black velveteen and had this mounted on little wooden slabs and made the girls work on that black. That black ground gave no reflection back on their eyes. We had a strike immediately. The girls wouldn't work. They all quit, and it took me about a week to settle it, but you go into any lamp factory and you will find now that every lamp factory is using that method.

Now, in every plant there are problems of that sort, which can be solved and which can be eliminated completely, if you get somebody who knows how to go about it. I could go on this way for quite some time, but I would like to close my remarks with this: the unfruitful works of darkness, and reproving them—and that lies within your hands, the reproving of these unfruitful works of darkness. Go through your plants. If you don't know enough about illumination, get somebody who does. At least it isn't going to cost you anything to know what are the conditions in your plant—how does your plant rate as compared with a first-class plant? That is of value for you to know. Whether or not your management will go along with the improvement that may be necessary is probably another story, but at least, having a report from an engineer as to what

the lighting conditions are, would be of value to you in presenting the proposition to your management.

Secondly, if you have men within your organization who have the right foundation upon which to build, it would do them no harm, and probably a great deal of good, to send them to take a course in some one of these schools which, as I have said, are run periodically, probably three or four of them a year, for which there is no charge and I am sure that it would bring results.

ACTING CHAIRMAN ROGERS: I know Mr. Blackwell will answer any questions any of you have. Now, we have heard Mr. Simpson's name mentioned and heard him quoted. Mr. R. E. Simpson is with the Travelers Insurance Company, Hartford Conn., and we would be glad to hear from him at this time.

Discussion of Mr. Blackwell's Paper

MR. SIMPSON: Some time ago I attended a meeting of an accident prevention committee, and during our discussion one of the men described an accident that occurred in his plant. It seemed a man turned from his work place, started to another part of the shop, fell over an armature shaft that was protruding in the aisle, gave a rather headlong plunge, struck his head against the corner of a machine and received a severe scalp wound, knocking him unconscious, and he lost about four weeks from work. In the record of that company there was a dual cause assigned to that accident: partly carelessness on the part of the workman, partly poor housekeeping on the part of the foreman in charge of the shop, and so it passed.

Later on, that committee was going through that shop and we came to the point where the man was injured. He was back on the job, with a bandage around his head. He worked at a turning lathe, dark-colored, as dark as the andirons in the fireplace here. In front of him and below the eye level, was a one hundred watt Mazda lamp. The bowl part had an enamel coating, the other part clear so that as he looked at his work he looked into the unshaded part of that one hundred watt Mazda lamp. I stepped into his working position. I am near-sighted myself, but before stepping in there I took off my glasses, and at the point where the armature shaft was in the aisle, another one had been placed. I could see it but not too distinctly, but I could see it enough so that if I were to walk out there, I would quite involuntarily avoid it. I stepped to the workman's place and stood there a minute and not once consciously did I look at that lamp. I turned away from the turning lathe, looked down and I could not see the armature laying on the floor. I then took off my glasses, stepped behind the workman, put them over his eyes and asked him to look down. He did and said he could see the armature much better than he could without glasses.

There was a dual cause for that accident, outside of that which the company had assigned; first, that man was near-sighted, almost as bad as myself; the second, he had been working under the glare of a light so blinding that if he had had normal eye-sight he could not have seen that armature.

I have had some correspondence with the men at the Council headquarters, with Mr. Cameron and others, with the idea of bringing about an illuminating committee on the part of the National Safety Council. There is an idea that in the membership of the National Safety Council are hundreds, probably thousands, of men daily in contact with working conditions. These men, safety engineers or inspectors, investigate and act immediately an accident occurs. If those men would only place themselves in the position of the injured man, provided they could do that without danger, and judge for themselves whether or not the lighting had any effect on the accident—was it adequate, was there a glaring light from a bare lamp, or from light such as Mr. Blackwell has described—then put that down on your statistics. If the accident was not a fatal one, find out whether

or not the victim had normal eye-sight. He is handicapped if he has poor vision and can't use good lighting to best advantage. If several thousand members of the National Safety Council would send in that information, I think we would have some basic facts, rather startling facts on the condition and effect of improper illumination in our shops.

Mr. Blackwell has mentioned the bare lamp. I think there are about forty-five million incandescent lamps used in our industrial plants, of which less than 15 per cent have adequate reflectors. I have gone into factories and time and again found all sorts of devices used for reflecting the rays because the men unconsciously realized that they could not see as well without a reflector as with one. Not long ago, I went into a shop and found a large lamp on which the workman had spread a layer of laundry soap to cut down the glare which would come to him directly in his working position. There are thousands of conditions like that under which the workmen of this country are laboring every day, and they have affected not only their condition, but also their earning capacity. If we could get that information directly from the members of the National Safety Council, we will have figures on which we can base a campaign to bring about better illumination in the industries generally, not only paper but all, and better illumination in the home, in the school, better health, better longevity to all concerned.

ACTING CHAIRMAN ROGERS: Are there any questions in regard to lighting?

J. J. TELLINGTON (Brown Company, Berlin, N. H.): I would like to ask Mr. Blackwell if the National Lamp Works, of the General Electric Company, furnish an illumination engineer to go into a plant and make a survey, free of charge?

MR. BLACKWELL: Yes, on request. I assume you have a contract for National Lamps. All you have to do is make the request through the local employee that you would like to have an illumination engineer make a survey of the plant and he will be forthcoming.

MR. TELLINGTON: Thank you. Our plant is at Berlin, New Hampshire.

ACTING CHAIRMAN ROGERS: We are in more or less of the same neighborhood and we have had men from Lynn.

MR. BLACKWELL: Also the General Electric Company at Schenectady, and, if you happen to have Travelers insurance, I am sure Mr. Simpson's services can be obtained. I might say further, in connection with the question of glare and the partial blindness that results, you can all experience this yourself. Some sunshiny, bright afternoon, go into a motion picture house and possibly for the space of half a minute you can not see whether the chair is occupied or not. I have watched people and seen some do some funny things. A man comes in and tries to sit on a woman's lap, and things like that, but you will find, after you have stood there probably for half a minute things begin to clear up. Conversely, when you go out from such a dimly lighted place, the bright sunshine almost hurts. Now, that is an exaggerated condition of what the employee is undergoing who is working with the glaring incandescent lamp in front of his eyes.

F. H. ROSEBUSH (Nekoosa-Edwards Paper Co., Port Edwards, Wis.): I would like to enquire if there is a code of any kind published in regard to illumination that would help a person who perhaps could not get the services of an engineer, to make an investigation of their lighting conditions.

MR. BLACKWELL: There is the American Engineering Standard "Code of Lighting Factories, Mills and other Work places." It was prepared by the Illuminating Engineering Society, Lighting Legislation Committee, and adopted by the American Engineering Standards Committee as the American Engineering Standard Code. The same Code has been published by the U. S. Department of Labor. I can't give you the bulletin number, but it is distributed by the Department of Labor at Washington.

I would suggest that you enquire whether or not your state has a Code and if it has, of course your State Code takes preference over the National Code because,

as I remarked, there are some minor modifications and requirements in the various state Codes; New York and New Jersey, Massachusetts, Wisconsin, Pennsylvania, Oregon, California are just a few that I happen to remember offhand.

ACTING CHAIRMAN ROGERS: For the benefit of the Massachusetts members, I might say I know that Massachusetts has a Code that is comparatively new and it was worked up through a committee of various associations in connection with the Department of Labor. I am sure you could get, any of you, a copy of that Code, by writing to the Department of Labor at the State House in Boston.

I know that you will gain a lot of help from Dr. Hourigan, who is the Plant Surgeon of the Larkin Company, Buffalo, N. Y. It gives me great pleasure to introduce Doctor Hourigan.

How to Administer First Aid in Both the Small and the Large Plants

By DR. P. H. HOURIGAN

Medical Director, Larkin Co., Buffalo, N. Y.

This subject is so big and so well known that it is rather difficult to get into the substance and out of it again, in the short space of twenty minutes. You are probably better acquainted with this matter than the speaker. I will merely try, in the short time allotted, to gather some few headings, to touch some high spots and some low spots, and will necessarily miss a great many. With a full conception of your knowledge of the problem and a rather uncomfortable feeling stealing on me, reminds me of a story:

A man on his way home, stopped at a fruit stand and bought a bag of chestnuts. He entered his house, closed the door, looking into the next room, saw his wife there sewing, and he said, "Sweetheart, I have brought you home a bag of chestnuts," and, without looking up, she wearily responded, "Go ahead, I'm listening."

First Aid is recognized as a great humanitarian measure, as well as an economic activity. All of the large plants and many of the small plants are sold on the idea. Some of the smaller plants are rather disinclined to put any investment in this activity. They are not so sure of what they are going to get out of it. Bill Gilbert, the safety man in the Chamber of Commerce in Buffalo, where Larkin Co. is located, tells a good story along this line: Bill is a Scotchman by birth and persuasion, an American by the process of naturalization. A friend, who is also a relative, came from Scotland to visit him. Bill took him down to see the great Niagara Falls. As they stood on Prospect Point, at the end of the Falls, looking at the water tumbling over the edge of the cataract, Bill said to the Scotch relative, "There is a story going about that if you drop a penny into the Falls you will get good luck." The Scotchman stood there, watching the great volume of water tumbling over the cliff, breaking itself on the rocks below and then rushing, fighting and crowding its way into the current farther on. After a bit he turned to Bill and said, "Ha' ye a bit o' shtring?" But it would be more profitable for the smaller plants to take a chance on the investment in First Aid, because they are going to meet the neglected problem afterwards in increasing costs, in their industry and in generally bad conditions, that will surely come back at them in the future. Another story comes to mind of a fellow who died. After the widow had bedecked herself in those so-called "widow's weeds" that make widows so attractive and enticing, she hurried over to order a monument. She had the usual inscriptions cut into the stone, ending with "Rest in Peace." After the funeral, when the will was read, it was found that the dead husband had not

looked kindly on the widow and this feeling was expressed in the will. The widow hurried back to see if the monument with its inscription had been completed. Everything had been already carved. The irate woman noting the words "Rest in Peace" remarked, "Till we meet again."

Let me give you some figures that may be interesting to you—95 per cent of all factories in the United States have less than 1,000 employees. Slightly over 60 per cent of all workers are employed in plants of less than 500 employees; 82 per cent of American industrial concerns employ 100 or less workers, so that the class that might be termed "Big Industries" is something like 18 per cent.

The basic principle of First Aid is the same, whether it is in a large industry or small. It, however, may be carried out in different ways. First, let us go over the type of equipment that might be advisable in industries of different sizes. I then want to come back and touch upon the details of First Aid.

In an Industry Having Under 100 Employees

I would suggest that a suitable First Aid cabinet would be enough equipment for such a plant, of course not enough for the largest plants and it might unfortunately be a rather neglected cabinet in a very small plant. With a First Aid cabinet would go the necessity of having someone who could handle the cabinet and the injury. The matter of the choice of the right individual is generally a difficult problem to solve. We are likely to get somebody who sells himself as a good man but is very much the wrong one. You are fortunate if you can get the right man or the right woman. The cabinet should be a strong box, dust-proof, clean, preferably of metal. Such a cabinet should contain:

- One first-aid for wounds packet
- One ounce absorbent lint
- Four packages absorbent gauze, 1 yard x 36 inches
- One package absorbent cotton, quarter pound
- One spool adhesive plaster, 1 inch x 10 yards
- Six cotton roller bandages, 2 inches x 5 yards
- Four cotton roller bandages, 3 inches x 5 yards
- Four gauze bandages, 1 inch x 10 yards
- Eight gauze bandages, 2 inches x 10 yards
- Four gauze bandages, 2½ inches x 10 yards
- Four picric acid gauze pads
- Six finger cots
- One triangular bandage
- One two-ounce bottle aromatic spirits of ammonia
- One two-ounce bottle general antiseptic and disinfectant solution
- One empty bottle for this solution
- Two three-ounce tubes Bicarbonate of Soda and Petrolatum, three per cent
- One three-ounce bottle boric acid solution, four per cent
- One two-ounce bottle castor oil
- One box of combines compress-adhesive tape dressings
- One dozen wooden applicators bound with cotton
- One dozen wooden tongue depressors
- Four wooden splints, 15¾ x 3¾ inches
- One tourniquet
- One pair scissors, one pair of tweezers
- Two packages of safety pins (small and large)
- One graduated medicine glass
- Six paper cups
- One first-aid manual

The First Aid manual of the Red Cross or Bureau of Mines, is a good thing to refresh your minds on the proper use of these materials. In addition to the manual you will want blanks for reporting accidents and blanks for refills when the contents of the cabinet runs low. In all the different size industries this First Aid cabinet or its equivalent is the essential thing to have.

A Plant Employing 100 to 300 Workers

This number would require a moderate size room with a floor space of about 200 square feet, divided by partitions, and this room should be centrally located with thought given to privacy and comfort. It should be well supplied with heat, light and good ventilation. The floor should be of impervious material as linoleum, tile, et cetera. The walls should be a mild shade of green, light tan, or light grey. The equipment should be the First Aid cabinet as described for the smaller plant. In certain types of industries, extra splints, bandages, et cetera. Where women employees predominate, suitable medicines and cot rooms are needed. Equipment in this size industry should have in addition, a table, waste bucket, two chairs, a cot, glazed sink, hot and cold water, a supply of towels, soap. A stretcher should be available and close at hand with a couple of blankets and pillows.

Industry Employing 300 to 1,000 Employees

Three to five rooms should be available, one a waiting room, the second one as I have already described for treatments and dressings, another room for physical examinations, room for laboratory facilities. This industry will need the same equipment as described in the previous types. The following additional equipment will justify itself:

- One table, metal with glass top
- Focusing light on bracket
- Chair with neck rest
- Head mirror
- Nasal and throat sprays in rack with solutions
- Pus basin
- Metal irrigating can
- Nasal specula
- Ear specula
- Ear curette
- Ear or nasal forceps
- Wooden applicators wound with cotton
- Eye solutions in dropper bottles
- Cataract knives, etc.
- Magnifying glass
- Waste bucket
- Ear syringe
- Petrolated gauze packing strips
- Sterile gauze and cotton

Industry Employing 1,000 to 5,000

Where it is possible, it is advisable to have a Dispensary in a separate building, especially in a hazardous or smudgy industry. The minimum number of rooms should be four. These may be divided by movable screens or low walls. In this way they may be made to include waiting room, Physician's Office, Nurse's room, also to be used for keeping records, physical examination room, small laboratory,

main surgical room, dental department, a room for X-Ray, physiotherapy, rest rooms and conveniences for an oculist and eye examinations. More space, separate rooms where the women are employed in large numbers and separate hospital rooms for severely injured cases. When the plant buildings are scattered, it is necessary to have a dispensary in a second building. In addition, contact must be made with some high class hospital.

The Larkin Co., of which I am Medical Director, comes within the class we are now describing. The number of our employees average from 3,000 to 5,000. Everything that is interrelated with medical problems is centered in the Medical Department. Here First Aid is administered and follow-up treatment when needed, we get out Compensation reports, duration of Compensation periods and the amount of Compensation payments are computed, and all Compensation payments are delivered through our Department. We follow up all cases at the plant, in the home or at the hospital. We have charge of the detail work of the benefit organization. Absence reports from all departments are daily sent to us. Follow up of absent employees at set periods are made by our visiting nurses. Physical examinations are made upon entrance and at various times during the continuance of employment. The oculist examination and method for convenient purchase of glasses are directed. Sanitary conditions of the people and the plant comes under our purview.

The Larkin (sick) Benefit Association gives in addition to the usual benefits an amount of money to help meet the cost of surgical operations. Folks are often dominated by necessity. The necessity for a hernia operation may tempt an effort for relief of this condition, wrongfully, through Workingmen's Compensation. Knowing that an operation for hernia is their right from the Benefit Association, they are relieved of the necessity of faking a story. This same experience applies even to appendicitis and many other operations. The follow up visits cut down markedly the absence percentage. Sickness and outside injury cases are separated from the Compensation cases. The Compensation cases are thereby met at their earliest development and naturally cut down in the extent of their continuance. A knowledge of the Compensation Law and a knowledge of the individual combined with a service that attracts have a great economic value.

All these different activities can be easily interrelated in an industry of this size so that you get a marked lowering of the effects of accidental injuries as far as the individual is concerned with a consequent lowering of Compensation rates. At the last New York State safety meeting an illuminated sign, placed in a prominent position by the State, read, "If the other industries in the State would follow the practice of the Larkin Co. costs of accidents in the past year would have been cut \$20,000,000."

Plants Employing 5,000 to 10,000

This type of plant needs the same class of equipment and a layout similar to the last class of industries. They will need additional or larger rooms, especially where the nature of the work is hazardous and the number and seriousness of the injuries is increased. If this large industry is not located near a hospital, they may find it necessary to maintain their own hospital. There are many such cases throughout the country. When in or near a large city and convenient to a first class hospital, suitable arrangements can be made to take care of very serious cases.

Over 10,000 Employees

And on up to the size of the United States Steel, the Ford Plant, the Bethlehem Steel or industries of that size. The United States Steel and the Bethlehem Steel have many hospitals of their own, which handle the very serious injuries incident

to their great activities. I remember 14 years ago visiting the Ford Plant in Detroit, just after Henry had decided he would build a hospital. A group of Detroit's best citizens were soliciting funds to use for constructing a hospital. When the great automobile manufacturer was approached he asked the privilege of being allowed to take over the whole project. He has since expended millions in constructing that marvelous hospital, where many of his ideas are carried out.

First Aid Work

In Buffalo, in order to meet the demand for the right person in the industry to take care of First Aid equipment, we conduct every year First Aid class under the direction of the Chamber of Commerce. The lectures are given by eminent surgeons who are generally officers of the Medical Society and the Academy of Medicine. Some 12 to 15 lectures constitute the course, followed by a thorough examination, the graduates receiving a Red Cross diploma. We graduate about 100 First Aiders every year, thoroughly grounded in First Aid ideas. Now a little bit of what we teach and what I think the First Aider should have in mind, combined with a knowledge he should possess to effectively handle First Aid problems. Of course, the man must thoroughly enjoy and be interested in this work, especially interested in the human side of it. He must have some sense of what society demands of him, what the State demands of him, what industry demands of him, but above all he must have a feeling of love and consideration for the injured. The First Aider must be a patient type of fellow and have considerable powers of observation. If he is the right man he isn't excitable but goes about his work carefully and soon learns the necessity for considering shock, which he finds present to a greater or lesser degree in almost all accidents.

Shock

Shock, in its severe form, shows its presence by the following symptoms: the skin is pale, white, cold, big drops of cold sweat are seen on the forehead, face, hands and other exposed parts, pupils are dilated, lips blue, hands blue, breathing is irregular. If you feel the pulse, it is weak and rapid and may be hardly perceptible. In this severe type of case, the patient is lying down, he pays little attention to what is going on about him, it is hard to arouse him. If you do succeed in getting a response, patient will tell you that he is tired, weak and cold. This type of shock may increase in severity and has been recognized as a cause of death. There are milder cases, even so mild as to show only a temporary weakness.

Treatment of Shock

There are three essential points in the treatment of severe shock as described above. First, the position. The patient must be lying down with head low. Second, cold must be counteracted by the use of heat. Third, weakness must be overcome by the use of stimulants. As little clothing as possible should be removed from the injured. He must be thoroughly covered with good heavy blankets or their substitute and heat applied by hot water bags, bottles or jars filled with hot water, bags of hot sand, bricks or stone or anything that will hold heat. Care must be taken that the patient, who is partially or completely unconscious, is not burnt. The demand for stimulants is met by giving something hot to drink,—hot coffee, hot tea, hot milk, hot water. The common medicine used for stimulation is the aromatic spirits of ammonia given in teaspoonful doses every half hour. You must be sure your patient can swallow before stimulants are administered in a liquid form. When the patient cannot swallow, the inhala-

tion of the fumes from aromatic spirits or better still, the inhalations from smelling salts.

Hemorrhage

The First Aider must know how to deal with hemorrhage. He must know the different varieties, the arterial, the venous and the capillary. The arterial coming in bright red spurts, the venous being of a darker color in a steady stream and the capillary an oozing. Every First Aid book will state this great truth that the great majority of bleeding cases can be stopped by pressure at the point of bleeding. We are so liable to overlook this great truth because it is stated so simply and in such a short sentence. Tourniquets are good things, just like razors, but a razor in the hands of a booze-crazed nigger is not a good thing and a tourniquet improperly used does more damage than it ever did good. I have never seen a surgeon of great experience talk on hemorrhages, who was not irresistibly impelled to take a crack at the tourniquet. The tourniquet or esmarch has great value but we must learn how to use and not to abuse it.

Infections

Nature has covered the body with skin. It is a marvelous organ and when you cut through that skin or damage or injure it, you destroy the protection of the body inside and open up possibilities of an enormous amount of damage. I have seen a case of a sliver, just a small wooden sliver, removed by the man's jackknife, kill the man in a week. This was in pre-Volstead times. The man was one of those jaundiced, yellow-faced, big-bellied fellows. He got the sliver in his hand and we saw him on the fourth day afterward. The hand and arm were much swollen, reddened and feverish. There was no resisting power to overcome the poison. The best type of assistance in quality and quantity was called in but nothing could save him. His wife died of the same type of infection just about a year afterward. But you can bet the children won't; we have two of them at the Larkin Co. and the slightest scratch of the skin brings them to the Dispensary for First Aid.

That story epitomizes the danger of infection from petty injuries. By careful watching of these small injuries, we have been able at the Larkin Co. (our pay roll runs from \$3,000,000 to \$5,000,000 a year) to make an enormous dent in the cost of compensation from infections. In 14 years compensation from infections has totaled little less than \$2,600. That statement should be an argument that would impress a Scotchman. All petty injuries are brought to the Medical Department for immediate care. As soon as infections do show the most intelligent care is applied. Propaganda to instill the danger of infections is continuously carried throughout the industry. We do not follow the method of giving the man a general bath because he has a scratch on his finger. We do not attempt, in such a case, to wash off his hands with soap and water because we are afraid that all the dirt and all the germs we know are on the hand, will be washed into the cut. We carefully clean the wound and its immediate neighborhood and then carefully apply tincture of iodine. After protecting cover has been applied to the wound whatever bathing may be necessary can be carried out.

Many of the Doctors and First Aiders and Nurses are now using mercurochrome but with the results which I have had, I am compelled to stick to the tincture of iodine. Of course, all local applications must be carefully watched. It is a common practice and a good practice to dilute the tincture of iodine with an equal quantity of alcohol, thereby cutting the solution down from a 7 per cent to a 3½ per cent iodine. You must be careful not to allow your alcohol to evaporate from your tincture of iodine. If evaporation occurs, your solution runs up not only to a 7 per cent but if the evaporation continues, the percentage gets

as high as 15 per cent or 30 per cent. If your patient comes in after the application of such a tincture of iodine you will not have a wound that has been properly treated for infection and that infection destroyed. You will have a wound that has been burnt by a caustic. The tincture of iodine becomes a caustic when a large per cent of the alcohol has evaporated. Time is about up. As I said in the beginning, this is a big subject and I haven't been able to more than touch a few of the high spots.

ACTING CHAIRMAN ROGERS: I will ask Dr. Hourigan to stay here in front for a few minutes because I know there are some questions you will want to ask him.

W. J. BRENNAN (St. Croix Paper Co., Woodland, Me.): I wanted to ask whether you advise treating cabinets throughout the plant, or do you prefer to centralize the treatment?

DR. HOURIGAN: That depends upon the ease with which the injured folks can get to the central plant. If in the central plant we have doctors specially trained and nurses specially trained, with equipment, and the patients can easily be gotten there, no first aid equipment is needed around the plant. If, on the other hand, the other condition prevails, why necessarily there must be cabinets distributed.

MR. BRENNAN: That is our policy and I wanted to substantiate that. I wonder if others are using a system we find very effective. We do not have first aid treatment throughout the plant because we wish to place responsibility upon one or two; but we do have a cabinet, called an emergency cabinet and in that we have a stretcher, burn ointment, tourniquet and some sterile gauze. I will quote one case to show you the efficacy of this thing. A man was struck by a block which was dynamited, some years ago. Internal hemorrhage resulted. A messenger was sent for the stretcher. He took the stretcher back, loaded the patient on it, carried him a considerable distance and a great deal of time was lost. Recently we had a similar case. A messenger arrived saying there had been a severe accident and the door opened and the patient was there. We put these emergency cases in such places as the block pile, on the river, in the steam department and for the one in the latter department, we supply an extra amount of burn ointment, while out on the block pile we pay more attention to the stretchers and pads and blankets and that sort of thing and we have in all of these places such things as would be required in that particular type of accident.

DR. HOURIGAN: There is no question but what that is high class service. With that, I suppose you train first aid teams. If you develop first aid teams, have them properly taught and then compete with each other, you are not only developing first aid but also thought of safety.

R. G. McCONNELL (Niagara Wall Paper Co., Niagara Falls, N. Y.): I would like to ask Dr. Hourigan about the sum spent in compensation for infection over a period of fourteen years. The sum mentioned was twenty-four hundred dollars; was that the cost per year or for the whole period mentioned?

DR. HOURIGAN: Twenty-four hundred dollars was the cost of infection cases for the period of fourteen years.

F. H. ROSEBUSH (Nekoosa-Edwards Paper Co., Port Edwards, Wis.): I would like to ask you, doctor, where you have first aid cabinets throughout the mill, what system do you have, if any, for following up that case to find out what happens to the man after he leaves the first aid station in the mill?

DR. HOURIGAN: In our plant that doesn't happen. Where that condition does prevail, why of course that accident should be reported through some central authority. How do you do it?

MR. ROSEBUSH: We have had the problem and it is a question of getting the report to the nurse in the first aid room. I was wondering if anyone had a quick system of follow-up so that within a short time you would be able to have your

nurse know of that case and follow it up through the foreman. We have not been able to solve it satisfactorily.

DR. HOURIGAN: Education is the thought I suppose. Now, in connection with the danger of infection, I notice that Dr. Ben Slader, of the Eastman Kodak Company, is getting out some wonderful pictures showing these different germs. The germs are streptococcus and syphilis, are realities, and they are just outside that cut, but it is only the doctor that knows it. The nurse may have a little idea of it, but if we could get it across through education, the thought that there is reality there, I think they would get their reports across.

MR. BRENNAN: I think there is no place in safety work to make distinction between tiny cuts and major injuries, because the tiniest cut, as shown you by the doctor, becomes very serious and we know that the major injuries get good care anyway. We in our plant make no distinction whatever between the tiniest skin-break and a broken leg. A report is made if a man merely pricks his hand on a wire rope and it is the foreman's duty to see that he comes in.

DR. HOURIGAN: Do you have a central hospital with nurses, or do your first aid people do that?

MR. BRENNAN: Our first aid is connected with the chemical department. All intermingled. Our plant is small enough and centralized enough so that they can come there and we would prefer to take a man off production for ten minutes—we feel we get a greater return in the end.

MOSE DANIEL (Hercules Powder Co., Brunswick, Ga.): The gentleman who just spoke, to my mind, has the situation just right. There is no difference, no matter whether it is a pin scratch, an abrasion or a broken leg or a very serious injury, because you can't tell. Now, the gentleman who asked the question about these cases, the answer to that is making the foreman responsible. We have a system now by which we have the foreman make out a ticket and report his injuries and the injured can't return unless he does that.

We have no kits throughout the plant at all, but this ticket is taken, with the injured man's name and history of the case, no matter how great or how small it is made out just the same and made out directly, and if he is a day late, the nurse takes it from the injured just as he gives it, then, if that occurred yesterday and comes in today, we have a duration put on there of two days, or three days, whatever it is, and we have found that works beautifully, very effectively. When that foreman gets that duration slip he gets busy and comes right back with the injured man and if possible he wants to avoid that duration because it reflects on his department. I have the plan, after the physical examination of the employees, of talking to these men before they go to work and I impress on them and teach them what first aid means, show them what first aid does and impress on them all I can, not to disregard any injury because we could recite case after case of very serious loss that originated as the most trifling accident.

DR. J. G. CUNNINGHAM (Dept. of Health, Toronto, Ontario, Canada): I think the idea that anyone can render first aid is costing a good deal and particularly with reference to infection. In Ontario, infection, as defined by workmen's compensation, is responsible for about one-sixth of the total compensation costs and in the defining of infection for record purposes, they only take the cases which would not have come to compensation except for infection. We looked into a few figures in connection with one group—and we first of all noticed that when the first treatment came on the day of injury, the number of cases was smaller, but as each day's delay appeared, the number of cases increased. We found that the great bulk of cases, remembering that these are infection cases that actually developed, we found that the great bulk of cases were the cases which the first aid man had seen first; there were somewhat fewer cases that the nurse had seen first and the fewest where the doctor had rendered first treatment. Now that is no brief for the physician; it is his job, and if it is done properly it will reduce

infection by ninety-five per cent, but it does emphasize the fact that not everybody can do it and effective first aid requires people properly trained.

WM. E. P. FULLAM (International Paper Co., Otis Mill, Chisholm, Me.): Dr. Hourigan mentioning the germs, put me in mind of an incident while sitting in a movie theatre. They were showing on the screen some kind of germ—I believe it was hook worm, greatly magnified. Just ahead of me were a couple of youngsters from the local school and when this worm commenced to wiggle, one of them said, "Jimmie, that's the kind of germ the teacher says is going to kill somebody if they spit on the floor and sweep it up."

ACTING CHAIRMAN ROGERS: Our chairman has asked that we close this part of the program as soon as possible now so that the important business of the meeting to follow may be cleaned up.

CHAIRMAN PEACOCK: We have several items of business before us. First of all we ought to hear from Mr. Rosebush, chairman of the special committee on the matter of a permanent secretary. What is your final recommendation, Mr. Rosebush?

MR. ROSEBUSH: Mr Chairman: It will take approximately ten thousand dollars to put this thing over as stated at the beginning of this meeting. If a man is engaged it ought to be a permanent proposition, for at least three to five years; also that the question of responsibility, that is, to whom this paid secretary or representative should be responsible, is a very serious question and, in fact, there seems to be quite a lot that should be talked about and discussed in having such a man. It is a serious problem and I am sure Mr. Rogers will agree with me that we are not certain in our own minds as to how it should be recommended to the section.

B. D. ROGERS (Bird & Son, Inc., E. Walpole, Mass.): As Mr. Rosebush said, we have no definite recommendations, but I will make a motion, that a special committee be appointed to investigate the advisability of a representative—we decided to call him a representative instead of a secretary—they are more welcome at mills when they come as representatives rather than secretaries.

L. J. PARANT (St. Croix Paper Co., Woodland, Me.): May I offer an amendment to the motion to the effect that the committee be instructed to confer with the American Pulp and Paper Association, in addition to conferring with the National Safety Council?

MR. ROGERS: That was in our minds, Mr. Parant, and that is included in the motion.

(The motion was seconded and unanimously carried.)

CHAIRMAN PEACOCK: Now the matter of reporting statistics. We have had this up for discussion for several years. Is anyone ready for a motion? The question has been discussed as to the advisability of the Pulp and Paper Section continuing to report its fatalities in terms of six thousand days, when as a matter of fact insurance companies and commissioners all over the country show they are compensated for in terms of about twelve hundred days.

W. F. ASHE (Thilmany Pulp and Paper Co., Kaukauna, Wis.): I move you, Mr. Chairman, that this section instruct the National Safety Council in reporting statistics from the Pulp and Paper Section, that they use the standard of one thousand days rather than six thousand days in computing our accidents.

W. A. GLEASON (Hammermill Paper Co., Erie, Pa.): I think that we also ought to include in that motion that the National Safety Council compute our past figures on the same basis, so that we will know whether or not we are going forward.

CHAIRMAN PEACOCK: Do you accept that in your motion, Mr. Ashe?

MR. ASHE: Yes, sir.

CHAIRMAN PEACOCK: We have discussed this a great deal in the past, gentlemen; it is not new to any of you who have been here.

(The motion was seconded and carried.)

CHAIRMAN PEACOCK: We are ready at this time for the report of the Nominating Committee, Mr. Gleason, Chairman.

Report of the Nominating Committee

W. A. GLEASON (Hammermill Paper Co., Erie, Pa.): Mr. Chairman and Gentlemen: The Nominating Committee, appointed by the Chairman for the nominating of officers for this section, have attended to that duty and offer in nomination the following:

Chairman, Mr. Kenneth L. Faist, Champion Coated Paper Co., Hamilton, Ohio.
Secretary, Mr. D. D. Thirkield, Sorg, Oglesby Smith Paper Company, Middletown, Ohio.

Vice-Chairman for Canada, Mr. A. P. Costigane, Ontario Pulp and Paper Makers Safety Association, Toronto, Ontario, Canada.

Vice-Chairman for South, Mr. G. W. Phillips, Champion Fibre Company, Canton, N. C.

Extreme Southern District, Mr. W. H. Jennings, Bogalusa Paper Co., Bogalusa, La.

Vice-Chairman for Middle-West, Mr. M. G. Hoyman, Kimberly-Clark Company, Neenah, Wis.

Vice-Chairman for East, Mr. N. F. Bartlett, Hollingsworth & Vose Company, Boston, Mass.

Vice-Chairman for Paper Box Manufacturers, Mr. H. C. Sackett, Alton Box Board and Paper Co., Alton, Illinois.

Engineering Representative, Mr. R. M. Altman, Marathon Paper Mills Co., Rothschild, Wis.

Regional Directors:

Maine: Mr. Alvin Record, International Paper Co., Chisholm.

New Hampshire: J. J. Tellington, Brown Co., Berlin, N. H.

Massachusetts: A. D. Wilson, American Writing Paper Co., Holyoke.

Michigan: C. E. Torrance, Bryant Paper Co., Kalamazoo.

New York: Samuel Pruyn, Finch, Pruyn & Co., Inc., Glens Falls.

Ohio: Ernest Augustus, Mead Pulp and Paper Co., Chillicothe.

Pennsylvania: F. W. Plowman, Scott Paper Co., Chester, Pa.

Wisconsin Valley: F. H. Rosebush, Nekoosa-Edwards Paper Co., Port Edwards, Wis.

Fox River Valley: W. F. Ashe, Thilmany Pulp and Paper Co., Kaukauna, Wis.

Chairman, Poster Committee: Amiel Umberham, Fort Howard Paper Co., Green Bay, Wis.

Chairman, Membership Committee: Earl E. Grant, Crystal Tissue Company, Middletown, Ohio.

Chairman, Contest Committee: A. Scott Dowd, "The Paper Industry," Chicago, Ill.

Chairman, Committee on Health Research: J. J. Plzak, Consolidated Water Power and Paper Co., Wisconsin Rapids, Wis.

Signed:

Ernest Augustus,

N. F. Bartlett,

W. A. Gleason, Chairman.

CHAIRMAN PEACOCK: What is your pleasure in regard to the report of the Nominating Committee? I might say this committee was appointed six months ago and they have been working ever since.

MR. ROGERS: I will make the motion that we accept the report of the Nominating Committee.

(The motion was seconded and carried.)

CHAIRMAN PEACOCK: Our secretary, Mr. Bergstrom, being absent, I will ask Mr. Rogers to serve as secretary. Are you ready for the election? Is there a motion that these gentlemen be elected as the officers of the section?

MR. PARANT: I will make the motion, Mr. Chairman, that the gentlemen named by the Nominating Committee be elected to the various offices.

CHAIRMAN PEACOCK: That means the Secretary will cast the ballot for all names? Are there any remarks?

(The motion was seconded and carried.)

N. F. BARTLETT (Hollingsworth & Vose Co., Boston, Mass.): Mr. Chairman, I would like to move that a rising vote of thanks be extended to the past officers and any retiring officers for the service which they have rendered to this section during the past year.

(The motion was seconded and carried.)

CHAIRMAN PEACOCK: On behalf of the officers who have served you, I take the liberty of accepting with all good will your vote of thanks. We will give Mr. Faist, our newly elected Chairman, an opportunity the first thing at the Luncheon Meeting this afternoon to make a speech.

MR. ROSEBUSH: Mr. Chairman, I hate to inject this new idea at this late time of the morning but it has occurred to me, and perhaps to some others. Now, we have been discussing the advisability of having a representative for this section and I am just wondering if it is in the minds of many of our members that we ought to have a closer knit organization, whether it would be wise for us to select from our officers, vice-chairmen and regional directors, an advisory board, say of six men, two of them for one year, two of them for two years and two to serve for three years, to act in conjunction with the officers as a sort of permanent organization or enough so so that we would have a holdover advisory board or board of directors or whatever you would care to call it. In that way we could get away somewhat from having practically an entirely new board of officers each year. It is not a new idea, in fact, it is an old idea but it can be worked out so that in case we should have, during the year, withdrawals from the list of officers, the advisory board could handle all such matters, in conjunction with the members. I just offer that as a suggestion, because I rather feel that some of the members would like to have more of a closer knit permanent organization.

CHAIRMAN PEACOCK: If you do not care to make a motion, let us keep the matter in mind, as you might feel you want to make the motion later in the day.

ADJOURNMENT

October 3, 1928

Luncheon Session

W. J. PEACOCK, Chairman

Head, Department of Personnel, Northern Paper Mills, Green Bay, Wis.

The luncheon session was called to order at one-thirty o'clock by the chairman, W. J. Peacock.

CHAIRMAN PEACOCK: In opening this meeting, I want to introduce to you, one at a time, all the new officers of the section. First of all, if I can do it without tears, etc., I am going to call on the new Chairman, Kenneth L. Faist, of the Champion Coated Paper Company, Hamilton, Ohio.

MR. FAIST: Ladies and Gentlemen: Mr. Peacock, in the other room this morning, said in about fifteen minutes he was going to give me a chance to make a speech. I don't believe I will make one. I know we are all very much interested in the meeting. We have some wonderful speakers today, and of course, we want to know the result of the contest, so I will merely state that I will do everything in my power to make the Paper and Pulp Section go over big during my term of office. I thank you.

(The newly elected officers and regional directors were then introduced to the section.)

CHAIRMAN PEACOCK: One of the interesting things in connection with our contest is the pace, or the atmosphere, something that starts off mills new to the contest at a much higher speed than you would ordinarily expect, and we are proud of the fact that a new contestant should figure so largely before the paper industry of the nation, in showing a perfect record in the six months' contest this year. I want to give all the time he wants to tell us about it to Mr. F. L. Irvin, Supervisor of Employment of the St. Croix Paper Company, Woodland, Maine—six months without an accident!

The Influence and Results of Safety in Our Plant

By F. L. IRVIN

Supervisor of Employment, St. Croix Paper Co., Woodland, Maine

I shall attempt to give you a general idea of the influence and results of the safety work at the St. Croix Paper Company in Woodland, Maine. Whatever we have accomplished can best be appreciated by an understanding of the work done in preparation.

Organized work in accident prevention began in January, 1927, with the creation of a safety department. Its success has been greatly influenced by the continuous guidance and stimulus of our general manager, who has spared no effort to follow closely every feature of the safety work. Unless the man at the top gives his interest, enthusiasm and full support to the safety organization, it cannot be expected that departmental heads, foremen and workmen will be safety enthusiasts. The general manager or superintendent is the key man to safety.

The St. Croix Paper Company has realized its duty to provide safe working conditions and has spent considerable money in safeguarding "danger spots." Consequently, there has arisen a direct relationship between our management and employees to make the mill a safe place in which to work. Most of the unsafe places have been corrected as a result of suggestions submitted by the workmen

in our monthly Safety Suggestion Contest. Interest is maintained because the management acts promptly to eliminate, where it can, the hazards that are reported. The workmen see the tangible results of their own ideas.

A varied and comprehensive educational work is carried on to teach and train our men to follow the safe methods of work. This includes:

(1) The poster services of the National Safety Council and the Elliott Service Company: The pictures and bulletins from these two sources are placed on bulletin-boards in conspicuous places throughout the mill, and have such an appeal to the self-interest of our men that we would not be without them.

(2) Distribution to every employee of a copy of "The Safe Worker," a monthly publication of the National Safety Council: This booklet is read with much interest and is taken into the homes for the family to read as well. This has the effect of making the family realize what an accident to the bread-winner would mean.

(3) Safety slogans printed on small, numbered, multi-colored cards and placed in every pay envelope each week: These carry general safety hints and personal messages from the safety committee, and are a continual reminder of the truths of safety. The immediate interest is prolonged by paying a small cash prize to the holder of the card bearing the lucky number drawn.

(4) A plant newspaper, "The St. Croix Observer," published every month: This is one of the most effective methods of driving home the safety idea. During the period of the recent National Safety contest our safety editor devoted many special articles to the contest, and his messages were a vital force in arousing the spirit and interest of the men to win the "Class B" cup.

(5) Motion pictures featuring a film on safety: These were held every third Sunday during the winter months and were so impressive that fully 75 per cent of our employees regularly attended the performances.

(6) First aid classes: A series of lessons has been given on the prone pressure and pulmotor methods of resuscitation, and these aroused much interest.

In addition to our work toward the prevention of accidents by safeguarding and a continuous educational program, we have equipped the company's hospital with modern apparatus, and have recently built a new, sunny and well-furnished first aid room. We have a complete line of Victor diathermy machines, such as the ultra-violet ray, both water and air-cooled; a high frequency machine; the Wantz generator; and a complete X-ray unit. These are for the benefit of the employees. The ultra-violet water-cooled lamp is used on all minor wounds, abrasions and cuts, while the air-cooled lamp is for skin infections and poisoning from wood bark, oils, and the like. We are certain that these lamps have prevented lost time accidents.

The influence of this safety work is typified by the attitude of the men toward small cuts and scratches which heretofore were greatly neglected. Many did not seem to realize the seriousness of apparently minor injuries, while there were others who feared that their fellow workmen would say that they were sullen if they reported to the first aid room for treatment. Intelligent and persistent safety propaganda has changed all that. Today, we have every man in the entire organization reporting for first aid treatment for the slightest scratch, thereby lessening the possibility of suffering, of a loss in wages to the workman, and of a decrease in the efficiency of the plant. And who knows but what a life has been saved by this practice?

The results are impressive and justify our claim that our employees are sold on the effects of safety. A comparative record of our lost time accidents for the past two and one-half years discloses that for 1926 there were 85 lost time accidents; for 1927 only 32, and the first six months of 1928—none.

At the close of 1927, it was evident that our safety campaign was taking effect. There was a reduction of 63 per cent in accident-frequency compared with the

previous year, and in November, 1927, we experienced the first "No-Accident Month" in the history of the St. Croix Paper Company. Moreover, we had fewer lost time accidents during the last four months of 1927 than during any similar period of that year, even though more hazardous work had been performed during the latter months. In September, a fire swept away half of the main paper machine building and badly damaged the dry-ends of two paper machines. Several days were spent in clearing away the mass of tangled debris; then followed weeks of reconstruction work on the buildings and the installation of dryers, calenders, winders and other equipment. During all that time there was a daily crew of 75 men of whom one-half were inexperienced in that class of work, yet there was not one lost time accident charged to that hazardous job.

These outstanding accomplishments show that the men have grasped the full meaning of safety and are practicing it. Hopes were high and care was the watch word throughout the mill from the first day of January to the last day of June to establish a perfect record during the 1928 National Safety contest.

Our general manager is leaving no stone unturned to improve his safety organization. He has with him here, today, eight St. Croix men, each representing a different department of the mill. They are here for the express purpose of gathering safety ideas and taking them back to their fellow-workers. Each of them should have a greater enthusiasm for safety work and be a force to keep alive the spirit of cooperation and good will between the management and the men to the end, as expressed by P. B. Juhnke, "that the workman shall live to enjoy the fruits of his labor; that his mother shall have the comfort of his arm in her age; that his wife shall not untimely be a widow; that his children shall have a father, and that cripples and hopeless wrecks who were once strong, shall no longer be a by-product of industry."

CHAIRMAN PEACOCK: I can tell you honestly, gentlemen, whatever is before us, we certainly have a surprise. Concealment has been the order of the day and George Burns, for once, has gotten away with it. George is the best little helper in the entire National Safety Council, so far as we are concerned. George thinks we are a bunch of Bolsheviks, especially because of our resolution this morning. If we were to give him a chance, he would burn us up, but we aren't giving him a chance. We think we are being led into some things and we hope George will see it possible to follow.

We are honored in the presence of Mr. Homer E. Niesz, President of the National Safety Council, who will present the National Safety Council Trophies to mills in A, B, and C Classes.

Presentation of National Safety Council Trophies

By HOMER E. NIESZ
President, National Safety Council

I am very happy indeed to be here and to have the privilege of presenting to the winners the trophies given by the National Safety Council in this safety contest. I want to congratulate the section on what it has accomplished during the period of its activities as a great section of the National Safety Council. It has made a real place for itself among the sections of the Council.

It has the enthusiasm and the ability to go forward and to accomplish the things that the section was created to do, namely, the inculcation of the idea of safety among the individuals constituting the membership of this section, the idea of getting accident-prevention advanced to the stage where there are no more lost-time accidents. That has been accomplished in a number of companies during the

past years in this organization, and if they can do it, I am sure that the others can do the same thing, notwithstanding the hazards that are inherent in the industry you represent.

The ideas brought forth by Mr. Irvin and the methods used in his company, I believe, are the fundamentals of accident prevention. I think he has stated the whole story very clearly to you. But I want to add just this: that I am very much gratified to find that they use one of the newest activities of the National Safety Council, our new publication, "The Safe Worker," an employee magazine which was started just a few months ago at my own instigation and recommendation and that of Mr. Beck, Vice-president for Industrial Safety; because we believe that the information it contains is of such service to the individual worker that it is going to be a very great help to the management in carrying on a safety campaign. You've got to get the individual worker to think safety and to act safely, and that, if it has enthusiastic backing by the management (as explained by Mr. Irvin), is going to do the job.

Now, you have had for several years a safety contest. Other lines of industry have undertaken similar work more recently. The success you have had in your contest has demonstrated that such a method is worthwhile. Now this safety contest, as I see it, is a stimulus to increase the safety in the plant. It is a means to an end. The winning of a trophy is not the end in itself, but merely the symbol of an accomplishment and that is the real objective of the contest—to do the job safely; that is the end, and the contest is the means and the trophy is the indication of what you have done.

For those who may not be familiar with the record of the contest in the past years, I might briefly recite the history of it. The first contest was for a period of one month and was instituted in 1925. Forty-one mills were entered in that contest, which was won by the Nekoosa-Edwards Paper Company. The second contest, in 1926, was for a six months' period and seventy-two mills were entered and this contest was won by Neenah Mill, Kimberly-Clark Company. The third contest, in 1927, was also for six months, with one hundred and nineteen mills entered and that year was divided into three groups, Group A, won by the Nekoosa-Edwards Paper Co.; Group B, won by the Niagara Falls Mill, International Paper Co.; Group C in which three mills tied for first place, all with perfect records of no lost-time accidents. These three mills were the Neenah Mill, Kimberly-Clark Company; Riley Mill, International Paper Company; and Gypsum Mill, U. S. Gypsum Company.

The 1928 contest, which is the fourth of the series, for the first six months of 1928, 124 mills were entered. This was the largest of the series, as you would naturally expect. The winner in Group A, which is the group employing over 500 people, is a mill which employs 592 persons, who worked 794,127 man hours during the contest period. There were four lost-time accidents, a total of 12 days lost time. Frequency rate—5.037 and severity rate—.015. This company accumulated a total of 526.545 credit, the highest of the 23 mills entered in this group. The winner was the Champion Coated Paper Company, Hamilton, Ohio. Mr. Kenneth L. Faist, your new Section Chairman, is the safety director, and it gives me the very greatest of pleasure to present him this trophy. Will you read the inscription, Mr. Faist, for the benefit of the members present, and have it included in the record?

MR. FAIST: "Award For Best Safety Record Among 23 Mills, Each Employing Over Five Hundred Persons—Champion Coated Paper Company, Paper Mill No. 2, at Hamilton, O. The Paper Industry Annual Safety Contest, 1928."

MR. NIESZ: The winner of Group B, employing between 200 and 500 men, has 438 people, who worked 565,977 man hours. They completed the entire period without a single lost-time accident. This mill was the first to enter the 1928 contest and is one of the new members of the National Safety Council. The safety

work is under the supervision of Mr. W. J. Brennan and I know you know the name of the company—the St. Croix Paper Company, of Woodland, Maine. The vice-president and general manager of the company is present and I would like to present this trophy to him. But the modesty of the general manager makes necessary the presentation of this trophy to the safety engineer, Mr. Brennan, to whom he gives the credit.

MR. BRENNAN: First I will read the inscription into the record: "For the Best Safety Record Among 38 Mills, Each Employing From Two Hundred to Five Hundred Persons—St. Croix Paper Company, Woodland, Maine. The Paper Industry Annual Safety Contest, 1928."

In behalf of the St. Croix Paper Company delegates here today, and the boys in the mill and the officers of the organization, I want to express our thanks first, and then tell you that this is the culmination of a sort of supreme effort on the part of our company. To many of you, this is a very enjoyable occasion, characterized by good food and agreeable companionship, but to us it is more. Now in order to understand that, you will have to know our experience of last year.

Mr. Parant delegated me last year to make a serious effort toward bringing one of those things to our mill. We started off with great enthusiasm, only to have our fondest hopes blighted by a death. It seems, of course, there was a bad reaction and as days went on accidents seemed to spring from the ground to drive our record lower, in spite of all we could do we went lower and lower, nearly to the bottom. I have other duties besides safety work and I guess at times we were in despair. I would go to the office, tell the general manager there had been another one and the thing that kept us going, gentlemen, was these few words—"Forget it and use that to build upon for another year."

So I would go forth to the boys in the mill with that message. We profited by our experiences of last year and as Mr. Irvin said, in November we realized a no-accident month, the first in our history. Everything sort of smoothed out following that. The men became safety-minded. We started in the contest, the same as the year before, with great enthusiasm and this continued from that moment until the 30th of June when all hands, foremen, superintendent and general manager, walked through the plant, until the whistles started to blow at midnight.

You have heard this sort of thing before, but I want you to realize our feelings and our position on that night. We are the most easterly mill in the United States, located on the Canadian border; there are no mills very near us. Because of our isolation, we have not the contact that some of you have, therefore we were much on our own except for the *National Safety News* and the good letters from Bill Peacock. I won't say more than this, but I want to pay a tribute to the men who are down at St. Croix today, eating their lunch from baskets while the wheels go round, while we are here in this beautiful hotel, taking it easy. It was not I nor Mr. Parant nor Mr. Irvin that did it, it was the spirit of the boys who said to each other, "It won't be me; you may break the record, but I'll be here tomorrow morning." And, gentlemen, it is spirit that wins contests and in winning contests we prevent accidents.

MR. NIESZ: The winner of the third group, C, employs 200 or less, and also completed the contest period without a single lost-time accident. One hundred sixty-six employees worked 177,744 man hours. The safety work of this company is under the supervision of Mr. R. G. McConnell, industrial relations manager, and the company, The Niagara Wall Paper Company, Niagara Falls, N. Y. I have pleasure in presenting you with this trophy. Will you read the inscription, please?

MR. MCCONNELL: "The National Safety Council—Universal Safety"—and that's what you all believe in—"The Best Record Among Sixty-One Mills, Each Employing Less Than Two Hundred Persons—Niagara Wall Paper Company, Niagara Falls, New York. The Paper Industry Annual Safety Contest, 1928."

I would like to say, on behalf of the employees of the Niagara Wall Paper

Company, we are truly thankful that we have been able to win this trophy and I express the sentiments of those employees back at Niagara Falls.

I had taken a few days' vacation and was in the midst of a great big cornfield when a telegram came for me to come to New York City and I found we were in for one of these trophies. I stopped off at Niagara Falls on my way to New York and found out that the first safety meeting that had been conducted in that mill was in February, 1910. We have conducted a safety meeting at least once a month in the last twelve years. It is about eighteen years, according to record, that they have been plugging away at this safety proposition. I myself have led off in the work with four of these contests, and you see by this record that it is a long, long trail before you arrive.

We never got very good results until we were able to develop a foremen's association, and believe me, that was some task to get that going. I worked on it four years and was never able to accomplish the organizing of that foremen's association until I began to interest the wives of the foremen. Finally, some of those women said to me, "Why don't you come to our house and bring the foremen along and conduct your meeting?" So I snapped one of these opportunities up and one day I told a fellow, "We're coming to your house this evening"—it was on a Sunday, May 9th. I landed there with 49 men and they organized a Foremen's Association in that lady's house. We continued to grow and develop right along in this industrial relations work ever since, we have had meetings regularly once a month for the last three years and have accomplished a lot of good work and these foremen have been right behind this safety meeting work.

I think you fellows who have led off in this Paper and Pulp division have created and developed marvelous results. You have set up a system now whereby we are beginning to receive literature through the National Safety Council headquarters, that talks in terms that paper employees understand. Now, you fellows have from twelve to thirteen hundred paper mills in the North American continent, I am told, and as you go back to sell this at home, it seems to me you have a great field and a possibility to grow and you are going to have a large section in this industry in years to come.

CHAIRMAN PEACOCK: Thank you, Mr. President, for your presence, for all your encouragement, and your appreciation of our methods. We are to witness the presentation of "The Paper Industry" Grand Trophy and we are very much pleased to have as the donor, and in person, Mr. Edward B. Fritz, publisher of The Paper Industry, of Chicago.

Presentation of "The Paper Industry" Trophy

By EDWARD B. FRITZ

Publisher, "The Paper Industry," Chicago, Ill.

Safety is a pretty big word. An ounce of safety is worth many cabinets full of first aid after the accident has happened. Safety might be termed "self-preservation," which is the first law of man.

When "The Paper Industry" was started, or before, I had traveled among the paper mills for a good many years, and I saw that there were many places that seemed unsafe; in fact, I got in a rather bad accident myself one time, although I was just running around the mill. To overcome this, and to educate paper mill men in safety has been one of our main points in publishing "The Paper Industry." Cutting out waste and saving lives or saving time are practically the same thing, because when we save lives and time we are cutting out waste.

It was not very long after "The Paper Industry" was started that we began to come in contact with the National Safety Council, and several years after that

we decided it would be a very good move to offer some kind of a prize, something to strive for. Last year the major cup was not presented; the three smaller cups were presented but the large one I still have in my office. I am not using it and I hope to give it out to somebody, but it is a fine thing to know that there are still three mills that have been running since the first of last year without an accident, and so, as long as those three mills run, two of them will have to have an accident some time or other, or else we will keep the cup.

The rules last year were quite different and it was on account of that that we could not decide. This year the rules were changed so that if there happens to be more than one mill at the end of the six months' time that has not had an accident, a number of men are to be selected as judges to decide which one of those mills should be presented with the trophy, or the one that had the largest number of men with the larger number of possible accidents.

The mill that is going to be presented with this trophy has made a wonderful record and I don't know of anything that has ever given me more pleasure than to present this trophy to them because they have made such a wonderful record. I therefore take a great deal of pleasure in presenting this plaque to the St. Croix Paper Company of Woodland, Maine. Mr. Parant, will you accept this for your company, with the compliments of "The Paper Industry"?

L. J. PARANT (St. Croix Paper Co., Woodland, Me.): "The Paper Industry Magazine of Chicago—Major Award—For Best Safety Record Among 124 Mills, Members National Safety Council—Won by St. Croix Paper Company, Woodland, Maine, during period January First to June Thirtieth, 1928. The Paper Industry Annual Safety Contest."

I don't know that I have any power of speech left. This is rather more than we bargained for. We winners of these trophies are placed in a rather embarrassing position in that we rejoice and may appear to be rejoicing over the misfortune of some other mills. I want to assure you, gentlemen, that we don't feel that way at all. We went into this contest principally for humanity's sake, and that brings to my mind my first awakening to safety work. Way back in 1908 I was connected with Finch-Pruyn Company, at Glens Falls, New York. We had had a number of accidents in our wood room on the barker through the use of the lombard attachment, I believe it was. I personally designed a guard for the lombard attachment and the guards were being put on, and the president happened to come through the wood room—Mr. Morris Hoops, president of the company. Having in mind possibly a promotion or an increase in salary, I called his attention to the wonderful guard that I had designed and mentioned the fact that it would save us a great deal of money in accidents that we had been having to pay for. His only remark was, "For humanity's sake."

They were the only words Mr. Hoops said to me and from that day on, gentlemen, I have been interested in the safety movement for humanity's sake; and we are—and when I say "we" I mean the President of the St. Croix Paper Company down to the janitor—we are interested in the safety movement for humanity's sake and nothing else. If we men here take that attitude—forget the insurance rate and the saving in money, and go into the safety movement for humanity's sake, we are going to accomplish wonderful results. On behalf of the St. Croix Paper Company, I rejoice in accepting this gift from "The Paper Industry."

MR. FRITZ: Aside from the prizes that have been given out, there have been a number of mills that have made perfect records, that have had no accidents, and for six of these mills we have prepared certificates of merit. The first is to the Finch-Pruyn Company of Glens Falls, N. Y. Will the representative of each company come forward and get the certificate?

(Certificate presented to Mr. Samuel Pruyn.)

The next one is the Atlas Mill of the Kimberly-Clark Company.

(Certificate presented to Mr. M. G. Hoyman.)

Seventeenth Safety Congress

The Neenah Paper Mill of the Kimberly-Clark Company, Neenah, Wis.
(Certificate presented to Mr. M. G. Hoyman.)

The next is the U. S. Gypsum Mill at Kansas City.

(No representative of this company was present.)

The next one is the U. S. Gypsum Company at Gypsum, Ohio.

(No representative of this company was present.)

The Riley Mill of the International Paper Company, Chisholm, Me.

(Certificate presented to Mr. Wm. E. P. Fullam.)

I wish it were possible to give each one of you people a trophy like the major award, but I think that by each man in each mill striving for the main trophy, they get some place, even though they don't get the first prize; and I know that as we publish the accident records, each month it seems as though the accidents for the same number of men are getting less. At least, each year they are getting less and this is a wonderful work. I want to assure you that so far as "The Paper Industry" is concerned, we will have equally as good a prize next year, so everybody strive for it.

CHAIRMAN PEACOCK: Now, of course we want to know how the rest of us stand and George Burns is here to tell us.

Outstanding Facts in the Contest

GEORGE BURNS (National Safety Council): As Bill said, I didn't distribute this report so none of you knew what is on these sheets or who won the trophies until the awards were actually made. We prepared eleven outstanding facts on this contest. Here they are:

1. 119 mills registered in 1927 and 124 registered in 1928. This represents an increase of 4.2 per cent.
2. In 1927, 33,786 persons worked 43,802,604 man-hours for an average of 1,296 hours per person.
3. In 1928, 36,357 persons worked 47,673,816 man-hours for an average of 1,311 hours per person.
4. During 1927, 1,468 lost-time accidents resulted in 28,396 days lost, while in 1928, 1,355 lost-time accidents caused but 26,368 days lost.
5. The 1927 average Frequency Rate is 33.514. The 1928 rate of 28.422 represents a reduction of 15.2 per cent.
6. The 1927 average Severity Rate is .649. The 1928 rate of .553 represents a reduction of 17.9 per cent.
7. During 1928, 64 mills had a frequency rate below the average, while only 60 mills succeeded in 1927.
8. During 1928, 76 mills had a severity rate below the average, while only 58 mills were below in 1927.
9. The 1928 ratio of persons employed to lost-time injuries is 27 to 1, with 19 days lost per injury. The 1927 ratio amounted to but 23 to 1, with 19 days lost per injury.
10. In 1928, the ratio of non-fatal to fatal injuries is 150 to 1, while in 1927 this was 147 to 1.
11. During the 1928 Contest, 8 mills completed the period without a lost-time accident as compared with 6 mills in 1927.

I have been perplexed since this contest started as to whether all in the contest really knew how we figured the points debit and credit. The rules read as follows:

- (A) Frequency—5 points shall be credited for each 1 per cent reduction as compared with the average frequency rate of 35.00. Likewise, 5 points shall be charged for each 1 per cent increase.

(B) Severity—1 point shall be credited for each 1 per cent reduction as compared with the average severity rate of 1.00. Likewise, 1 point shall be charged for each 1 per cent increase.

We determined that the average frequency rate had been 35 for the past three contests. Now, the average severity rate of 1.00 is greatly below the average for the section as a whole, as yearly statistics are based on the six thousand day charge. Contest figures are but one-sixth, due to the fact that you only used the one thousand day charge for death. To bring out how the above point rule affected the final ranking, just let me point out the first two items that appear in Group A. First ranking mill, the Champion Coated Paper Co., Mill No. 2, with 592 employees, worked 794,127 man hours, with four lost-time accidents, resulting in 12 days lost time. Now their frequency rate was 5.037, their severity rate .015. The Nekoosa-Edwards Paper Company, Port Edwards Mill, ranking second with 522 employees, worked 802,165 manhours. They had three lost-time accidents but they had 167 days lost time, as compared with the winner's 4 accidents and but 12 days lost time.

The winner had a frequency rate of 5.037; the second mill had a frequency rate of 3.740, but the winner had a severity rate of 0.15 and the second mill a severity of .208.

Based on the rules the winner's frequency rate was 85.609 per cent lower than the average, or a credit of 428.045 points. The record mill's frequency was 89.300 per cent lower than average or a credit of 446.500 points.

However, the winner had a severity rate of but .015, which is 98.5 per cent below the average and earned 98.500 points credit; while the second mill earned but 79.200 points credit as their severity rate of .208 was but 79.2 per cent below the average.

Thus the winner accumulated 428.045 points plus 98.500 points, or a total of 526.545, while the second mill's points credit totaled but 525.700.

Pretty close, to be sure, but under the point scoring plan the severity played an important part even that it had but one-fifth the weighting as frequency.

I don't know that it is necessary to go into detail on all other mills. It is all printed and my only hope is that we are going to continue for the next year. I don't know what action the section took this morning as I could not be present, but I hope the new Contest Committee will get together just as soon as possible and let us not have any last-minute hurry-up orders. This year, in the Council, we have had three very successful contests, one in the Petroleum Section in which we had eighty-five units entered, and one in the Public Utilities Section.

The latter contest is really outstanding. The officers last January at a meeting in St. Louis, decided they would attempt to put on a contest and they declared they must have fifteen units entered in order to award a prize. They established a minimum, feeling that possibly it would be difficult to secure a representative registration. The contest was on a frequency basis only. The result was when the final day of reckoning came, we had seventy public utilities, entering a hundred and fifteen units. The trophies to winners were awarded this afternoon at the Pennsylvania Hotel.

CHAIRMAN PEACOCK: We didn't give the new chairman a chance to say something for his mill. We will let him get on his feet and while he is saying something of the achievement, the method of achievement in his mill, maybe he can line up his regional directors for a meeting after this one.

KENNETH L. FAIST (Champion Coated Paper Co., Hamilton, O.): Last year we were practically in the same place Nekoosa-Edwards is this year. We ran an awfully close second. When I went back to talk to our safety committee and our foremen, they were exceedingly disappointed that I had not come back with the cup, especially when they found out how close the race had been so they went in with renewed effort and said they were going to get the cup this year. They

are waiting and made me promise that I would wire them immediately as soon as I found out. So that is the next thing I have to do.

In our record of four accidents, one was a man who had taken a trail from a driver over to the calender and got a cut on his eye. The doctor felt he could put a patch on his eye and the man could perhaps go to work but the danger was such that we thought we would be taking an extra hazard, so the doctor ordered him to take a few days off. One of the other accidents was a sprained ankle, and he lost two days. The doctor thought it would be better for him to take off those two days rather than run around on it. One of the other accidents, if it can be called such, was one of the young ladies on our sorting line claimed she had sprained her ankle. She didn't report it to the Medical Department but said she had been hurt. It so happened that during the day, she was seen uptown doing shopping; however, we decided as long as she declared she had been hurt in an accident that we would count it.

I am well pleased that I am going to go back to the boys back home, for that's where the credit belongs, to the safety committee men and the foremen and our superintendent, Mr. A. O. Rolfe who went personally on the first day of the month around to each man and gave him a personal talk and told them he wanted to bring back the trophy this time. I thank you.

ADJOURNMENT

SEVENTEENTH ANNUAL SAFETY CONGRESS
NATIONAL SAFETY COUNCIL

Petroleum Section

New Section Officers

General Chairman—C. W. SMITH, Director of Safety, Standard Oil Company (Ind.), Chicago, Ill.

Vice-Chairman—R. S. BONSB, Chief Safety Inspector, Standard Oil Co. (N. J.), New York City.

Chairman Atlantic Division—L. W. EVANS, Safety Engineer, Atlantic Refining Company, Franklin, Pa.

Chairman Great Lakes Division—J. P. SUTTON, Manager, Industrial Relations, The Ohio Oil Company, Findlay, Ohio.

Chairman Mid-Continent Division—E. D. MURPHEY, Safety Engineer, Mid-Continent Petroleum Corporation, Tulsa, Okla.

Chairman Gulf Division—C. L. HIGHTOWER, Safety Director, Texas Pacific Coal and Oil Company, Fort Worth, Texas.

Chairman Rocky Mountain Division—L. F. HOWBERT, Continental Oil Company, Denver, Colorado.

Chairman Pacific Division—R. E. DONOVAN, Standard Oil Company of California, San Francisco, Calif.

Engineering Committee—

Chairman—J. C. BERNID, Safety Director, Sinclair Refining Company, East Chicago, Ind.

F. L. NEWCOMB, Supervising Engineer, Standard Oil Company (New Jersey), Elizabeth, N. J.

K. M. FOWLER, Assistant Safety Engineer, Pure Oil Company, Chicago.

H. W. BOGESS, Sinclair Oil and Gas Company, Tulsa, Oklahoma.

V. H. HAYSLIP, Humble Oil and Refining Company, Houston, Texas.

B. V. OSBORNE, Standard Oil Company (Ind.), Casper, Wyo.

S. C. DAVIS, The Texas Company, Los Angeles, Calif.

Publicity Editor—T. N. SHAW, Director, Industrial Relations, The Midwest Refining Company, Casper, Wyoming.

Program Committee Chairman—S. W. CANDEE, Director, Industrial Relations, Tidewater Oil Company, New York City.

Statistics Committee Chairman—J. W. MYERS, Standard Oil Company (New Jersey), New York City.

Executive Committee—THE OFFICERS AND

R. S. BONSB, Standard Oil Company (New Jersey), New York City.

E. J. SENNE, Vacuum Oil Company, New York City.

D. J. WALLACE, Mid-Continent Oil and Gas Association, Tulsa, Okla.

V. R. CURRIE, The Texas Company, New York City.

GEO. F. PRUSSING, Union Oil Company of California, Los Angeles.

Petroleum Representative—H. N. BLAKESLEE, National Safety Council, Chicago.

Retiring Officers

Chairman, GEORGE F. PRUSSING, Union Oil Company of California, Los Angeles, Calif.; *Vice-Chairman*, DR. R. P. ANDERSON, American Petroleum Institute, New York City; *Chairman Atlantic Coast Division*, S. W. CANDEE, Tide Water Oil Company, New York City; *Chairman Mid-Continent Division*, T. N. SHAW, The Midwest Refining Company, Midwest, Wyo.; *Chairman Pacific Coast Division*, F. A. SCOFIELD, Associated Oil Company, San Francisco, Calif.; *Secretary and News-Letter Editor*, A. A. NICHOLSON, The Texas Company, New York City; *Poster and Slide Committee Chairman*, O. W. HUMPHREY, Standard Oil Company (N. J.) Elizabeth, N. J.; *Publicity Committee Chairman*, RALPH E. MOTLEY, The Atlantic Refining Company, Philadelphia, Pa.; *Program Committee Chairman*, RAY E. MILLER, Marland Companies, Ponca City, Okla.; *Statistics Committee Chairman*, J. W. MYERS, Standard Oil Company (N. J.), New York City; *Field Representative*, H. N. BLAKESLEE, National Safety Council, Chicago, Ill. *Engineering Committee: Chairman*, C. W. SMITH, Standard Oil Company (Ind.), Chicago, Ill.; F. L. NEWCOMB, Standard Oil Company (N. J.), Elizabeth, N. J.; C. L. HIGHTOWER, Texas Pacific Coal & Oil Company, Fort Worth, Texas; R. E. DONOVAN, Standard Oil Company of California, San Francisco, Calif. *Executive Committee: THE OFFICERS AND* E. J. SENNE, Vacuum Oil Company, New York City; R. S. BONSB, Standard Oil Company (N. J.), New York City; C. C. BENEDICT, Standard Oil Company of New York, New York City; A. L. BARTH, The Atlantic Refining Company, Philadelphia, Pa.; V. R. CURRIE, The Texas Company, Houston, Texas; D. J. WALLACE, Mid-Continent Oil and Gas Association, Tulsa, Okla.; E. D. MURPHY, Mid-Continent Petroleum Corporation, Tulsa, Okla.; R. B. ROAPER, Humble Oil and Refining Company, Houston, Texas; H. L. EGGLESTON, Pan American Petroleum Company, Los Angeles, Calif.; C. P. ANDERSON, Richfield Oil Company, Los Angeles, Calif.; H. M. WOLFLIN, California Petroleum Company, Los Angeles, Calif.; W. C. LYNCH, General Petroleum Corporation of California, Los Angeles, Calif.

October 2, 1928

GEORGE F. PRUSSING, Chairman

Secretary, Safety Board, Union Oil Company of California
Los Angeles, Calif.

The first session of the Petroleum Section at the Seventeenth Annual Safety Congress was called to order at nine-thirty o'clock by the chairman, George F. Prussing, Secretary, Safety Board, Union Oil Company of California, Los Angeles.

CHAIRMAN PRUSSING: The Sixth Annual Session of the Petroleum Section of the National Safety Council now opens; and I take pleasure, as retiring chairman of your body, to welcome you here and to give you a little résumé of what has taken place in the section during the year 1928.

This is not a formal or written report. Most of you know as intimately as I do what has been the work of the section. We have been fortunate in the character and amount of information that has been circulated through this section during the past year, but I think it is fitting to speak of the high lights so that we may remember what has been accomplished, perhaps if only as a background for what the coming years may bring forth.

In the work of this section heretofore, the country has been divided into three divisions, the Atlantic Division, under Mr. Candee; the Mid-Continent Division, under Mr. Tracy Shaw; the Pacific Coast Group, under Mr. Frank Scofield; and these groups have within themselves held meetings and kept in touch with their

members during the year. I am, of course, personally more familiar with the work on the Coast, and in the absence of Mr. Scofield I can say that there it has been possible to combine the Pacific Coast organization with an already existing one, the Safety Section of the California Chamber of Mines and Oils, and in that way function as a distinctly local organization, with meetings that take place regularly, with an annual Pacific Coast Safety Congress or Conference, in which the oil industry has for the past five years been the largest single group. I know that similar meetings have been held in the Mid-Continent and on the Atlantic Coast, and that in the Annual Congress of the American Petroleum Institute safety has come to have a definite part on the program.

Those of you who have been at previous congresses will remember with appreciation the work done in past years by Capt. A. A. Nichoson, our secretary and editor of the *News Letter*. Due to the condition of his health, it became necessary, early this year for Capt. Nichoson to resign his active position with the Petroleum Section, a fact which we all regretted, not only because in his resignation we lost a very valuable member of our organization, but primarily because of the reason behind that move. I am happy to say that Capt. Nichoson has improved wonderfully in the last year in health, and might even have attended the sessions here this week if it had seemed wise.

On Capt. Nichoson's resignation, the work that he had been carrying so well was turned over to a man whom we deliberately drafted into the organization for that purpose.—I am afraid somewhat against his will—Mr. R. S. Mutch, of the Texas Company. He has carried it through very successfully. I feel the thanks of the group are due to Mr. Mutch for the way in which he has carried on.

Another active part of our work has been the preparation of posters, an exceedingly difficult task, as any of you who have ever tried to prepare poster material will know. Mr. Humphrey, of the Standard Oil Company of New Jersey, has been the chairman of our Poster Committee and has supplied to the National Safety Council a wealth of such material.

Another important function that has been carried on with a great deal of success during the last year has been the preparation and editing of articles dealing with safety in the petroleum industry and their release to the *National Safety News* and to trade journals generally. That work has been under the direction of Mr. Motley, of the Atlantic Refining Company, who during the year, because of the change of his work, found it necessary to resign his position as chairman of the Publicity Committee, but before resigning completed the entire assignment for the year and turned over to the Council enough material to keep the trade journals well supplied for the balance of 1928.

Another part of the work of this section for every year, a very important part to those of us who come to the congresses, is the preparation of a program for the congress itself. That work fell on the shoulders of Mr. Ray Miller, of the Marland Companies, and I want to commend him for the character of the program which he has prepared for us.

A part of the background in the technique of every safety man are the statistics of his own and other companies with regard to accident frequency and severity. To make those statistics of use as between one company and another, between one industry and another, requires technical skill as a statistician; and this organization of petroleum men has been fortunate that the chairman selected for its Statistics Committee has been a man trained in that work. Mr. Myers has for a number of years headed that Statistics Committee; and those of us who have been in touch with the revisions that he has made in the standard report form used by other sections, will agree with me that he has made that report form fit the needs of this organization, as it previously did not.

During the past year the Petroleum Section has undertaken to prepare certain technical data for the use of the members of the section. That work has been

in charge of Mr. C. W. Smith as chairman of the Engineering Committee, and associated with him have been engineers in the three divisions.

A pamphlet on "Safe Practices in Pulling Wells" and one on "Safety in Gasoline Service Stations Operation" have been released and have had wide circulation, a circulation that really is phenomenal when you consider that such information is not always widely accepted by industry. But in this particular case, because of the way in which it was prepared and the fact that the industry had a chance at revision, it was given a great deal of publicity; and perhaps more than anything else, the fact that the information itself was good, has given these first two pamphlets a great sale. There has just been released the third pamphlet on "Safety in Loading Gasoline Tank Cars." It is too early to say what the circulation of that pamphlet will be. It cannot, of course, have the tremendous vogue that was given the second one on service station operation, but it, too, is an excellent piece of work. I have just read the last draft of the fourth pamphlet, one on handling pipe, and I believe you who have seen it will agree that the standard of excellence set in the first two pamphlets has been well maintained. There are more to come, and the work of the Engineering Committee, in my humble opinion, has become the most important single activity of our organization, a thing that we can point to and say, "This thing we have accomplished, and it is good."

The changes that must take place in any organization, if it is to grow, have come to me from time to time by way of suggestion from members of the section. A little later I should like to lay them before you so that when our Committee on Resolutions and Nominations makes its report on Wednesday morning, you will be prepared to discuss these points with a greater knowledge than you might if the resolutions came to you at that time more or less out of the blue. The Chairman of the Committee on Resolutions and Nominations, Mr. Senne, will be glad to hear from any member of the section between now and Wednesday morning, if you have any further suggestion along the line of reorganization, resolutions, memorials, or nominations, which should be brought before the section in its business session.

We have a very interesting program laid out, and because I want to run this meeting on schedule, I am going to ask leave to continue my own report and the outline of the changes in organization that have been suggested to me, from time to time throughout the program up to Wednesday morning, at which time these changes will be laid before you in a formal manner. For the time being, therefore, I am going to discontinue my own remarks and turn to the program as outlined for us.

Those of us who must be called the younger generation in the oil business, I think have no greater privilege (certainly such has been my own case), than meeting and working with men who have been literally the founders of this tremendous, though relatively young, industry. It was my privilege to know Lyman Stewart, and it is a memory which I shall keep with the greatest of pleasure for the rest of my life. And there are men in every large oil company in the United States who belong to that group, the first men in the industry, we might call them, the men who have started and led the industry to the position it now holds. It is my privilege to introduce to you a man of that character, a man who for nearly fifty years has had his place in the oil industry, and who throughout that time has met the one basic standard of success, which has been put thus: That a man in any organization is a success if he has the esteem of the men under whom he serves and of the men who work for him; he may have the one or may have the other, but he is a success if he has both.

I should like at this time to present to you Mr. Edward Prizer, Chairman of the Board of Directors of the Vacuum Oil Company.

Address

By **EDWARD PRIZER**

Chairman of the Board, Vacuum Oil Company, New York City

When Mr. Cameron asked me whether I would come here and speak for a few moments, he said it would be just an informal act; and I wrote him that I would do so on condition that I might come and talk as I might talk in our own board room; on that condition I would cheerfully come.

I don't know but I am something like the minister who apologized to his congregation on Sunday morning and said he had been so busy he had had no time to prepare his sermon, and would have to trust upon the inspiration of the Lord. He said, "Next Sunday I will come better prepared." So if you have me again, perhaps I will come better prepared.

As your chairman said, my memory goes back, not quite fifty years, but forty-seven years, pretty near. I have been thinking over this question of safety since I first joined the petroleum industry, and some things have very much interested me.

Forty-seven years ago, it is a fair statement, the worker carried the risk. He had redress in common law, but the manufacturer was protected by contributory negligence; and therefore between common law and contributory negligence, the worker fell between the upper and the nether millstones. I remember a circumstance before the days of compulsory liability insurance, where we had two men working on a tank, one helping the other, one holding the ladder and the other going up. The man going up the ladder let slip a heavy wrench and killed his helper at the bottom of the ladder. Under the law that man had no redress at that time, because of contributory negligence absolving the employer of the liability.

Today that sort of a principle could not exist, for two reasons. There were a lot of shyster lawyers who made a business of carrying on damage suits based upon their nuisance value, to extract from employers payments for injuries, real or assumed; and the lengths that they went to compel employers to pay to avoid such nuisance, were quite remarkable. I remember one or two cases in Rochester, where unjust claims were taken by such lawyers, were set down for hearing at seven o'clock in the morning, in a country district not reached by railroad, and as automobiles had not yet been invented our treasurer was required to get up at four o'clock and drive out into the country and present our side of the case; otherwise judgment would have been given against us by default. We had cases where our carting was done by contractors having wagons, which carried our signs. When an accident occurred, some lawyer would come along and say, "Your wagon ran into and injured my client," and we said we had no wagons. "Well, the wagon was carrying your sign, and it doesn't make any difference; we are going to sue you anyway. If you don't want the bother of being sued, you had better make payment anyway."

Well, that went on for a considerable time, until there began to be an awakening of conscience through the country, largely led at the time by President Roosevelt, that it was manifestly unjust for the industrial worker to carry the risk; that it must be carried by the industry itself, and that the unavoidable risk of injury and death should be put upon the cost of the products and thus distributed to the community as a whole. Now, I can't say that industry itself overly welcomed this movement. I know for a while there was a great deal of question whether it was wise, whether it might not lead to more evils than the old system; but anyway it went through, and I think there are no industrial organizations, employing a considerable number of men, that are not thankful that the law itself prescribes what shall be done in the case of injury and harm to the employee.

Well, now, the effect of those laws touched the pocketbook of the employer—

that was the first result—and he began to see, on examining his works, how many accidents there were that might be prevented if he deliberately set about to do it. That was his first reaction; and I know a great body of employers in every state where there was a compulsory liability law, who went through their plants with very great care to see whether there were unprotected spots that might result in the injury of others through being unguarded, whether there was not carelessness that might be avoided, and whether there might not be some system of improving the condition of their working people in regard to injury.

But, after a time this went further. There came a feeling on the part of the employer over and beyond a mere question of the money. There was a moral side that he should consider. While he might have been, in the old times, somewhat hardened to industrial accidents and thought they were necessarily a part of industrial operation, now he began to think that he wasn't working with machines as regard to his labor; he was working with men and women, people like himself, who were entitled to every possible consideration and assistance to prevent accidents happening through their own carelessness, the carelessness of other people, or the operation of machinery; and therefore there was a complete revolution on the part of the employers as a whole.

And I know that a great many have gone to lengths that they never would have dreamed possible at the time the first compulsory insurance was talked of. There are few large employers today that don't go beyond the hazard of the shop or the factory. They provide for sick benefits. They consider that a man who is going through the valley of life is liable to something else than getting his hand or his leg hurt. He may get pneumonia, or typhoid fever. You can't throw his family on the charity of the community when he is sick. And therefore something had to be done outside of the mere hazards of the shop and of the factory itself. So we have a system of sick benefit, which I think nearly all progressive concerns now take into careful consideration.

But quite a few of them got a bit further. They say if an employee dies, no matter from what cause (not because he is killed in the factory), but if he dies from disease or his automobile is run into and he is killed, there is his family, and that family should not be put as a charge upon the benevolence of the community, but that industry should take care to a very considerable degree of the needs of that family, particularly where there are small children, until they can restore themselves and get on a self-supporting basis. It has been one of the great pleasures to me in our organization that our death benefit plan has been operating all over the world in every place where we have employees. It has been one of the finest things that our company ever adopted, and has lifted the burden off of many depressed and unhappy families, who did not know where they would turn when the bread-winner was gone, through disease or something of that kind, and they had to look to the future and establish some system by which they might be self-supporting.

Now, I want to say that the word "accident" frequently implies something unavoidable. That isn't so. No accident is ever without a cause. The cause lies back somewhere; and in order to reach and prevent the accident, you must stop the cause. In my business experience I have known a number of cases where the cause was self-evident. When I was in Rochester we had an absolutely ironclad rule, before the days of employer liability, that no man should enter an empty tank which had contained oil unless somebody was there right with him, mainly and principally to have a rope around him, no matter how he might have thought that tank had been steamed out. But one day we missed one of our men, a good worker. We hunted around the works, and found him suffocated in the bottom of one of the tanks that he thought was properly steamed; he had gone in alone, contrary to rules, and was suffocated. We had the same thing happen in one of our tanks in one of our German refineries.

Well, that is carelessness. Sometimes carelessness goes to almost a ridiculous degree. For instance, insanity. We had a man in our Polish refinery who came down one day with a new suit of overalls on. He got them smeared up, didn't like the looks of them, so he drenched himself pretty well with gasoline to take off the smear, and then thought while it was drying he would have a quiet smoke, and he went into an outhouse and lit a cigarette and burned himself to death. You would think that was almost impossible, but it did happen.

Now, I remember a circumstance in Rochester, to show that accidents always have a cause. Our man used to come down to the office with an old horse and a democrat wagon, and that horse would stand without hitching. He usually took a quiet nap while the man went in for orders. One day the circus was coming, and when the man came out to get on his wagon and gathered the reins together, there was a great crowd everywhere, in the streets; people were way out in the middle of the street, and the sidewalk was all jammed. The man thought, "Well, I'll sit here; I won't push through that crowd, and anyway I want to see the circus."

So he sat there in his wagon, the reins in his hands. But when that horse smelled the elephants and looked around and saw them coming behind him, he woke up as he never woke up in his life. He went down through that crowd, and if he hadn't run into an electric light standard, he might have been going yet. He mowed the people down, breaking arms and legs and doing a great deal of damage. Legally the people had no right in the street. Legally our man had a perfect right to be there with his horse. He had just come out of the office, and had a right to do that. The horse was under legal control; but he had no business to be there, just the same, and the people had no business to be in the street. Well, it was our horse, and we felt the responsibility sufficiently to pay eight or nine thousand dollars to patch up broken legs and broken arms, bruised heads, etc. Well, certainly you can trace cause and effect in that.

Now, in the control of your people in your works, constant vigilance and education are necessary. We don't all realize that the old adage, "Familiarity breeds contempt," is absolutely true. A man gets used to doing things over and over again, and finally he gets careless, something happens, injury follows. I think that all employers owe an educational method with their working people, whether they are clerks in the office, whether they are workmen, whether they are salesmen, or what they are, because this reacts a great deal more than just in the industry operation. A man needn't be considered a coward because he is considering safety first. If he is going across a much traveled street, with automobiles flying to and fro, it is not cowardice if he waits until the sign is in favor of his crossing over. If he is driving an automobile, it is not cowardice to exercise great safety.

I was interested in a report in Massachusetts, that of the accidents that they analyzed; very few had come from speed; they had come from recklessness and inattention, but very few from defects in the automobile itself. People don't think. Their minds are on something else. I remember one of our doctors in Rochester who was badly injured once. He was driving down the street, his mind very busy on a case, and he turned right in front of a tram car, and his vehicle was smashed and he was badly injured. The first thing he said was that the street car driver was not responsible. He said, "I heard him clanging his bell, but I was so occupied with thought of the case, that I simply forgot and paid no attention."

That very often happens in the works. The question is how to educate your people.

Then we have got to go a little step further. We have got to make sure that our people are physically and mentally sound for the task that they are to perform. Therefore there has been growing up a system of physical medical examination for employees. When we first installed that there was a good deal of resentment, on

the part of our workers; but we found out some things that were very useful. We found out that men were doing things, lifting work, that the condition of their hearts didn't justify. They might drop dead. Others had a hernia that had been undiscovered by anybody but themselves and perhaps their own families, and they were doing things that they were totally unjustified in doing. Of course, that was an outgrowth of the employers' liability, but at the same time it resulted in more or less adjusting men to their work and giving them a longer lease of life than they possibly would have if they had gone on with the labors that physically they were quite unable to do. And of course there is a nervous condition and reaction to rapid running machines that requires tests to see whether the operator is tuned to that sort of work, not liable to get his hands or his feet or something else in the machines through lack of nervous and mental reaction to his peculiar line of work.

All of these things are in the line of safety. Now, there has been a gradually growing idea as to the sacredness of human life. It didn't exist when I first went into the business. I am frank to say there was a very strong feeling that labor was a commodity, that you could bargain for it as you could a ton of coal, and if one man got hurt and died or was killed, there were plenty more to take his place. I think we are all changing from that attitude of mind, that instead we believe we are all the same, of the same material, the same mental and spiritual make-up, no matter what our duties are; and that those that are in position to do it, must overlook, supervise, and help to prevent injury and loss of life. We must increase the average life of our people as a whole if we are to prosper.

We hear a good deal about the declining birth rate; but as against that there is the increase in life expectancy; and we can all contribute to that by various methods of safety—safety not alone as a mere machine operation, but safety as to disease, safety in the home, the use of the visiting nurses which are employed by many of the large corporations to follow up the sick, to go into the home and see what can be done, whether the sick one is getting the proper care, the right sort of nursing and food. All these things lead to this principle of safety, and we have got to consider it everywhere on a broad and humanitarian line.

I am glad in my business experience that this thing came right up to the employer. It was a very decided shock. He thought, "And now it is going to cost me a lot of money, and the thing to do is to prevent my paying out undue sums." But it did relieve him of a whole lot of shyster tricks and annoying demands for trumped up damages. As a rule, if a corporation or large employer was known to have money, it was the custom to give a very considerable verdict in favor of the plaintiff; and if unjust, it meant an appeal and carrying on; and then finally the nuisance got so bad that the employer would hunt up the fellow's lawyer and say, "What will you take to call it off? We are tired of it." That was the principle. Now we have a system that is just and fair, and we all must endeavor to find out the best practice, in the matter of injury and disease, among our body of employees wherever they are, and concentrate, constantly teach this practice. If you don't constantly press upon the point of carefulness, of consideration not only of themselves but others, they will fall down some time and then something will happen. I am sure none of us want accidents to happen. We look back upon accidents that have happened in our particular corporation or company with intense regret, knowing how easily they might have been prevented if we had only thought longer and further and been somewhat more careful.

In our company we are constantly preaching in every form, in our literature, in our works bulletins, in our instructions, this vital point of protection to the human element in every known way possible, not simply industry happenings, but from disease and from breakdown from work that they were not fitted for, giving them some other work that they are fitted for, trying to make them look forward to a happy and prosperous old age—not as we often see, broken-down,

crippled old men, who have served out their full years, thrown onto the cold world, with very little to take care of them. One of the things contributing to this spirit has been the pension systems which the various companies have organized, where a man can do his efficient labor to the end of his working capability, and then he feels he has a cushion that he can rest upon with comfort and satisfaction.

CHAIRMAN PRUSSING: Mr. Prizer, on behalf of the section may I thank you for the inspiration that you have given us? It must be a privilege to work for a company in which the guiding spirit is also an inspiration.

We are familiar with the work that the American Petroleum Institute has done, its leadership of the industry and its contact with our Government politically; but within the American Petroleum Institute, between company and company, there has been going on a technical work that does not get into the newspapers. Trade journals have carried some of it. That work has been the work of standardization.

I don't know what it is in the human mind that so violently rebels against waste, but there must be something there, because whenever waste is called to the attention of thinking men, they wallop it. There is no other expression for it. Apparently there is nothing that so arouses trained technical men as to find a leak. And when the industry got together in the American Petroleum Institute, almost the first thing to which attention was called was the tremendous loss which the industry suffered in the lack of standardization in its technical requirements, its machinery, equipment, methods. It wasn't merely that things were different, but it was the outstanding fact that as between different materials for the same identical use, there must always at any one time be a best. To discover that, to find the classifications into which materials and usages could be grouped, and then within each to find that best, is a very difficult job for even trained men. It is being very successfully met through the efforts of the American Petroleum Institute.

We had hoped today to have with us Mr. Carl Young, the Director of the Division of Standardization of the American Petroleum Institute, who has led this work for a number of years. Unfortunately it is impossible for Mr. Young to be present in person. He has, however, delegated one of the engineers of the Institute, Mr. D. V. Stroop, to take his place here before you and to present the paper which he had himself hoped to give you.

Standardization and Its Relation to Accident Prevention

By CARL A. YOUNG

**Director, Division of Standardization, American Petroleum Institute,
Dallas, Texas**

Accident prevention and standardization are intimately related. Materials manufactured in accordance with a carefully prepared standardization program bring to the user definite assurance that such materials comply with certain known and accepted specifications covering either dimensions or physical and chemical properties, and often covering both. Such a program should provide greater safety to the individual and a correspondingly greater increase in his personal efficiency.

A cardinal principle in any line of endeavor is to "start right" and a thorough knowledge of materials is of prime importance in oilfield work. Many preventable accidents in the oil fields are due to lack of knowledge of the materials with which the work is preformed. Some one "takes a chance" and then—something breaks and an accident often follows.

The present discussion is confined mainly to the oil business, and to the work of the American Petroleum Institute in standardizing drilling and producing equipment.

The Institute has established standards on the following materials: Belting, boilers, cable drilling tool joints, rigs and derricks, tubular goods, rig irons, rotary drilling equipment, wire lines and manila cordage, all classes of pumping equipment, and steel tanks for oil storage. Some of these standards are dimensional only; others are dimensional and include specifications on chemical and physical properties. In all but two of these standards, provision is made for special marking with the official monogram of the American Petroleum Institute. This mark, stamped on a piece of equipment, is visible evidence to the user that such equipment has been manufactured in accordance with A. P. I. Standards.

The relationship of standardization to accident prevention might be illustrated by all kinds of accidents which, for the present purpose, may be divided in two classes:

- (a) Those resulting in monetary losses only, or "material accidents."
- (b) Those resulting in monetary losses, including injury to life or limb, or "human accidents."

The oil derrick, which is the first structure erected when drilling for oil, is cited as an example covering both cases. Innumerable accidents, many fatal, have resulted when an overloaded derrick has been "pulled in." This was particularly true when wooden derricks were generally used. Individual companies and rig builders had their own designs and ideas as to strength; some designs were worked out with due attention to engineering principles, others were based only on a minimum cost. The class of lumber was often left to the discretion of the rig builder, who may or may not have furnished the best grade. The American Petroleum Institute has established standards on various types of derricks and has stipulated a minimum strength capacity, which must be stamped upon the derrick, and which must be guaranteed by the manufacturers. This gives the driller definite information as to the strength of the derrick with which he is working. Another important item is the derrick foundation. Faulty foundations permit the derrick to settle unevenly, resulting in collapse when the drilling strains are applied and have often been responsible for many fatal accidents. The Institute has formulated specifications for derrick foundations, which should do much to overcome this danger.

The same general condition applied to threaded connections, particularly on tubular goods and taper threaded joints used on drilling tools. Before the A. P. I. Standards were adopted, threads of similar pitch and diameter made by different manufacturers did not properly interchange, although visibly appearing to be identical. Such material parted when drilling strains were applied, often resulting in both material and human accidents. This situation has been corrected by the adoption of definite specifications on practically every threaded connection used in the drilling and producing of petroleum. These standards are maintained by the use of master gauges made in accordance with A. P. I. specifications and officially certified by the U. S. Bureau of Standards at Washington, D. C.

The exploding of oil field boilers, due sometimes to faulty material, but more often to careless supervision or firing, has been one of the most severe hazards in the oil fields. Cases are known where firemen have completely disappeared in an explosion. To assist in overcoming this condition, the Institute has adopted the A. S. M. E. Boiler Code, thereby obtaining minute physical and chemical specifications on the steel used in the construction of oil field boilers, and which also includes workmanship, finish and inspection. In addi-

tion to this, and of equal importance, the Institute has adopted a code on the proper care and use of boilers in the field, which, if followed, will reduce the probability of accidents to a minimum.

An accident that occurred in California several years ago on a rotary rig illustrates what may happen when some one "takes a chance." The drill pipe had twisted off in the hole and the crew was endeavoring to fish it out at the earliest possible moment, since the longer the drill stem remained in the hole without circulation the more liable it was to freeze and junk the hole or make a long side-tracking job necessary, either of which would be extremely expensive. In the course of the work it became necessary to change the engine sprocket and it was found that the keyways in the new sprocket did not match exactly the keyways in the shaft. The driller resolved to take a chance and endeavored to shim up the key to what he thought was a fairly tight fit. When the full power was applied the engine sprocket loosened up and moved out of line to such an extent that the chain broke and lashed out, severely injuring one of the crew. Of course, in these days, such accidents are prevented by building a frame work around the chain. Nevertheless, had the sprocket been the right fit so as to maintain alignment, it is safe to assume that the accident would not have occurred. The Institute has adopted uniform sizes of keys and keyways in relation to shaft sizes, and the observance of this standard would have eliminated this accident.

This accident also illustrates a characteristic mental attitude of the workman. If his tools do not properly fit, causing delays, etc., he often becomes impatient and, to make up time, will take chances, and whenever he takes a chance, he is inviting an accident. In contrast to this, he is not subject to harassing delays when using properly standardized equipment, but proceeds in his duties with assurance, content in the knowledge that as far as can be foreseen, precautions have been taken in advance to supply suitable material.

Accidents are often the result of ignorance of the materials themselves or the proper method for handling the materials, which can be overcome by proper education of the men in their prescribed line of work. Codes on the proper care and use of equipment should play a very important part in accident prevention. It is fair to assume that a man who has been trained in the care of equipment along certain prescribed lines, will suffer much less from accidents than one who has not been so trained.

The Institute has now, in various stages of completion, Codes on Recommended Field Practice covering the principal materials used in the drilling and producing of petroleum, which are being circulated throughout the entire United States and abroad. These codes should be studied by the men in the field. Supplemental to these codes, field posters have been printed giving condensed rules which are placed in conspicuous places in the warehouses and bunk houses, where field men generally congregate. Space is provided at the bottom of the poster for the company's signature under the words, "The Above Instructions Must Be Observed," and, in that way, the rules printed on these posters become mandatory orders. The sizes of these posters permit them to be tacked on "Safety Bulletin Boards," alongside the Safety bulletins.

Safety directors should insist on the use of standardized material whenever possible. This will tend to prevent accidents, and, at the same time, will be directly beneficial to their companies in the economies that naturally follow.

The national standardization of fire hose couplings is an outstanding example of the value of standardization in accident prevention. The great Baltimore fire of several years ago would not have attained such great extent but for the fact that fire fighting equipment sent in from neighboring cities could not be used because the hose connections used in the various cities were not interchangeable.

The bulletins of the Petroleum Section of the National Safety Council, explaining the correct method of handling or inspecting materials in the field, should prove of iestimable help in preventing accidents. The American Petroleum Institute is endeavoring to assist in this work with its codes on field practices and field posters. Also, through its standardization program, the underbrush of odd sizes of threads is being cleaned out and many extra sizes in various types of equipment are eliminated which will provide a safe and sound basis of selection. Education and knowledge of the proper methods of work are necessary to accident prevention and the establishing of proper standards and codes is a contribution toward that end. There is undoubtedly a limit in the effectiveness of mechanical safety devices. Beyond the point of adequate protective appliances, progress must be made in the mental training of the workers. The use of standardized material and the practice in standardized methods produce an orderliness of mind and habit which must result in more efficient and safer workmen.

The training of new recruits in the selection of proper materials and in the correct way to use these materials will react to their own and to their employer's advantage, and will establish a higher plane of general efficiency and safety. Intelligent standardization of materials and formulation of codes on the proper care and use of equipment are essential elements in such a program.

CHAIRMAN PRUSSING: I suppose that this section and its membership represents a pretty good slice of the American Petroleum Institute. I doubt if there is a company member of the petroleum section that is not likewise a member of the American Petroleum Institute. We therefore feel rather close to the Institute; and that the Institute has also recognized that closeness is borne out by the fact that the technical work done by this section has been supported not only morally but financially by the American Petroleum Institute.

In that technical work, we have sought to carry on the work which you have just described, carrying it perhaps beyond the point where the initial failure, which may cause loss of money and injury to persons, is mechanical, to the point where the initial failure is human. Certainly that work is no less valuable to the industry than the work of standardizing the mechanical elements of our industry; and that this has been recognized by the Institute is to me most gratifying.

Teaching men how to do their jobs successfully is, of course, a valuable part of every business; but to teach them how to do that job safely is just as important, because when a man does it safely, ninety-nine times out of a hundred he is doing it efficiently as well. The two things are inseparable. I think all of us know that the safety records established throughout the country in every industry have been established by companies that have been financially successful, and that means that their workers individually have been efficient.

Through the cooperation of the American Petroleum Institute, this section has had the benefit of a paid representative. He has been a member of the head office staff of the National Safety Council. Acting directly under the guidance of our Managing Director, Mr. Cameron, Mr. Blakeslee has been the means of coordinating that part of our work which comes down to the real brass tacks of the situation, the preparation of codes of instruction which makes it possible for certain hazardous occupations to be analyzed by the best minds in our industry and set forth in such a way that they may be used as simple guides for the instruction of new men and old throughout the United States. I mentioned that before, and I want to emphasize it again, as the most important part of the work we have been doing.

But more than that, more than the mere preparation of technical data, there is another element in education which cannot be overlooked no matter with what class of mind you are dealing, and that is the matter of inspiration, because unless

you can make a man want to learn, you can't put anything inside his head. The human mind is so constructed that it can close itself absolutely to the introduction of a novel idea. It is one of its peculiar characteristics. And to overcome that innate objection of the human mind to acquire anything new, requires inspiration.

During the past year we have attempted to set up a means of inciting interest in accident prevention right down to the last man on the job. That has been done through the inauguration of a competition. Competitions are not new; they are part of sport, part of life; and they are uniformly successful when they are well thought out. In the petroleum section during the past year we have had such a competition, and in that competition there have been entered literally scores of operating units of the larger oil companies of the United States. At the luncheon next Wednesday the results of that competition are to be announced. The real results of that competition will never be known except to the men out on the line—the safety men who have used it as a stimulus for accident prevention; and those men may never approximate the full benefit of it. It is there, nevertheless, because it has been the means in more cases than we can know, of making men willing to receive instruction, and that primarily is the purpose of such a competition. In the business session I hope somebody will bring forth a resolution suggesting that such competitions be made part of our regular work, that at least for six months during every year we compete, one with another, in a friendly way to see which of us can set up the best record in accident prevention.

I said that I was going to outline some suggestions that have been made to me for your consideration as a better means of carrying on the work of this section during next year.

We have been dividing the country heretofore into three very large sections. The entire petroleum industry in its producing, marketing and other aspects, divides itself rather naturally into six instead of three such geographical sections. It has been suggested, therefore, that because of the growth of our membership, which has more than doubled in the last five years, that we take cognizance of the natural divisions of this country and divide ourselves into six groups which we will call, if the scheme carries, the Atlantic, the Great Lakes, the Mid-Continent, the Gulf, the Rocky Mountain, and the Pacific Divisions. The particular advantage of such a realignment is that during the twelve months which elapse between these annual national meetings, more work can be done in smaller groups. The mileage is cut down, contacts made, and acquaintances are more easily maintained.

Another point, really a technical one, is that the petroleum representative be made the secretary of the organization. The National Safety Council headquarters in Chicago has the facilities for doing that work, which a secretary normally does in this sort of organization. Mr. Blakeslee, in his position as petroleum representative, being in Chicago from time to time in his travels throughout the country, can very well direct that work and in that way do officially what he has done more or less unofficially for the past year.

Another suggestion has been made, if the country is divided, as has been suggested, into six groups, each of these groups, through its chairman, be responsible once in six months for issuing to the rest of us and to themselves a *News Letter*, and in that way the burden will be lightened for each of them, yet so spread as to give representation and interest throughout the country.

It has also been suggested that following the same line of thought, each of these six groups be made responsible for providing the publication office of the National Safety Council with four posters each year. Posters are perhaps the hardest form of propaganda to develop in such form that it may be used nationwide. We all use posters; perhaps we all make them in rough form for our own local use within each refinery, or departments; but it shouldn't be difficult

within each of these six major divisions to select from such posters those that have a general appeal, and to send at least four of them to headquarters each year.

In the same way it has been suggested also that each of these six groups be responsible for providing at least one article for publication in trade journals during the course of the year; and that the position which was formerly known as chairman of the Publicity Committee, be eliminated, and in its stead that we appoint one man as publicity editor to co-ordinate the work of providing articles for release and to edit the stories as they are written. This will provide a channel for and supervision over the publicity work of the section.

If this reorganization scheme is agreeable to you, it will mean that our Executive Committee will be enlarged, obviously, by three additional division chairmen. It has therefore been suggested that the executive committeemen who have heretofore been elected at large be eliminated, and that the Executive Committee be composed merely of the officers of the section, the chairmen of the committees, and the past General Chairmen.

We have spoken of the work of our field representative. We all know him and of the work he has done. He has visited, I suppose, every member of the group, in his own bailiwick, and what he has learned of "Follies and Progress in the Petroleum Industry" should be of interest to us. Mr. Blakeslee, will you please tell us what you have seen, and if you call a spade a spade, I don't think anybody will worry about it.

Follies and Progress

By H. N. BLAKESLEE

Petroleum Representative, National Safety Council, Chicago

The National Safety Council is well pleased with the enthusiastic support that has been given the Petroleum Section by its members during the past year. The Council realizes that the circulation of the Petroleum Section Safe Practices Pamphlets has been so great and so satisfactory only because these pamphlets represent the work of the petroleum industry and the value of the pamphlets is known before their publication, hence the orders for the pamphlets follow.

In considering the follies in the usual sense we anticipate a lot before the show and get mighty little to take away with us after the show, but the Petroleum industry has never before been more interested in its follies or more intent upon the lessons learned than it has been in the past year.

Explosions in the manufacturing division have been an outstanding cause of fatal accidents. The failure of high pressure equipment has taken a toll of lives, but the most depressing accident of the year can be charged to the failure of a low pressure still. Information that was given to the press on this accident indicates that a still sprung a leak under extremely low pressure. It was pumped out, steamed out, and the man-heads were removed. A nearby still sprung a leak and caught fire. Evidently gas accumulated in the still with the open man-heads and was ignited. A tongue of flame flashed out of the end man-head burning 67 men that had responded to the fire call.

There may have been a small quantity of liquid left in the still after it was pumped out. The first lesson learned here is one of construction. Erect stills and attach pump-out lines so that all fluid will gravitate toward the pump-out line.

Our second lesson is that steaming a still out for a given length of time does not signify that it is gas free. Stills that have been steamed out should be tested by a reliable vapor indicator to determine if gas in a combustible quantity is present. The human nose is not a reliable vapor indicator.

The third lesson is that only the workmen necessary to combat a fire should be permitted in a fire zone in a refinery. Absolutely limit the number of men required on a fire hose and use no more. Keep others out of the area of possible explosions.

It seems that the failure of most high pressure equipment has come after a shut-down and water in the charging fluid has settled to the bottom of the chamber. Later on when operations have been resumed, this water becomes suddenly heated, flashes to steam and something must let go. If tests fail to show that such an accumulation of water does not exist the still should be pumped out, cleaned and recharged before starting up. It appears that most of the men losing their lives were not engaged in the operation of the stills that failed but were doing other work. Most of the fatalities were due to burns from the burning oil that was showered on workers in the vicinity. Consequently, it seems that work that could be done elsewhere should not be done in the immediate vicinity of a high pressure still in operation. If stills must be erected in a congested area, protect other workers with fire-walls.

The deaths of four tank car loaders have come to my attention. Two men were burned in an explosion and fire in a supposedly gas free tank car in which they were taking a smoke. First it is unreasonable to suppose that an empty tank car is gas-free. It should be treated as not gas-free unless determined gas-free by a vapor test. Second, workers should leave their matches and smokes outside the refinery limits and then a temptation to have a smoke can do no harm.

The death of one car loader has been attributed to the provision of inadequate walk-ways at the loading rack. Another report indicates that a car loader fell from the top of a tank car. These two cases raise the question of a platform alongside the dome on tank cars and walkways from loading racks to tank cars. American Railway Association specifications call for a platform and ladder on one side of the car dome only. Specifications do not require this platform to be a certain number of feet above the rails or a certain number of feet from the mid-line of the tank car. If these two measurements were made standard and a platform were provided on each side of the car dome, refiners would have no trouble in equipping their loading racks with practical, substantial, well protected walkways.

If you agree with me, I hope you will have your engineering department determine what these two measurements, distance of platform above the rails and distance of the outer edge of the platform from the midline of the tank car should be, and I will make an effort through the proper channels to get the car builders to adopt these measurements as standard. There are many unsafe walkway arrangements used at loading racks today that should be corrected, but the problem of building a walkway that will fit all tank cars has not been entirely solved.

A cable pulled out of a leaded joint and dropped a set of triple condensers, killing a mechanic. It may be proper to suggest that if you have not recently checked up on the method of fastening wire lines in sockets, you should do so. This applies to the producing operations as well as in manufacturing operations. The American Petroleum Institute has recently prepared a poster giving definite instructions on the proper procedure in socketing wire lines. Zinc is recommended in preference to babbitt or any other metal for socketing as it makes the strongest fastening. The National Safety Council Safe Practices, Pamphlet No. 26, Manila and Wire Rope, also gives definite instructions on this subject.

Marketing division reports tell of a truck salesman driving off a highway to his death, a salesman being killed by an automobile after stepping off a street car, and a service station salesman being killed by an automobile in crossing the street from the service station to get a package of cigarets. These fatalities are not peculiar to the petroleum industry and can only be prevented by constant alertness on the part of the workers and proper consideration of safety of others by the public.

However, one accident has occurred which should cause us to do real deep

thinking about the service station storage tanks and lines. Four men, excavating for a sewer were killed by an explosion of gasoline vapors in the excavation they were making. Evidence at the Coroner's inquest brought out the information that a nearby service station had suffered a large shortage in gallonage and shortly before the date of the explosion a leak in the pump line had been found and repaired. The gasoline percolating through sand had presumably formed an explosive mixture in the tunnel. Only pipe-fitters, skilled in the high class construction required on gasoline tank and pump equipment installation, should be employed for this work, making it possible to take every precaution to prevent leaks. Without a doubt many conscientious service station salesmen have been held accountable for shortages that were caused by leaks. Frequent tests for tank and line leaks should be made to prevent shortages and to prevent percolating gasoline from reaching a nearby well, basement or excavation where it may create a hazard.

Marketing organizations that are giving this situation consideration among their resale accounts are doing much to insure the permanency of these accounts and much in the protection of the consumers of petroleum products.

A guard improperly installed may become a hazard. A driller in the producing department misjudged the distance and rammed the traveling block into the crown block. Two cap screws that held a shield to prevent the traveling block from hooking on to the finger board were sheared, and the shield fell on the head of the driller standing in his position at the rotary draw works. The driller may have been guilty of crowding on too much steam but I understand the manufacturers of this device originally provided four cap screws to hold it to the block, but due to the time required in making changes on the traveling block the number of cap screws had been reduced to two. The company experiencing this accident has since provided a cable between the shield and the traveling block and is also studying ways of making it impossible for the traveling block to strike the crown.

We are told that much has been done in correcting vision of truck drivers to prevent accidents but the work of the driller demands even closer focal accuracy than that of the truck driver. Is the vision of the driller not worthy of more definite consideration than it has had?

Hydrogen sulphide gas still continues to take a number of lives. Dr. Lederer has told us of its hazards and its scientific control. The enormous production of the West Texas field is making it necessary for more and more refineries to handle sour crude as well as exposing more production men to the deadly gases. The realization of the danger of hydrogen sulphide gas is more widely known and greater precautions are being taken to keep it confined. Workers that are exposed are required to wear proper mask protection, medical men better understand the human defects that make workers more susceptible to the gas and have made progress in methods of treatments that is reducing time lost from this source.

Two lives were recently lost when a derrick caught fire, presumably from a spark from a hatchet that was being used by the deceased on the crown block of the derrick. One man jumped to his death and the other tried to climb down the derrick and was burned to death. The day was warm and still. The well was known to be making a large quantity of gas. Under those conditions, the first mistake was made in using tools that could create a spark. The derrick was provided with a crow's nest but no emergency exit. Had a cable exit been provided from the crown of this derrick, these men probably would have escaped unharmed.

Reports have been received telling of two fatalities from pipe rolling off a truck and trailer and killing men. In the first case a chain holding a bolster came unfastened letting the bolster tip and the pipe rolled off on the truck driver. More care in chaining the bolster down or a chock placed under the opposite end of the bolster probably would have saved this life. In the next case a trailer had been partly unloaded and the trailer was being moved. Two stakes had been put in place in the side of the trailer bed but binding chains had not been used. As

the trailer moved the load shifted with sufficient force to snap the stakes and a double of drill pipe rolled off on a workman. The precaution of putting binding chains in place or chocking this pipe so it could not move before starting to move the trailer would have saved this life.

A number of fires and explosions have occurred in the operation of natural gas gasoline plants and the presence of flame or a spark has caused them all. In handling this invisible high power explosive the utmost precautions should be taken:

- a. Care should be taken to keep all gas compressor packing glands adjusted to prevent leaks.
- b. Magneto wires should be securely fastened so they cannot jar loose and cause an ignition leak and create a spark.
- c. Magneto terminals should never be removed to stop an engine or while the engine is running. A spark of sufficient strength to ignite combustible vapors may result between the terminal and the spark plug or between the terminal and the base of the engine.
- d. The preceding instruction holds true in attaching magneto terminals to a gas engine in motion.
- e. Keep a constant check for gas leaks on all gates or valves, cylinder-gaskets, and line fittings.
- f. Where it is necessary to place boilers at all near gas compressors a fire wall should be built to divert away from the boiler fires any gas that might escape from the compressors.
- g. Use only vapor-proof electric lighting equipment such as vapor-proof globe covers, wiring in conduit, etc.
- h. Install all switches and fuse boxes, even though vapor-proof outside the compressor room.
- i. Provide ventilation that will remove the gases that may accumulate and especially the heavy gas from near the floor.

The problems of preventing fire and explosions in natural gasoline plants may be summarized as:

- 1—Preventing gas leaks.
- 2—Keeping sparks or flame out of the possible gassy area.
- 3—Proper ventilation to dissipate gas that may escape and otherwise form a combustible mixture.

A laborer was burned to death on a pipe line repair job when a lighted lantern ignited the gas accumulated in the excavation where the repairs were being made. This emphasizes the necessity of the use of vapor-proof flash lights only, on pipe line repair jobs. A roustabout attempted to thaw out a flow line at a tank with a blow torch. He killed himself and one other man. Two fatalities in producing operations have been reported as caused when petroleum vapors were ignited by sparks from non-vapor proof electric switches. These cases of ignited vapors can be prevented by safe practices in keeping open flames and sparks away from petroleum vapors by using only vapor-proof electric lights and switches, non-ferreous tools and also by using more care to prevent the accumulation of combustible mixtures. As such a small percentage of petroleum vapors mixed with air forms a combustible mixture it is best practice to assume that a dangerous mixture exists in the vicinity of petroleum leaks of any kind.

Among the most significant indications of progress in accident prevention is the interest of the petroleum trade publications. It is almost impossible to pick up an issue of any of them without finding an article dealing with accident prevention in the petroleum industry and the majority of these articles are written by operating executives.

Purchasing agents are specifying equipment, complete with all practical protective devices and manufacturers are making the safety of their equipment a sales feature. Most safety engineers have progressed beyond the problems of safe-

guarding and propaganda to interest the managers and workers and are now searching for the safest practices that can be used on the job and are thereby actually helping the workers protect themselves on their job. This is resulting in production being speeded up by getting work done in the proper and safe way

CHAIRMAN PRUSSING: I think you will see from Mr. Blakeslee's paper that he is in pretty close contact with what is going on around the country.

At the risk of talking too much, I'd like to mention just one serious accident, of which I have unfortunately very intimate knowledge. In the little desert town of Kingman, Arizona, hard by the main line of the Santa Fe transcontinental road, is the bulk marketing station for that district owned by our company.

The traveling mechanic whose business it was to go from station to station and to make such minor repairs as he found necessary wrote to the head office that at Kingman, Arizona, there was a valve on a gasoline tank which he had previously packed and which he again found to be leaking, and on his further examination he recommended that the valve be replaced because it was old and defective. There is nothing new in that. The technique for making that change is very well established. This tank was the central one of a group of five vertical tanks, 11 feet in diameter and approximately 30 feet high. The five tanks contained stove oil, kerosene, white gasoline, ethyl gasoline, and engine distillate, respectively. Instructions were sent to him (which as a matter of fact he did not receive) that two tank cars would be put at his disposal, that he was to empty the gasoline tank into the two cars by the usual facilities provided, that a Homestead valve or plug cock was being sent to him by express, and that he was to make this change in the usual manner. Records that I have dug up disclose that he had gone through that same routine many times in the previous five years. But on the particular morning in question, which was the day after he had written to the head office and told them of this valve, he ran out of work. In looking about the station he found a Homestead valve exactly like the one that he had sent for from Los Angeles. He therefore decided that he would save himself the burden of having to sit around under a temperature of one hundred and fifteen degrees, and he undertook to change that valve without waiting for the tank cars to arrive.

His first move was ingenious. He made a flapper of rubber and lead, attached it to the end of a forty foot piece of three-quarter inch pipe, and with the aid of a helper whom he had hired locally, he got up on the top of this tank, removed the upper manhole cover, and sought to place this flapper valve over the inside of the four-inch outlet nipple. He fished around for possibly an hour with that device trying to find the nipple, but he couldn't find it, the reason being that it wasn't there, which he did not know. This particular tank was old and the nipple did not project into the tank.

But he was a bright boy, and he had another idea, and that was to put water in the tank, raising the gasoline out of the danger zone, and providing enough leeway so that he could make that change with a wide-open outlet pipe before the gasoline got down to the outlet. He therefore took a garden hose and started running water into the tank; but unfortunately Kingman is a town where there is not very much water. The pressure was weak and he was only able to run in about two feet of water by four o'clock that afternoon. Not at all discouraged apparently, he decided to make the change with only two feet of water in the tank. He disconnected his pipe, started to rotate the valve off the nipple. But there again he ran into a mechanical difficulty. The valve was too big to pass around the full circle because the tank had been set on a concrete base. But, as I say, he was a bright boy, so he took the bonnet off the valve. That particular valve was not made in such a way that taking off the bonnet left the discs in place, and when the bonnet was removed immediately a geyser ap-

peared in front of him, a geyser that rose to a height of ten feet. There was seventeen feet of gasoline in the tank. Then he was in trouble. He called for help, having only one helper with him, and the agent in charge of the station and a truck man came to his assistance. They poked rags into this open bonnet, but the rags immediately went out through the outside opening. He then, as a last resort, attempted to spin the bonnet off and stab the Homestead cock in place. He got the bonnet off all right, but when he was going to stab the plug cock on, he found he had forgotten to open it.

It resulted in literally drenching those men to the skin in gasoline. The gasoline flowed across the yard—the stream of it was very clearly visible afterwards—went down the railroad track for several hundred feet, and finally crossed it. Way down there, hundreds of feet away from the source of all the trouble, it met the one thing that gasoline vapors seem to seek out every time—it met a lighted switch lantern. The fire actually started at that point, and raced up the stream of gasoline, and finally came to the tank.

It so happened that when the fire reached the tank, the mechanic and his three drenched helpers were separated; two were running toward the warehouse to get more rags. Two were immediately adjacent to the tank. Of course these two were at once enveloped in the flame. One ran one way and one another. The two men who had thus far escaped, saw them, and one of them ran toward his friend, who was coming out with his clothes on fire, and sought to save him. He, too, was added to the holocaust. The fourth man, seeing what had happened, ran in the other direction, tearing his clothes from his body until he was stark naked, and thereby escaped.

We didn't hear of the fire until some hours afterward, because all of our employees there were killed. I arrived on the scene before the fire was out, and was able to reconstruct the story from the one man who escaped and from the facts which we found on the ground.

Three men were burned to death. The station, of course, was largely destroyed. Two of the other four tanks failed, from internal pressure due to the surrounding lake of fire. The Santa Fe Railroad had been put out of business on its trans-continental line for some twelve hours. The town had been endangered. People had flocked from every part of the city, and when the tanks failed there was an immediate rush in every direction, due to the explosions, and people were hurt in the stampede. About everything that could possibly happen in a fire happened; and all because of the fact that a man had attempted something that he knew perfectly well was wrong.

I suppose that is an extreme example of what safety men have to provide against—absolute, almost insane, mental failure on the part of an employee who does know better. And yet when we look back over what has been accomplished, I don't think that we need be discouraged.

This is the last time that I am going to be on my feet to speak to you before I retire as chairman of the section. I want to thank you for the cooperation that you gentlemen have given me in the past year. It has been one of the greatest pleasures of my professional experience to have been chairman of this group. It has been exceedingly difficult to handle from the extreme other edge of this continent the work that the chairman of such a section must handle. Naturally everything had to be done by correspondence. But in spite of that difficulty there have been compensations which have been very real. It is a very great privilege to meet personally and by correspondence and through cooperative effort men who are doing the same sort of thing that you yourself are interested in. It has been a privilege and it has been very much of an inspiration, and for that, gentlemen, I thank you.

ADJOURNMENT

October 3, 1928

GEORGE F. PRUSSING, Chairman

Secretary, Safety Board, Union Oil Company of California
Los Angeles, Calif.

The second session was called to order at nine-thirty o'clock by the chairman, George F. Prussing.

CHAIRMAN PRUSSING: I want to repeat very briefly the scheme of reorganization I announced yesterday, so that there may be discussion of it from the floor. The first point was to divide the country into six instead of three districts. Those six districts would cover the entire country. The Atlantic Division would include Maine, Vermont, New Hampshire, Connecticut, Massachusetts, Rhode Island, New York, Pennsylvania, New Jersey, Maryland, West Virginia, Virginia, Kentucky, Tennessee, Georgia, North Carolina, South Carolina, Florida, Alabama, and Mississippi.

The Lakes Division would include Ohio, Indiana, Michigan, Wisconsin, Iowa, Illinois, Minnesota, North Dakota, South Dakota, and Nebraska.

The Mid-Continent Division would include Kansas, Missouri, Oklahoma, and Arkansas.

The Gulf Division would take the three states of New Mexico, Texas, and Louisiana.

The Rocky Mountain Division would include Montana, Wyoming, Utah, and Colorado.

The Pacific Division would include Idaho, Washington, Oregon, Nevada, California, and Arizona.

Now, that grouping is subject to your discussion and suggestion.

The next suggestion was to make our petroleum representative the secretary of the section.

The next one, to make the divisional chairmen each responsible for two issues of the *News Letter*, one each six months; also for four or more posters; also for at least one article for release through the *National Safety News* or the trade papers under the guidance of a publicity editor who would take the place, under this scheme, of the chairman of the Publicity Committee; and to have no members of the Executive Committee at large, but to include only the officers, chairmen of committees and the ex-general chairmen, thus solving the problem of what to do with ex-general chairmen.

Have you any discussion of this scheme? It has been worked out by a relatively few on your Executive Committee, but all have been apprised of it. There has been practically no objection on the part of your Executive Committee. The only questions that have been raised have been as to the allocation of these states, which is merely a matter of detail, but should be so worked out as to satisfy everybody. If there is no discussion or objection to this plan, I'd like to hear a motion for its adoption.

E. J. SENNE (Vacuum Oil Company, New York City): I move that this section adopt the new organization program as described; and I also move that the plan be submitted in full in the next *News Letter*, so that all members will have a general idea in writing of just what the change is.

(The motion was seconded and carried.)

CHAIRMAN PRUSSING: Mr. Myers, chairman of our Statistical Committee, has been very active in helping us get our form of report that we make to the National Safety Council and on which our contest has been largely based, into such shape as to be workable in our industry. I want at this time to ask Mr. Myers briefly to give us an outline of the work that the Statistical Committee has done in the past year.

Report of Statistical Committee

By J. W. MYERS

Standard Oil Company of New Jersey, New York City

There are two or three things that I thought would be of interest to the section as a whole, some of which constitute things we did not do.

On that latter, the first point was a request from the Committee on American Standards for Accident Statistics, which is attempting a thorough overhauling of the statistical methods now in use. I was asked to represent—I wasn't clear what—but apparently the National Safety Council, and attended one meeting. It was clear from the beginning that they were undertaking a very important and arduous task. I didn't feel that my knowledge of the accident problem in the petroleum business equipped me to speak for the other divisions, and in view of that and the amount of work involved, I finally decided to resign from the committee; so I do not know just what the progress of that job is, but it certainly is clear that they are undertaking quite a job. I had a word yesterday with Mr. Stewart, from Washington, and he said that they were making progress, but I didn't get a chance to go into details. At the first meeting the main dispute was on the schedule of time losses for permanent disability, particularly the six thousand day rule for fatalities. That seems to rub a good many people the wrong way, and I don't know what the outcome of it is.

Another point which was worrying them is the fact that the improvement in medical treatment, particularly where hospitals are available and fully equipped medical departments in large corporations, is enabling them to cut down the disability; and they think that that fact will require some alteration on the schedules.

The second point that I thought would interest the section is the proposed revision of Safe Practice Pamphlet No. 21. This pamphlet has been in effect for some years, and covers the entire National Safety Council methods. Some months ago a proposed draft of the revision was sent to us for comment and suggestions, and we went over that very carefully. I don't know what the status of it is, but there are two or three important things in there that I believe will affect the figures. In the first place it doesn't seem to us that they have satisfactorily defined the average number of employees. That figure under the proposed pamphlet is used in connection with the working schedule to arrive at hours of exposure, where you don't draw that figure directly from the pay roll. Of course, if you start out with the wrong definition of average number of employees, you can carry that error into the final figure on which your frequency and severity are found.

Second, the definition of a lost time accident. For years we have been working on the definition that it was a case which caused either death, permanent disability, or lost time beyond the date of injury. The last part of that definition is important, particularly when you get into the safety contests and the rate gets low, because it involves the line of demarcation between a no-lost time case and a lost time case. They are proposing to modify that definition so as to count only as lost time any disability which causes lost time beyond twelve o'clock noon of the following day. My own experience indicates that there is still a considerable lack of uniformity on the interpretation of that definition of a lost time accident, but undoubtedly as far as our industry is concerned, we have made considerable progress in clarifying that definition. I question the wisdom of changing that, when we are just getting well informed on the definition which has been used so many years. However, whether you want to take any official action on this, I leave to you to decide. I haven't seen anything in this program which indicates that the Chicago headquarters proposes to put this new

pamphlet to the sections generally for decision. Perhaps the thing isn't important; but you all know from practical experience that the question of the date of injury and the next day and what the effect is when they lose time, medical treatment, and all that, must make quite a difference in the handling of one day cases. And I would think that any substantial change in that definition will affect the comparability of our figures and just cause confusion at a time when we are sort of just getting out of the woods. They are also proposing some changes in the schedule of time losses.

The other point that I thought would be worth while mentioning would be the statistics covering the safety contest. I don't know what the plans are, but I would like to suggest that the figures be made public in the transactions of the petroleum section—not by name of company, but in the same manner as our accident statistics are published in the annual report, by code number; and I would suggest that the same data be given to all of us, the hours of exposure, the number of employees, the number of lost time accidents, divided in various classifications, and the frequency and severity rate. That will give us several things. First, it will tell us how many participated in this contest. Secondly, it will tell us the size and character of the companies who participated, thereby giving us some clue as to the significance of the rates which they were able to obtain. Naturally in a small outfit the rate isn't of as much value in comparing it with your own as if it were a large company.

CHAIRMAN PRUSSING: Thank you, Mr. Myers. I think that we might entertain from the floor at this time a motion to put into the *News Letter* for the section that form of report on our contest figures which Mr. Myers has suggested.

MR. SENNE: I make that motion.

(The motion was seconded and carried.)

MR. SENNE: Following up a thought of Mr. Myers' with reference to the matter of possible change in the plan of statistics, I believe that this section has gone into that matter quite thoroughly. Mr. Myers has spent a great deal of time for the benefit of this section. The plan was thoroughly understood, was accepted by the section at a previous congress; and I move that for the present we make no change in our method of statistical data. I move that we remain as is rather than reconsider the question.

R. S. BONSB (Standard Oil Company of New Jersey, New York City): I second that, because statistics are very confusing to the average man anyhow; and the more you change the methods, the more confusing it becomes.

MR. MYERS: Before the question is called I would like to say this: I don't want to leave any impression now that I am trying to lead the petroleum section away from Chicago. I want to make this point clear, that if the petroleum section decides to adhere to our regular rule, and the Safety Council as a whole makes that change regarding the next day, they will send their literature out generally, and you will find a great deal of confusion. Therefore, I thought possibly a better course would be to make some effort to have them urge the National Council to very carefully consider this matter before they change the rule, so that we could in the end follow them and follow all the other sections. I think it would be unfortunate if the petroleum section rule were different than the national rule, and that our first efforts should be, therefore, to urge the Council not to change the national rule, because they send out safety pamphlet 21 and they don't defer to decisions of individual sections. If one of our members sent to Chicago for the rules today, they would send out 21, and you would have greater confusion than if you followed any new ruling of the Council. It is unfortunate that the thing has gotten under way, but I would urge you to play ball with the National Council and try to keep the thing uniform.

C. L. SWIM (Skelly Oil Company, Tulsa, Oklahoma): I am inclined to agree.

with Mr. Myers, but I am wondering if there isn't another step that we might take to advantage. There are rumors around from time to time that we don't all count lost time accidents the same under the present rule. It seems to me there might be a clarifying of that proposition. I am not prepared at the moment to say in what way, but I am inclined to say it is worth our thought. For instance, it might be a fair definition of lost time accident, that when a man in addition to being unable to start the next shift or next day, as under the present rule, is unable to come back to the job at which he was working. In other words, if there is a shifting of a man to a job that is easily made, that he can do, and still draw a full day's pay, but isn't a job he was doing when he was hurt—it seems to me sometimes that maybe we are kidding ourselves. That is the last thing we ought to do. I just want to leave that with you. I am inclined to think, Mr. Chairman, that it would be well and proper for us to appoint a committee of one or more to work with the National Safety Council, and I think we should stay with them and possibly work along the line that I have suggested, of clarifying possibly as to what for statistic purposes shall be counted on a lost time accident.

CHAIRMAN PRUSSING: Mr. Myers has been very close to the National Safety Council Statistical Division, Mr. Swim, and I think that we can very well leave it to Mr. Myers to continue to keep that contact and as chairman of the Statistical Committee to work that out.

There is a motion before us. Is there any further discussion?

MR. MYERS: I wonder if I could propose an amendment to that resolution. That the Petroleum Section go on record as urging adherence to the present rule.

MR. SENNE: I withdraw my former motion and yield to Mr. Myers' new proposal.

(Amended motion was seconded and carried.)

CHAIRMAN PRUSSING: We come now to the matter of asking our Committee on Resolutions and Nominations for a report as to whether they have at this time to offer any resolutions. Mr. Senne is chairman of our committee.

Report of the Resolutions Committee

MR. SENNE: I offer the following resolution:

The Petroleum Section of the National Safety Council, in Congress assembled, reaffirms the policies which have guided it during the past years of service.

The progress of safety and accident prevention work, its highest purpose and aim, can only be maintained through coordinated effort combined with constant and systematic cooperation.

The petroleum industry as a whole has precedence in the council of this Section, which always has in mind its common interest.

The approval by the most important branches of the industry of the activities of the Petroleum Section and the universal recognition of its service, are significant of its value and permanency.

The many friends within the industry, especially those in active membership of the Petroleum Section, who have freely and unselfishly contributed in spirit and in accomplishment toward the success of safety work have earned an expression of thanks and an assurance of confidence which now is due; and

WHEREAS the broadening of the safety movement and its beneficial influence could not have succeeded, nor would the future of the Petroleum Section have so promising an outlook today, without the material aid and moral support which the American Petroleum Institute, through its generosity, has bestowed;

From a standpoint of constructive thought and of human endeavor, the welfare of the industry has been extended and enhanced; and

WHEREAS the Petroleum Section recognizes the necessity and importance of these requisites,

BE IT RESOLVED that its thanks for meritorious work by individuals be and are hereby expressed and recorded, and that a vote of thanks be extended to the American Petroleum Institute for its valued help; and further

BE IT RESOLVED that this memorial be adopted by this Congress and made

That the secretary be requested to forward a copy of same to the president of a part of its official minutes; and furthermore the American Petroleum Institute.

MR. BONSB: I move the adoption of the resolutions.

(The motion was seconded and carried.)

CHAIRMAN PRUSSING: I think it might be proper also to mention at least a few of the other organizations in the country who have given this section their fullest cooperation. The Bureau of Mines has stood with us shoulder to shoulder in our endeavors ever since this section was organized, and in fact they were doing safety work long before this section got under way. I think our thanks and our appreciation are due them. In the Mid-Continent field, the Mid-Continent Oil & Gas Association has been the leader in carrying forward constructive safety work. Their membership and ours overlaps to a large extent in that district, and I think that that organization should also have an expression of thanks and appreciation. And out on our own Pacific Coast, the Chamber of Mines and Oil, the local organization of oil men, has done everything to make it possible for us to function out there as a real live organization.

I would be glad to entertain a motion that at least the names of these three organizations be put into the record as deserving our special thanks at this time.

MR. BONSB: I make a motion that the names of these three organizations be put into the record as deserving our special thanks.

(The motion was seconded and carried.)

CHAIRMAN PRUSSING: I am going to call on Mr. Senne again at this time for a report of his committee on nominations for the coming year.

Report of Nominating Committee

E. J. SENNE (Vacuum Oil Company, New York City): As chairman of the Nominating Committee, I have the honor to submit the following names in nomination for offices of this section:

Chairman of the Atlantic Division: L. W. Evans, Atlantic Refining Company.

Chairman of the Lakes Division: J. P. Sutton, the Ohio Oil Company.

Chairman of the Mid-Continent Division: E. D. Murphey, Mid-Continent Petroleum Corporation.

Chairman of the Gulf Division: C. L. Hightower, Texas Pacific Coal & Oil Company.

Chairman of the Rocky Mountain Division: L. F. Howbert, Continental Oil Company.

Chairman of the Pacific Division: R. E. Donovan, Standard Oil Company of California.

General Chairman: C. W. Smith, Standard Oil Company of Indiana.

Vice-Chairman: R. S. Bonsib, Standard Oil Company of New Jersey.

Publicity Editor: T. N. Shaw, Midwest Refining Company.

Chairman of the Program Committee: S. W. Candee, Tide Water Oil Company.

Chairman of the Engineering Committee: J. C. Bernd, Sinclair Refining Company.

Chairman of the Statistics Committee: J. W. Myers, Standard Oil Company (New Jersey).

CHAIRMAN PRUSSING: You have heard the report of your Nominating Committee. Are there any further nominations from the floor? If not, it is in order to make a motion to close the nominations, and if you want to include in that a motion to ask the secretary to cast the unanimous ballot of this section, I think that can be done.

V. R. CURRIE (The Texas Company, Houston, Texas): Mr. Chairman, I move that the nominations be closed, and that the secretary be requested to cast the unanimous ballot of the Petroleum Section for the nominees.

(The motion was seconded and carried.)

CHAIRMAN PRUSSING: Mr. Smith would normally at this time take the chair and the present incumbent would retire; but for reasons which are obvious, inasmuch as Mr. Smith is on our program this morning, I am going to take the liberty of continuing to serve you at least until luncheon.

We are fortunate in being able in this organization to call on men who know safety from the standpoint of operation. With all due respect to the professional safety man, in an organization of this sort I think the less that we hear from each other, the more time we have to learn from some people who are in the organization from the operating end. I'd like at this time to introduce to you Dr. E. R. Lederer, Vice-President of the Texas Pacific Coal & Oil Company, who will speak on "Corrosion Hazards in Refineries."

Corrosion Hazards in Refineries

By E. R. LEDERER

Texas Pacific Coal and Oil Company, Fort Worth, Texas

Before I go into my paper I feel that it isn't out of place, inasmuch as I am called to appear before you as a member of the refinery operating division of the petroleum industry, to say a few words of appreciation of the work the safety engineer has done for us. I remember the time, ten or fifteen years ago, when the word "safety" was more or less ridiculed among the refiners and also in the production division. Executives, especially the ones in the financial end, who were not in the safety end, were inclined to look upon safety work as more or less of a nuisance, and the men employed at that time to do this work were mostly inexperienced men, who tried their best, but they were nothing else than clerks who figured the accidents and made accident reports.

When I consider what the safety engineer is today, I can only congratulate you upon your work. It was an uphill fight. You knew in your heart that you did the right thing, the good thing, that you did the necessary thing for the petroleum industry, and just the same you had to fight for recognition. You know as well as I do that today you have this recognition, and you have the full appreciation and cooperation of every executive in the oil industry. I believe the smaller companies feel today, more than the big ones, what good you have done to the industry, not only in dollars and cents, but from a humanitarian point of view, and from the point of view of efficiency and loyalty which you create among the employees in their relations to their employers. We all are employed to give service to our companies; and that this service today is safe and given in a joyful manner, the industry certainly owes a great deal to your good work.

In presenting this paper to you I do not make any claim for new discoveries or original ideas. I have to confine myself to a summary of the corrosion problem as it confronts the refinery executive today. It has become a major problem with the rapid expansion of the refining industry and the consequent development of new oil fields, to take care of the continually growing demand for raw material, i.e., crude oil.

In very few cases the refiner of today is in a fortunate enough position, so he can select his crude. Most refineries with an appreciably large capacity have to draw on several sources of supply, of varying quality and characteristics. Some of the large new pools developed during the last few years, especially in Texas and Arkansas (like Mexia, Luling, Smackover, Panhandle, and the latest West Texas fields) produce oils which have aggravated the corrosion problem inasmuch as the distribution of the corrosive agents in the products manufactured from these crudes has been quite different from the previously known and refined sulphur crudes, like the old Lima, Mexican, and Californian oils. This evil confronts the production man, pipeline executive and, in a much more diversified and extreme degree, the refinery manager.

Corrosion in refineries is a combination of all the possible corrosion problems, aggravated and intensified by special problems, due to individual operating conditions. We knew in years gone by that certain chemicals and compounds had corrosive action on metals which we had to use in our refinery equipment; with a normal amount of vigilance, maintenance and repair, and counteraction by the use of some chemicals, we were able to operate our refineries (as old fashioned as they might seem to us today) at a fair efficiency and safety from unexpected break-downs. When Lima, and later on Kansas and Illinois, crude first offered a sulphur problem, it was rather easily overcome by the Herman Frasch copper oxide method. Today this method would not be effective on all crudes, besides being uneconomical, due to the enormous amounts we would have to use on the thousands of barrels of sulphur crudes charged to stills every day.

Today our situation is much more complicated and difficult because the necessary use of certain chemicals (like sulphuric acids and strong alkalines) for the elimination of sulphur and its compounds, is apt to introduce additional corrosive agents into our operation. With the depletion of some of the older pools, the crude produced shows an increased percentage of "salt-water," containing calcium and magnesium chlorides, which are hydrolyzed and form hydrochloric acid, often concentrated to a considerable degree during the process of distillation; this represents another menace which attacks refining equipment on another front and necessitates continuous prophylactic measures.

Commercial perfection of several cracking processes, and their increasing use in order to produce sufficient motor fuel for the rapidly growing demand, added additional hazards to refinery operation through corrosion. Sulphur compounds show increased corrosive action at high pressures and temperatures and desulphurization of stocks, which is quite helpful in the distillation process at atmospheric pressure, is insufficient at the high pressures and temperatures applied in cracking; in spite of such pretreatment sulphur is formed in various stages and corrodes different parts of the cracking equipment, presenting a perpetual hazard and source of expense. Revivification and new applications of vacuum distillation of corrosive stocks will, I am sure, present new corrosion problems to us. Recently developed contact filtration of acid treated stocks, in the presence of fine clay and steam, intensifies corrosion by erosion or abrasion; material which might be sufficiently corrosion-resisting, cannot withstand the ever-wearing action of this combined attack. It seems, therefore, that every new effort toward increased efficiency of operations, larger yield, new and improved products of better quality, is

confronted with new handicaps of a chemical and mechanical nature, which demand just as much attention and study as the development work itself—and all this mostly due to corrosion.

Economists have stated that corrosion destroys annually from one hundred and fifty million to two hundred million dollars worth of refinery equipment in the United States, equivalent to about 15 cents per barrel of crude produced; we know from experience that in spite of all the highly developed equipment manufactured from corrosion-resisting alloys, it costs from 20 to 30 cents a barrel more to refine "corrosive" crudes, due to increased repair and replacement costs and higher depreciation of the equipment. This is the economic side of the problem. Very serious is the human phase of all these hazards, involving health and life of our employees. Before we were fully aware of the danger lurking in the poisonous and destructive vapors evaporating from such crudes in storage or produced during distillation, we had to experience serious damage to the health of a good many of our employees and lament even the death of a number of them in the fulfillment of their duties. Naturally, these human and economic phases quickly made us realize the importance of this problem and to strain and combine every possible effort to combat it and solve it. And today we find a great deal of talent, energy and time of executives, chemists, engineers, and metallurgists, of all the industries concerned and connected with the oil industry, cooperating to overcome corrosion and its hazards.

A great deal of research work has been done and vast sums expended by these industries to overcome these difficulties. Corrosion problems have formed in recent years an important part of the programs of the meetings of all the associations, and scientific societies connected with these industries. Very valuable contributions to our literature have been made along these lines by the scientific staff of these companies. The Government has contributed some very interesting data in a number of circulars and pamphlets; all these publications, including articles in our current trade magazines, really form a text book on corrosion, which ought to be studied and kept up to date by every refiner. In order to better appreciate the hazards of corrosion, it seems advisable to analyze briefly the character and causes of this evil, which gnaws on our equipment and our constitution, day and night, year in and year out.

Corrosion has been explained as the inclination of metals to return to the original ore, forming soft, soluble compounds. This softening or dissolving status is also known as "corrosion fatigue." We distinguish:

Atmospheric Corrosion, due to the presence of carbonic acid, hydrogen sulphide, sulphur dioxide, and hydrochloric acid in the air. The moisture in the atmosphere containing these corrosive chemicals—often in large quantities—attacks exposed metals and weakens them often to a point beyond safety; deteriorates woodwork and electric insulation, causing short-circuits, burned-out motors and even explosions. Selective painting and coating of metals with corrosion-resisting paints, treating of woodwork with creosote, regular testing and careful examination of electric wiring, conduits, and motors will reduce the hazards from this type of corrosion.

Corrosion by Water: As you know, water is needed in refinery operation to produce steam and for cooling purposes. Water containing a high percentage of organic or inorganic acids or their salts, or an excessive amount of alkali or solids, will produce poor steam; and such steam will have corrosive action on valves and lines, will cause valves and steamlines to leak or even to give way very unexpectedly. It will pit and weaken fluesheets and firebox sheets by electrolytic action, with consequent damage to operation and hazard for life. A good many boiler explosions have been traced to such corroded sheets and many a man has been painfully scalded due to corroded valves or steamlines. Engines are often

put out of commission due to corrosive action of water on water jackets. Condenser coils or cooling coils submerged under water, tubular condensers or dephlegmators, through which water passes, show accelerated deterioration due to corrosion on the inner and outer walls. In cases where saltwater is used as cooling water, corrosion is increased by electrolytic action; the difference of temperature inside and outside the pipe or tubes plays an important factor in the speed of destruction.

Frequent and careful chemical analysis of refinery water, proper treatment of water, wherever possible *before* it is used for boiler feed water or cooling purposes, selection of the right metal for coils and tubes, are recommended. It is cheaper and safer to invest the necessary capital for a good efficient water treating or evaporating plant, than to fight continually destruction of material by replacement at a high cost for lost time in operation.

Soil Corrosion: A great portion of refinery piping is under ground; it is subjected to corrosion by acids or alkalis of the soil proper or contained therein by seepage. The soil might contain strata of alkali or salts, which dissolve in the moisture of the ground, especially after heavy rains; it might contain ashes from fills; seepage of saltwater, caustic, or acid washwater, or weak sulphuric acid from an acid sludge pit in a distant corner of the refinery site, will contaminate the soil until underground pipe, concrete foundations, or tankbottoms resting on such soil, gradually corrode and give away.

Analysis of the soil for acids or alkali will determine the grade of protection piping should receive. Protective coating and wrapping of varying thickness, in extreme conduits, are recommended. Special care must be applied by the operators not to dump acid or alkali on the ground, but catch it in specially provided catch-basins, or in case of a leak in acid lines, the contaminated soil should be replaced by fresh, clean dirt; if any metal is attacked through such seepage, it should be cleaned promptly and recoated or repainted. Dumping of acid sludges within a short distance from any metal equipment should be avoided. These sludges are a recognized nuisance and source of danger. They can be converted into useful fuel or should be removed to a safe distance.

Corrosion Due to Chemicals: This is the type of corrosion the refiner is mostly concerned with. It is mostly caused by the sulphur contents of crude oil and subsequent formation of hydrogen sulphide and sulphurous acids, due to the presence of water in the oil and condensation of water during refinery operation, which absorbs sulphur and forms sulphuric acids of varying strength. Sulphur is also introduced into refining operations (as previously mentioned) during the treating process of either topped crude, or distillates of gasoline, naphtha, kerosene, and lubricating oils, or heavy cylinder stocks with sulphuric acids to remove sulphur, asphaltic compounds and other decolorizing impurities. The percentage of sulphur determined by analysis of crude oils, cannot be considered as a criterion of its corrosive action; it is rather the chemical composition of the organic sulphur compounds and the distribution of sulphur in the different cuts obtained during the process of distillation, temperature and pressure conditions of the distillation, which seems to influence this type of corrosive destruction.

The storage problem of sulphur crudes in refinery tanks is really identical with tank farm storage; the turnover is generally much quicker in a refinery than on a tank farm. This, however, does not prevent sufficient corrosive action on refinery tanks, which has to be considered seriously. Right here we have to mention again the destructive action of "salt water" mixed with the incoming crude, containing calcium and magnesium chlorides, which are hydrolyzed to hydrochloric acid. Steel roofs exposed to the combined action of sulphur vapors and acidulated moisture in the vapor space above the oil level, deteriorate rapidly. Iron-sulphide scale is formed, the roof becomes pitted, full of pinholes or even large holes and is ready to collapse. The iron-sulphide scale drops to the bottom of the tank where the

saltwater is settled out and, being of different chemical composition than the steel of the tank bottoms or the first ring, we have two different metals in an acidulated solution, which promptly starts galvanic action and decomposes the metal of bottoms and shell. An added hazard is the spontaneous oxidation of the rust scale on the inside of the roof, where often, also, free sulphur is accumulated, which creates enough heat to glow and cause an explosion of the oil vapors in this space. Quite a number of such deteriorated and dangerous steel roofs have been replaced by wooden roofs covered with Johns-Manville patented insulation; however, the wood deteriorates rapidly when exposed to hydrogen-sulphide gas and must be well protected by heavy coatings of paint and should be grounded carefully. The bottoms and the first ring of such storage tanks should be protected with asphalt or cement, special non-conductive paints with sufficient elasticity so as not to crack and insoluble in oil and water. I believe the time will come soon when bottoms, first rings, and possibly roofs, will be protected and saved by electro-plating or gunspraying of protective coatings.

During the distillation process heat is applied in an increasing degree; dissolved hydrogen-sulphide will distill over first, then the saltwater will be concentrated, magnesium and calcium chloride decomposed, hydrochloric acid gas formed and distilled over; sulphur compounds will be broken up and new ones formed at different temperatures; they can be found in every fraction of the oil and in a large percentage in the residue left in the still or separator. Corrosive action by these newly formed acids on the equipment is very effective. Shell stills are more subjected to it than pipe stills, where the velocity of the oil through the tubes is generally too high to permit much corrosion, except in return bends, where the natural friction of the flow weakens the metal and corrosion accelerates deterioration. In shell stills special attention must be given to rivets in the vapor space, which are subjected to more rapid corrosion than the submerged parts. Treatment of crude with ammonia, injection of anhydrous ammonia in the vapor phase, neutralization of crude or cracking stocks with lime or soda, separation of saltwater and salt under pressure in specially constructed vessels; heavier walls on tubes of pipe stills and on the pipe for vapor lines, cast steel return bends, are some of the protective measures taken to retard corrosion. For condenser coils, heavy cast iron or special alloy pipe is used; tubular condensers, heat-exchangers and coolers are constructed from special alloys; very often excess ammonia vapors entering such condensers with the oil vapors will attack these alloys and such action has to be offset by circulating plenty of clean water to dilute the ammonia sufficiently.

In cracking operation the hazards of corrosion are greatly augmented by high temperatures and pressures. There is very little action by hydrochloric acid, as cracking stocks must be dried carefully; even a small amount of water will cause a serious explosion due to the extreme force of suddenly formed steam in a closed pressure system. In this case the refinery superintendent has to be his own safety engineer, or his equipment and operators are in imminent danger of annihilation. Weakening of the equipment of sulphur corrosion, however, is a continual source of danger. Corrosive action is different in the liquid and in the vapor zone, increasing the hazard. The slightest crack in a valvebody, return bend, tube, vapor line or expansion chamber, not caught in time, can cause terrible destruction and loss of life.

The most rigid material inspection of the entire equipment at certain intervals, regulated by the age of the installation, by experienced and trained inspectors, is advisable. Careful examination of the most exposed parts during each shut-down and extreme vigilance of operators during runs, directed and checked by foreman, plant engineer and superintendent, are necessary. Records should be kept of the life and condition after each run, of each tube, return bend, plugs, certain parts of the vapor lines, valves, fittings, hot oil pumps, pyrometer wells, etc. Replace-

ment of these parts at regular intervals which, based on experience, will assure a sufficient safety factor, is advisable.

Special care and attention must be given to installations, where large vessels are used for expansion chambers—riveted, welded or both methods combined. We have records that the walls of these vessels have corroded as much as one-sixteenth of an inch per month; these chambers are heavily insulated and inside inspection alone will not disclose corrosion beyond the danger point. A piece of test-steel of the same thickness and grade the vessel is constructed of, suspended in the vessel and carefully weighed and inspected under the magnifying glass after each run, will be a fair indication of the progress of corrosion on the vessel itself. Coating, lining, and electro-plating of the vessels are not very satisfactory; so far, it is not practical to build them out of corrosion-resisting material containing special alloys.

During distillation and treating operations, and much more so during cracking operations of sulphur crudes, considerable volumes of hydrogen-sulphide vapors escape, which are extremely poisonous, quickly cause unconsciousness and death because of the paralytic action on nerve centers, controlling respiration and heart action. The United States Health Department has found that as low as 100 to 150 parts per million affect people; 1,000 to 2,400 parts are fatal. Presence in a hydrogen-sulphide atmosphere deadens the sense of smell, reduces the ability to sense danger and so increases the hazard for the employee. These gases also affect the eyesight and handicap clear view for observation necessary to perform his precise duties.

To minimize these hazards, it is advisable to use closed gas-tight look-boxes, if possible in the open and not in a building, remote valve control on all lines, collect all vapors and gases in a tight recovery system, scrub them through alkali solutions or in purification plants. There are low places in refineries, like pump and manifold pits, inside of tank dikes or firewalls, where these heavy gases collect; they escape from leaky pumps, valves or pipe connections which must be repaired. It is very hazardous to approach these places and work on such equipment unless properly protected and guarded. The same danger exists when cleaning stills, tanks, or tank cars, which contained such crudes or untreated intermediate products. It is advisable to wash out and steam for a considerable time, test the atmosphere first before men are allowed to enter, use perfect electric safety lamps and keep equipment well ventilated during cleaning operation.

Sulphur corrosion is also encountered in treating plants, acid and acid recovery plants, and acid sludge fuel systems. As stated before, sulphuric acid is in general use for treating of light oils and lubricating oils for the removal of sulphur, asphalt, and to obtain better colors. Light oils, like gasoline, kerosene, absorption oils, and light viscous neutrals, can be treated with much less acid per barrel than heavy lubricating oils. Corrosion by strong acid, that is concentrated acid of 66 degrees Baume, or 93 per cent acid contents, is not a serious problem. By using the right material for lines, tanks, pumps, or blow cases, this grade is practically harmless. The danger of corrosion comes from weaker or diluted acids, as are formed in the separation of the heavy sludges, cooking with water and before concentration. Cast iron lines, pans, and concentrators corrode gradually, become soft and break, if the castings are not made from carefully prepared raw material and free of sand-holes and defects. They become soft and brittle and give away without hardly any notice. Special acid resisting alloys are on the market for the different stages of concentration; lead-lining and lead-lines are in general use in such plants, but special care has to be paid to the temperature of the acid in such containers and lines, and the lead has to be analyzed for impurities which might make it unsuitable for the purpose.

It is most important to keep a treating plant and acid plant free from leaks, even small acid leaks, when permitted to continue, have been known to be the cause of serious accidents and damage to life and property. In blow-case pits or

manifold pits, where such acid accumulates and becomes diluted with the water in the soil or by rain, immediate corrosion sets in, destroys concrete work and metal, seeps into the ground and corrodes lines even at great distances from the original leak. Men working in such pits or on such lines become acid burned, tank bottoms suddenly give away. Acid vapors from concentrating towers dissolved in steam are harmful to men and animals, deteriorate insulation on wires and electric equipment, cause short circuits and fires. Careful inspection and testing of such equipment by plant and safety engineer, strenuous efforts to maintain the equipment in absolute tight shape, combined with cleanliness, will reduce the hazards in such plants.

Alkali corrosion is noticeable when acid sludges are neutralized with alkali and used as plant fuel. It causes fire brick and cement foundations to crumble and to deteriorate rapidly; boilers and stills settle and sag and form a serious hazard. Special brick containing alumina or chromium should be used in such settings. A far better way is not to neutralize the sludge, but separate the weak acid as far as possible and burn the sludge mixed with fuel oil, using lines, fittings, and pumps made of brass or other acid-resisting metals.

We should not overlook corrosion in the refrigerating plant. Sodium chloride or calcium chloride brine of various concentrations pit lines and valves from the inside and outside, causing failure. Frequently such leaks or breaks cause the brine to become saturated with ammonia, and the latter, escaping as gas, often causes serious accidents. If the brine is not kept clean and slightly alkaline it will attack metal and form rust which will corrode bolts, coils, pipe, and other parts of the equipment.

The men responsible for refinery operation are aware of the serious hazards of corrosion; chemistry and metallurgy give us the causes for this destructive action and combine their efforts to combat and overcome it. So far, this has been only partly accomplished in a commercial, practical way. Visualizing clearly the danger for life and equipment, until we are sure of victory over this enemy, we welcome and appreciate every possible advice and assistance the safety engineer can give us.

CHAIRMAN PRUSSING: Thank you, Dr. Lederer. I don't need to tell you, gentlemen, that you have an opportunity here to ask questions of a man that undoubtedly can answer them.

H. E. DISCHINGER (Roxanna Petroleum Corporation, Wood River, Ill.): May I ask you, Dr. Lederer, what, if any, paint you have adopted for storage and tanks where hydrogen sulphide oil is stored?

DR. LEDERER: We have experimented a lot with Rub-shell No. 2 and No. 5. We use both. I wouldn't say that we have come to a conclusive result yet. We have used it even in tanks, cone bottoms, where we get out acid sludges, and it has actually lengthened the life, using No. 2, about thirty per cent. We have also used the paint on lines which go through fills or soil which is either filled by dredging or has been used previously, and we have had very good results.

We have found, however, that ordinary coal tar paint has not given us very satisfactory service, but I attribute this mostly to the fact that the pipe was not cleaned properly. Just brushing a pipe with a steel brush is not sufficient. A company whose products are in use in Texas, which advertises in the trade journals, the W. K. M. Company, has put on the market now a machine which cleans the pipe inside and outside so thoroughly that you can take a magnifying glass and not find dirt. We have made tests with this cleaned pipe, and have found that when this pipe is covered either with Rub-shell or some of the other paints, the life has been extended. You understand I am not advertising this paint. I am just speaking from our experience, and I am satisfied that there are other products on the market which are probably just as good.

MR. DISCHINGER: Have you found during your investigation that the use of

No. 2 Rub-shell contributes to the fire hazard as oxidation takes place, if the atmosphere is permitted to attack or if the paint is scratched in any way?

DR. LEDERER: Personally I don't think we have had any experience like that. I am glad you mention it.

DR. LEDERER: It is a problem to get a paint to protect the iron oxide from attacking, and also get a paint which is fire resisting.

COMMANDER ELLSBERG (Chief Engineer, Tide Water Oil Company, New York City): Dr. Lederer, would you consider a tank with a floating roof as being a safer proposition and one likely to last longer than an ordinary tank for West Texas crude?

DR. LEDERER: We have experimented on this and haven't found any advantage in the floating roof on gasoline or crude.

COMMANDER ELLSBERG: It rusts out just as fast?

DR. LEDERER: Absolutely.

COMMANDER ELLSBERG: How about the reduction in explosion hazard?

Explosion is Caused by an Explosive Mixture

DR. LEDERER: Well, you have a certain reduction in explosion hazard, because an explosion in a tank is caused when you form an explosive mixture. You have to have a certain amount of flammable vapors and a certain amount of oxygen, and then for some reason, galvanic action or static electricity will cause an explosion. Of course, by keeping your floating roof down to the level of the liquid or as nearly as possible to the level, you have not the dangerous vapor space, which the dome or cone-shaped roofs have, and you avoid the danger of forming vapors and having an explosion. But as far as corrosion is concerned, you have still the corrosive action.

COMMANDER ELLSBERG: How about the gas seal around the edge of the roof, between the floating roof and the side of the tank, as the roof goes up and down? Does that last well enough to allow a decent seal?

DR. LEDERER: Yes, if you have a good turnover in your tanks and don't expect to store your gasoline or your crude over a year, you have a very good service with that. But if you expect to store gasoline or kerosene or gas oil or fuel oil or especially crude oil—crude oil is the worst, naturally—for any length of time, you will find corrosive action on the shell at the upper level of the liquid. Of course the galvanic action and the possibility of forming rust, if the bottom of the steel roof is submerged in liquid, is very slight, much slighter than in another shaped roof; but there is corrosive action. I know of floating roofs which have been removed because they were corroded. But if the roof rusts out, you can replace that. If you have a fire or explosion, it may cost you a great deal more.

COMMANDER ELLSBERG: Would you say it is possible on a running tank for gas oil or gasoline of this West Texas crude, to use with reasonable certainty a gas recovery system so as to prevent any air from getting in the tank at all, and preventing spontaneous combustion? Are the diaphragm valves that you would need for that sufficiently reliable on such a case, or will they clog up very quickly?

DR. LEDERER: They are not very reliable. They have to be carefully watched and replaced very often. We all know that there is not such a thing as an absolute gas tight tank. The tank breathes. It is bound to expand and contract with the different temperatures. That is the reason why the Standard Oil Company of Indiana resorted to the very wonderful idea of using big gas bags. They

take the same gas in and out. There is no fresh air coming in, and in the fresh air there is the danger.

COMMANDER ELLSBERG: What type of tank would you recommend, from your experience, as being the safest—not the one that will last the longest, but which while it lasts will give you the least explosive and fire danger?

DR. LEDERER: I wouldn't use anything else but steel roof covered with say Johns-Manville cover.

COMMANDER ELLSBERG: You wouldn't use a floating roof there?

DR. LEDERER: You can use it, but I know that most tank roofs will deteriorate, and it has been found by actual experience that floating roofs don't last much longer than the ordinary gas tight steel roof. You know you have to replace, so naturally you use the cheapest and not the most expensive. And even on the steel roof I wouldn't take the heavy standard specification steel roof. I would take the lightest steel which will stand the weight, and then cover it first with practically gas tight asbestos roof, and watch them very carefully from the inside. We tried to paint gasoline tanks inside, but without very satisfactory results. The paint scaled, why, I don't know. Probably we were not careful enough in the beginning to get clean sheets; the shop coat wasn't done right. However, we tried spraying chromium and nickel metals just for tests. (It is very expensive, by the way.) But just for tests on certain surfaces, and we found out it has a very wonderful effect and really protected, and it is not soluble in gasoline.

COMMANDER ELLSBERG: One company at least is putting steam in some of its run-down tanks for gas oil and a cut between gasoline and gas oil, to try to keep them from blowing up due to spontaneous combustion. Would you recommend that?

DR. LEDERER: No. Keep away from moisture. The dryer you keep your stuff, the better you are off, absolutely.

J. McCOLLUM (Standard Oil Company of New Jersey, Bayway Refinery): I was interested in the question asked by Commander Ellsberg about floating roofs. We have had considerable experience with floating roofs with very bad results, originally because the stocks very rapidly corroded the springs and the secondary sealing material. We therefore worked with the manufacturers of the roofs, and they developed an outside spring, of which we have two at the present time, and which we are so far getting good results from. They have been on only six or eight months, but to date they look good. We are also experimenting with a floating roof brought much closer to the shell of the tank, within three or four inches, and using granulated cork to make the seal, coating the cork either with shellac or Rub-shell paint referred to. We think that holds considerable promise.

We have been so much concerned with the explosion hazard that we have about come to the conclusion that our greatest possibilities of reducing that lie in the direction of floating roofs. As far as metal spraying is concerned, that, as Dr. Lederer said, seems to be prohibited because expensive. We found the cost runs close to a dollar a square foot. Another thing that I think has had some effect was using a copper content in our steel. We found an affinity of copper for the sulphur, accelerating rather than retarding corrosion, and we get better results from the straight steel. So far as the Rub-shell paint goes, we have been using considerable of it and getting very good results from the No. 5 for the roof coatings and No. 1 for bodies.

In the direction of reducing corrosion on pipe lines, although we haven't used it long enough as yet to make a definite recommendation one way or the other, we think that the sand-spun centrifugal cast iron pipe, which several manufacturers are manufacturing at the present time, made of a beautiful homogeneous metal, hardly any thicker than ordinary steel line pipe, and at a cost per foot no greater, holds considerable possibilities for reducing corrosion there. For

ordinary line work throughout the refinery, for condenser coils, we haven't used it as yet.

CHAIRMAN PRUSSING: Is that a pressure pipe?

MR. MCCOLLUM: Yes, they make it in one hundred and fifty and two hundred and fifty pound class and up.

As to the corrosion mentioned about soaking drums, for example, we have gotten remarkably good results from simply lining them with cement, sprayed on with a cement gun. Also, I found that in lead lining vessels, if one per cent antimony is used, it seems to reduce the wear and maintenance on them very much indeed.

Ventilating receiving houses was also mentioned. I might mention that our method consists of running an inlet pipe up sufficiently high to insure getting clean atmosphere, and using wing blowers and maintaining a slight pressure on the house, with the outlet near the floor of the house.

F. L. NEWCOMB (Standard Oil Development Co., Elizabeth, New Jersey): I listened with a great deal of interest to Dr. Lederer's paper, since I have been intimately connected with corrosion work since November, 1920, when I was in charge of inspection of cracking equipment. It has been my big job to read everything I can find on corrosion. I feel Dr. Lederer's paper very adequately covers the subject, and in the entire paper I found but one thing with which I would like to take a little exception. He stated that hanging a plate in your apparatus would be a good indication of the corrosion which you were getting on that particular part of the apparatus. I don't agree with him. It is a well known fact that any metal under stress will corrode much more rapidly than a piece of metal that is not under stress. It is impossible from hanging a plate in a vessel to put the same stress on that plate that you have in the walls of the drum. We tried that stunt and found we had been considerably fooled. Some of our vessels got in a very dangerous condition before the plate showed sufficient corrosion to indicate that the vessel was in bad shape. I would just like to issue a warning not to rely too much upon that plate. I would advise you to drill holes into your vessel and then plug them up, so that you would know exactly where the walls stand.

WILLIAM JONES (Standard Oil Company of New Jersey, Bayway Refinery): Has it been your experience, Dr. Lederer, that the iron sulphide on the roof gets built up so strongly that it breaks down and falls to the bottom of the tank?

DR. LEDERER: Yes, we have found that. In connection with this, it brought us to investigate a very funny incident in one of our gasoline tanks. We had some old fashioned absorbers there, that were built out of twelve-inch diameter shells, and we had used one of these absorbers as a scrubber for sour gas. One day we decided to discard this scrubber absorber. We disconnected the pipe and threw the things down, and when we let it down on the ground opened the top manhole plate, a big flame shot out—and a big flame in a gasoline plant is a pretty dangerous proposition. We finally got the fire out. But we couldn't understand how an absorber pipe of twelve inch diameter, which had never been exposed to water or anything could burn. Finally we cleaned it out, and we found that not only all the shavings inside, but also part of the wall, had been converted into iron oxide and iron sulphide, and when these were exposed to air, there was enough oxygen there to burn. That led us to investigate some of the tank groups on tank farms where we had quite a bit of Texas sour crude. We found on the bottom, pieces of iron oxide which did not come from the bottom, because the bottom did not show large enough pitting to show a big piece of scale, while the roof did show it.

MR. JONES: (Showing Dr. Lederer a piece of metal.) I took that piece off

of the roof last night. I had to break that off with a hammer. It didn't fall in. This is a sixty day accumulation.

DR. LEDERER: But if you leave the same tank for six or eight months, the thing will gradually fall down. There is another thing. I believe that through the deterioration of the steel under it, the close contact of the steel linings from pittings is destroyed, and the steel is not as homogeneous as it was before.

MR. JONES: The gauge blowers on the tank didn't get this.

DR. LEDERER: There is a certain vibration in the roof, which might break this loose and cause it to fall to the bottom.

MR. JONES: Do you consider that hydrogen sulphide itself is poisonous?

DR. LEDERER: If dry it is more poisonous than corrosive, but if absorbed by moisture, it forms weak acid and becomes corrosive. Dry hydrogen sulphide gas is only poisonous and not corrosive.

MR. JONES: Wouldn't its affinity for oxygen in the atmosphere tend to accelerate corrosion?

DR. LEDERER: No. If you oxidize it while it is in the dry state, you will probably form sulphur dioxide. But if it is moist and then the oxygen comes to it, then naturally the corrosion is accelerated.

R. H. MENKIE (Tide Water Oil Company, New York City): Dr. Lederer, in getting a maximum effectiveness against corrosion by the use of Rub-shell paint on flat surfaces, did you find it necessary to sand blast the surface before applying paint?

DR. LEDERER: We found that the cleaner and smoother the surface, the closer the contact of the paint and the steel or the iron or whatever, will be. As I said before, when we cleaned with steel brushes alone, we didn't get good results, but after we cleaned it by machine, we got excellent results, and the cleanness and smoothness of the surface had apparently some effect.

MR. MENKIE: You would consider sand blasting advisable?

DR. LEDERER: In every case. When we take a tank down and built it up again, we don't use any more steel brushes. We sand blast it. It is cleaner, quicker, and we know we make a good job.

CHAIRMAN PRUSSING: I want to thank you again, Dr. Lederer, for your kindness in addressing us and for the answers that you have given to all these questions.

I would like at this time to introduce to you your next General Chairman, Mr. C. W. Smith, Director of Safety and Assistant Manager of Industrial Relations of the Standard Oil Company of Indiana, who will speak on the work of the Engineering Committee.

The Engineering Committee and Its Work in the Petroleum Industry

By C. W. SMITH

Safety Director of Standard Oil Co., (Indiana), Chicago

When asked to address you on this subject, I guaranteed that a report of this committee's activities would be given at this Seventeenth Annual Safety Congress. I realized that it could not be a subject merely discussed by one man, but must be a report of the committee as a whole. So I will state at the very beginning that I am voicing the sentiments of the committee and I (quite accidentally having been chosen as its chairman) am merely acting as its mouthpiece.

You all realize that in the line of our regular duties in our separate companies, we have too small an amount of time to do justice to a committee of this kind but such work has been made possible the past year by the generous action of a

large percentage of the members. However, in spite of the generous action in the giving of time on the part of the section and committee members, I fear that little would have been accomplished if it had not been for the untiring efforts of our representative, H. N. Blakeslee. Much credit is due him for his help.

As the time drew near for me to review the activities of this committee, I found it more and more difficult to describe them. This was brought about by the fact that the work of the Engineering Committee during the past year has been mainly the work of gathering together the material for the publishing of four Safe Practices Pamphlets, and this work was not so much the work of the committee as it was the work of the Petroleum Industry itself. I do not know that I can describe another work which has so effectively used the resources of the entire organization.

Open Doors When Filling Tank Inside Car

The committee, before each pamphlet was published, searched carefully and industriously for the experiences of the entire industry on the subject. How well these resources have been utilized is perhaps best emphasized by the fact that up to the present time only one criticism has been made on these Safe Practices Pamphlets after publication and that one not of a serious nature. We doubt if other publications have a better record.

We have found that there is one great value in the mere preparation of the safe practice pamphlet. We have received many letters from safety engineers who worked up the material for these pamphlets and many more who helped criticize this material before publication. Nearly all these letters testify to the effect that these men have received a liberal education on the subject itself through their endeavors to submit material. Many also state that they have been enlightened on existing unsafe conditions of which they were previously unaware. I could write a letter like that myself. But the real and greater value of the safe practice pamphlet, we believe to be the fact that, it is possible through this medium to place in the

Request the Customer to Stop His Motor

Salesman "Alert—Eyes" on the Fill Spout

hands of the man on the job, direct educational material;—educational material which is specific, applicable, and which he can readily understand. It has been the aim of this Committee to have these pamphlets full of material of just that kind.

We believe, of course, that a large percentage of the Petroleum Section safety engineers have broad knowledge on these subjects. But few of us have it readily at hand, summed up in concrete form, and handled in such a simplified way as to be suitable to hand to the man on the job.

This Overflow Usually Happens

One safety engineer has expressed himself in the following manner: "I am interested in everything that is written about my job and believe that most normal men are. By tying the story of the job up with the way to avoid injuries, we are offering those actually engaged in operation, information that will be of interest to them. If the information is of interest to them, it will be useful." He goes on further to state that he has purposely attempted to get criticism on this particular pamphlet (No. 1) and has failed to find a single workman who would criticize the idea but every workman interviewed—showed considerable interest in the subject matter.

In the case of another pamphlet (No. 2), a safety engineer informs me that he distributed personally a copy to each of his service station men. Two weeks later he went back over part of his route and in most cases the service station salesman

began his conversation by words of praise for the interesting and valuable information he had received in reading the pamphlet.

These illustrations have been so numerous that the Committee is considerably encouraged in believing that the methods used in combining the story of the job with the ways to avoid accidents in a practical and simple way have hit the mark.

Few of our oil workers have a college education and many have even less than a high school education. By making our Safe Practice Pamphlets of an elementary

Getting Ready for a Pinch or a Tumble

nature and including the story of the job, we are making them of greatest value to the man that we most desire to reach—the man on the job.

In summing up the advantages of this material, one would, therefore, include the following:

1. Its value to the Safety Engineer who is not familiar with the particular operation. Few of our safety engineers have had the advantage of working on the many jobs in the petroleum industry and lack information for the details of the job.
2. It is a source of information for the new foreman who is learning his job as foreman. It provides him with specific information regarding situations to avoid and how to avoid them.

3. It provides the superintendent with information whereby he can give his foremen specific instructions regarding accident prevention on the specific job.

4. Reading the pamphlet will more definitely clarify the mind of the experienced worker as to the things to do to prevent accidents.

5. It will furnish the new man with information regarding self protection and the protection of his fellow workers that in the past has sometimes been gained only through costly experience.

This Man Knows How

6. The information should be of interest and of value to clerical help in conducting cause classification of accidents and statistical work.

Due to the fact that the committee feels that its efforts have to-date been a success, though the amount of material has been limited, it is looking forward to another year which it believes will be much more productive of valuable work.

It is the hope of the committee to have its membership increased and thereby get more shoulders to the wheel. It is their idea to cover every subject of major interest to safety engineers in the oil industry. Our pamphlets this year cover one subject in each division of the industry. It has also been suggested that the Committee could well spend some of its time on suggestions for the much needed solution of our standardization problem. It is highly probable that this phase of

Exhaust Fumes Cause Headaches

Mighty Little Exposed to a Blow-out

Protect Your Hands and Face from Steam and Hot Water

he work will be considered. It has also been suggested that if the Committee is enlarged, it can in various ways be of great help to the Committee which is publishing our news letter. It can possibly be of worth while service by contributing to the monthly news letter, the solution of certain engineering problems that have come before them, and the reporting of unusual operating hazards and how they are overcome.

The committee has done one thing which has not yet been presented for your criticism. It is their idea that this vast amount of valuable material which has

See that Shift Is in Neutral or Motor Stopped

been collected from all companies within the industry can become more valuable if also presented in picture form. When the idea was first presented to me, I confess I had many misgivings. I thought it to be an endless task which might result in a mass of material which would rarely be used. I was persuaded, however, that my first thought on the matter was wrong. We have since had the pleasure of helping to produce in picture form the story of pamphlet (No. 2), "Safety in

Gasoline Vapor Is Heavier than Air

Gasoline Service Station Operation." It is my opinion now that none of these pamphlets will be complete until the story is told in pictures also.

Although it is impossible for me to take the time of this meeting to review all or even one of these pamphlets, I am going to ask for just enough of your time to present to you these 57 views that tell the story in pictures of safety in gasoline service station operation.

It is the belief of this committee that these pictures have a valuable place in the education of the workman. It is really the same story that is told in the pamphlet. We realize their use will be limited to group meetings, but such meetings are held everywhere. One safety engineer who has found us out and knows the committee is working on this scheme, is already knocking at our gates for the first film and he shall have it as soon as possible. He is having group

meetings of service station men and it is the kind of material he wants. These films will be available to the industry and held at the National Safety Council headquarters at Chicago.

In closing, we wish to say that we thank the whole petroleum industry for the wonderful help they gave us the past year. Such cooperation as we have received is bound to bring forth the best safety work possible for any industry.

These pictures, as you will understand, are really prepared to show to service station salesmen. Therefore I will not go through them in the manner I would if I were talking to service station salesmen. But perhaps with every one of these pictures you men will say, "I have had an experience like that."

Attention to Business Prevents Accidents

The safety supervisor can take these pictures and the pamphlets out to the men directly on the job and show them these things. We took this film and showed it to a group of service station supervisors. They had already received the pamphlets and supposedly had read the pamphlets, and besides that there isn't a question there about which we hadn't talked to them before. When we talked about the pictures, they sat there and made notes about various problems. I believe that was their first real knowledge of many of them, no matter how much we had talked before.

ADJOURNMENT

October 3, 1928

Luncheon Session

C. W. SMITH, Chairman

Director of Safety and Assistant Manager Industrial Relations, Standard Oil Company of Indiana, Chicago

The luncheon session was called to order at one-fifteen o'clock by the chairman, C. W. Smith, director of safety and assistant manager of industrial relations, Standard Oil Company of Indiana, Chicago, Illinois.

CHAIRMAN SMITH: Fellow members, we are met here today to do something which has never been done before in the Petroleum Section. I take great pleasure in introducing Mr. C. J. Hicks, executive assistant to the president, Standard Oil Company (New Jersey) who will present to us the trophies which have been contested for during the past year.

Presentation of Petroleum Section Safety Contest Trophies

By C. J. HICKS

**Executive Assistant to the President, Standard Oil Company (N. J.),
New York City**

I am reminded of a gathering that I attended fully thirty years ago, in New York City, where we were met to do honor to a man who had done great public service, Dr. Theodore Cuyler, whom many of you have known. He was a very short man, but he rose up and seemed six feet high, and he said, "Crowns for those who win them." I will never forget how he started that speech.

We are met here today to award trophies on behalf of the National Safety Council to those who won them. It is the sort of crowns we believe in in this country. I have some facts about this contest. It was inaugurated February first for a period of six months, and the petroleum industry was divided into seven sections, manufacturing, marketing, producing, natural gasoline, pipe line, marine, and construction. Each division entered as many units as they wished, and a unit was interpreted to mean a subsidiary company, a division, or a refinery. You get the conditions of the contest from that.

The National Safety Council has prepared these beautiful plaques or trophies. I think they are works of art. We are going to have some photographs ready later. There are seven of these trophies to award today to the divisions or units that have won them.

First we come to the manufacturing division. In this division there were twenty-eight units; and as I look over these statistics, I am reminded that this was a real contest, because there are 98 units represented in the winning of these seven trophies, and those 98 units reported a total of 2,930 lost-time accidents; so there was some real competition.

The manufacturing division trophy has been awarded to the Bayonne Works of the Vacuum Oil Company. If there is some one here representing the Vacuum Oil Company, who will receive this trophy, he may come forward, please. May I say this additional word? The frequency record at the Bayonne Works is the remarkable frequency record of 2.63, and you get the significance of that when I tell you that the average for the entire manufacturing division was more than

15.00. The Bayonne record of 2.63 compared with 15.00 is a very remarkable record; and on behalf of the Council I am very glad to award this trophy to the Bayonne Works of the Vacuum Oil Company.

MR. REED (Superintendent of Bayonne Works, Vacuum Oil Company): I feel very proud in accepting this beautiful trophy on behalf of the employees. They are the ones that are directly responsible for it. In winning this we didn't establish any new record. The 2.63 accidents per million hours represents one accident per 38,000 hours. Our best record was a period of 236 days, which represented 980,000 hours. That went seven months and twenty-one days. During the past forty-four months we have had thirty months without accidents during those particular periods. That represents 70 per cent of the time.

Another thing we feel very proud of. We have three small departments. They have 45 men, and we didn't go back any further than when we were keeping records, which is for a period of seven years; and during that time with these 45 men there hasn't been a single lost-time accident. It seems like a long time to go. In promoting safety I think everybody realizes it is a hard thing to sell. I think the principal drawback has been among the foremen and sub-foremen. The management would suggest safety devices, methods, and I think in most cases the foremen and sub-foremen would feel they would interfere with their production, and it took a long time to educate them that the management was thoroughly back of it, and were willing possibly to sacrifice a little production in order to get better safety records. I think it usually happens that when anybody stands up well in safety records, often people, who are possibly not so good, accuse you of bringing the men in on a stretcher in case you have an accident; but I want to assure you that we have not done that in this case.

MR. HICKS: I note here that the Brunswick, Pennsylvania, plant of the Atlantic Refining Company came in second, with an accident frequency record of 3.54 compared with the Bayonne Plant record of 2.63.

Now, in the marketing division, the trophy is awarded to the Associated Oil Company of California. They have a record of 10.20, covering the experience of over 1,300 employees. That is compared with a record of over 17.00 average of the entire marketing division.

S. W. CANDEE (Tide Water Oil Company, New York City): I do not belong to the Associated proper, but because of the close affiliation between Tide Water and Associated, and the fact that an Associated man could not be here from the Pacific Coast today, they have asked me to accept this trophy on behalf of the Associated Oil Company. They further wish me to state that this contest has had a decided effect on reducing the accident record in the marketing division of the Associated Oil Company, which operates, as you likely know, on the Pacific Coast. They said, although their record has not been bad for other years, the report of this contest and the contest itself has been spread through the entire organization and has had a decided effect on reducing accidents throughout the Associated Oil.

MR. HICKS: In the marketing division it has been a real contest. There were 13 units entered and until the final month there was seesawing between the Skelly Oil Company, the Freedom Oil Works Company, and the Associated of California. So it has been a very close contest.

In the producing division, the trophy is awarded to the Illinois Division of the Pure Oil Company. This isn't a record of three point something, but it is a record of no lost-time accidents during the six months of the contest. That is during a period when the average in this producing division was 40.19. That gives you the significance of what has been done in this particular case. I am very happy on behalf of the Council to award this trophy.

W. L. ARNDOR (Superintendent of Illinois Producing Division, Pure Oil Co.): We have been about eighteen months during which we have had only one slight accident. Through our foremen we go around to our men at all times and instruct

them. We have had a little experience which helped us in getting them to be careful of accidents.

MR. HICKS: You had some real competition from the Midwest Refining Company. For five months, with 800 men, they didn't have a lost-time accident; but during the last month they had six.

We will pass on to the natural gasoline division. That trophy has been won by the Dawes, West Virginia, Division of the Pure Oil Company, with a no lost-time record for sixty-five men as compared with an average record of 14.00 in that division.

G. W. HOFFMAN (Superintendent, Pure Oil Company, Dawes, West Virginia): I am very happy to accept this trophy on behalf of the company and the men of my division. Mere words will not express our happiness in winning this trophy. We consider it very much of an honor, and wish to extend our thanks to the National Safety Council and the men of the petroleum section who have conducted this contest and made it possible for us to win this prize.

MR. HICKS: In the natural gasoline division, the Council has felt that special recognition is due to the Wentz Oil Division, Ponca City, Oklahoma. They went through the period of the contest without an accident to natural gasoline employees. A certificate has been provided for them and signed by the president and national officers. We will be very glad to award this special certificate which has been prepared and signed. They have had it beautifully photographed, so that the company can use a photograph with their employees in promoting the safety work.

The pipe line division trophy we will award to the Midwest Refining Company, Midwest, Wyoming. The record of the Midwest Company is a record of no lost-time accidents to one hundred pipe line employees, and this is in the face of a record of more than 47.00 the average in that entire division. We are very glad to have the opportunity to award this.

T. N. SHAW (Midwest Refining Company, Casper, Wyoming): On behalf of the employees of our pipe line department, I am very proud to accept this trophy. This represents, however, only a third of their time with no lost-time accidents. They haven't had one in that department since May, 1927; and this splendid record was accomplished with what we believe to be the keynote of safety work, and that is holding the foreman directly responsible for the safety of his men. When we got through playing with safety and made it a business proposition, we began to accomplish results, through the foremen to the men with their educational work.

MR. HICKS: In the pipe line division, as in the case of the natural gasoline division, the Skelly Oil Company, of Tulsa, Oklahoma, has passed through this same period with no lost time, with a force of slightly less than one hundred men. Therefore, the Council has prepared this special certificate for the Skelly Oil Company.

C. L. SWIM (Skelly Oil Company, Tulsa, Oklahoma): I might mention that, like Mr. Shaw, we have run up to the time I left, ten months, without a lost-time accident, and they had a record of almost that good for the last two or three years. The same thing was done that Mr. Shaw has been talking about.

MR. HICKS: Now, there are two additional divisions, the marine division and the construction division; and the honors have been carried off in both of these divisions by the General Petroleum Corporation of California—in the marine division with an accident frequency record of 10.70 compared with an average of 19.00 for the division and a force of about 275 men; and in the case of the construction division, with an average of 15.85 as compared with an average of 59, with a force of 300 construction workers. I understand Dr. Jewett is here, and we will be very glad to award these to him on behalf of these two divisions.

DR. JEWETT (General Petroleum Corporation of California, Los Angeles, California): In behalf of the management and of the employees of the General

Petroleum Corporation, it gives me pleasure to accept these beautiful trophies. The fact that the medical director is here would indicate that the medical service plays at least a part in the safety work. The medical service is a part of our rounded out personal program, which includes employment, proper placement, proper promotion; it includes medical service for keeping a man physically fit and on the job; it includes the safety work under the safety committee and the safety inspectors, one in each department. And back of all this firmly stands the management. We have contented employees, which I think is a big factor in it. The management, working with the employees, with the proper organization, gives us the team-work which is necessary to win such trophies.

MR. HICKS: Just this word in conclusion. I have some figures here. I will not attempt to read many of them; but these 22 companies, from which these 98 units come, are practically the same as those that entered the contest a year ago, and therefore the comparative figures are rather interesting. In the marketing and construction divisions, there has been an increase, a slight per cent of increase, in the frequency record. In the other divisions there has been a decrease; but there are so many men in the marketing and the construction divisions that the average decrease for the year is only 1.31. There has been an average decrease of that much in the frequency of accidents during this period as compared with the same group a year ago.

CHAIRMAN SMITH: It is highly probable that these contests will go on another year; at least they will if you want them. And if they do continue another year, we of course hope that instead of this number of units entering, that there will be twice as many. You all must admit, while we honor these people so highly for being able to win these trophies, we mustn't let them do it again.

ADJOURNMENT

October 4, 1928

C. W. SMITH, Chairman

Director of Safety and Assistant Manager Industrial Relations, Standard Oil Company of Indiana, Chicago

The Thursday morning session of the Petroleum Section was called to order at nine-fifty o'clock by the chairman, C. W. Smith, director of safety and assistant manager of industrial relations, Standard Oil Company, Chicago, Illinois.

CHAIRMAN SMITH: Yesterday, we were very sadly disappointed not to have with us Mr. D. J. Wallace. We were all positive that we would hear from Mr. Wallace and I now wish to state that his telegram came in a bit too late yesterday to announce it during the meeting. However, I wish to take the opportunity this morning to read his message to us.

"While last minute developments make it impossible for me to attend the Congress my best wishes are with you. The Industry in the Mid-Continent area has intense and sincere interest in the activities of the Petroleum Section and wish you every success in your efforts to better the accident risks of the Industry.

D. J. WALLACE."

I am sure we all appreciate this message from Mr. Wallace whom we all know so well and who has done so many things toward the success of this Section during the past years.

Our first talk this morning was to be one by Mr. W. H. Boggess, Superintendent of Safety, Sinclair Oil & Gas Company, Tulsa, Oklahoma. We also greatly regret that Mr. Boggess will not be with us. I have Mr. Boggess' paper here and I am going to hand the paper to the Secretary to be read into the minutes.

Safety Organization in Producing Fields

By HENRY W. BOGGESS

Superintendent of Safety, Sinclair Oil and Gas Company, Tulsa, Okla.

The subject assigned to me would lead one to think that such organizations differ from those in other branches of industrial activities. I am of the belief that the kind of organization and the method of procedure necessary to keep it alive is much the same in a producing field as it is in any other industrial work.

There may be one reason why organizations in producing fields cannot function as they do in refineries or other places where work is centered at one point. Obviously, that reason is the scattered operation. However, in these modern times, when the automobile is as generally used and roads are superior to what were a few years ago, even this thread worn objection, on analysis, becomes unsound.

At the outset, let us say that all Safety Activities may be well grouped under two general headings:

1. Education of employees,
2. Safeguarding of equipment.

It should be manifest that the more important of these two is the former, education of employees. On this point, however, there are those who hold that safeguarding of equipment is of prime importance. I base my opinion that education is more important than safeguarding purely upon the experiences I have had in my own organization. I do not wish to infer that safeguarding is not important, I merely want to clearly state that I believe that education is the prime endeavor.

It has long been contended that eighty per cent of industrial accidents arise as the result of the human element. In the company I have the honor to repre-

sent, the number of accidents that may be charged to acts of commission and omission on the part of the human element rises to ninety per cent and slightly more. Education is the only known and developed instrument with which to combat the various causes that link to comprise what we term the human element.

Human nature is a queer thing. The human baby is about the only animal which, at birth, is void of knowledge or instinct. Yet it has latent within its brain untold powers of developing knowledge. Whether or not these powers are ever brought into existence depends largely upon environment and circumstance. Safety education can be both environment and circumstance. It is certain that this latent knowledge must be developed. The baby must be trained. So it is with man.

When man starts on a job he is susceptible to training but not necessarily trained. Especially as relates to Safety, employees of the petroleum industry must be trained. Safety is new in the oil business and its economies must be instilled into the hearts and minds of men before they can fully appreciate and understand its monetary and humanitarian laws.

Most people have to learn that a bargain isn't a bargain unless it is usable and needed. Most of all, a bargain isn't a bargain if it cannot be afforded. Short cuts, undue haste and many other similar acts that involve chance taking are not bargains and their inevitable costs, accidents, cannot be afforded.

There is one by-product of our industry which no chemist has ever yet found a way to use, and that is an accident.

With the incessant milling of labor turnover and the shifting of men from one type of work to another there is much need for Safety education. It is imperative, if accident prevention work is to become fully efficient, that employees be taught the value of working with a proper regard for order. Men must come to learn that chaos of thought or action is an outstanding enemy of Safety.

I believe that all Safety men will agree that safeguards and safety appliances are best used and most effective only after the men who use and operate them have been taught the fundamentals of Safety. It is recognized that no place of work can be made fool proof, and that no machine nor appliance is ever more safe than the mind of the man who operates it. Without doubt, the effectiveness of safeguarding of equipment will depend largely upon the success of educating employees. Granting then, that education of employees is of prime importance, we arrive at the problem of how we can best educate them.

It is next to impossible to individually reach each employee on the job, hence the necessity of grouping them together is apparent. Chaotic grouping of men may be somewhat effective, at least they can be lectured to, but seldom if ever can such unorganized meetings reach the active interest of men sufficient to arouse definite, purposeful action.

An old maxim: "what is everybody's business is usually nobody's business" lucidly explains why it is necessary to organize and delegate duties. Safety is everybody's business, but without proper organization, the responsibility of furthering its cause cannot be placed on each employee's shoulders. Education is indispensable to desired results in Safety, likewise proper organization is indispensable to education.

I have had the argument presented to me that there are *some* men who cannot be taught. If such men do exist who cannot be taught, it should be plain that these men have no business in the world's greatest industry. To the argument that some men are not teachable, there is but one reply: the art of education depends more upon the teacher than upon the pupil. All normal men, and certainly none of us hire other than normal men, can be taught and are receptive to learning if they are rightly approached. The teacher holds in the hollow his hand whatever method of approach he chooses to employ.

It appears clear and reasonable to me that a man can be taught more readily than he can be forced. The day of handling men like they were handled by the *old school* is past. We are living in 1928 and we are working men in 1928, most of whom are twentieth century products. They will not respond to 1890 tactics. Men can no longer be driven and that is right. A little of the milk of human kindness dispensed with the forethought of a modern leader will do much to soften the hardest of hearts and bend the most stubborn of wills. Canning and hell-raising and firing won't do it.

Any boss can fire a man. Firing is no particular indication of ability. It is the duty of the leaders of men to lead in the true sense of the word and not depend so much upon their obscene vocabularies to accomplish their tasks. Leading the strayed from the thorn strewn byways on to the rosy highways of life is eminently more worth while than kicking them into the ditch.

After all, what do we live for if not to make life less difficult for one another? Whether you think so or not, that is what the efforts and labors of each of us really amount to. This is truly the unseen and the unintentional objective of life. A thorough analysis of any man's work will bring you to this conclusion.

I have tried to put this one thought over to our field superintendents and foremen: make a man afraid of you and you will never know the secrets of his heart. An employee must be on sympathetic and friendly terms to produce his utmost and to cooperate fully on all mutual undertakings. Safety is, of course, a mutual undertaking. Furthermore, efficiency is purely and simply an off-shoot of fraternal relations. Safety thrives best where efficiency dwells supreme.

Here we have another reason for the existence of a Safety organization. First for the purpose of education and then for the purpose of building and cementing mutual understandings and friendships which are so essential to efficiency and Safety. The Safety Engineer who thinks that a meeting of employees is a place to impose his own ideas makes a great mistake. His ideas may be excellent, but field men do not like things crammed down their necks. They resent, as you would if you were in one of their places, being told the particulars of their jobs by men who are presumed to have little or no practical experience. *A field organization should be mostly a medium through which the ideas of experienced workmen can be gleaned in order that these ideas may be put into effect and passed on to others who do not know.*

If I am expected to outline to you something new in the way of Safety organizations, then I am expected to do more than will be possible for me to do. Most Safety organizations, in essentials, are alike. Almost every conceivable plan has been tried and practically all engineers are agreed upon a standard. The National Safety Council recommends that standard. I have no thought of recommending anything other, but merely to briefly tell you how Sinclair Oil and Gas Company makes this standard workable in producing fields.

Sinclair Oil and Gas Company establishes and maintains Safety organizations known as Safety chapters in each and every producing field where twenty or more men may be congregated. All departments are represented. Our first Safety Chapter was organized June 9, 1925. That Chapter, as well as all others that have been subsequently organized, are still in existence and have regularly an average attendance of over eighty per cent of all employees not on duty at each monthly meeting. It is not now, nor has it ever been our policy, to make it mandatory that any employee attend these meetings. There is no penalty imposed upon an absentee whether he miss one or twelve meetings. All Safety Chapter meetings are held at night on employee's time.

Several of these Chapters represent a large territory, and in some cases employees drive twenty-five to thirty miles on their own time in their own conveyances at their own expense. This arrangement does not seem to dampen their ardor; quite contrarily does it seem to stimulate interest in accidental prevention work.

Interest is aroused by reason of allowing employees to run their Safety organizations without interference from the management. The management's part in these organizations is merely to keep sufficient information and data before them so that no meeting can be dry and uninteresting. It is our belief that the key to a successful Safety organization lies in giving employees an active part in the running of that organization. Their subsequent interest and participation is a natural sequence.

Each Sinclair Oil and Gas Company Safety Chapter operates under a constitution chartered by the Safety Department. This constitution sets out the ideals and purposes of the organization; allows for a rotating Safety committee of three members, each one of which serves a term of three months and no one of which can serve more than three consecutive terms. A secretary-treasurer is also provided. In no case can the superintendent in charge of the operation be chairman of the Safety committee. Under the constitution, the superintendent in charge can only be an honorary member of the committee.

The constitution also provides for a regular order of business to be followed at each meeting. This order of business does not permit the discussion of labor questions. Copies of this constitution embodying this order of business will be readily forwarded anyone desiring same.

In conclusion, I want to add that Sinclair Oil and Gas Company believes in the effectiveness of its Safety organizations. After three years continuous existence, all of our Safety chapters are still functioning, not with a lesser degree of earnestness and zeal, but with increased faith in their propriety founded upon the knowledge that since the institution of these chapters, accidents have steadily and consistently declined in number. There has been no great momentary decline in our frequency curve, for which we are thankful, but, rather, our decline curve has been gradual. That decline curve has never yet shown an upward average trend but has consistently pointed downward. This, we think, indicates that our Safety policies are built on firm foundations.

When our chapters were first organized, in 1925, our frequency rate stood at 81.3 per million hours. During 1926, that frequency rate was brought down to 70.9 per million hours, and during the year 1927 it was brought down to 51.2 per million hours. For the first six months of this year, 1928, our frequency rate is 33.8. From present indications, the close of the year 1928 should find us with an average frequency of not more than 30.0. To those of you whose work is confined to refineries where hazards are mostly specific and where labor turnover can be more or less controlled, this frequency may seem high, but for a producing company working more than six million hours per year and engaging in large development projects under very trying conditions, we feel that a frequency rate of not more than 33.8 is fairly good.

Finally, may I offer you one more thought. We believe that our Safety chapters dispense with the necessity of Safety inspectors. From a monetary viewpoint in a large organization, the items of salary and expenses constitute no small amount. Through the medium of our chapters, we have tried to get our employees to appreciate that inspectors are mostly nonessential and duplications and that the job of inspecting and reporting is specifically the job of each and every employee. We have tried to place the responsibility of Safety on the shoulders of each individual on the pay roll, where, if you will admit as we believe—that Safety is primarily an educational endeavor, it most assuredly belongs.

CHAIRMAN SMITH: We have with us this morning a man representing an institution which has given this section a great deal of help, in fact they have given the petroleum industry a great deal of beneficial help for many years. The Bureau of Mines of the United States Department of Commerce is the organization of which I am speaking and we have with us Mr. H. C. Fowler of Washington,

D. C., who is representing that organization. Mr. Fowler has spent a great deal of time with the Petroleum Industry, giving us valuable aid, searching out for us and reporting the information regarding Hydrogen Sulphide gas. I do not know of anyone whom I would be more pleased to introduce than Mr. H. C. Fowler.

Safety Activities of the U. S. Bureau of Mines in the Petroleum Industry

By H. C. FOWLER

Petroleum Engineer, U. S. Bureau of Mines, Washington, D. C.

The safety activities of any organization are proportional to the experience, opportunity for service, and adequacy of that organization. This statement applies equally to the individual and to the group. Effective safety work is accomplished by carefully reviewing the past in the light of the present and by judiciously applying the findings of experience in future developments.

The prevention of accidents is approaching a stage of development where the subject can be treated as a science, not an exact science where mathematical calculation always can be applied, because safety deals with human beings whose actions and reactions are not subject to finite determination, but a science, nevertheless, based upon fundamental laws.

If safety is accepted and treated as a science, then two interrelated principles must be considered, namely, "factors of safety" and "safety factors." Factors of safety have been applied to the stresses in materials since the first artisans began to fashion their crude structures and devices. In modern industry the designing and construction engineers provide factors of safety to cover contingencies which may be brought about by stresses induced by any of the known forms of overload and by deterioration; but the "safety factor" rests largely with the men who use the equipment. The "safety factor" is the human equation which precludes accident prevention from becoming an exact science.

The Bureau of Mines in its studies of accident prevention in the petroleum industry has recognized the importance of these two interrelated principles. They in turn have a definite relationship to the safety activities of the bureau. Safeguarding, in the broader sense, is a matter of good judgment based upon experience and training and good engineering practice.

The Relation of the Bureau of Mines to the Petroleum Industry in Accident Prevention Work

At the present time there are only two engineers of the Bureau of Mines working directly on petroleum safety problems. At first glance, this number may seem to represent a very limited personnel for the study of such an important problem. However, these two men do not stand alone in their efforts to reduce accidents. Back of them is the whole organization of the Bureau of Mines with a broad experience in accident prevention work; this background includes the constructive ideas of men who are known nationally and internationally as leaders in the science of preventing accidents. It is only right that the petroleum industry should have the full benefit of the experience of an organization that was established primarily to promote safety in the mineral industries.

In many ways the Bureau of Mines holds a peculiar position in its relation to accident prevention in the petroleum industry. The bureau employs no labor

Read by permission of the Director of the U. S. Bureau of Mines before the Petroleum Section, Seventeenth Annual Safety Congress, October 4, 1928, New York City. (Not subject to copyright.)

in the same sense that an oil company employs drillers, gasoline-plant operators, stillmen, service-station attendants, and the other 43 or more groups of labor required in the petroleum industry. For this reason, the contact of bureau engineers with workmen is less direct than the contact between company representatives and employees of a company. In general, the bureau must deal with the composite group rather than with the individual.

The Bureau of Mines has no regulative jurisdiction in matters of petroleum safety. Whenever suggestions are given, they are offered on the basis of fact after careful study of the available data on any subject. The acceptance or rejection of these suggestions is entirely within the power of the recipient.

The problems of the petroleum industry are the problems of the Bureau of Mines, but because it is not a producing, transporting, manufacturing, or marketing organization, the bureau has directed its petroleum-safety activities toward the major problems confronting the industry rather than toward the problems of the individual. The impetus for detailed studies should come directly from the managements of the companies.

Early Work of the Bureau of Mines in Petroleum Safety

Safety in the petroleum industry was in its infancy at the time the Bureau of Mines started its safety work. As early as 1913 a number of publications dealing with various problems of accident prevention in the petroleum industry were made available to those who desired the information. Outstanding among the earlier publications, are the papers by Burrell and others which deal with the inflammability and explosibility of gasoline and other hydrocarbon vapors and air. (Bureau of Mines Technical Papers 115, 117, 119, 121, and 127.) The original findings of those investigators are a present-day source of valuable information.

The first active safety work in the petroleum industry on the part of the Bureau of Mines began in 1920, when first-aid training was given to refinery employees in California. In 1922, under the supervision of the Petroleum Experiment Station at Bartlesville, Oklahoma, a first-aid trainer gave instruction to refinery and oil-field employees in Kansas and Oklahoma. In June, 1923, a petroleum engineer was assigned to the San Francisco office to study safety conditions in the petroleum industry, and in December, 1923, another engineer was assigned to the Bartlesville station to work on similar problems.

At the time these two engineers began a definite study of petroleum safety problems, some of the larger companies already had established safety departments or were feeling their individual ways by using their insurance departments as a means of safety contact with the men.

Methods of Contact and Means of Disseminating Information

Upon definitely entering the field of scientific investigation of the problems of petroleum safety, the bureau found it necessary to outline a program in order that the work might progress systematically. The following tentative program for petroleum-safety work was drafted in 1923 by H. C. Miller, the first engineer of the Bureau of Mines to make a detailed study of petroleum safety. This outline has continued to be the working plan of the engineers who later have made similar studies.

"1. Visit the safety organizations and representatives of the oil companies and acquaint them with the scope of the technical safety work which the Bureau of Mines is entering.

"2. Obtain from the various companies and other available sources accident statistics for the past several years, from which can be obtained the cause, relative importance, frequency, and severity of various accidents.

"3. Familiarize ourselves with the best methods of preventing accidents, as demonstrated by the oil companies who are most advanced in this respect.

"4. Establish cordial relations with the safety organizations and representatives, superintendents, and foremen at the operations we visit, and as occasion permits disseminate suggestions for improved practices which shall be free from the objections of the practices we find.

"5. Collect photographs, blue prints, sketches, and other information suitable for use in the preparation of safety bulletins and technical papers and other safety publications of the Bureau of Mines.

"6. Coordinate and develop safety work at the request of the companies.

"7. Disseminate among the operators, foremen, and workmen (through the safety organizations of the companies that maintain these departments) * * * the arguments in favor of new or increased activities along any lines of endeavor or research that will increase safety in the petroleum industry; and of equal importance, point out potential hazards that change of methods may cause to become actual hazards unless adequate safeguards are provided."

Much of the contact work has been done by personal interview. However, where personal visits have not been feasible, correspondence has often obtained favorable results. It has been gratifying to note the increasing number of inquiries on safety problems; especially those questions coming directly from workmen—proof of a growing interest in accident prevention by the men who are exposed to the hazards.

Another method by which bureau engineers make available the information which they have gathered is by serving on the committees of various safety organizations. Informal talks at field safety meetings for foremen and workmen, and prepared lectures before petroleum-engineering students at universities are also a part of the work of these men to help reduce the number of accidents. Upon several occasions where immediate action has been necessary to meet an emergency, engineers have been sent to confer with officials of oil companies and to assist in coping with the emergency.

The permanent records of the safety studies of the Bureau of Mines are found in its publications. Exclusive of special articles printed in trade journals and other periodicals, 60 reports dealing with petroleum safety and health (including fires and explosions) have been published. These 60 publications—and several others in the course of preparation—cover many phases of the petroleum-safety problem. It would not be feasible in this paper to enumerate all of the subjects, but a complete list may be obtained from the petroleum division, Bureau of Mines, Washington, D. C.

Accident Statistics

At the beginning of its active petroleum-safety work, the Bureau of Mines quickly sensed the need for carefully analyzed and weighted statistical information on accidents. A considerable amount of effort has been directed toward investigations that will place such data in a readily comprehended form before operators, safety engineers, superintendents, and the men who are engaged in hazardous work. The first report (Miller, H. C., *Industrial Accidents in the California Oil Fields*) of petroleum accident statistics was issued in December, 1923. The figures used in this paper were based upon the accident experience, during 1921 and 1922, of 10 representative producing companies in California. Later the studies were extended to include the whole petroleum accident-experience of the States of California and Oklahoma during certain years. (Bureau of Mines Technical Papers 382 and 392.) Beginning with the calendar year, 1923, a report has been made annually of the fatalities in the California petroleum industry. It is realized that complete analyses of all accidents, if it

were feasible to make them, would establish more definite criteria of the trend of accident prevention than are established by using the fatality figures alone. However, fatality figures are an index of safety progress, and it is possible that figures for nonfatal accidents may follow similar trends. With reference to California fatalities, Shea says: (Shea, G. B., Review of the Fatalities of the California Petroleum Industry During the Calendar Year 1927.)

"A retrospective view of the fatality record for 1927 and a comparison of it with those of previous years show that California petroleum industry is gradually reducing the number of injuries causing death." Unfortunately, the accident commissions of some States have no jurisdiction over industrial-death cases, and therefore complete records of fatalities are not available for making comparative studies.

As an outgrowth of the work on the various analytical investigations, a comprehensive form was evolved for recording accident statistics. Later this form was modified to meet the requirements of regional safety organizations.

Drilling and Production

An outstanding value of the statistical analyses was to indicate in what divisions of the industry the larger percentages of accidents were occurring and what equipment was responsible for the greatest number and most severe of the accidents. After a careful study of accident records (Miller, H. C., Industrial Accidents in the California Oil Fields) (Fowler, H. C., "A review of the petroleum accident records in Oklahoma during 1923": Proc. Nat. Safety Council, 1924), it was apparent that drilling and producing operations presented the greatest hazards at the time the statistical studies were made. With these facts as a guide, field studies were started, and the following publications were issued in the order named:

Technical Paper 369, Mechanical Safeguards in Rotary Drilling.

Bulletin 272, Safeguarding Workmen at Oil Derricks.

Technical Paper 419, Safe Practices at Oil Derricks.

Technical Paper 422, Prevention of Pipe-Tool Accidents at Drilling and Producing Wells.

These four publications deal with drilling and producing practices and equipment in almost every oil-producing section of the country. They represent the combined thought and study of petroleum and safety engineers, drilling and production superintendents, manufacturers of tools and equipment, and men who handle the tools and equipment at the derricks. Many companies are following the recommendations suggested in these published reports.

Natural-Gasoline Plants

A comprehensive paper on safety at natural-gasoline plants is now in preparation. The author, G. B. Shea, presents the main safety problem of natural-gasoline manufacture concisely: "A combination of hazards exists peculiar to the handling of two highly explosive and flammable substances, namely, gas and gasoline. * * * Owing to the fact that the treatment of gas must be done under pressure and to the high flammability of gas and gasoline, a certain risk always attends the process of recovering gasoline from natural gas." One of the chief factors, then, in safety at natural-gasoline plants is the prevention of fires and explosions.

All phases of plant design, construction, and operation have been studied and discussed in detail. There is good reason to believe that when Shea's paper is released for distribution, it will be used by men of the natural-gasoline department of the industry in a manner similar to the use made of Bulletin 272

(Miller, H. C., Safeguarding Workmen at Oil Derricks) by men in the drilling and producing departments.

Compressor Stations

With the introduction of the air-gas lift and of methods of increasing the recovery of oil by forcing compressed air or gas through the oil-bearing formations, a serious hazard from explosive mixtures became apparent. Lewis, writing on the subject in 1917, said, "The presence of air in the gas should be taken into account and factors of safety adopted accordingly."

Lindsly cites an example of an explosion of 400 feet of 2-inch pressure line at a compressor station in the Elliott pool, Nowata County, Okla., in which "the line was split open and flattened out and in many places was blown into small fragments." He describes "explosion preventers" and thermostatic-control devices which were installed at the plant after the explosion.

In July, 1927, at the bimonthly meeting of safety men in the Mid-Continent area, R. Van A. Mills, then in charge of the oil recovery section of the Bureau of Mines, gave an outline of explosion hazards in repressuring old oil properties. Mills discussed several examples of explosions at air-compressor plants, explosive mixtures of air and gas, the causes of explosions in compressors and pipe lines, general safety precautions, and safety precautions observed in the Bureau of Mines high-pressure laboratory, applicable in part to field plants.

The number of explosions that have occurred, and conditions that have been found to exist that are favorable for explosions, have caused the bureau to begin a definite study of the explosion problem. Engineers found plants where the fluctuation of air-gas mixtures varied as much as 8 per cent. Near the limits of explosibility this practice is very dangerous. C. J. Wakenhut writes, "At the present time analyses are made twice a day (at some of the plants), but I doubt if this gives a sufficiently accurate control. I believe a recorder similar to the methane recorder used in mines would be a safety measure." The whole subject of safety at compressor plants will require further study and experiment before definite conclusions can be reached.

Refineries

Refineries are more easily organized for safety by the companies than are the producing fields where men frequently are scattered over wide areas. Up to the present time the Bureau of Mines has published no reports dealing specifically with refinery hazards—with the exception of papers on hydrogen sulphide. However, studies of other safety conditions at refineries have not been overlooked, and the development of safety problems peculiar to the manufacturing processes has been followed as closely as possible. It is likely that a study will be made of the design and operation of refineries from the standpoint of safety and of fire prevention.

Hydrogen Sulphide

Hydrogen sulphide is no longer an unfamiliar word to the petroleum industry. The injurious effects of this poisonous gas were first recognized by the refiners along the Atlantic and Gulf coasts upon receiving shipments of crude petroleum from Mexico. In 1925 the Bureau of Mines and the Public Health Service, under a cooperative agreement with the American Petroleum Institute, studied the causes and effects of hydrogen sulphide poisoning. Bulletin 231 (Sayers, R. R., and others, Investigations of Toxic Gases from Mexican and other High-Sulphur Petroleums and Products) is a report of this investigation.

The former experience of the bureau was very useful when "poison gas" was encountered in the Texas Panhandle and fields in the southwestern part of the

State. Engineers and chemists visited these fields at the request of the operating companies. They conferred with company officials, determined the concentration of the gas in several areas, suggested certain changes in operating methods and the use of proper breathing equipment, and in other ways worked with the operating companies to start safety campaigns to cope with this outstanding hazard.

Two reports have been published giving the findings of the more recent investigations. These are:

Report of Investigations, Serial 2776, Hydrogen Sulphide Poisoning in the Texas Panhandle, Big Lake, Tex., and McCamey, Tex., Oil Fields.

Report of Investigations, Serial 2847, Prevention of Hydrogen Sulphide Poisoning in Handling and Refining High-Sulphur Petroleums.

One of the most difficult problems of protection was to teach the men the value of precautionary measures—previous to the time that they were “gassed.” There are still some men who refuse to believe that hydrogen sulphide is an extremely poisonous gas; as a matter of fact, it is even more toxic than hydrogen cyanide (Yant, W. P., and Sayers, R. R., “Hydrogen sulphide, as a laboratory and industrial poison”), and one breath of the gas may cause death.

Reports of fatal accidents caused by hydrogen sulphide are still received. Subacute cases are too prevalent. Conditions show a need for continued work on this subject in the fields and at the refineries. The Bureau of Mines realizes that the papers on hydrogen sulphide which it has issued only point the way toward the control of this serious industrial hazard. More research work must be done. The actual prevention of the accidents rests with the companies and the men.

Spontaneous Combustion of Sulphur Compounds

Another safety problem associated with high-sulphur crudes is the formation of sulphur compounds (presumably iron sulphide) in tanks and other containers. Upon exposure to air when conditions are favorable, spontaneous combustion takes place, sometimes followed by explosion of petroleum vapors. Fundamental research is required to determine the true nature of these compounds, the conditions under which ignition takes place, and methods of preventing the formation of the substance. This study is directly related to the corrosion or equipment phase of the hydrogen sulphide problem, which is being earnestly studied by the industry at this time. Several experiments have been started by the bureau, but no conclusive results have been obtained thus far.

Fires and Explosions

Previous reference has been made to the work of Burrell and others on explosive mixtures of petroleum vapors and air. Refinery fires and safe methods of freeing tanks and other containers of dangerous vapors are related subjects that have attracted the attention of the bureau. The determination of atmospheres that are explosive is of great assistance in preventing fires and explosions. A simple portable device for detecting small quantities of petroleum vapor (Jones, G. W., and Yant, W. P., Detection of Small Quantities of Petroleum Vapor with the Burrell Methane Indicator) has been developed. Many oil companies are using this indicator for testing tanks, tank cars, and other refined spaces where dangerous quantities of petroleum vapors—either explosive or asphyxiating—are likely to be present. The studies already made of fire and explosion hazards show a need for further work on these problems.

Bowie (Bowie, C. P., Extinguishing and Preventing Oil and Gas Fires: Bull. 170) in 1918, made a study of oil-tank fires at wells. Several “wild” oil and gas fires in the Mid-Continent area have been brought under control through

the assistance of bureau engineers. Where extreme fire hazards have prevailed, conferences have been held and reports have been made directly to the companies or organizations most concerned.

A "Bibliography of Fire Hazards and Prevention," is issued semiannually in mimeographed form by the San Francisco office and is available upon request. The bibliography gives a direct reference, with a short abstract, to all current articles appearing in trade journals and other sources that deal with fire hazards in the petroleum industry. A similar bibliography of articles pertaining to "Safety in the Petroleum Industry" is published conjointly.

First Aid and First-Aid Meets

It is the duty of every person to be able to render proper assistance to his fellowman in time of injury or sudden illness. Moreover, the Bureau of Mines believes that the teaching of first aid to employees implants the fundamentals of the proper safety attitude where they do the most good.

At the beginning of the bureau's active safety campaign in the petroleum industry, a considerable amount of missionary work was required to convince some operators and many workmen of the value of first-aid training. In fact, upon more than one occasion, a minimum class of 15 men could not be organized in areas that should have furnished several times that number, and the arrangements for training had to be cancelled.

Quite in contrast are the reports of recent training. "One hundred per cent training" has become the objective of many companies. During the recent campaign in the Seminole field, which covered a period of three and one-half months, 3,000 men completed the prescribed course. This probably establishes a record for men trained in first-aid in any one petroleum district. An effort is being made to adequately reach the fields of west Texas where hydrogen sulphide is so important a factor. The Rocky Mountain district is requesting more and more training. During 1928, training has been given for the first time to petroleum-industry employees in many of the Appalachian areas. It is hoped that within a short time there will be few remaining producing districts and refining centers where bureau instructors have not given training.

The number of first-aid instructors is limited, and the areas to be covered are extensive. Therefore it is especially necessary to reach key men of the companies who will become qualified to instruct their fellow workers.

The Bureau plans to offer a course of advanced training for oil-field and refinery employees. This course will be given to qualified men in conjunction with first-aid training. Tentatively, the advanced course will cover such subjects as:

- Hydrocarbon vapors and other gases (including hydrogen sulphide).

- Methods of detecting and determining the concentrations of these gases.

- Breathing equipment (their construction, care, limitations, and places where they should be used).

- Artificial respiration (including the use of inhalers).

- Approved lamps for use in explosive mixtures.

The complete outline of this advanced course is nearly perfected and should be available within a short time.

The bureau does not feel that the main objective of first-aid training lies in turning out teams for competition in first-aid meets. Far more important is the fact that men are given a feeling of responsibility, impressed with the need of carefulness, and made better able to handle an emergency when it occurs. However, the spirit of friendly rivalry and good sportsmanship developed by these contests goes far in maintaining the necessary interest in safety. It is a matter of much pride and an incentive to greater effort to know that a petroleum team placed second in the recent International First-Aid Meet at Butte, Mont.

The need for consistent and persistent education of employees in safe ways of thinking and acting has been stressed repeatedly by the Bureau of Mines. In helping companies to start their safety programs, one of the first injunctions always is: "Get close to your men; make personal contacts and maintain them." The bureau can do this only to a limited degree, but company representatives have few barriers—provided a certain finesse is used. The employees' minds must be molded and trained to think of safety as a part of the day's work.

The aptitude of workmen is another important consideration. A man has no right to endanger his own safety or that of his fellow workers by attempting to do work for which he is not fitted.

"Employers of labor are giving more and more attention to medical examinations. When the method of selecting workmen according to physical qualifications has become general throughout the petroleum industry and when men are placed only in positions for which they are fitted physically and mentally, many avoidable injuries will cease to appear on the accident records of American oil companies. Organizations that have adopted this policy are finding marked improvement in their accident records. Labor turnover is reduced and the undesirables are gradually eliminated, thus making it possible to build up a personnel of workmen who are anxious to stay on the pay roll and are qualified to do so. In time, all of the major companies will require rigid physical examinations of prospective employees, because only in this way can they obtain first-class workmen." (Fowler, H. C., *Prevention of Pipe-Tool Accidents at Drilling and Producing Wells*; Tech. Paper 422, Bureau of Mines.)

Nowhere, perhaps, has more progress been made by applying technical skill, based upon accurate research, than in the petroleum industry. The safety work of this great industry must keep pace with the progress made in developing methods, processes, and equipment. Commendable reductions in accident frequency and severity have been brought about through the efforts of organized safety work in all branches of the industry; but new methods, processes, and equipment introduce new hazards. New workmen continually are seeking employment; and they introduce new problems. Accident prevention work is never in stable equilibrium; it must go forward. Otherwise there will be a backward movement. Consistent progress in safety depends upon the coordination of the working principles of the science of safety. Factors of safety must be applied carefully; the "safety factors" must be handled with consideration and care; technologic research must point the way to the practical application of theories, because methods of eliminating hazards and preventing accidents are not evolved out of thin air.

The Bureau of Mines is deeply interested in the problems of safety and health in the petroleum industry, and in so far as its resources will permit, it is anxious to help in their solution.

MR. SWIM (Skelly Oil Company): In certain districts, or I might say certain oil companies, there seems to be a particular hazard in oil well fires caused from, I do not know just what. These fires have not just occurred in the wells of my company but in several other companies. As near as we can make out, there seems to be a certain gas which accumulates at a well and sometimes during the removal of pipe a fire results. This has been the experience in my company and in a number of other companies and there seems to have been at least a half dozen serious fires resulting from this gas. It is the theory of our people that there must be an iron oxide gas that is stirred up when you start to do anything at these wells. Before you realize it you have a fire on your hands. You can not use water because the well is making a lot of gas. Have you any suggestions, Mr. Fowler, as to what might be done to prevent a fire in a problem of that nature?

MR. FOWLER: I am afraid I am not able to answer your question with regard to that point. I do not think I am familiar enough with that phase of the subject.

MR. SWIM: You may be familiar with the district to which I am referring, Mr. Fowler. It is out in the western part of Texas, known, I believe, as the Panhandle Field.

MR. FOWLER: Gentlemen, I believe Mr. Swim now brings up that phase of spontaneous combustion which has been a problem to many of us for many years. The problem of iron sulphide gas is new to me, I must admit, and I would not attempt to suggest any precautionary measures to be taken at this time because it is something I know nothing about. I would have to make an investigation before I could express an opinion. No doubt his theory is right. From what we have found out so far, iron sulphide in a very minute form is very likely to oxidize in the presence of air, and if conditions were right, there would be an explosion and very likely a fire would result at these wells. It seems to me that there is a very difficult problem to be studied.

MR. SWIM: The original attempt was to drill for oil and in each instance they have all struck this gas above the oil.

MR. FOWLER: Is the gas inside the casing?

MR. SWIM: I think that it is.

MR. FOWLER: Is it shut in at the casing head?

MR. SWIM: Yes.

MR. FOWLER: It is quite possible that this is like the condition described by one of the gas companies where they stated that sometimes when they were blowing some of their gas lines out they would get a black deposit and sometimes it would be blue. Spontaneous combustion from iron sulphide is not a new problem, by any means. You will find it in the mining industries. They run up against a condition not unlike that described by Mr. Swim. At the time the Panama Canal was dug, I believe they had a similar condition down there. It seems to me that what needs to be done is to go back and find out where this hazard has occurred in every industry and try to apply protective measures.

R. S. BONSB (Standard Oil Company (N. J.)): I would like to ask Mr. Fowler when the publication he spoke of on natural gases will be out and how can we secure such publications? I would also like to ask him whether it is a free publication or whether it is to be one of those dollar publications?

MR. FOWLER: I smile, gentlemen, because this matter of "dollar publications" at the Bureau of Mines has become quite a mooted question. We have tried to give at least one copy to each company without charge. However, we are very limited as to a supply and if the supply has become exhausted then the only way to obtain these publications is through the Superintendent of Documents, and then it is at a nominal cost which is usually a charge for the printing of extra copies. I think there are one or two publications that cost as much as a dollar but I believe most of them range in price from fifteen cents to forty cents.

To answer Mr. Bonsb's question with regard to securing the publication on natural gases, this publication has been reviewed once and returned to the office. As I told you a few moments ago, these papers are not written by just one man although one man's name may appear on the front cover, so of course it necessitates a great deal of time being spent to get such a paper ready. There is a question as to just when this publication will be available because the wheels of the governmental printing office grind very slowly and this being a publication with many illustrations, it will require, I would say, from two to three months, and possibly longer.

MR. SWIM: I believe, Mr. Fowler, that I have been able to think of that area I spoke of a short time ago. I think it is called the Sanford Area and believe the difficulty occurs at the time they put in their pipe or do anything else at the wells. They strike the same sort of gas.

MR. FOWLER: Had the gas been blowing through the pipe previous to that?

MR. SWIM: I think so. We had a well, for instance, that caught fire and burned

the rigging down and the state authorities made us shut in. I know we had to pay the gas crew an extra bonus and double time for working around the well because it was such a risk. I don't believe we are the only company having such experience with these fires.

MR. FOWLER: The Bureau of Mines is now making several experiments and while I am not in a position to tell you what those experiments are going to show or how nearly applicable they will be to field practice, I am sure they will give some help. I know we have had the benefit of various chemical engineers who have given us different theories to work on. We have packed some pipes with iron sulphide and have added to the iron sulphide from time to time, and we have also divided the sulphur. These pipes have been buried in acid soil, some have been buried in alkali soil and some in new soil to try and find out what has been taking place. We think we have got to find out just what is taking place before we can do any combating of the situation.

MR. MULLHAUPT (Kendall Refining Co.): I think these fires starting at the oil wells start at the tanks. I know we had one at our own plant. Now, I believe if the oxygen which is present can be eliminated at that source when operating, it might result in less of a hazard.

MR. SWIM: I appreciate the different suggestions that are being made but I can assure you gentlemen that I still do not think you have the correct slant on what I am trying to bring out. I am sure that I am correct in stating that every one on the ground is thoroughly satisfied that that gas contains something that is not usually contained in ordinary casing head gas. It is not a situation that has arisen in my own company alone but I might safely say it has occurred in at least a half dozen other companies.

CHAIRMAN SMITH: I might say, gentlemen, that Mr. Fowler gave us just a slight insight on his topic last year and I am sure we were all very interested and extremely glad to have such an interesting paper read to us this year. Mr. Fowler, we thank you.

CHAIRMAN SMITH: Going on with our program which has been arranged for this morning's session, we have with us a man who has been greatly interested in and also who has done a great deal of valuable work on Fire and Accident Prevention. The Conewango Refining Company has just completed a year's work on this particular subject and a great deal of this work has been led by Mr. James H. Herbert. At this time I take great pleasure in introducing Mr. Herbert, president of the Fire and Safety Marshals of the National Petroleum Association and also of the Conewango Refining Company at Warren, Pennsylvania, where he is assistant superintendent.

Group Activity in Fire and Accident Prevention

By JAMES H. HERBERT

**President, Fire and Safety Marshals of the National Petroleum Association,
Warren, Pa.**

About nine o'clock, on a hot July morning a little over two years ago, a small fire started in a pump house in a Pennsylvania refinery. Although the fire spread quite rapidly and made the pump house almost immediately inaccessible on account of the oil burning on the floor, it seemed to almost every by-stander that the fire could never reach to any great proportions because it was just in a pump house. When no visible attempts were made to extinguish the fire, the by-standers inquired and found that the water pumps which provided water for the fire hose could not be reached because they were in the pump house.

The sirens of the town Fire Department were soon announcing the arrival of fire fighting equipment. Many people were disappointed, and selfishly so, because,

liking the spectacle of a large fire, they believed that it would now be controlled and extinguished. However, the Fire Department seemed to be wasting time. A number of people failed to appreciate that there were no water hydrants in the vicinity of the refinery because it was located just outside of the Borough limits. It took several long minutes for the firemen to find a satisfactory location in a small nearby creek where their pumper might obtain water for the hose streams. Then, the hose sections had to be attached, and it was found that there was only enough hose for two water streams at the scene of the fire.

By the time water was brought to the fire, the pump house was a seething mass of flames, the still receiving house was on fire and several nearby run-down tanks were in flames.

In a comparatively short time a small fire had developed into one which threatened the very existence of an entire refinery.

The ineffectiveness of water, with the exception of its use as a cooling medium, in fighting an oil fire, is understood by practically every one. Only three streams were available during the first day of the fire, and only five the day following.

A long story of explosions and fire and smoke may be shortened by a brief statement that the entire refinery was demolished by a fire which lasted over four days. Approximately one and one-half million dollars represent the money value of the oils and equipment which were destroyed. Fortunately, no one was injured while fighting the fire but many men watched their source of income burn to a mere nothing.

Approximately one month after this disaster, a tank on the property of another refinery in this same district was struck by lightning; as a result, seven tanks and a wax house were burned before the fire was extinguished.

Shortly after this, a tank on the property of still another refinery in this district was struck by lightning. This fire was extinguished before any appreciable damage could be incurred.

Ten refineries are situated in the above mentioned district. The executives in each one of them began to worry not a little bit about the recent fires. At one of their weekly cooperative group meetings they decided that they should cooperate in some way in studying the causes of refinery fires and efficient methods of extinguishing them.

As a result of this decision, the fire marshals of the refineries in this district were instructed to assemble weekly at a predetermined refinery to inspect it in a search for fire hazards. The marshals were asked to make recommendations relative to the betterment of hazardous conditions. They were asked to recommend any amount of fire fighting equipment which they believed to be necessary to make the equipment at any one refinery complete.

This cooperative plan was adopted by the executives of these ten companies because they realized that, up till that time, the fire marshal in each refinery was working alone. What experience each one had had with fires was gained from fighting fires on the property of the company by which he was employed. What conclusions each one had relative to fire prevention were a result of their own theories which in turn were based upon their own individual experience.

The fire marshals in these refineries are not employed to act alone in this capacity because the average size of the Pennsylvania refineries does not warrant such an expenditure. The majority of marshals are usually assistant superintendents or yard foremen. They do hold responsible positions in the manufacturing departments and are, therefore, competent men.

Generally, the fire marshals paid particular attention to this side of their work only at times immediately after a fire was experienced on their property or on that of a nearby refinery. At other times, they may have kept an eye open for fire hazards but seeing the same conditions day after day, they soon become

accustomed to them to the extent that they dispelled any thought of their being hazards.

In the operation of the Cooperative Group Plan ten fire marshals, for instance, including the fire marshal at the refinery where the inspection is made, inspect a given refinery. With such scrutiny there will be failure to observe very few existing fire hazards. When any particular problem arises, there will be ten theories to assist in solving it, and these theories will be based upon experiences at ten different refineries.

This plan followed so exactly the cooperative spirit prominent in various departments of the National Petroleum Association, that the Fire Marshal's Department of that association urged the other districts to follow the same procedure.

The undeveloped resources which were brought forward through this work, and the potentialities of each group of fire marshals proved to be of such value that hearty cooperation was given to the work by many groups of refineries. The group work can, of course, be carried out only in districts where the geographical location of several refineries permits the fire marshals to meet together without anyone man having to travel any great distance.

During the refinery inspection tours, one fact seemed to stand out very clearly. Every fire hazard was an accident hazard, and a great number of hazards which were conceived at first to be in the accident category could also be considered a possible contributing factor in a fire hazard. It was very evident to the fire marshals that they could inspect a refinery in the search for accident hazards at the same time that they were inspecting for fire hazards. The two ideas run so closely together that one allies very easily to the other.

The work of accident prevention was then officially assumed by the fire marshals, and the original belief that they could consider safety as well as fire in their investigations proved to be not only possible but very desirable.

In inspecting a refinery in a given group, the fire and safety marshals, as they are now called, should and do act in the role of a competent advisory board whose suggestions, if followed, may determine at a crucial moment not only whether or not a refinery may be saved from destruction but also whether or not a life may be saved.

In becoming a member of such an organization each marshal more thoroughly appreciates his responsibility. He becomes a more competent man.

The activities of the groups are kept before the executives of the member companies in any district because copies of the minutes of every meeting are forwarded to the manager of every company represented. In this manner, the suggestions offered by the fire marshals to the X.Y.Z., Refinery, for instance, are read by the manager of the A.B.C. Refinery. Therefore, membership in such a group is stimulating for any company because it encourages the adoption of methods and equipment which should be a part of every progressive oil refinery.

The groups have supported two very important activities. They are, Fire Drills and First Aid Training within the refineries.

It is very difficult to talk to the employees in a refinery in such a way as to keep them continually alert toward the prevention of fires and accidents. Such a procedure is not an uncommon one, but it takes continued perseverance and the effect is not always as desired. Talks to the employees should not be discouraged but their effectiveness will be 100 per cent greater if the men are trained in First Aid to the Injured and in Fire Drills.

The Bureau of Mines has very graciously cooperated with the fire and safety marshals of the National Petroleum Association in assigning instructors to teach the principles of First Aid to the employees in the refineries in the various groups. The results of this instruction have exceeded all expectations. The employees are not only able now to administer proper aid in case of accident, but have been shown indirectly the results of carelessness. Every man who has completed the first aid

course prescribed and given by the Bureau of Mines, automatically becomes a safety first disciple. It is very interesting to observe the change in attitude which employees take toward accident prevention after they complete this work. In several instances, employees who had to be warned continually of accident hazards are now the ones who are issuing the warnings and making the suggestions toward more safe working conditions. It is a very splendid spirit.

The Fire and Safety Marshal's Department of the National Petroleum Association is attempting to keep this spirit fresh in the employees' minds by a proposed First Aid Contest which will be held for the first time during the coming Spring, probably at the semi-annual meeting of the association.

Fire drills produce an analogous effect upon the minds of refinery employees. Continued adherence to regular and systematic drills not only prepares the employees to be ready at any time in case of fire but also makes each employee a fire prevention man. Every time the fire whistle blows to announce a fire drill, every man thinks of what the sensation would be if the whistle were announcing an actual fire. They more thoroughly appreciate the danger of fires and it has been proven that, as a result, the men are very prompt in making suggestions toward the removal of any condition which they believe to be a fire hazard.

One advantage of dividing all the fire and safety marshals of the National Petroleum Association into as many group organizations as possible is the ability of being able to have each group study certain problems which are of interest to all the groups. For instance, one group may investigate to determine the proper method of applying raw steam to a burning tank. Another may investigate to determine the proper method of applying foam to a burning tank. Another may study the subject of safe loading rack construction, and so on. At the Annual Meeting of the Fire and Safety Marshals each group makes a report of its investigations and conclusions. Many interesting conclusions to important problems, may in this manner, be obtained by every fire and safety marshal. In an equal interval of time it would be practically impossible for a single group to investigate as many important problems. And very few marshals could intelligently do all this work without the cooperation of others. In a similar manner, any current problem which arises before any one group may be referred to another for comments.

The fire and safety marshals of the National Petroleum Association have been organized for not quite three years. Their work and plans for the future are still in a formative state. What success they may have experienced has been a result of the attentive cooperation of each individual fire and safety marshal. There are still many problems facing them, but the knowledge that they each possess a willing attitude toward this cooperative spirit leads one to a very firm belief that their success will grow.

This department heartily endorses this Group Plan, and it is the department's desire to be of all possible assistance to any organization which is contemplating the adoption of similar work.

MR. COOK (Travelers Insurance Company): I would like to ask Mr. Herbert a question in regard to safety measures under fire. Many times we run against a situation where people congregate around a tank or a well during a fire and many do so with the intention of giving aid, I suppose. However, it seems that too many congregate at such times and along with the by-standers who happen to be around, it results in a good number of injuries and even deaths which perhaps could otherwise have been avoided in cases where explosions have occurred. It has occurred to me that a fire crew around a fire should be limited to as small a number as could be considered efficient. Can you tell us what number or how many you would consider necessary for a crew around a tank on fire?

MR. HERBERT: I believe that would depend greatly upon the individual fire and its size. I agree with Mr. Cook that it does appear many times that there are 2

number of unnecessary by-standers visible. I do not, however, feel competent to answer that question without knowing the exact circumstances. I think that might be answered by some of the men present who have had experience along this line.

CHAIRMAN SMITH: I think with Mr. Herbert that the question is quite a general one and would be a difficult one to answer because it depends upon conditions which occur at the time of the fire.

MR. HERBERT: I might say the principal way of avoiding having too many men and to my mind the only way to be sure of having the proper number of men in a crew is to have fire drills within the plant. To my mind that is the only way and I have no doubt it is the safest. I say it is the safest because when you have fire drills at a plant that plant is usually divided into sections and each section has a number of men, and every man in that section has a different duty to perform. All the duties should be planned out ahead of course. You will find that such drills show a greater amount of efficiency at the time of a fire than the plants not having fire drills. A plant which has not had a fire drill is usually the most confused organization at such a time. Most of the fires that I have seen have proven so. This plant I spoke of in my paper would not have suffered such a loss had they organized a system of fire drills. The only way safety can be applied to fire fighting is to have fire drills and drills for safety.

R. S. BONSB (Standard Oil Company (N. J.)): How often have you found it effective to have these fire drills? Are drills held regularly; are the men paid extra when attending these drills and do you have them at the same time?

MR. HERBERT: The drills are usually held regularly. Some plants have their fire drills once a week, others have as many as three a week. Some plants have them every two weeks but they are held regularly. In many instances the president or some of the executives have cooperated to such an extent that they have encouraged the idea of competitive drills between the different tours or the different sections at which time they will offer a prize. Every man has his specific duty to perform and usually the tour which gets the prize or is chosen the winner the men are usually compensated in some manner. Some plants will give the winning tour a treat—for instance, a dinner is given by the executive of one of the companies which is more or less in the form of a reward. Another might give a day's leave and so on. The drills are usually held about the same time. The men are not always told when they are to have a fire drill. At some plants a whistle is blown.

I believe your second question was about pay? They are not paid.

MR. BONSB: I can't see what benefit they would derive out of a drill if they were always informed beforehand when a drill was to take place.

MR. HERBERT: Well if they should have a whistle blown for a drill and then the men find out it was done just to fool them they are not going to pay very much attention to fire drills when it is really necessary.

MR. MULLHAUPT (Kendall Refining Co.): Then it is your belief that they should know when a fire drill is to take place?

MR. HERBERT: Yes.

MR. MULLHAUPT: Do you not destroy the effectiveness if they know beforehand and are all ready for it?

MR. HERBERT: I do not believe you do.

MR. BONSB: I should think it would be best to have them unexpected, sort of offhand. I was just wondering if in your experience, Mr. Herbert, it would not be better to have those drills come unexpectedly, because the unexpectedness of a thing rather unnerves a man and he is usually on his mettle.

MR. HERBERT: That may be true, but I personally, am against it. I think that continual fooling them will not produce the desired effect.

MR. BONSB: I do not see why you call it fooling them. You mean you would

inform them of the day? I personally think you would lose the efficiency of the drill. Take any fire drill at a public school, they give the alarm and the children always file out very orderly and there has been no notice given previously to the sounding of the alarm. They go right through it and when a fire drill really comes they are used to it. Fire drills at plants are expensive things to hold unless you get efficient and worthwhile results.

MR. HERBERT: I admit fire drills are expensive.

MR. BLAKESLEE (Petroleum Representative, N. S. C.): I believe this matter is one of personal opinion. If men are trained to fight fires and know how to go about this work, it makes no difference whether they have been trained by surprise drills or not as long as they know how to go about fighting the fire. It is their knowing what to do that gets results.

CHAIRMAN SMITH: I think that is about right.

GEO. F. PRUSSING (Union Oil Co. of Calif.): The same method as that Mr. Herbert outlined in his paper has been applied simultaneously on the Pacific coast. I believe we had almost the same sort of fire there as Mr. Herbert described as having got away from them. Afterwards we made an investigation to see just why the fire got away. In the fire mentioned we were left in total darkness due to an explosion which occurred and destroyed the incoming lighting and power lines. After some study we adopted a zoning plan, making each operating force a fire-fighting force as well, so that we know now that when a fire occurs we shall have available men trained in fire-fighting.

The scheme before was to depend upon the maintenance men for the fire-fighting force. We all know they are not always present at night hence you must depend on the operating men.

The scheme finally adopted we call "problem fire drills." In any given zone every man has a specific fire duty. He is trained in the performance of these duties, one day a week immediately after going off shift. The men are assembled, specific fire duties outlined for them in their particular zone. The causes of the fires are taken directly from fires occurring there or elsewhere so that the problems are based on actual experience. Some men are assigned to handle the apparatus, but, in every case the exact duty is assigned. Other men shut down the equipment and stand by.

The men are paid for overtime and after they assemble and the problems are outlined for them and duties assigned, they go to their regular operating positions. Instead of calling a fire drill by fire whistle, the code signal is given, with the little call bell that is used in most of the plants for the purpose of calling men to the telephone. These men then go through their fire duties as outlined, some assigned to the fire apparatus, others bringing water or foam to the end of the hose, others placing foam pumps into operation. All cooperate to the utmost, and the theoretical fire is put out.

These fire drills after being tried in one refinery were introduced in all refineries and in many of the pipe line stations with the result that at the end of six months the men were begging for new problems as they had gone through the entire list that had been prepared for them. We have had these drills going more than a year and there never has been a fire that has gotten beyond its initial state. I want to add my word of commendation to Mr. Herbert's idea. (Applause.)

MR. HERBERT: I think it would be a very fine idea to have the Fire and Safety Marshals from each of the different plants make an inspection of other plants and get the different ideas from each of the different plants and compare their experiences with experiences of their own. Of course I realize that there may be some doubt as to whether or not they might get the impression that such a procedure might develop into a spying system. I know we do not consider it in that light in Pennsylvania fields. The men going about there have considered this phase as being in the light, more or less, of legal advisers. They do not go down

town, for instance, and talk about those matters on the street corners and they do not go about stealing the different methods from the different plants.

CHAIRMAN SMITH: Then there has not been an objection. In other words they are nearly as friendly as "Safety Men."

MR. HAMLIN (Standard Oil Company): During these fire drills, do you designate a certain place before the drill takes place?

MR. HERBERT: The place is usually unknown to the men.

MR. HAMLIN: Do all the different departments turn to every fire drill?

MR. HERBERT: Well, in the case of the Pennsylvania plant, it being a small plant, that is possible, but I would not care to state just what would be feasible at a large plant. That would depend upon the size of the plant, I rather think.

Member (Knowlton Olean Works Vacuum Oil Co.): I would like to ask Mr. Herbert what equipment they have?

MR. HERBERT: I will just give you a brief description of one plant which has the foam equipment. They have regular forty gallon extinguishers. They also use the regular foam system which is piped from what is termed the A and B tanks.

MR. PRUSSING: You have mentioned one method of fighting fires which in our experience has come in for a good deal of criticism. We have put in the plants under our control, various types of fire fighting apparatus and have also used the steam smothering system. In some of the natural gas plants, in certain of the buildings, steam smothering lines were part of the original equipment. We have never had a fire in one of these plants in which these buildings were involved. At the time the problem fire drills went into effect, one of the operations that had to be gone through was the flooding of specific buildings with the steam. It just happened that at one of the large plants a small building was to be abandoned and the executives of the company agreed to permit the building to be set on fire so that we could see whether or not we could put it out. The steam apparatus was hooked up and a line connected to a supply of absorbed oil. The valves were opened up slightly and the oil leaked on the floor of the building at a fairly good rate. The building was then set on fire. The foam system was available and there was plenty of water but the point was to see whether the steam smothering apparatus was really worth anything. It was interesting to learn, that all the steam we could pour into the building did nothing but accelerate the fire. This was due, I believe, to the fact that the building was equipped with a ventilating system. At all events, the building melted down before the steam could be put on to it. The result was we abandoned any reliance on steam for fire fighting in gasoline plants and made connections for using the foam system.

TRACY SHAW (Mid-West Refining Company, Casper): Our experience has been just the reverse. We found that the steam system worked very effectively when we had a fire where high test gas was burning. You could flood foam over it and it would have no effect. We have tried to fight such fires where we have put the foam in a regular blanket and have had the various companies send their men to our plants and demonstrate the different systems of foam apparatus but they have never been able to put out a fire for us with the foam system. We found we could fight a fire with steam and put it out in a very short space of time.

CHAIRMAN SMITH: Can you give us any information in relation to the ventilation of the buildings when you had these fires? Have you had any experience with the ventilation as a draw back to the use of steam?

MR. SHAW: No. The actual fires we have had to contend with the steam has always put them out effectively. If the buildings were ventilated it did not seem to make any difference. We always poured the steam in great volumes and kept it up.

MR. HERBERT: Speaking along the same lines that Mr. Prussing and Mr. Shaw have just told us about. We have found from past experience that the steam

proves very effective at certain times but there are times when it can not be used so successfully. I think it is most effective where the velocity is reduced, going from say a two-inch line and increasing to a four-inch line, giving a blanket effect.

MR. SHAW: Relative to the air and ventilation, I recall that while at a fire, I think it was about 1922, at a well that was producing approximately twenty-five hundred barrels of oil every twenty-four hours, we put that fire out with steam. I know you will agree that there was nothing around that well but the wide, wide world. There certainly was plenty of ventilation and the steam system worked very effectively. I must say we hooked up a lot of steam, used three lines. It took fourteen hours to rig it up and approximately fourteen seconds to put the fire out. We poured the steam directly at the point of the top of the casing and the flame. The flame probably ranged about fifty feet high above the top of the casing. We just poured the steam around the top and it went out.

CHAIRMAN SMITH: It would seem that as it happens in that particular case, you had lots of steam to depend upon. Some plants may of course not be so fortunately situated. It is a very interesting experience to learn about and I am sure we all appreciate hearing about it.

There is one other announcement I want to make while we are all here. It is sort of a personal announcement. You know we fellows all primarily have a job somewhere, a job with some organization and one which requires most of our time. Yesterday they gave me the honor, and I do consider it a great honor, of becoming Chairman of this section. It just happens that I too have a job besides being your Chairman. It is a lot bigger job than it was last year—all our jobs are bigger than they were last year. That was what I heard somebody say the other day—that our job is more than turning over nails and putting guards around belts, as it was possibly a few years ago. Our jobs have grown. You know what that means to most of us as much as you know what it means to you in your own organization. Our job is a research work which requires lots of thought and lots of time. I am coming to one point, perhaps you have jumped there already. That is this: the value that this Section is going to be to its members depends upon how much time each member will spare us to help out. It does not depend upon your Chairman alone, thank goodness, or upon the other officers. One of the most pleasing things that has happened to me since I came to this Congress, happened yesterday, after they had elected me Chairman of this Section. As I left the room yesterday after the meeting had adjourned, I had gotten as far as the door and many of the members here said "Smith, we are going to help you out all we can, and whenever you want any help just write us about it and we will give you whatever help we possibly can." I was extremely pleased about that. There were so many offering their help. I think you will all agree with me when I say that a few years ago, there would not have been very many members grouping around the new Chairman offering their help. I am going to say they are with us one hundred per cent because I really believe they mean it. There will be many times when the men in this room will need the help of others, I am sure. We all know that it is quite a job to bring about these meetings and that they entail a great deal of expense. I know we all want to get as much out of these meetings as we possibly can and also give as much as we can to the success of such meetings. It all depends, in my opinion, upon everybody doing his part and I hope you will all continue to be with us for the success of this Section.

I am going to submit a proposition which I think will bring about better interest in this section. It is that questions be written before these meetings and submitted by the different men involving general hazards, general safety problems, and so forth. Then these questions can be distributed to each man in this section and each man will answer the question in his own way, and regardless how small the matter involved may be, every fellow's viewpoint will be there. We may take a hundred and fifty answers or questions but it may be that the one hundred forty-

eighth answer on the same question may throw an entirely different light on that particular situation.

We could take—let us say—one hundred questions regarding the entire field, have them bound together and sent to each member. He could then refer to the questions which are of vital importance to him and in that way we would get each of the fellow's viewpoint. I do not suppose that there are any two men in this entire group who follow the same principle.

I believe we can arrive at the most stimulating and best way for the success of these meetings by sending out a regular questionnaire.

As an illustration take Dr. Lederer's paper, which was very important and helpful to most of us. I happened to ask the question with regard to preserving metal. He gave the answer right then and there and many of us profited by having the benefit of his knowledge. I'll bet there were at least twenty-five men who had the same question in mind, who were not going to get up and ask that question. Asking questions will certainly stimulate interest and we all will get ideas that will prove of great value to each and every one of us.

MR. SHAW (Mid-West Refining Co.): The Executive Committee is going to try and work out a publication program. You will receive a request for your experiences and any information you may have at hand, for use of our Section. You will have an opportunity to prepare papers. I would like to put over this one point to you. I take a great interest and spent a great deal of time in the Boy Scout movement. When we take a new member into the troupe the thing I try to impress upon him is that he will get out of scouting just what he puts into it. You will get out of this Section, gentlemen, just what you put into it and you will get more from your research work in the preparation of papers, probably, than anybody else. When we call upon you in regard to certain things for publication we hope you will give the best you have in it.

CHAIRMAN SMITH: I want to say that we have an Engineering Committee which has promoted some very valuable ideas. It is the intention of this Committee to promote more of this work. While it may not meet with just the specifications you gave, I assure you the Committee will give all consideration and will try and cover during this coming year all you have talked about.

Yesterday most of us saw the film strip which was promoted by the Engineering Committee of this Section. I forgot to tell you that this strip is available to anyone at the National Safety Council Headquarters if you desire to use it. We do not feel that this film is complete, in fact we know it is not complete. I recall one thing in particular that happened after this strip was made and before I left Chicago. A truck went in to one of our service stations to get gasoline and it so happened that the gasoline tank was situated under the front seat. The man put the hose in and started the pump. While he was pumping the driver stepped around to the other side of the truck and took up the floor board and began to clean the terminals of the truck battery. He apparently was using a screw-driver, and while he was cleaning the terminals a spark and a flash were produced. The truck caught on fire and was burned up and the service station was nearly burned up and that was all caused by a spark. That is one of the new problems which we have run into since getting out this service station film strip.

We have Mr. Newcomb with us, perhaps he will tell us something about high pressure equipment.

MR. NEWCOMB (The Standard Oil Development Co.): You all heard Dr. Lederer's paper yesterday and no doubt found it as interesting as I did. It has been my sole job, almost, for the past few years to study corrosion in all its forms. Particularly have I devoted a great deal of study to cracking equipment. We are inspecting cracking equipment in some nineteen different plants at the present time, six of which are in foreign countries, and I propose to give you a little talk now

not on how corrosion occurs but how we find it, and that has not always been so easy either.

When we first started seven years ago, we did not have much knowledge. We tried various methods to determine where corrosion started. First we drilled a few holes through the shell and found it was not as thick as when we started. We took one still that was condemned at a certain plant and drilled it at various points. At that time I found most noticeable corrosion at what was practically liquid level. It has been eight years since I did that first experiment, and I believe that ninety per cent of the corrosion will be found at the disengaging surface. Of course we do not overlook the other part of the equipment in our investigation.

One safe way we found to inspect cracking equipment is to inspect every single inch and piece so that you can determine the thickness of it. I will give you just a little idea how we go through cracking equipment. In the first place we made an inspection of a drum on the inside to see how far down it went from the surface, particularly examining the rivets with a magnifying glass to find how much corrosion was on the head. We found in some cases no head at all. We go over every inch and if it is not too thick we sound it all over with a hammer. We can tell by sound where it is thin and where it is thick. Then we drill holes, usually about nine-sixteenths. Then when it comes to the tubes in the pipe sills, we have developed a tubular micrometer which will reach in any point on the inside of the tube up to about twelve feet. We can expand that micrometer to reach any length. It is made with three pins sticking out of the cylinder held by a cone on the inside, the cone being moved by a screw shaft on the handle. A total limit of the micrometer is one inch on a four inch O. D. tube.

We also use the same method on our various pressure pipes from one part of the equipment to the other in so far as we can accurately use it. We also use long inside calipers to determine inside diameter of pipes. In many cases we found excessive corrosion and in many instances the tops corrode much more readily than the bottoms. We pass a light through the tubes and in this way we can tell whether there is excessive corrosion or not. Just as soon as a tube gets out of round the light becomes an eccentric beam of light and it becomes much more eccentric as it passes through the tubes.

We reach in with special tools into the valves. We measure the gate valves with split rings if valve is used for a throttle valve. For the various plug cocks we use the calipers. We put on special links so we can reach down into things. We measure every plug, get the thickness, and so forth.

I might state further on the oil equipment we drill particularly at points where the oil enters into the drum. Every safety valve is taken down during our inspection and by so doing we find out whether it has stuck in any way since the last inspection of the boiler. We find in many instances, that if we take a safety valve and pop it, it will pop much higher than it is set at. If we find that the valves are sticking and that this occurs between inspection periods, we then get the people at the plant where this occurs to have them taken down and inspected in between inspections. In this way we go over very thoroughly, every single part of these plants.

I have one man in particular who travels completely around the world and then when he comes back he starts out and makes another inspection around the world. We have an office force of several men whose duty is to check the inspection reports and do the necessary computations on them as they come in.

That is a very brief resumé of how we are handling this proposition. I might say we do this work in this country every four months, and in foreign plants it is done by my men once a year and by local people twice.

ADJOURNMENT

SEVENTEENTH ANNUAL SAFETY CONGRESS
NATIONAL SAFETY COUNCIL

Power Press Section

New Section Officers

- General Chairman*—J. B. GIBSON, Western Electric Company, Inc., Chicago, Ill.
Vice-Chairman in Charge of News Letter and Publicity—S. H. SLAYMAKER, Fairbanks, Morse and Company, Beloit, Wis.
Vice-Chairman in Charge of Program—R. G. MÄRTER, National Enameling and Stamping Company, Milwaukee, Wis.
Secretary—C. H. GERDING, Western Electric Company, Inc., Chicago, Ill.
Exhibit Committee Chairman—W. J. LARSON, Clum Manufacturing Company, Milwaukee, Wis.
Engineering Committee Chairman—T. O. MEISNER, American Can Company, Maywood, Ill.
Slide Committee Chairman—F. J. MARES, Perfection Stove Company, Cleveland, Ohio.
Statistics Committee Chairman—J. E. WALTERS, General Electric Company, West Lynn, Mass.
Poster Committee Chairman—M. A. KROGER, Chevrolet Forge Division, General Motors Corporation, Detroit, Mich.
Membership Committee Chairman—J. C. MACLAGAN, J. H. Williams and Company, Buffalo, N. Y.

Executive Committee: THE OFFICERS AND

- LOUIS BORAKS, Liberty Mutual Insurance Company, Boston, Mass.
W. J. GRAVES, Michigan Mutual Liability Company, Detroit, Mich.
A. L. KAEMS, Simmons Company, Kenosha, Wis.
J. W. HENNING, Automatic Electric Company, Chicago, Ill.
E. ROTH, Aetna Life Insurance Company, Hartford, Conn.
G. S. THOMPSON, Detroit Insurance Agency, Detroit, Mich.
G. A. KUECHENMEISTER, Dominion Forge and Stamping Company, Ltd., Walkerville, Ont., Canada.
J. E. ROCKOFF, Detroit Steel Products Company, Detroit, Mich.

Retiring Officers

Chairman, J. W. HENNING, Automatic Electric Company, Chicago, Ill.; *Vice-Chairman in Charge of Program*, J. B. GIBSON, Western Electric Company, Chicago, Ill.; *Vice-Chairman in Charge of Publicity*, W. F. DITTMER, Westinghouse Electric and Manufacturing Company, East Pittsburgh, Pa.; *Vice-Chairman in Charge of News Letter*, S. H. SLAYMAKER, Fairbanks, Morse and Company, Beloit, Wis.; *Secretary*, A. L. KAEMS, Simmons Company, Kenosha, Wis.; *Exhibit Committee Chairman*, W. J. LARSON, Clum Manufacturing Company, Milwaukee, Wis.;

Statistics and Engineering Committees Chairman, T. O. MEISNER, American Can Company, Maywood, Ill.; *Poster and Slide Committee Chairman*, M. A. KROGER, Chevrolet Forge Division, General Motors Corporation, Detroit, Mich. *Membership Committee Chairman*, W. J. GRAVES, Michigan Mutual Liability Co., Detroit, Mich. *Executive Committee*: THE OFFICERS AND LOUIS BORAKS, Liberty Mutual Insurance Company, Boston, Mass.; HERMAN SCHWAB, Aluminum Goods Manufacturing Company, Manitowoc, Wis.; E. ROTH, Aetna Life Insurance Company, Hartford, Conn.; R. G. MARTER, National Enameling and Stamping Company, Milwaukee, Wis.; F. J. MARES, Perfection Stove Company, Cleveland, Ohio; G. S. THOMPSON, Detroit Insurance Agency, Detroit, Mich.; G. A. KUECHENMEISTER, Dominion Forge and Stamping Company, Ltd., Walkerville, Ont., Canada; C. H. GERDING, Western Electric Company, Inc., Chicago, Ill.; G. E. WALTERS, General Electric Company, West Lynn, Mass.; J. E. ROCKOFF, Detroit Steel Products Company, Detroit, Mich.; J. C. MACLAGAN, J. H. Williams and Company, Buffalo, N. Y.

October 1, 1928

J. B. GIBSON, Chairman

Safety and Health Division, Western Electric Company
Chicago, Ill.

The first session of the Power Press Section at the Seventeenth Annual Safety Congress was called to order at two o'clock by the chairman, J. W. Henning, assistant superintendent, Personnel and Operations, Automatic Electric Co., Chicago.

CHAIRMAN HENNING: As chairman of this Section I am going to turn the meeting over to Mr. J. B. Gibson, our vice-chairman, who has had charge of the program. He will occupy the Chair for this meeting.

CHAIRMAN GIBSON: It seems quite appropriate that the Power Press Section should open with a luncheon as it is a well known fact that the power press people are a hard working people and I think the doctor will bear me out that good food, well served in a pleasant atmosphere improves the digestion. We will all have a chance to renew old friendships and make new ones, and we hope you will all enjoy the meetings during the week.

I think we are particularly fortunate in having with us today Dr. Harry Myers. We had to make arrangements with him way back in March in order to get him, as we understood he was wanted by other sections. From my own experience I know there is no speaker better qualified to strike the keynote of the Power Press Section than Dr. Myers, and it is a great pleasure for me to present him to you at this time.

Some Principles of Safety That Make for Success in Life

By DR. HARRY MYERS

Superintendent of Personnel, Frigidaire Corporation, Dayton, Ohio.

I feel very much complimented to see a great number of people in this audience who have heard me speak before and that you are here in the face of the fact that I am going to talk on such a subject; for I know that in most of the addresses that I have made I have discussed some of these principles, and here many of you are willing to hear it all over again. This is a very great inspiration to me.

I don't mind telling you that I could easily have found some other subject to discuss, but I am fond of talking on this particular subject for two reasons:

First—Because it is so necessary to the day's work.

Second—Because so few people are really thinking in terms of principles.

Now, can I prove these two statements? Take a look, if you please, at the first. Is it very necessary that we first find the principles involved before we can do good work? Well, let us see what some of our greatest men say. Let us consider Emerson first, and when we quote Emerson, we are quoting one of the most fundamental thinkers that America has ever produced. Hear him, then—

"Without *ambition* one starts nothing. Without *work* one finishes nothing. The prize will not be sent to you. You have to win it. The man who knows *HOW* will always have a job. The man who also knows *WHY* will always be his boss. As to methods, there may be a million and then some, but Principles are few. The man who grasps Principles can successfully select his own methods; but the man who tries methods, ignoring Principles, is sure to have trouble."

Consider the methods of Lincoln, upon whose principles rested the very life of our nation. Ingersol said of him, "Where no Principle was involved, he was easily swayed, willing to go slow if in the right direction, sometimes even willing to stop. But he would not go back, and he would not go wrong." Yes, he thought and acted in terms of Principles, and any executive today can learn the greatest personal lessons from Lincoln—the Executive.

Henry Ford says, "All of our apparent going forward is simply a progress farther into the heart of Principle. It is not a learning of new things, but a new learning of the old."

We could go on and quote the ideas of many of our great men and you would find running through it all this thought that we must find the proper principle involved if we are going to do anything right.

How in debt we are to those who can think out the fundamental principles! If you examine history or the great men of our present day, you will find that one of their greatest characteristics is that they think in terms of simple principles and define the issue clearly.

No one has stated the principles of modern business better than has Mr. Sloan, president of the General Motors Corporation. He says:

"Our principles completely expressed, as I see them, and they apply to every other business as much as they do to that of General Motors, are: Get the facts; Recognize the equities of all concerned; Realize the necessity of doing a better job every day; an open mind and hard work. The last is the most important of all. There is no short cut."

Please note that he says these principles apply to every other business and I believe if you analyze them you will find they do apply to every other line of work represented here today. Won't you agree with me that these ideas coming from the man I have named, proves my first statement, and that is, it is very necessary to find the proper principles to do the day's work right.

The Second Statement

Now let us see if we can prove the second statement. Is it true that very few people are thinking in terms of principles? Well, you try this out for yourself today! Ask anybody this question, "What are the principles involved in your job?" See what they say! Ask them then what were the principles of men like Lincoln. Ask them then the principles of any other of our great statesmen. Ask them the principles of our great industrial leaders and see what answer they give you. Yes, go back to our Greatest Teacher, Jesus Christ, and ask people what they know of His principles and I believe if you will carry out this experiment, you will find that very few people are thinking in terms of principles, but rather

in terms of isolated incidents. Yes, we know far more of historical facts than we do of principles. Yet these historical facts are really of less consequence to us for they can do practically nothing for us in our personal development or our work.

I heard Dr. Harry Emerson Fosdick preach a wonderful sermon on this subject. In brief he said, "There are two kinds of religion, the religion about Jesus, and the religion of Jesus. The first concerns itself with the historical facts of Jesus' life, and the second, with his ideas and ideals—his principles. Now the historical facts are something we can do nothing about personally, while his principles are the things that we can reproduce in our own lives. Yes, these are the "reproducibles." This was a wonderful sermon and I am glad it has been included in his recent book, "Adventurous Religion."

Now then, you ask the average man what these principles are, these things that truly influence us in our work and personal development and see how few people can tell you. I feel sure that if you carry on the experiment you will agree with me that very few people are thinking in terms of principles. So then you need not wonder why I am so interested in discussing this subject, and do so whenever I can.

The Principle of Your Work

I wish that I could carry out the experiment right here today and ask each one what are the principles that underlie your job, but the crowd is too large and the time too short to do this. If I could, I would like to ask every Safety Director, every Industrial Physician, every Personnel Manager, what are the principles that underlie your work?

So, Mr. Safety Director, let me ask you, "Is your job saving fingers, toes, legs and arms, yes, and lives?" To this I would answer "Yes" and again "No." And you, Mr. Industrial Doctor, what is your job? Is it creating a healthy working force by applying the potent principles of medical science to people as we now apply the science of physics and chemistry to products? To this I would answer "Yes" and then, great as that job is, I would have to say "No." And Mr. Personnel Manager, wherever you are, what is your job? Is it creating an intelligent and interested working force, ironing out human grievances and producing a harmonious working organization? To this also, I would say "Yes" but then again "No."

No, the work of every one here is the work of your company, and the work of your company is to make things at a profit that people can buy. Now let me see if I can prove this statement. If you have not already bought a Frigidaire, when you do buy it and I am sure you will, for it is incredibly quiet (Laughter); Oh yes, the advertisements are true; it is Beautiful and Dependable. Well, when you do buy this Frigidaire, are you going to ask of the salesman, "What is your Safety standing in General Motors?" "Do you have a Medical and Personnel Department in your company?" No, you will not be asking any of these questions, and mark you if you are buying a Frigidaire, you are our boss. Yes, we like to make this statement down at our plant, "We are all working for the same boss and that boss is the customer." No, the questions you will be asking are those which will assure you that Frigidaire is the kind that you want to buy and that the price is the price you should pay for it. So if you, the customer, the Big Boss, are not asking about our safety work and our medical and personnel departments, does it not prove to us that perhaps our job is far broader than we ordinarily think of and that all represented here today must be interested in production just as much as those actually engaged in it? I believe that is the true conception of your job, and the fact of the matter is that the safety, medical and personnel work done in your plants are the very things that help to make the kind of product that people

want to buy and at the price they want to pay for it. Yes, it is a definite fact that we could not make good Frigidaires at low cost unless we did have a safe shop and healthy people and a harmonious working organization. So that the principles that make for Safety undoubtedly must be the same principles that make for good work.

Now let us see if we can prove this statement. What are the things that are necessary to do good work? What are the things that every foreman must provide for his men before they can do the work of that department? There are six definite things:

1. A Clean and Orderly Department.
2. Proper Equipment.
3. Proper Materials.
4. Proper Instructions.
5. Proper Supervision.
6. Proper Pay.

But now, no foreman can give these things to his men unless the men themselves carry out the six things that are necessary to do good work. And here are the "Six laws of good work."

1. Follow instructions willingly.
2. Be clean and orderly.
3. Take good care of property and materials.
4. Work well from whistle to whistle.
5. Work every day and tell your foreman when you cannot.
6. Work well with others.

Now, I wonder if you see the relation of these two sets of laws? I believe here are the most valuable "pair of sixes" you have ever seen.

Responsibility of Foremen and Men

Now, let us see the perfect tie up between these two sixes. The foreman must provide a clean and orderly department, but he can never do it unless his men are clean and orderly. He must have proper equipment and material, but he can never do so unless his men take good care of the property and material after he does give it to them. He must give proper instructions, but what's the use unless the men want to follow these instructions willingly. He must give proper supervision, but how can he unless his men work well from whistle to whistle, and every day that they can, and well with others? Now if the foreman provides the first five, and the workman carry out his six, the foreman will then be able to provide his sixth, "Proper Pay," for pay is just the score card representing work well done. Now, my friends, we are not departing from our subject, we are in truth talking principles, and we are talking principles of good work, yes, principles of success.

Think then, if you will, about the principles that underlie these principles. Do you know that the second and third laws of good work have the power in them to change almost any man from a failure to a success? Do you know that they contain the very force that makes for progress of a man or a company. I wish I had several hours just to develop these principles. For once again, my friends, I am afraid that you are not thinking in terms of principles about these things. For instance, the average man thinks of a clean and orderly department in terms of janitors. Yet you can never keep a place clean just with janitors no more than our mothers could keep the home clean and orderly unless all of us kids would help by being clean and orderly. No, there is no greater mistake than to think of getting your plant clean and orderly by increasing the janitor force. The only way it can be done is to teach each man that he must be clean and orderly, and take good care of property and materials, and this will mean that expenses

will come down and the condition of the plant will improve just as when in the practice of medicine, I knew that my patient was getting better when the fever came down and his general condition improved.

Teaching These Principles

All of these things we try to teach our people both in lectures and by the use of our booklet, "You and Your Work," and if any of you are particularly interested, we will send you this literature if you will write for it. This I know, if you will grasp these principles and try to teach them to your people, you will soon see a wonderful improvement in both your men and in your plant. And, of course, in your product.

Have you thought of the principles behind the third law? Have you thought that this is the very foundation of success? Do you see in it one of Christ's principles, "To him who hath shall be given, and to him who hath not shall be taken away even that which he hath"? In fact, I believe the principles underlying the second and third laws are such a definite part of a successful life that we could absolutely change the world if we could get these two things done universally. I hope I am not too optimistic or enthusiastic, but I do believe that just as we have wiped out the scourges of yellow fever, malaria and many other diseases by getting whole districts clean and orderly, I *also* believe if we could get people to be clean and orderly and take good care of property, we could wipe out the scourge of unemployment and likewise of poverty, for it is a definite fact that the principles that underlie good work are so sound that there is not a thing going to be asked of any of us to make us better at our work, but that will make us better wherever we are.

We try to impress all of these truths upon every one in our plants through our booklets and our posters. Sometime ago we put this on our posters:

"There are always jobs some place for people who do good work. Do you know of any one out of work who follows the six laws at his work, and the second and third in his home? If so, please send his name and address to our employment department."

I do not believe we have ever put up anything that has created more thought in our plant. I have talked to many of our men about this and all agree that people who do these things are not out of work very long. No, they know how to work. That is, they know how to make things at a price that people can buy and this is what makes work, and moreover this is what makes success.

A short time ago, I was in one of our Employment Offices, with a visitor. In walked five young fellows, about twenty-one years of age. I asked them if they were coming in for work. They replied, "Yes." I then asked them where they came from and if they had all come together. The spokesman said that they all lived in a nearby town and that they had driven up in his father's automobile. I said then that I wondered if they knew how to work. They all replied, "Sure, we know how to work," and I answered, "Well, there are a lot of people who think they know how to work, but they don't." "Now these laws which you see before you, we believe, are the laws of good work, and I am going to show you how truly they describe people who can do good work."

"The second and third laws, 'Be Clean and Orderly, and Take Good Care of Property and Materials'—tell us more about people than anything else we know of; so I am going out and look at your automobile and if it is as clean inside as we want our plants to be, and if the mechanism is as good as we want our machinery to be, I am going to give you fellows jobs." I could see by the expressions on their faces that they were not very anxious to have me make this investigation, and I am wondering now just how many people in this audience would like to have their boss decide whether you would be retained or fired just

on the condition of your automobile or other property, and yet, my friends, there is no one test that will tell more about you than this. Well, one look inside of their automobile and it was easy to decide that we did not want these young men in our plants, for there were cigarette butts and burnt matches all over the floor and a big hole burned in one of the seat covers.

I tried to show them just what this told me about them, that it told me to a certainty that they were so unconcerned and so careless that they would not even throw a cigarette butt or a burnt match out of the window. And I told them that I was sure if we had many men like that our plants would soon look like their automobile, and with such carelessness we could not make good Frigidaires. Yes, I showed them that most people today, who are behind in their bills are in debt because they are not clean and orderly, and do not take good care of property and materials, that due to such neglect they were consuming more than they produced and that no one could ever get ahead who did this. These boys agreed with me that they did not represent good workmen, and that we should not be expected to give them jobs in our plants unless they changed.

These are the things we are trying to teach right out in our employment office before men are even interviewed, and I regard the teaching of these principles as one of the most important things that can be done in any employment department.

Safety and Success

But here we are at a Safety Meeting and are supposed to be talking things of safety. Now, let us see if these are not the things which really underlie safety. If a foreman provided these five conditions necessary for good work and his workmen really carry out his six laws, upon which all good work depends, what per cent of your accidents will automatically be wiped out. You will find this a most interesting check-up. If you will analyze your accidents in light of these two pairs of sixes, I believe you will find that practically all of them are caused by one or more of these things not being done.

I have asked many managers, safety directors and foremen to make this analysis. I have asked them, "What part of your accidents have been caused by people falling over things that should never have been there? What part of your accidents have been caused by something misplaced which fell upon someone? What part of your accidents have been caused by people stepping on nails, broken bottles and other things that come along with dirt and disorder?" For you see all of these questions indicate a violation of the second law and would not happen if a plant was clean and orderly. You will probably be astonished, unless you have thought it out clearly, to know that many of these men say that from twenty-five to forty per cent of accidents result from these things, and certainly if we would take then the lowest figure of twenty-five per cent, we would be very fair in our estimate. And I feel sure, just from my own experience as a family physician, that an equally large per cent of accidents about homes come from the same causes.

Now, let us look at the second principle, proper equipment. Analyze your accidents and see what per cent come from improper equipment, equipment that is not running as it should or equipment that is not properly guarded. And mind you, I do not mean to infer by this that equipment must be new or a type that is too costly for your own plant operations. I have seen many foremen confused on this point. By proper equipment we certainly mean equipment that is necessary to do work and that the plant can use economically. Ofttimes a plant must content itself with some improvised machinery because it does not have enough work of a certain kind to buy improved machinery. But I do mean this—whatever machinery you have, old or new, is it working properly or is there something about it that is not quite right, something that easily could be fixed in a very

short time and the only reason that it is not fixed is on account of carelessness and indifferent management? It is surprising to see the number of men working with small tools that are not intended at all for the use that is being made of them. Many workmen are hampered by just such things, and I really believe that it is a very simple matter to judge the type of foremanship you are dealing with, just by the kind of small tools that men are made or allowed to work with.

You see this subject of proper equipment is a large one and it reflects in no uncertain way the type of supervision in a plant. Yes, let me walk into a plant and find the machinery and tools in good condition and I will immediately tell you a lot about the management of that plant. There is an old expression that "a man is known by the company he keeps." I believe we can add a new one and say "a man is known by the equipment he keeps." If I were a foreman, one of the first ways I would prove my interest in my men would be by the kind and condition of the equipment I made them work with. It is all very nice outside of the plant "to say it with flowers," but in the department let us "say it with equipment."

Fundamentals of Safety Efficiency

Now, I just had to throw all that in to get you to see what I mean when I say, "What per cent of your accidents are caused by poor or improper equipment?" Estimates from men well qualified to know, place this as high as 25 to 35 per cent, and once again let us take the lowest figure, 25 per cent, so that we are, at least, reasonably accurate; and if you will add to all of this the fact that carelessness is one of our biggest factors in all accidents, and that dirt, disorder and poor equipment are the main signs of carelessness, it would be hard to place high enough estimate upon these two principles as causative factors in accidents.

In a similar way question yourself on the next three principles, proper materials, proper instructions, and proper supervision. I believe you will agree with me that most of the remaining 50 per cent of accidents come from poor materials, poor instructions and poor supervision. We will say perhaps ten per cent for improper materials, twenty per cent equally for improper instructions and poor supervision, totaling all these you will find this accounts for one-hundred per cent of all accidents. Now, maybe you will find these estimates too high. If you do, cut them down to any per cent that you think correct, and I honestly believe that any analysis of your own accidents will easily convince you that most accidents come from a violation of one or more of these principles. And if you will add to all of these different factors the influence of individual carelessness which accounts for these violations, I feel sure that you will find the cause of all of your accidents. And if you analyze these principles I believe that you will find the principles that underlie a safe shop are the same principles that underlie a successful shop. Yes, the principles of Safety are the principles of Success.

And if you as managers and foremen, safety, personnel and medical directors will see that these two sixes are done in your shop, you will bring about the very conditions that will mean safety, harmony and good work which always make good production and low costs. And if you will view your job in light of these principles you will find that your work is not a special department off by itself, but a real part of the whole production program, and I believe this understanding of your work will produce a type of cooperation that will always mean success for all concerned.

I feel absolutely sure that if you analyze all of these things, you will agree that the principles of safety are always the principles of success, and as you go back into your plants, this is the success I am wishing for you, and I hope you are wishing for me.

CHAIRMAN GIBSON: Dr. Myers, on behalf of the Program Committee, I would like to express our formal thanks and I feel sure I voice the expression of those who are here this afternoon. I am quite sure that Dr. Myers in this speech struck the right keynote.

ADJOURNMENT

October 2, 1928

J. W. HENNING, Chairman

Assistant Superintendent, Personnel and Operations, Automatic
Electric Company, Chicago

The second session of the Power Press Section at the Seventeenth Annual Safety Congress was called to order by the chairman, J. W. Henning, at ten o'clock.

CHAIRMAN HENNING: The first item on the program is "Reports of Committees" but we are going to dispense with that at this time. We will have these reports tomorrow morning.

We have with us this morning a woman very capable of talking on the subject, "The Woman Operator in the Punch Press Department." Lots of women have been employed in punch press departments but I don't think a man ever gets as close to the subject as a woman could and I think it is very fitting and very fortunate that we have this woman with us who will give us this talk today. She no doubt will bring out very many interesting points. We all have this problem of how to handle women and there are different things about them that a woman might see and know that a man would not and I believe we will learn a lot on this subject today.

The Woman Operator in the Punch Press Department

By RUTH I. STONE

Chief of Women's Personnel Department, Operating Branch,
Hawthorne Works, Western Electric Company, Chicago

I feel that I am not qualified to discuss this more than yourselves but perhaps I can bring a message to you and I am going first to read a letter that was sent to me. I will hold up the envelope so you can see it is a bona fide letter. The first part of the letter is of a personal nature so I will not read it. The writer is a girl who came to me before Christmas with two fingers entirely gone and part of the third. This is the letter dated February 27, 1928:

"The company has not settled with me yet. The Legal Aid Society said I have lost the use of my whole hand so I told it to the man in the Insurance Company and they are trying to do away with as little as they can. Miss Stone, don't you think they should have been more careful about having the machines guarded better and the left lever was tied? It was simply carelessness of the foreman. There are so many accidents here only on account of the careless foreman. Can't something be done? As long as I've worked in the Western Electric Company I've never seen one quarter as many accidents as I have here in two months. It will not help me but some other poor girl."

After having received that letter I have come down here to talk to you, not only about machines and the carelessness of foremen, but to see if there is not something we might do for some other poor girl, as this letter states, so she will not lose her hand or her fingers.

Now, may we be quite informal in this discussion. How many of you represent factories where women are employed in punch press work? Will you kindly hold up your hands? Well, that is fine, there are quite a number of you, so it is a common problem.

You know as well as I do that there are certain places where women cannot work on account of the machines and the size of the pieces to be handled. It

is almost entirely a question of weight as far as I have been able to determine. There may be some other reasons which will be brought out at the end of the discussion, but the only reason I see why a woman will or will not work in the punch press department is the weight of the part she has to handle.

What are you going to do about the girl who comes to work in the punch press department? How are you going to lay the scenery so she may play her part? I think the first thing to consider is this: the safe working conditions. I am asking for just the same working conditions that would be safe and good for men.

First, taking up the subject of light, which is of particular importance when you are working with small parts. I have worked on a punch press machine and I know what I am talking about in this respect. You need a good light and when you go back to your punch press department, I ask that you find out if you have a light on the machine that is good, see if you have a glare. If there is a glare, equip your light with a frosted bulb.

There is another thing to consider and that is noise. Often the dropping of a pan will frighten a girl, causing her to fall against the machinery and be crippled. You cannot keep it quiet, that is out of the question, but the aisles should be clear so that nobody is stumbling or falling against the machines, or unexpectedly dropping parts behind a girl who is operating a machine. Such sudden, unexpected noises cause accidents.

Then comes the question of seating. I was surprised in looking over the exhibit to find that many do not use chairs. I am told that some people like to sit and some like to stand when they work. That is perfectly true, but to use the treadle without sitting would be a terrible strain and I cannot imagine anyone doing it all day. I hope I may be successful in persuading you to provide chairs and fairly comfortable ones with backs. If any of you have worked in a punch press department you will know that the noise is fatiguing and that is something you cannot help, but we can reduce a certain amount of fatigue by allowing the girls to sit down. I think a comfortable chair should be provided instead of a box or a stool and you would then find a difference in production.

Also, everyone who works in the punch press department should have a physical examination. I knew of a case where a girl had an epileptic seizure and slumped forward throwing her arms in behind the guard. No one was to blame for that accident, but there must be lots of people in punch press departments who should not be there any more than she. Some people are subject to dizziness, some are apt to have nausea and other things that cause a girl to faint, and the punch press department is no place for the girl below par. Please see that your girls have a physical examination. In that way you will protect yourself and the girl as well.

I have visited a number of factories where all of the girls wore caps. I remember at one such factory I asked the manager, "Why do all of your girls wear caps?" The manager answered, "That was the first safety thing we did, we put caps on the girls." Excellent, but conditions have changed during the past ten years. The girls are not wearing long hair, they have bobbed hair and they have it marcelled, which costs a dollar and a quarter and then when they have to wear a cap it makes them warm and the marcel comes out.

That may sound like a trivial thing to you but it is not trivial to the girl. She has a "date" for the evening and has her hair marcelled for which she has paid her good money, but when she takes her cap off the marcel is all out and her hair is smooth and she is unhappy and has worried about it all day. If you would only consider the girls, you would remember that the girls you have on the job are more interested in the "marriage market" than a market for the goods she is producing for you.

Of course, girls are always thinking about their appearance and you have no

use for the girl who comes to work without regard for how she appears. I agree with you that a marcel is not essential to a good punch press operator, but the good operator is the careful girl and she is going to be appreciative of any little consideration you may give her. May I ask how many of you require the girls to wear caps? Several of you. May I ask you to go back to your punch press departments with the idea that you are not going to insist upon the girls wearing caps unless they are needed.

One man told me his girls were wearing them because they always had. Of course, they always have, but it is no longer essential in certain new types of machinery.

Then comes the question of special clothing. May I ask once more for a showing of hands? How many of you require the girls to wear some kind of a work costume, overalls, coveralls, or any other special kind of working clothes? There are a number. That is very interesting but I cannot see the reason for it. It may be that I have not thought through things far enough but I have not seen the necessity of having girls wear a special uniform in the punch press department.

When I first studied the question of women in the punch press department I looked for data about accidents of women but I found nothing except this little pamphlet, "Industrial Accidents to Women," which is put out by the Women's Bureau of the Federal Department of Labor. The states included in it are New Jersey, Ohio and Wisconsin, but they do not separate the punch press from power driven machinery.

However, it states that three-quarters of all accidents affecting women occur in the manufacturing group. One-half of these are due to machinery. Forty per cent of all of the accidents are due to power working machinery. Sixty per cent of these accidents are in the upper extremities. Seventy-two per cent of those involve thumbs and fingers, and that shows where we come in as the punch press, I believe, is the worst of all. At least in a New York State report the punch press was quite the worst—I might say, by far the worst. The large majority of the accidents are in the power driven machinery and the accidents are usually in the upper extremities.

As we consider the accidents in the punch press, let us consider the cause of these accidents. According to this report, one cause is that the machine repeats. Let me ask you to go back home and put your foot on the treadle and see if your machines repeat. I know of one company that has a fine record with regard to safety but through a slight accident they discovered that many of their machines would repeat. It was the fault of the engineering department and the foreman that there was no repeating device on them and it was just luck that nothing serious happened. There are two other reasons; one is "the guard did not lower far enough." That is one of the most tragic things one could imagine. Think of the girl sitting down at the machine with that hazard, the guard that will not protect her. If we give her a guard why don't we adjust it properly?

We owe that to the girl. We teach her to use a guard but when it does not lower far enough it is of no use. It would be much better to sit her down there and tell her about the terrible machine, tell her she is liable to lose her fingers or hand but that there is nothing to do about it but be careful. If the guard is not what it should be, all the protection is removed.

As to the result of these punch press accidents, when a girl has lost some fingers she is limited in the kind of work she can do, just as a man is. Not only that, but there is also the social effect. You don't like to look at the hand of a woman who has lost one or two or three fingers. Even if it does not make you particularly sad remember there are many things around the house she cannot do, such as washing and other kinds of housework. In several cases the report mentions

that her husband has to help her with the work and that certainly ought to gain your sympathy.

Safety men say to keep the fingers away from the point of contact, that that is all there is to safety in the punch press department, to keep the fingers away from the point of contact when the power is on. How are you going to do it? You must build safety in the tool. I learned that from you. There are several ways you can put the piece in and take it out without the fingers coming within the point of contact. It can be fed in automatically, by dial, by mechanical slides, and tweezers.

A number of the people in the smaller shops are going to say, "We can't afford to put those things in." They feel they cannot afford the elaborate equipment, the elaborate slides and feeds, so it cannot be done because of costs. You can do what we have done, you can use tweezers. In taking the piece out we are using several methods, gravity, compressed air, knockout and tweezers.

No matter what the job is, except where we have the automatic or dial feeds, we require every girl, regardless of the kind of guards there are, to use tweezers, and that rule applies to the men as well.

May I interrupt to mention barrier guards. When I sat down in front of the machine I found it very difficult to feed the parts into the machine because I could not see as I should through the diagonal strips. When it is vertical, one can focus but with this bar one cannot see what is going on behind. I didn't like it. I am speaking from the viewpoint of the worker, when I say that if you have the vertical you can see easily but when you use the diagonal it is difficult to see.

As to tweezers, I have several here that have been broken by operators recently. We have swing guards and barrier guards, and take every precaution, yet these things happen and they happen right along, not only to the new girls but the old ones as well. This one was broken by a girl who has been working on a punch press machine for fifteen years.

Experience in the Employment of Tweezers

You are going to say that tweezers cost too much money, by slowing production, that you could not stand for anything like that. I am honestly convinced they do not.

We started using the tweezers about 1906, long before I came with the company. They tell me that when they gave the tweezers to the men for the heavy press work they had to increase the piece work rate about fifteen per cent in some cases and as high as twenty per cent in others, but they never increased the rates of the girls who worked on the small parts.

We have a young woman as an instructor who tells me that when they handed out the tweezers some years ago she and two other girls were the only ones who had not lost fingers. She has been an instructor fourteen years and she said not long ago, "Miss Stone, I am here to tell you that the day they take tweezers out of the punch press department, I am taking myself out." That girl supports her father and mother and she could not afford to be without work but that is the way she feels about it, she would not work there without them.

Recently we had the time study man make some observations. The pieces were removed by air and the girl used tweezers in feeding and it took her 3.46 minutes to run a hundred parts through. Then she fed by hand and produced a hundred in 3.40 minutes. There was six hundredths of a minute difference between feeding with tweezers and feeding by hand.

Then he made a series of tests with other piece parts and other machines because he felt there should be more difference and to prove if the tests had been conducted properly. Four tests were made and the results were as follows:

By hand	By tweezers
Minutes per 100 parts	Minutes per 100 parts
6.9	7.8
5.5	5.0
7.0	5.7
5.0	4.3

These are the actual figures and as you can see the tweezers caused no loss of time in three of the five tests. However, as a concession to your prejudice or inexperience of your operators, let me admit that they might slow production as much as 20 per cent. Based on this supposition, one of our cost men figured in making a standard part for the telephone the use of tweezers eliminated a hazard which presents itself 11,066,000 times a year, and the increase in the total cost of the part would be only six-tenths of one per cent.

You can't tell me that you can't get the people in the punch press department to use them or that it will affect your cost too much. That possible six-tenths of one per cent increase in the cost of production is no excuse for unsafe methods.

I would like to have you tell me later why you think women should not be employed in the punch press department. I know of a firm that had women in their punch press department but because there were a number of accidents they decided to take them off and put boys there. However, they found they did not do at all. The women were quicker with their fingers.

The woman is not naturally mechanical, she does not think she knows it all, so she is willing to follow instructions, much more so than men or boys. Because she is afraid of the machine, she is not going to try any short cuts.

Most of the women obey the rules, but occasionally you will find one who does not. We had a girl who must have had previous experience on a press because when she was given tweezers to feed the small parts, she held the guard back with her elbow and began feeding it with her fingers. Of course, she got into difficulty, lost her thumb nail; she was lucky that it was not her whole thumb or her hand. I can promise such disobedience is the exception among the women operators.

Usually when a new girl comes into our punch press department, it is half a day before she will allow the instructor to leave her. She will ask her to teach her for a couple of hours and then she will ask the instructor to sit beside her for another hour. These girls are too scared to try anything unusual and you know that would not be true of the men, the men would be trying all methods of feeding.

The girls are cheaper than men or even boys and I don't see why it is not to your advantage to put them in the punch press department and make it safe for them.

I will be glad to answer any questions you may wish to ask but don't ask too many as I may not be able to answer them.

CHAIRMAN HENNING: If there are any questions you would like to ask now is the time to do it.

THOMAS CRAIG (Irving Pitt Mfg. Co., Kansas City, Mo.): Is there any objection in asking women in the punch press department or any other department to wear a uniform, assuming that it relieves her of the financial burden of buying clothes to work in? I have in mind a large plant where there are a number of girls employed and we found that the clothing they were wearing was not suitable for work of any kind and therefore a uniform was adopted. I think this is decidedly to their advantage financially and it is much neater.

I would like to know if there is any objection to wearing a uniform.

MISS STONE: In my mind not at all. It is cheaper, much cheaper. They can be bought for five dollars or less and she could not get street clothes for that amount. There is no reason at all why the girls should not wear them, but

remember this, women don't want to look alike. You men try to dress alike. When you dress for the evening you all dress alike, but when a woman dresses up she wants to look different from any other woman in the room. If she happens to meet another woman with a dress just like her's, she would never wear that dress again.

H. J. PUTNAM (American Can Co.): I would like to hear what your policy is in shops where there are belts, what do they do about guarding the belts?

S. H. LIBBY (General Electric Co., Bloomfield, N. J.): I would like to say regarding the guarding of machinery and belts that we have had more trouble with our male help than with the female. The young fellows today have a bunch of hair up on the top of their heads that no girls would stand for at all. The boys and young fellows are the ones who are more liable to get caught than the girls, that is our experience.

MR. PUTNAM: We have had a good many accidents. We have had twice as many accidents in the kick press department than we have had in the power press, or power punches, and we have just about come to the conclusion that it is as efficient to work with presses number two.

CHAIRMAN HENNING: We did all we could to guard against accidents on kick presses, but still we had them, so we discarded the kick presses, replacing them with number one and two power presses, in this way we eliminated our accidents and in every case increased production. This is an actual fact.

C. W. SCHEITHING (Oxweld Acetylene Co., Newark, N. J.): We have a guard that we believe is the last word in efficiency. I have some pictures I am going to put up outside of this room and everyone can look at them. The pictures show you how it works. I can assure you it is very efficient.

MISS STONE: We may not be able to eliminate all of the noise but that feature does need attention. There are certain things which we should try to get rid of as quickly as possible. We have a new machine, whose production I do not recall, but I can tell you it makes no noise at all and there is no hazard at all.

HARRY MOODY (Rochester, N. Y.): I am not advertising anybody's business but we happened to find a little guard through a salesman and if there is anyone who would be interested I will be glad to tell him about it. This applies to foot presses and it is one of the best things I have ever seen. We happened to have a group of 35 foot presses in our particular plant and our experience was unfavorable. We attempted to do everything and finally we happened to learn of this device.

MR. PUTNAM: Miss Stone, you have not had any accidents for the past five years?

MISS STONE: No, except a girl who fainted, and one who was ill.

MR. PUTNAM: I would like to know how you do it. I don't know whether others have had the same experience or not. We have a number of operators and we think we have a good plant. Miss Stone has been in one of our plants, I know. I think our machines are well guarded, as well as we know how to guard them, but in spite of all that we have accidents and plenty of them and the question is, "What to do?"

CHAIRMAN HENNING: You are speaking of the punch press department?

MR. PUTNAM: Yes.

MISS STONE: I have been in your plant as you say, Mr. Putnam, and I have never seen more beautiful machines or machines better guarded, and I don't see why you should have accidents if you have your girls undergo a physical examination.

You may occasionally get a girl who is temperamental like the one I told you who nipped off her thumbnail. The girl who is trying to find short cuts all of the time is not the girl to have on a punch press machine; she tries too many tricks. Such a girl came to us some time ago and the foreman said, "That new

girl knows too many tricks, let's get rid of her." We did, and three weeks later she lost her hand in another factory on a punch press.

M. L. DANNELLS (Reynolds Spring Co., Jackson, Mich.): I would like to ask Miss Stone whether she thinks there are more accidents where there are boys and girls working together in the same department?

MISS STONE: I know of a plant that had a run of bad luck and they investigated and found that it was caused by the boys speaking to the girls. They had boys as inspectors and they found they were talking to the girls; so they made a rule that no man should speak to a girl while she was running a punch press and they have not had an accident this year as a result of that.

G. S. THOMPSON (Detroit): In walking through our plant I always touch an operator before I speak to him. It is just purely a matter of psychology. I go through the plant a number of times and sometimes I do not speak to anybody, but if I do want to I just touch him on the shoulder and in that way you have their attention and you put them in a receptive condition to transmit to them your instructions. As has been said we have had accidents where some man or some woman was speaking to another and distracted their attention and we stopped that, with the result that we have had very, very few accidents that can be traced to that cause.

S. F. WALTERS (General Electric Co., West Lynn, Mass.): I have to disagree with the gentleman who just spoke. There are some operators who, if you were to touch them while they are working, would jump and be frightened almost to death. When I am going to speak to an operator I hold out my hand to let them know I want their attention and then they stop the operation completely. We had an accident some time ago and we found it was caused by the girls discussing a dance that had taken place the night before. I investigated this case and found the cause; they did not have their attention on the work and the girl had a narrow escape.

MR. THOMPSON: I don't mean to come up behind them and hit them on the back and scare them to death. I mean to attract their attention to you, that you are going to speak to them. I go through the punch press department perhaps a number of times a week and sometimes I do not speak to anyone, but if I did want to speak to anyone I would get their attention first before attempting to talk to them. Our girls all stand, none of them are sitting down, but we allow them to rest occasionally. Our conditions may be a little different from others but I am firmly convinced that you should get the operator's attention before you attempt to speak to him and in that way you will save trouble and accidents.

MISS STONE: I was brought up on a farm and one of the first things I learned was this, that before going into the stall of the horse you should always speak to the animal before you put your hand on it, and I think that would apply to humans as well.

CHAIRMAN HENNING: I will say that is quite a come-back.

L. BORAKS (Liberty Mutual Insurance Co., Boston, Mass.): I think the rule that they have at the Western Electric Company is very good, where the men operators are not allowed to converse with the women during the working period. It is good if you can enforce it but I think that would be a very difficult thing to do. These boys and girls are mostly at an age where they are attracted to each other; it is a perfectly natural thing. A boy will be running a press and there will be a girl directly in back of him and he will turn to look at her, especially if she is attractive. This is natural and the boy will be looking at the girl in back of him or the one in front of him and that will take his mind off of his work and in that way he may lose a finger. I really believe it is a serious problem to have boys and girls working in the one plant, more especially so in the punch press department, where it is necessary to have the boys or men to

handle the heavier parts, the heavier work. On the foot presses we have the slide feed but on the power presses we have automatic and we have the standard guards.

On the foot presses the accidents are not as severe as they are with the power presses. The finger may be pinched and you may even lose a finger but there are not as many lost fingers with the foot presses and the accidents are not as severe.

CHAIRMAN HENNING: I think it would be the reverse sometimes.

MR. BORAKS: I think the quality of the work may not be maintained by the foot press operator, because about four o'clock in the afternoon the legs become weakened and they can't always keep the work high enough to get the impression of the form and the work is not then of the best quality, but I feel that the accidents are not greater and not as severe, that is sure.

H. L. BRIGHT (Standard Oil Company of New York): There are certain cases where there are no guards and it would be very dangerous to touch the operator but I think you can attract his attention without that, just let him know that you want to speak to him and this can be done without either touching or speaking to him.

WILLIAM J. CULLEN (Royal Indemnity Co.): With regard to the accidents that occur, I would like to know if the accidents are investigated as soon as they occur?

MR. PUTNAM: Yes, they were.

MR. CULLEN: It seems to me if you can ascertain the cause you can correct that and in that way reduce the accidents.

MR. PUTNAM: We did all that. We have guards and we have almost built fences around the machines to avoid these accidents. Sometimes it is because of carelessness but we have these guards. We have people in the American Can Company who do what they are supposed not to do and what are you going to do with them? There has been a marked improvement at times and then we feel we are getting somewhere when someone throws a monkey wrench in the machine and we have to start all over again.

ROBERT H. LUCKENBACH (E. G. Budd Mfg. Co., Philadelphia): May I ask the gentleman from the American Can Company what inspection you have of the guards; do you have a proper inspection of the guards in the departments where the accidents occur? We have a punch press department and we use tweezers like Miss Stone told you about and these tweezers show you what would have happened if they were not using them. We had an accident some time ago and we traced the cause of it and we found it was due to the carelessness of the supervisor of the department, we laid it right there.

We know that the operators must be instructed to use the tweezers and the guards, or whatever it might be, and we have a strict discipline. The operator who is found to be disobeying instructions is sent home for a day so he can think it over. This is hard on his pocketbook and it may seem very hard to many of you, but by doing this we feel we are saving the operators' fingers and hands.

I want to say to you right now there is not a punch press department that cannot be made safe and if there is I want to see it. I have been in charge of punch press departments and I know what I am talking about. The machines can be guarded, it can be done, but you have got to get behind it, you have got to have a follow-up system, an inspection, and you have got to keep after it.

If you do not keep after production it is going to go down and the same is true of safety. I think the answer to your problem is a follow-up system of inspection, put the efforts behind the safety department as you do behind production.

MR. PUTNAM: We are doing everything we can along that line. We prepare a report that goes out to every superintendent each month, but in spite of all

the precautions we are taking we still have accidents. I don't know the cause and I am getting discouraged.

There is nothing to do except keep after them. We have gone thoroughly into the matter of protection and discipline, and also supervision.

MR. WALTERS: We have certain rules which the foreman must follow. The foreman must look after the men, he must see that the equipment is right and he must clean up.

If there is an accident the foreman must report it then and there to the proper authorities, he must investigate the cause immediately and report it that morning or afternoon, whatever the case may be. In other words, the foreman does not say, "My God, another accident," and then investigate it some other time. We get after it right away because you have got the whole thing right there.

Just one hour before I left to come to this convention I had one of the foremen up on the carpet for failing to report an accident at the time he should have done so. He said the reason was because they were so far behind with the work; and I said, "I don't give a damn what you get out; follow your instructions as they come from the management."

MR. PUTNAM: We have a report of all accidents immediately.

MR. BORAKS: I would like to know how many accidents you have a month and compare that with the number of employees.

MR. PUTNAM: I could not give you the exact figures.

MR. BORAKS: You have to have the number of employees to tell whether your accident record is good or not and what you consider bad may be a good record for some of the rest of us. If you could just give us the approximate number.

I have been through a number of plants, including the Continental Can plant, which I think would be similar to the American Can plant, and I really would like to know the approximate number of employees and the number of accidents per month.

MR. PUTNAM: I could not tell you how many punch press operators we have but I should judge about 4,500 or perhaps 5,000, and we have perhaps two or three accidents and perhaps more.

MR. BORAKS: I would not call that a bad record. I am talking from a knowledge of the game, I have been in this business for sometime. There are a number of plants where there are only fifteen punch press machines and they have four to five accidents a year so I think the average of the American Can Company is very good. They have from 4,500 to 5,000 operators and only two or three accidents a month. When you consider the production of the American Can Company I would not be discouraged at all.

If they did not have the guards they would have, instead of two a month, two hundred. Yes, sir, the American Can Company has done a wonderful job, I think. Their machines are well guarded.

The Continental Can Company employs a large number and they have had the same difficulty. We are never able to entirely cut down the accidents because of the human element, the foolishness of the employees and the damn foolishness of some others are going to cause some accidents and I think we ought to compliment the American Can Company with its 4,500 operators for having only two or three accidents a month.

MR. PUTNAM: Instead of two or three a month it is apt to run up to five at times.

M. A. KROGER (General Motors Corporation, Detroit): We do not make a uniform product and I think the gentleman from the American Can Company has something to throw his chest out about. Just stop and consider the work.

It is just as the insurance man said, we must consider the human element and also consider what Dr. Harry Myers told us about supervision. The foreman must keep constantly after it.

MR. PUTNAM: I am not encouraging laziness but I think our record is poor compared with some others.

GEORGE P. DE MELLIER (Royal Indemnity Co.): It might be interesting to classify the accidents so we would know which were minor and which were major. It might also be interesting to know the number of men and women employed.

MISS STONE: We have about 300 employed in the punch press department; about 100 women and the balance men.

ROBERT H. LUCHENBACH (E. G. Bugg Mfg. Co., Philadelphia): There is also the question of noise in the shop as the cause of accident.

MR. PUTNAM: We were working on a Russian contract and we had some Russians as inspectors. One of them came to me and he looked like a Bolshevik to start with and he came into my office and said, "Mr. Putnam, I wish you would do something about the noise out there. I am afraid it will ruin my musical ear, I am a violinist."

MR. DE MELLIER: I would like to ask Miss Stone if the sweep guard is satisfactory or whether it sometimes causes injury to the arms? Have you had any trouble of that kind?

MISS STONE: No. The force of the sweep guard depends on the pressure on the treadle. The new girl is apt to put a good deal of pressure on the treadle, but the older operators do not. I used one of the machines and I nearly wore myself out I used so much energy that first day I worked on it.

The guard comes down and knocks the arm, and the operator pulls the hand away. It is sort of a reflex.

W. JOHNSON (The Hoover Co., North Canton, Ohio): I would like to ask your opinion of the sweep guard and the screen guard. I would like to know which guard you consider the better, which one is the more successful in preventing accidents and getting production at the same time?

I want you to consider the matter of injury and production in giving an answer.

MR. PUTNAM: I don't think there is any comparison between the two.

MR. PERRY (Dayton, Ohio): I will say we had a sweep guard on trial for three months and we threw it out. We asked the operators what they thought about it and every operator had the same kick. They are sweeping back and forth like that; I would not have one in the department.

MR. JOHNSON: I want to state my question a little more clearly. I referred to the sweep guard that sweeps the hand away and not the swinging gate, or the swinging guard, but the hand sweeper guard; that is the one I refer to.

MR. PERRY: The one that travels in front of a man's eyes?

MR. JOHNSON: Yes, that is the one I mean.

MR. PERRY: There is a home-made one and also a manufactured type on the market.

MR. JOHNSON: Either the standard manufactured guard or the home-made one, it does not make any difference what kind. The guard I want to know about is the sweep guard, that sweeps the hand away when the press comes down, whether that guard is more successful.

MR. KROGER: There is a guard in the exhibition but I think the sweep guard is being condemned all over the country because too many hands and fingers are being lost as a result of its use due to the fact of improper adjustment.

Hands and wrists have been broken in making the sweep. Sometimes the set-up man will neglect to adjust it properly. Due to the desire for production the operator will try to work around it. The sweep can be adjusted so it will not cover the front in one place.

I have had some experience with this having lost a finger in the guard and I think it is a bluff. The guard in itself is meant to do a lot of good but if it

strikes the wristbone in the proper place, with a quick, short stroke, somebody is going to be injured. It does not feel very sweet I can tell you.

MR. BORAKS: I think that is an important question. Many people are prejudiced against a certain guard and I think the question should be, before you get a guard, whether it is adapted to your particular work and the sweep guard would not do where the work has to be held while the press is being operated. In a case like that the sweep guard would not be any good, it is going to damage the man's hand.

You must find out whether you can use the sweep guard at all and then I venture to say that you could only use it a certain percentage of the time. There are a great many operations where the sweep guard is not adaptable, but I can't see where the sweep guard is any worse than any other guards of the standard type.

If you hold the piece, what guard is there that will cover all of the work that you are doing? I don't know of any.

There is the gate guard that comes down and covers the work before you begin the press and that has its limitations the same way. I think if the gentleman wants advice on the subject he had better apply to one of the Advisory Board—not because I am a member—but if he will state his conditions to one of the members of the Advisory Board, they may be able to advise you as to the right kind of a guard for your particular operation. There are several members and they will be glad to help you.

MR. DE MELLIER: After our experience with the sweep guard we have been instructed to discontinue to recommend it.

MR. JOHNSON: We are using all of these things and my idea was to get an exchange of ideas in the hopes that we might get something that would be better, that would be more successful. I am interested in buying something that you will tell me is successful, that was the idea of the question.

I looked over the photographs outside and I was trying to decide on something that is better than we have in the plant. I think that is well worth time and I think this exchange of ideas is well worth time; in that way we can put in something in our plant that is working successfully in some other fellow's plant.

CHAIRMAN HENNING: If you have any more questions I would suggest that you keep them until Thursday when there will be further discussion of this subject.

I think we should express our thanks to Miss Stone for coming here and I would like you to give her a rising vote of thanks.

(Rising vote of thanks given to Miss Stone.)

CHAIRMAN HENNING: We will now hear from Mr. A. L. Kaems, of the Simmons Company.

Discussion of Punch Press Guarding

By A. L. KAEMS

Safety Engineer, Simmons Company, Kenosha, Wis.

I will take up your time for just a few minutes. I am going to talk to you about the small plant. I am not interested in the American Can Company or the General Electric Company or any other large plant. I want to tell my friend from the American Can Company with his five thousand presses that he has nothing to kick about.

We just heard a great deal about the different guards. Now I want to make myself clear about this. We have heard about the sweep guard and all of the others and I want to tell you that I sold guards for twenty-five years and I sold

the best guards that were on the market and when I put the guards in a plant I would have to sit back and wait for the letters to come in telling me that the guards were not working out as they should.

Now take the sweep guard for a left handed man and what happens? He knows how to run it left handed and he goes about it that way and he tries to get around the guard.

I know of a case where a man invented a guard and spent a lot of money on it, and a girl used it and she lost four fingers; the press repeated, and so it goes. We have some good guards that are being made today but we also find people who will find a way to work around them.

As I told you, I helped sell all of these guards and then I came to the conclusion that it was all wrong, because there were accidents no matter what kind of a guard you had. You will continue to have them as long as the man can put his hand in the danger zone.

Take the railroads, they have invented everything; they have put up gates at the railroad crossings, and yet there are accidents because people will go under the gates; and it is just the same with us, we will never stop punch press accidents as long as we must use them.

After giving up the selling of guards I started out along a different line and we have been successful. I went to different plants and worked this thing out. I am with the Simmons Company and we have 700 presses, and if the Good Lord does not throw a wrench into the works we will be able to say at the end of this year that we have not lost a finger since 1919 in our punch press department.

We have not done anything except to just take care. We have just used "horse sense" in our business; that is how we get by. Now to show you how easy it is. You heard Dr. Myers talk about efficiency and equipment; that is all you need, but it is sometimes hard to get. We have to consider the tool maker, and personally I think he is a wonderful fellow. The tool maker must have the imagination to do things, and it is so hard to come to them and tell them what you want as so many times they resent it, because the man feels it is his business and he don't want anybody to monkey with it.

That was the trouble in the beginning. I am going to show you a few little things. Here is a little thing I want to show you. The man had to put his fingers right here where the punch came down and I said "Why don't you slide it in?" and he said "It can't be done." I have a sign in my office which says "It Can Be Done." When this man said to me "You can't do it, Mr. Kaems;" I said to him, "Well, think it over tonight and come back in the morning and tell me whether you think it can be done or not." In the meantime I kept on thinking it could be done and when he came back in the morning and said "It can't be done," I pointed to the sign "It Can Be Done." He said "Well, Mr. Kaems, that may work sometimes but not this time." Then I showed him how it could be done and he has not said since that time "It can't be done."

My wife tells me sometimes that I swear but I tell her I don't. I want to tell you that we have not fallen down yet but we have come damned near it several times. You can see that you can slide it in like this just as easily as can be. I had something in mind about this. I knew it would have to jump this opening and I thought of skis. When a man comes down on his skis he does not land on the snow. Oh, no, they have a platform to allow him to jump, and then they have a slide, and they raise the front of the slide—so that is the way I did it. It is just as easy as rolling off a log. This man I speak of, when he saw that, said "I will never say a thing can't be done again."

We had a job where the man had to lay the part on so that his fingers were always in the danger zone, and I said "Turn the job around." They said "How

are you going to locate it?" I measured it and found the widest part and slid it in this way. Here is another job where the man can slide it in, like this. That material costs about sixty-five cents and it increased the production one hundred per cent.

We have gone on from one job to another. Here was a job where they were making parts for automobiles and the way they did was to put it in one way and take it out the other way. There was an accident, a boy was hurt and the superintendent said it was the boy's fault; he started to run the press and in an hour and a half he met with the very same accident that the boy had.

I was sent there to look up the accident and when I was asked if I could make it safe I said I would try. I took the two pieces home with me and Sunday morning I sat down and figured it out. My wife said, "What have you got there? You are working all week and then you come home and work on Sunday too."

I turned it half way around and cut the end here. Now the gage pin comes up here and the man said, "You can't work it because of that pin." I said "That is how I am going to work it." I put it in like this and when the piece was finished it came out like this. I ran the gage pin from the top down and not the bottom up. When he saw it he jumped up and down and said, "You got it, you got it."

We have equipped every one of our presses with slides, and the accidents on the presses were decreased. You will say "Oh, that is for the big plant, they can afford to do it; we can't do it."

So many people forget the little things that are right under their hands. These things can be done in the small plant where only 10 to 50 presses are employed and where there are a number of operations a day. Everything is ideal and all the man has to do is set it up. If you do this you will stop punch press accidents. If you tell your troubles to one another and talk these things over you will get results just as we have in our plant.

CHAIRMAN HENNING: Has anyone any question to ask Mr. Kaems? I think that is the answer for the small plant. That little piece came from our own plant. We don't make it any more in one operation, we do it automatically now and they are turned out by the millions. Mr. Kaems, I believe you have another matter which you wish to bring up at this time.

Resolution on a Departed Member

MR. KAEMS: It is willed that one of our co-workers whom I have known for twenty-five years, one of the hardest working men in this work I ever knew, an old punch press operator who had lost a finger himself, has passed from us. He gave the greatest of assistance in the work although he never took a very active part.

I therefore, move you that we pass a resolution regretting the death of our friend Herman Schwab, and that his widow be notified of this and that this resolution be spread upon the minutes.

To the members of the Power Press Section in Session.
Greetings:

In as much as it has pleased almighty God, the ruler of all things, in His wise providence, to take from our midst our beloved member, Herman Schwab, who passed from this life on September 3, 1928, a man who labored faithfully and won the friendship and esteem of the members of this division.

Be it Resolved, That we pay tribute to his memory by pausing in our deliberations and stand silent for one minute; and

Be it Further Resolved, That a copy of these resolutions be forwarded to his widow; and

Be it Resolved, That a copy of these resolutions be spread upon the minutes of this section.

Signed:

John Henning
Theo. Meisner
August Kaems
G. S. Thompson.

(The members arose and stood in silence for one minute.)

ADJOURNMENT

October 3, 1928**J. W. HENNING, Chairman****Assistant Superintendent, Personnel and Operations, Automatic Electric Company, Chicago**

The third session of the Power Press Section was called to order at 10 o'clock by the chairman, Mr. J. W. Henning.

CHAIRMAN HENNING: The first order of business this morning will be the Report of the Nominating Committee, Mr. Meisner, chairman.

Report of the Nominating Committee

T. O. Meisner (American Can Co., Maywood, Ill.): The report of your Nominating Committee has been prepared, as follows:

Chairman, J. B. Gibson, Western Electric Company, Inc., Chicago, Ill.

Vice-Chairman in Charge of News-Letter and Publicity, S. H. Slaymaker, Fairbanks, Morse & Company, Beloit, Wis.

Vice-Chairman in Charge of Program, R. G. Marter, National Enameling and Stamping Company, Milwaukee, Wis.

Secretary, C. H. Gerding, Western Electric Company, Inc., Chicago, Ill.

Chairman Exhibit Committee, W. J. Larson, Clum Manufacturing Company, Milwaukee, Wis.

Chairman Engineering Committee, T. O. Meisner, American Can Company, Maywood, Ill.

Chairman Slide Committee, F. J. Mares, Perfection Stove Company, Cleveland, Ohio.

Chairman Statistics Committee, J. E. Walters, General Electric Company, West Lynn, Mass.

Chairman Poster Committee, M. A. Kroger, Chevrolet Forge Division, General Motors Corporation, Detroit, Mich.

Chairman Membership Committee, J. C. MacLagan, J. H. Williams & Company, Buffalo, N. Y.

Executive Committee, The Officers and—

Louis Boraks, Liberty Mutual Insurance Company, Boston, Mass.

W. J. Graves, Michigan Mutual Liability Company, Detroit, Mich.

A. L. Kaems, Simmons Company, Kenosha, Wis.

J. W. Henning, Automatic Electric Company, Chicago, Ill.

E. Roth, Aetna Life Insurance Company, Hartford, Conn.

G. S. Thompson, Detroit Insurance Agency, Detroit, Mich.

G. A. Kuechenmeister, Dominion Forge and Stamping Company, Ltd., Walkerville, Ont., Canada.

J. E. Rockoff, Detroit Steel Products Company, Detroit, Mich.

CHAIRMAN HENNING: Gentlemen, what is your pleasure with regard to this report?

R. W. NEWCOMB (Brewer Tettehener Corporation): I move the Report of the Nominating Committee be accepted.

(Motion seconded and carried.)

CHAIRMAN HENNING: This is the Drop Forge Meeting. I don't know anything about it, so I am going to turn the meeting over to Mr. G. A. Kuechenmeister, personnel manager, Dominion Forge and Stamping Co., Walkerville, Ontario, Canada, who knows all about it.

CHAIRMAN KUECHENMEISTER: I heard a story the other day, that an optimist is a man going out to play golf, and a pessimist is the same man coming back.

Your chairman says I know all about this subject, but perhaps after the meeting you will not agree with him. We want some very frank, free discussion of our problems, and I think it would be a good idea to have a list of all of the companies represented at this meeting.

(Twenty-four companies were represented.)

Most of the companies represented here have a drop forge department connected with them.

This program seems to have been inverted; the paper appears last and the discussion first. I think we should have the paper first and have that lead up to the discussion, so I am going to ask Mr. Rice to present his paper at this time. Mr. Rice will talk on the subject, "The Growth of Safety in the Drop Forge Industry." It is my pleasure to introduce to you Mr. Rice.

The Growth of Safety in the Drop Forge Industry

By L. M. RICE

District Chief Engineer, Liberty Mutual Insurance Company, Chicago

With many of us, boyhood memories can recall the old village blacksmith shop and with all the romance of youth we saw the smithy develop a horse-shoe or a part of a wagon chassis and listen to his anvil music, but I never did learn why a blacksmith must draw a few musical notes from the anvil with his hammer before directing his striker where he was to hit the forging with the sledge hammer.

In later years when we came into the developing of safe practices and safe equipment, along with the increasing demand for heavy forgings and mass production, some of the early song seemed to take on discordant notes as we recall the somewhat dilapidated wooden shack with stacks of worn out horse-shoes piled in various places, old carriages and wagons in various stages of junk scattered around the yard. The old wrought iron anvil, the huge leather bellows, the open fire built in a stone and brick forge, minus in many cases a stack, for it would not be a blacksmith shop if we did not have some means of clouding the natural light so that the smithy could better judge his temperatures, at least that was what our heat treaters used to tell us.

From this setting we have stepped over a period of years to that of the modern forge plant with its fireproof building, high, roomy and with all the light good building design can provide, equipment for the removal of waste heat, exhaustion of smoke and gases, with forge fires enclosed in furnaces and mechanical means provided for loading the furnaces and ejecting the heated stock. When the stock is heavy we find mechanical means for conveying the stock from the furnace to the forge. The old anvil is gone and in its place we have dies and drop hammers.

The dark and dingy shop where the smithy had developed heat color skill in the tempering of his product is no longer a necessity in the heat treating, for our modern heat engineer depends not upon color, but rather upon the metal content specifications, time and pyrometer readings, and we find very little variation in his results.

It is not so many years ago that the forging of a piece of metal of a few hundred pounds was a rather difficult problem due to limited fire capacity and handling facilities, and frequently a lack of men skilled in the production of that class of work. Today, this has been made comparatively simple and easy with our improved equipment.

Our changing economic factors; such as the increasing value of human labor, the changes in modern business methods from the old custom of waiting for

orders to come in and then attempting to fill a requisition for which suitable equipment was not available to the present method of confining ourselves to a product for which the plant is especially equipped, at the same time anticipating the next year's output and going along without excessive pay roll change. The increasing development of mass production, along with various other factors in the trend of changing business methods, has made this change in our forge shop of today, and undoubtedly others will follow in rapid succession as the stimulus of competition urges us on.

With all of these changes potential accident hazards have materially increased, due to the demand for quantity production, heavier stock, heavier equipment, increased shop traffic, the disposition of gases, waste heat and the like.

The span of a comparatively few years has shown a tendency to specialize the industry into product groups, each with its special equipment and each with its process hazards.

Our state and national casualty rating bureaus, under the supervision of the various state insurance commissioners, recognize some twelve or fourteen forging groups so recognized by reason of their special equipment, processes, raw stock and finished product.

The actuarial experience of the various states indicates the accident losses of the heavy or general forging group to be approximately three or four times as serious as that of the light forging groups such as Razor and File manufacturing, depending upon the liberality of the respective compensation acts. Drop Forged Tools follow that of general forging in seriousness with our friend the blacksmith trailing third with the hazards dropping off along the line down to the Razor and File groups, which have the best experience.

It is evident that the general forging division of this group requires the safety engineer's most serious attention, both from the viewpoint of safe practices and safety engineering revision.

The struggle for quality and quantity production has induced the development of both heavy and expensive equipment, which in turn follows with a difficult repair and handling problem because of the weight and severe usage. The investment in the equipment and the loss of use during repair periods rather militates to the advantage of the safety engineer because the production division is more than anxious to make the equipment such that there will be a minimum of breaks in production due to loss of use either of equipment through mechanical failure or man power because of accidents.

Housekeeping

We have all learned long ago that an orderly house is essential to both safety and production and this is particularly true in a forge shop. So it follows that we find our modern shops bending every effort to keep stock moving in a continuous direction toward the final operations with as little handling and parking as possible, likewise keeping the waste cleaned up as that tends to slow up traffic. So we find use being made of buckets and portable stock trestles that can be quickly picked up by the crane or tractor and conveyed to the next location. Automatically this aids in reducing the handling material accidents to both fingers and feet.

Dies

Our old accident records seem to indicate that eye injuries were more prevalent in the die shop than in the forge because of chips and hot metal

burns. The answer to this is goggles and where the goggle idea has been sold and enforced, we have very few cases.

Provision should be made in the die shop for handling the dies, such as holes in the sides for lifting irons, as the weight and shape of the dies are difficult to handle otherwise.

The old system of trucks, rollers, bars, etc., used in setting dies brought the safety man a lot of grief. With the aid of hoists, monorail systems and in some cases a special tractor with provision to set or remove the die in or from the block, both time and accidents have been saved.

Die keys should be carefully selected as improper stock, improper heat treatment means grief. We recall an eye case recently caused by a sliver from a key while the key was being driven to position. Had goggles been worn the eye would not have been lost. It has been a problem to determine just what sort of stock is best adapted or even the proper heat treatment for die keys to stop the cracking, splintering, upsetting or mushrooming that the die key is subject to. Improvement in the selection of stock and heat treatment has helped, but not completely cured the causes. It, therefore, follows that we should make use of goggles as an added precaution.

The die setter should be responsible for seeing that the keys do not project out so far that they will cause injury to the operators. In key setting dies we have gone from the sledge to the dolly bar and sleeve and in some cases the pneumatic ram. Their use, of course, depends upon the circumstances under which they are to be used, some find a preference to the dolly bar with all of its unsatisfactory features, while others are able to get better results from the pneumatic ram, both from a standpoint of efficiency and safety.

Die Storage

Do not neglect the die storage either in the piling of heavy dies or the shelving of small dies. We get a serious accident frequently when the piling is made on unstable ground or where the shelving collapses from overload. It is so easy to overload that it happens before we realize it and while checking shelving see that protection is afforded against dies falling off the shelves on someone's toes.

Operating Methods

From the old practice where the blacksmith was a forger and wood worker, as the case might be, competition has made us specialists. Each of us is now limited to certain operations even in the development of a forging and if we hope to get the most out of a job we find it necessary to develop and adopt methods of operation that not only save material handling, but protect our equipment against breakdowns and above all protect the men from possible injuries.

Rules

General rules of operation are all right in a general way, but to obtain the least friction and the best results, departures and additions must be worked out. If we help the operators protect themselves and get the most out of their time, for after all the operator is a part of our organization, and if we are efficient we are going to draw out his best ideas and sell him on the best methods suggested, if we hope for efficiency.

There are few rules that in general apply to most forge shops such as:

- (A) Before starting work make an inspection of the equipment and make sure everything is in order.

- (B) See that the dies are warmed up before using. You may save broken dies with the subsequent loss of use, and time along with the attendant die changing hazard.
- (C) Provide scale guards and use them.
- (D) Before adjusting scale blowing lines, be sure that the hammer is not in motion and the ram blocked.
- (E) Provide long enough handles on the swabs used in swabbing dies so that the hands of the operator do not get under the dies.
- (F) All stock flash and other extraneous material should be cleared away so that it will not interfere with the treadle or make stumbling hazards.

It is not so long ago that we were experiencing a number of serious accidents by men cleaning scale from dies with a piece of cloth or short handled brush, but I think we are well away from this practice now. If some of us are not we should be, for if practice is continued it means amputations sooner or later.

On the smaller forging jobs we have some of the hazards of men getting their hands under the ram, but it is not nearly as frequently as that of cold work chiefly because the stock is too hot to handle with the hands and tongs must be substituted, and where long handled tongs are used we find less cases than where short handled tongs are employed.

Both types of equipment call for constant safety engineering revision, some more or less general and some special, as for instance, many operators of a few years experience have seen pulleys come off the machine and go on a trip down the shop and in many instances causing serious injury. This can be prevented by use of a suitable guard that will retain the wanderer even if the shaft breaks off.

Then there are other potential hazards that go along with special equipment or peculiar shop practices that exist because of the layout or special process hazards. This is where a good plant engineer and the safety man can work together and eliminate the hazard not common to average circumstances and it seems that most shops have some of these.

Safety Shoes

Like nearly every other safety device, we must first show why they are an advantage. Two shops that I have in mind made accident analyses of their cases and the committee through their inspector and ex-committee men made it a point for a few months to point out what safety shoes would likely have accomplished in each case and found volunteers to start wearing them and now they are being generally worn and it is having a material effect on the lost time cases.

Goggles

Goggles are almost invariably a contested safety device with the result that some shops require that they be worn by nearly every operator, some on special jobs and others not at all. They are without doubt necessary if we hope to save eyes. Some processes are such that eyes are frequently destroyed unless goggles are worn and on others at long intervals. Only a few days ago a blacksmith was holding a hammering tool for a striker when a scale on the center of the hammering tool flew and took an eye out for the blacksmith. This scale was not due to a mushroom head for they do not use that kind of tools, but was caused by the metal scaling under the blow. Goggles would have saved his eye.

Furnaces

Heat very naturally becomes a factor in the forge shop. Radiation of heat from the furnaces and stock in process is apt to become a problem that affects production and induces accidents during the hot season.

Some shops have reduced this factor so that they are not seriously troubled by providing suitable buildings, making use of water screens, chain screens and by the use of charging and ejecting rams and supplementing these with either blower fans or exhaust fans and at the same time keeping the stock moving, thereby eliminating radiation heat from the stock.

Furnaces are sometimes insulated to check radiation, other times by simply using sheet metal where space permits and let the air space hold the heat so that it can go upwards.

The transition from the old open forge fire to the modern oil or gas forge furnace has led us over a trail marked with numerous serious accidents, much of which has been overcome with improved burning devices and education in handling, but we are by no means at the fool-proof stage. If we neglect a safe ignition formula, such as seeing to it that the furnace doors are open, the use of long torch rods, the admission of oil and air in proper quantities and the wearing of goggles, we are sure to come to grief from unexpected flare backs even if we do not wreck the furnace.

It is not presumed that we can cover more than the high spots of all the various phases of the forging process that make accident combinations, but rather to give us a talking start on what can be done to improve our present devices and working practices, and develop ideas for better and improved engineering revision, such as aids in handling stock in process, improved devices on our equipment and the like.

Having done all these, if we have not made arrangements to foster the safety spirit, our accidents will continue and we will lag behind in the safety movement. Some sort of an organization is absolutely necessary; now that may take on the standard form used by casualty bureau standards or it may depart somewhat to conditions that fit a specific plant. You may have a safety inspector who makes the men his co-workers, it may be a small committee of the foremen and it may be the boss likes to make his foremen one committee and have a faculty of keying those foremen up so that they are alert to accident prevention. In any event, they must know all of the details of the accidents and give those accidents enough time and thought to know how to stop them and if this is done you will eliminate your cases, at least you will find yourselves in the front ranks of your contemporaries who have few accidents. But you cannot do it if your reports read—Cause?—Carelessness. There is a cause for every accident.

CHAIRMAN KUECHENMEISTER: Mr. Rice is one of the few speakers who present the subject as he was asked to do it. Very often a subject is assigned to a speaker and he gets up and goes off on a tangent, but I think you will agree with me that Mr. Rice has presented the subject as he was asked to do, and I also think you will agree with me that there is enough material in that paper for us to discuss for a week.

Now, the only difference between the three men who are scheduled to give five minute talks and the rest of you is that they knew they were going to be called upon. We are going to call on them first and then if you do not enter into this discussion I have the names of the companies represented and I am going to call on you to discuss this paper and we will stay here as long as there is anything to discuss.

Discussion by Mr. E. J. Wallman

E. J. WALLMAN (Safety Engineer, Great Lakes Forge Co., Chicago): We have all the problems that Mr. Rice has mentioned. You know that the drop forge department is one of the dirtiest you can mention, and for that reason, I suppose, as well as many others, we do not at the present time always get the type of man we could desire, the type of man who knows how to take care of himself.

As Mr. Rice said, the production today is increasing so rapidly that we have not been able to take the proper steps in safety work, or probably have not been able to keep up to production in the safety work.

The drop forge hammer and drop forging is one of the hardest things to guard. You can use pulley guards and belt guards and guards of different types, but you can't find any way to guard the work in the zone of the hammer and still do your work.

About four or five years ago we were in a rut at our plant. The production was increasing rapidly. In 1920 and 1921 the production was not so much, but 1923 and 1924 went off with a bang and we were unprepared to handle it. We had the same old type machines that we had had in 1920 and 1921. These machines had been used during the war and our company was in a rut in 1924. We had more accidents in 1924 and 1925 than we intend to have for the next five years.

The company, when they got the figures, said we would have to do something about it. I had been with the company for some time and I did not know anything about safety. I got some literature from the National Safety Council (of which we were not members at that time) and the subject was brought before the company and we decided there was only one thing to do, and that was join the National Safety Council; which we did.

I knew Mr. Kuechenmeister was doing a great deal of safety work in his plant and I got the fundamental principles from him; and since that time we have made rapid strides in getting ourselves where the rest of the live industries are in the matter of safety.

The first thing we had to do was to properly equip the plant and the next thing was to organize the foremen. We told the foremen that they were responsible for the accidents that happened in their departments. One of our first steps, and one which I consider the greatest of all, was the universal wearing of goggles.

I believe it was in 1923 that we went out and bought ourselves a lot of goggles and gave them to each one of the men. Everyone had goggles but that did not mean anything and then an accident happened. It happened to one of our best men we had in the drop forge department, a young fellow about 28 years of age. He was working at night; he went to use 110 pounds of compressed air and the compressor was turned on and you know what happened, the hose ripped one man's eye out.

We said at that time, "This will never do"; and I believe it was at that time I got in touch with Mr. Kuechenmeister and he said they were using goggles. This particular drop forge man had his goggles in his pocket so we decided to fix a certain date and put a notice up on the Bulletin Board telling the men they must have their goggles fitted and from that time every man had to wear his goggles, no matter who he was, from the president of the company to the milkman who delivers milk to the plant. They all have to wear goggles when they come into the plant.

Of course, we have done a few other things along this line and one of them is the matter of throwing the belts off. They say that "Necessity is the mother of invention." You know how it is when they are throwing belts off. A man would get up there with a big bar and he would throw the belt off. Sometimes it would go off and sometimes it wouldn't and one day the belt did not come off and the

man used a hammer in pushing the belt and it was a lucky thing that he was not hurt, but nevertheless it might have been serious; so we kept thinking about it, this throwing off of the belts. The man would shove them off with the bar and then a belt man of ours thought of this idea and it not only saves time in throwing off the belt but also saves the contact point and we do not have accidents.

(Mr. Wallman here described a belt remover.)

We have had accidents and I suppose we will continue to have some but there are several things, we find, that have helped. We do not trim the forgings cold, we trim them hot, and if you do that you will not have the punch press accidents. We do not make the forgings one at a time and in that way the man does not have to get his hand in the danger zone. That has eliminated most of our punch press accidents.

As Mr. Rice said, the accidents are mostly in the die shop, but we find they have decreased considerably since we have worn the goggles. About 80 per cent of our accidents were in the die shop, but now the tables are turned and there are only about ten or twenty per cent. It takes so much high pressure air to blow the scale off that it comes hot, and even if the man has goggles on, sometimes they do not fit as they should and the scale enters behind the goggles. I think that's all.

CHAIRMAN KUECHENMEISTER: There is one thing Mr. Wallman spoke about that I wish we had put more emphasis on and that is the belt remover, because I know something about that belt remover.

There are three terms used in civil government that we might very well use in our work—Mal-feasance, Mis-feasance and Non-feasance. Mal-feasance means doing a wrong thing; Mis-feasance, doing a thing in the wrong way; Non-feasance, not doing the thing that ought to be done.

We had an accident a short time ago and a man suffered a severe dislocation of an ankle. He was injured in throwing the belt off and I considered myself at fault because I did not do the thing I should have done. One year ago I heard of this development of Mr. Wallman's. He showed it to me at the convention and gave me the blue-print and I showed it to the superintendent and he said it was a mighty good thing and we talked it over with the foreman; but they all said, "That is all right for some one else but we never have anyone but an experienced man throw off belts and there is not a possibility of an accident."

A month ago a green man did it and suffered this dislocation, and I believe it is my fault that that man was hurt. I did not fight to have the belt remover used; but I started to fight after that. I wrote to Mr. Wallman—not to send me the blue-prints, but to send me the belt remover, and I got it. I gave it to the foreman and said it was to be used, that a man had been hurt and I felt responsible for it because I had not fought for it a year sooner. I said, "I wanted this used a year ago and you told me that nobody but an experienced man ever removed the belt, but here was this accident a month ago, and I consider it was my fault because I did not fight." The men are using the belt remover and I want to say right here that you will save yourself a lot of grief by using it. I know what I have gone through this past month and you will save yourself that if you will get the belt remover and make them use it. It will prevent accidents. Mr. Kroger is the next speaker.

Discussion by Mr. Kroger

M. A. KROGER (Safety Engineer, Chevrolet Forge Division, General Motors Corporation, Detroit): When I received the request some time ago to speak for five minutes on this subject, I thought how impossible it would be to discuss this subject in five minutes.

You have heard what Mr. Wallman has said; he has told you about the belt remover and several other things about safety; but when I received this request

I began to think of a five minute talk and it seemed like a very limited time to me for this subject. I realize you want to be fair in the matter, but I am from a large drop forge shop and I feel I could tell you very little about what we are doing in five minutes.

But I do want to tell you men who follow the drop forge racket—we will call it that instead of game—in the fifteen years of time that I have spent in the drop forge work, I have seen men come and I have seen men go.

In 1926 we had a very, very interesting talk in the Power Press Section on the education of our employees and we got them to go along this line for the Drop Forge men. We had no Drop Forge Section and we kept pounding and hammering and last year the Drop Forge sessions were started.

Drop Forging had been overlooked for so long and it is one of the oldest in the industrial game. It originated with the blacksmith shop, but it has been almost entirely overlooked by the National Safety Council.

As I have said, I listened to an address several years ago that interested me very much. I don't remember who gave the address but it was about educating the employees and I went back to the plant and immediately undertook this educational plan.

You know how the old journeyman used to do his work, I think we have a wonderful opportunity to do educational work; and there is no better place to start than in the employment office. We have the different classifications; the hammer man, the man for the heat treating and the die room and one thing we have got to consider is the question of labor turnover. A man comes to the employment office and is asked where he worked before; and he says, "The Blank Company, I worked there for two or three years and it is a wonderful shop." He is employed and sent into the shop.

Now the way I think you should do is to take the man and instruct him in the way you want things done. It is not a hard job, take him right from the employment office. The fact that I am trying to emphasize is that if this can be done in the biggest drop forge shop in the world it can surely be done in the others. We work with the individual employee and if we can do it, why can't the smaller shops do it?

Many of you have in mind that you cannot do this because you have not the time and the equipment to educate men, when you have hammer men, drop forge men and others; but I say to you that without a possibility of doubt you can accomplish this. Regardless of the number of hammers and the amount of labor turnover I still maintain that it can be done, it has been done and it will be done.

CHAIRMAN KUECHENMEISTER: Mr. Kroger has brought another angle in his discussion and I think he is perfectly right. You can instruct the men in the drop forge shop, probably more so than in some other sections, because of the apparently few classifications of men that you have. I know what Mr. Kroger is doing at his shop. I know the size of his shop and I know that if he can do it the smaller shops should be able to do it also.

The next man in this discussion is Mr. J. C. MacLagan.

Discussion by Mr. MacLagan

J. C. MACLAGAN (Director of Personnel, J. H. Williams and Company, Buffalo): It is a most encouraging thing this morning to see so many drop forge men here at this session. I think there are more here this morning than there were last year. Drop Forge sessions are young and we have got to grow, but it is encouraging to see that we are making progress.

I would like to tell you a story first before I go on with my discussion, as I think it applies to our attendance at these sessions. Some people went to visit a wonderful garden and they picked up some of the seeds and placed them in their pockets

and when they got home they planted them and got beautiful plants in their own yards. Now would it not be possible at this convention to gather the seeds that the various speakers give us and place them in our pockets and then at some future day they may bear fruit and help us with the work that we are doing?

We have come here this morning to listen to the speeches and exchange ideas, but I wonder how many of you men are going back home to use the things you have heard discussed? Do you get some neighbor or some man whom you consider as a competitor to come into your office and check up with him what he is doing about the things that are troubling you?

We have had some troubles and I have talked to other men and find they have, too. We have had trouble with pins falling; so we have developed a screen which fits over the operator's head and extends back to the wall. This can be opened at the top, it is placed on hinges so that the man can open it when he has to make any repairs, he can push it out of the way. We have had some of these made and it is just in the experimental stage at the present time. We don't know whether it is going to work or not; but we have had this trouble and in the discussion I would like to know if any others have had this trouble and how you are handling it. I think everything has been interesting this morning and I am in hopes we will have a great deal of discussion.

CHAIRMAN KUECHENMEISTER: Now before I throw this open for general discussion I want to tell you something that happened recently. A man was using tongs and the tongs kicked back and struck him in the abdomen, and the only reason that he is alive today is that the end of miracles has not come yet. At first the doctors thought he would not survive until morning but he is alive today, after having had peritonitis and pneumonia.

We got the story of the accident and some of the fellows said, "He was a damned fool, all he had to do was to stand to one side and it would not have happened." After we investigated the matter we found the true story to be this:

The foreman in charge of making tools for the upsetters told one of his men to make a hollow punch by beginning with a $2\frac{1}{2}$ inch diameter and taper it at a 7 degree angle. When the tool was almost completed the workman realized he was not coming out right and spoke to the foreman. It was then discovered that the diameter should have been $1\frac{3}{4}$ inches instead of $2\frac{1}{2}$.

The punch was laid aside and a new one begun. The foreman in charge of the upsetters needed the tool badly, so after discussing the matter with the tool room foreman they decided that the mistake would not ruin the hollow punch and that because of the large hole a vent hole was not needed.

The tool was put into the machine and soon after a forging stuck in the punch. Just as a helper was about to tap the stuck forging with a sledge to loosen it, it shot out of the punch and drove the end of the tongs into the operator's abdomen.

None of the foremen believed it possible to get enough compression in the hollow punch to cause the accident, but after trying out a few more forgings it was found that such was the case.

A vent hole was put into the punch and there was no more trouble.

Since then we have heard of similar cases in other shops and I want to warn you that if you are using hollow punches without vent holes, look out for trouble.

Now, I am going to ask for volunteers to enter into this discussion and if you don't volunteer I have the names of the companies represented here and I am going to call on you. We have forty-five minutes and we want a lot of discussion.

R. E. NEWCOMB (Brewer Tetchener Corporation): I would like to know how many new men he handles in a day.

MR. KROGER: It would not make any difference. You can handle anywhere from 15 to 200 men a day. We do that in the drop forge department. When it comes to instructing the men, it is no harder to instruct 200 than it is to instruct

50. We get them together in the morning and they are given a physical examination and then somebody from the employment department brings them into the shop.

I want to say to you that you can hire 150 men a day and you can take 75 in the morning and 75 in the afternoon and have them take the physical examination. I am emphasizing the fact of the physical examination because I think that is a very important thing and should not be overlooked and then you want to take the men and give them their instructions and inject just a little safety talk. I don't see why you cannot handle 50 men as easily as you can handle ten men. Does this answer your question?

MR. MACLAGAN (J. H. Williams & Co.): I don't think you can handle 50 men as well as you can five or ten. You get to know a man personally. I have never hired that many men at a time and I would not care to. I would not want to handle more than 20 men at one time.

MR. KROGER: You don't often get 50 at one time. They come to the employment office and then they are examined and they are then brought to the department. I don't remember a time when we had 50 all together. Not more than 18 at a time, and that would be for the day and night shift and they would be taken separately.

I would not attempt to address 50 men and expect to get over the idea as thoroughly as I would with 18.

MR. NEWCOMB: I do not know whether I made the question plain or not. We had a sudden continuous employment of men. We had one shift and then we put on a second shift and we are going to put on a third shift. We have all of these new men coming in. They are not all hammer men, some are in the drop forge shop and others are going to other departments, but they are coming in all day long.

They go to the employment department and then if they are taken on they go to the doctor's room until they are released by the doctor and if I tried to talk to all of them I would not be able to do anything else for a month, that was the point I wanted to bring out.

MR. KROGER: Well, you are hiring all of these men and you said they take a physical examination, didn't you?

MR. NEWCOMB: Yes.

MR. KROGER: You are hiring them all day long?

MR. NEWCOMB: Yes. From morning to night.

MR. KROGER: After they are employed, what becomes of them?

MR. NEWCOMB: They are examined and then they are sent to the foreman and he turns them over to the shop instructor.

MR. KROGER: Is there any possibility of curtailing your employment?

MR. NEWCOMB: No.

MR. KROGER: Well, I don't know the size of your shop or the number of hammers you have, or your production, but it is mighty hard for me to see that this cannot be done without much trouble.

I would suggest to you that you arrange your employment period so that it will not extend over the entire day. You notify your employment man just what your needs are and have the men sent to you in groups of three to five.

I want to ask this question: have you a safety office?

MR. NEWCOMB: Yes.

MR. KROGER: Then I believe it would be the safety man's job to spend a certain part of his time with these men and the rest at his desk and elsewhere.

You cannot spend all your time in the employment office, you have to go about the plant.

Our plant covers twenty acres—I don't think your plant is that large—and you

could not cover the safety work of such a plant and hire men, or attend to these men who are hired all day.

CHAIRMAN KUCCHENMASTER: Does the foreman instruct them?

MR. NEWCOMB: He sends them to the instructor.

CHAIRMAN KUCCHENMASTER: Does he give them a safety talk?

MR. NEWCOMB: He is not a safety man. He is a production man, he instructs the man to operate the machine.

CHAIRMAN KUCCHENMASTER: It seems to me he should instruct them how to operate a machine safely.

JOHN J. O'CONNOR (Chicago, Ill.): There are a number of things to consider about the man who is coming into the shop to work. The first thing he thinks about is what kind of a foreman am I going to have? What kind of a place am I going to work? I think it is well to place in the hands of the new employee a book of rules. This may be on safety or general cleaning, or something of that kind.

He can look this book over and he will remember what he reads; but in going into a new place where everything is strange, the employment man, or the safety man, tells him a lot of things and the chances are that he will forget most of them.

The foreman can tell the man things that he will pay much more attention to than if they were told him by someone like the safety man, or someone else. That is the point I want to make, that the man will pay more attention to the foreman.

We expect our foremen to pay as much attention to safety as we do to production. Our foreman tells the men under him about the safety rules and we also have talks by the safety inspectors.

When a new man comes in the safety inspector takes him out and shows him his locker and the place where he can get his lunch, etc. I really think you can get results when the foreman becomes interested in the safety work and regards it as a part of his job.

MR. NEWCOMB: That might be all right in a small plant but I do not see how you could work that out when you have 150 men coming in in a day.

CHARLES E. FOUHY (Willys-Morrow Co.): It is hard for the safety engineer to get into personal touch with the employees and attend to their education and do the many other things he must do. The foreman knows the men better, he is in closer touch with them and he should instruct the new men in the safety work and tell them all about the accidents, minor as well as major.

When there is an accident they notify my office and I investigate it, whether it is a minor or a major accident. If I am not in my office the girl gets in touch with me and I go and make a personal inspection. I go to the hospital and I think that is the best way to handle the safety work.

If the doctor finds there is a skin eruption, a dermal disease of any kind, he notifies me and I investigate it. He sends me a report every morning and I go over it and notice if one department is having more accidents than another; and if there are more accidents than there should be, that means they are slacking up and need a little bit of supervision; so I get busy and caution them and I get hold of the foreman and get him back in the old safety track.

We have had wonderful results. It is impossible for one man to get in touch with 13,000 employees personally, so we have got to place the responsibility upon the foremen of the departments. I have found the greatest help of all in safety work is personal contact day by day with the foreman of the various departments.

They have got so now that they call me on the phone to help them out, and I believe if the safety engineer will get in constant touch with the foremen, with the men who have charge of production, that you are bound to get mighty fine results.

THOMAS LAW (Oneida, N. Y.): I have never had the problem of hiring 50 men in one day or one month; the most we have hired at one time was four. We

always have one experienced man for each four in the drop forge room. I tell the management that I do not want more than four or half a dozen at a time and in that way you can check up the work.

There is no question in my mind that when you take green men into the drop forge room or the press room you have got to stay with them for two weeks, they have got to be supervised.

GEORGE THOMPSON (Detroit): This is all very interesting to me because it happened to be my unhappy experience to have supervision over a plant that increased its employees from 9,000 to 21,000 in three weeks. That is a complete increase of much more than 100 per cent. The labor was nondescript and they were taken on to do work of a highly skilled nature.

It would have been impossible to have the men go from the employment department to their respective departments. This plant is a mile long and five stories high and 800 feet broad and everything is manufactured in it.

In a case of that kind the personal contact would not be expected, but you know if you look through a ladder you can see as well as anybody. Some of the men were sent to the departments and were rambling through the plant and I found them on the roof. You know how it is in a plant of that kind. Some of the fellows thought they were being smart when they directed these new men to go right up a certain stairs which took them up to the roof. They thought it was a wonderful joke; but it was not a joke long, because these fellows got up there and did not know how to get down, as there were fourteen different entrances on the roof to take them down and they did not know which one to take.

After we had had some of these experiences we said "Here let's get organized." So we decided to handle them every hour. They were taken to the safety department and given their instructions, as many instructions as we could in a general way, and they were then turned over to a guide and that guide took them to the departments they were intended for, he would give them to the different foremen.

What was the result? Before this plan had been put into effect we had had four broken legs and three crushed feet, they did not know where to go and they got in the way of trucks, they did not know the reason for stepping out of the roadway into the passage way and the truck hit them.

After putting this plan into effect we had no broken legs and no crushed feet. If a foreman wanted men he put a requisition in for them and we sent them every hour. They wanted us to make it every half hour but we refused to do this. You can instruct the men in the fundamentals of safety in five minutes.

We worked from six o'clock in the morning until eleven o'clock at night. We kept the night men separate from the day men; we hired them and then told them to report at such and such an hour and we took the night men in groups of one hundred to three hundred.

This plan may be just the one the speaker needed. With regard to foremanship work; the man gets his instruction from the foreman. He explains to him how to run the machine and I want to tell you that if you put the responsibility on the shoulders of the foreman he will assume them and be glad to do it, because he knows he is going to get a better and more efficient workman if the man is interested in him and he knows just what he is going to do.

CHAIRMAN KUECHENMEISTER: I think this whole matter is one of organization. Most of you heard Dr. Harry Myers speak Monday afternoon and he talked about the fundamental principles that you have got to deal with, and they apply whether it is a big plant or a small plant. The method of applying these fundamental principles will vary according to the size of the plant. You must remember that the workman is human and you have got to keep after him, you have got to prod him to see that he is adhering to the rules, and then you should also realize that the foreman is the boss of the department in every way.

In our organization the foremen are absolutely sold and have been for the past four years but they must be "pepped" up every so often.

We must arrive at the fundamental principles and this matter of safety is the foreman's job. We make him responsible and it is up to him to teach the men.

I will say this: it is the foreman's duty to get out production but when we ask him to do that we don't expect him to run around and get the material and all that is needed to get out production. We have auxiliary departments to help him, and we believe it is up to the Safety Department to provide the material to help the foreman do his safety work.

L. M. RICE (Liberty Mutual Insurance Co., Chicago): This discussion has brought to my mind an experience that I had in 1914. We were running three plants and had 9,000 men employed and we had been working along this line of getting production and teaching safety and we knew we would have to spend a lot of money.

I remember at the time I talked to one of the foremen and he said "Well, one thing we can do and that is to better instruct the old men as well as the new ones." We went over the accidents and found there were only a few in each department and then the suggestion was made that perhaps the man who met with the accident would have met with it if he had been outside of the shop and it was suggested that each foreman should bring out and feature those things where the men might be hurt, and accordingly this information was given to us, these things that were essential, and it was my job to get that information.

We had rules printed and put up on posters; they were written in different languages. We followed this for two or three years and after checking up we found there were fewer new men getting hurt. We got the foremen to take care of getting data and observing the men because it is impossible to be all over the plant.

I think we should have the rules, it is a courtesy to the men we employ and we owe it to ourselves, to have him properly instructed. I thank you.

MR. NEWCOMB (Brewer Teteheuer Corporation): Did the men get the rules?

MR. RICE: We made the rules up on cards and the cards were given to the sub-foremen.

MR. NEWCOMB: Did the card cover all the problems?

MR. RICE: Yes.

MR. NEWCOMB: They gave the proper instructions you wanted them to give to the men?

MR. RICE: Yes. The foreman observed the men under him and noted the things on a card and it was turned into the timekeeper's office. When there was an accident he would tell how long the man had been there.

MR. NEWCOMB: Did the foreman do the work himself?

MR. RICE: It was generally done by the sub-foreman and he generally had an old employee sign it, or supplement what he had said.

MR. NEWCOMB: This was an advantage to the employee, himself.

MR. RICE: Yes, the fellows were always glad to sign.

MR. NEWCOMB: Our company is planning to have goggles worn by everybody they employ and I would like to have the experience of the gentleman here this morning with regard to that particular subject.

A man will put on ordinary lenses and he will say he cannot stand them. In many cases we have tested the man's eyes and found them to be better than the standard required. Now what are we going to do with that fellow? Are we going to get prescription glasses for him and exact a nominal charge from him?

Has anybody any experience along that line? I would like to add that we plan to charge two dollars a pair for prescription goggles.

JOHN J. O'CONNOR (Chicago, Ill.): I will tell you our experience. A man comes to us and says he has to have prescription glasses. We have his eyes

examined and if it develops that he has to have prescription lenses the company pays for them. We pay for the time he takes to go to the doctor and back and then we get the goggles and give them to him.

MR. NEWCOMB: You give them to him?

MR. O'CONNOR: Yes, they are no good to us.

MR. NEWCOMB: Then if he leaves you he can go to the next shop and he can take them with him.

MR. O'CONNOR: The Pullman Company has a department and they have a young man take care of it. He knows all about "plus 4" and "minus 4" and he will get the prescription from the doctor and put the correct lenses in the goggles. They are then examined by a doctor and given to the new man.

We have not done that. The majority of men who have had corrective lenses take them away with them, it depends on the individual.

MR. NEWCOMB: We thought they should pay for them.

CHAIRMAN KUECHENMEISTER: I hope you can arrange to let them have them for this reason, by doing so you can often spread the idea of wearing goggles.

I know of a case where a boy left us and went to work in another town several hundred miles away and he wore his goggles, he refused to work without them and a few days later the boss came in with an armful of goggles and put them on every man in the plant and today every man in the entire shop is wearing them.

We have been trying for years to spread this gospel of goggles.

MR. O'CONNOR: Six thousand had to have corrective lenses and the safety man tells me that only three men returned their goggles. I met a man who had been with us; I met him about three or four weeks after he had left.

He told me he was the only one in the new shop where he had gone who was wearing goggles but he said "I learned my lesson, I wear mine." Sometime later I met him again and he told me that about 75 per cent of the men were wearing goggles because he had established a precedent.

THOMAS D. LAW (Oneida, N. Y.): Does anybody have any experience in equipping the men with goggles who light the oil burner furnaces?

MR. MACLAGAN (Liberty Mutual Insurance Co., Chicago): What type lighter do you use?

MR. LAW: They go down there early in the morning and they get the furnace going. There are twenty-eight or thirty of them to light up. I don't know all about it myself.

Now the man goes in there and he is supposed to stay there until it is lighted, but one morning the man was in there and he had the torch and it was lighted. He had not put the light on but something happened and you can imagine what the man's chances were. I was wondering what you would do in a case of that kind.

E. J. WALLMAN (Great Lakes Forge Co., Chicago): We use torches that are five feet long and we have an arrangement on the end made of a coarse, heavy wire, about nine inches square. We have about half a dozen of those things and we keep them in a barrel of kerosene and they are put in the barrel when they are not in use. They go in and get them in the morning and light the torch in the furnace before they turn on the valve, and in that way they very seldom have any accidents in going around the furnaces. We had one accident but the man was not badly hurt.

MR. NEWCOMB: We have a piece around the burner and there is no flare-back. It spreads in every direction as it leaves the valve.

MR. MACLAGAN: Don't you get the flame from the side?

MR. WALLMAN: You will have trouble if you use the open goggles.

MR. NEWCOMB: Well, we thought it well to start this way, to wear the open goggles, because we think if you start with the closed goggles you will have so much trouble in getting the men to wear them, so we thought we would start with the open ones.

M. A. KROGER (General Motors Corporation, Detroit): Mr. Chairman, it is not a question of open and closed goggles, it is not a question of the men wearing them, it is a question of starting right and the type you need to meet different conditions.

I know there are a lot of men who do not like the cup goggle; now I am not against the cup goggle, believe me I love them, I think they are all right, I think they are fine, but there is a place for them and the place is not in the drop forge shop.

I think it is well for you to use the open goggles first and then lead up to the closed goggles, the cup goggles. If you start off with the cup goggles they will not go across, the fellows will say they can't wear them, they steam up, they get swaty, but if you can get him to wear the open goggles first and then lead up to the cup goggles, show him how they will protect his eyes you can get it over and the men will use them.

Start with the straight goggles and you will find that the men are putting something in the sides to keep things out of their eyes and then you come along with the cup goggles and say "Look, this is what you need." In that way you are going to sell the idea to that man and the others also.

That is my idea; I know a lot about this goggle question, some of the gray hairs I have come from worrying over them. I am sold on the proposition of the cup goggles but you have got to sell the idea to the men and sometimes to the management. It is a hard proposition in the drop forge heaters because the cup goggles get so intensely hot.

CHAIRMAN KUECHENMEISTER: We get men from all plants and they come in and they are wearing goggles and we say to them "Buddie, you must wear the type of goggles we wear." The man will say "Well, I wore this kind over at such and such a plant," and then we say "Yes, but we are three years ahead of them. You must wear the cup type here."

I want to tell Kroger that he has got a lot of men who are willing to wear the cup goggles because some of his men come over to us and they wear them in our plant.

I want to tell you of a case that we had. A fellow came back to us who had worked for us a few years ago; his brother was the last man to lose an eye in our place. This fellow came back to our plant from Kroger's and he did not want to wear the cup goggles. The first time I saw him wearing the open goggle I said "You damn fool, you ought to know better than to wear that type goggle. You know you have to wear the cup type." That man is wearing them today.

I will agree with Kroger that it is a lead-up proposition. We led up to it. It is all right to lead up to them but don't wait too long to get the cup goggles.

You may have some complaints about the goggles steaming up, etc., but when the goggles get to the same temperature as the room you will not have any trouble unless you go into a different temperature, and if they do steam up a little let them wipe them off. Tissue paper is the finest thing in the world to use and we have an unlimited supply of it for the men to use.

I am very enthusiastic about this subject of goggles and I want to tell you to insist upon the men wearing goggles and the type of goggles with side screens that are best suited to the work he is doing.

MR. MACLAGAN: I can sympathize with Mr. Putnam, of the American Can Company. We went through such a period this summer. It was necessary to hire a lot of new men and it is a hard proposition to get experienced men, and we went through this period and it was very discouraging.

MR. WALLMAN: With regard to this proposition of goggles; I talked it over with the general manager and he said if it was a question of production or goggles, that goggles came first.

We had a big Swede there, and there was not a job in the plant that he could not do, he was a wonderful producer, he was one of the best men we had in the plant but when we started to put in the goggles he objected to wearing them and we let him go because he would not wear the goggles. Now that happened right in our plant and that is what we would do with a man if he did not wear the goggles in the plant.

This rule applies to the foremen as well as the men, and it applies to everyone around the shop. If the President of the concern goes into the shop, as he occasionally does, if he forgets to wear his goggles he will go back to his office and get them. He would not think of going through the shop without his goggles on.

MR. MACLAGAN: What type do you wear?

MR. WALLMAN: Well, we had the same experience as Mr. Kroger. We used the open goggle first but now we use the enclosed type.

About six months ago we had an increase in the force and we had to put on some of our experienced men as assistant foremen, on both the day and night shifts. They took the new men and handled them.

We had our safety rules and we started these men right. I just want to tell you one little instance that came up. About a week ago a foreman came into my office and said "You remember that man we hired, that hammer man we hired the other night." I said "Yes, I have been waiting to see his name on the report." The foreman said "Well, I had him setting the dies and I went over there and everything seemed to be all right and then when I turned my back he was setting the dies without the block under it." I said "What did you do?" He said "He is not running the hammer, I took him off of that job and made a heater out of him."

After three or four weeks setting dies we will give him a chance to run the hammer because we feel he will have had enough experience.

We don't hire 50 or 100 men a day but some days we hire as many as ten. We don't want to put on a lot of new men on the hammer job or the drop forge job. We are making a quarter of a million forgings a day. We have been making small forgings, they do not run much over two pounds.

We have tried to work out our difficulties and we have the special instruction for the new men and we feel in that way we can build an organization that we can be proud of.

JOHN J. O'CONNOR (Chicago, Ill.): I would like to ask Mr. Wallman about that belt remover. Have you any literature about it?

MR. WALLMAN: I have one of the belt removers here with me and some photographs. I will be glad to show them to anyone who wishes to see them.

I want to say that we had some trouble about the men getting hurt in placing their hands under the dies. One man was hurt and he nearly lost his hand. I talked to the foreman about it and then everything went along all right for a while and then the same thing happened again. The foreman said "Just let the man go." I said "All right." Then we put another man on the job and the same thing happened again. I talked to the foreman again and I said "John, we can't keep firing the men, we will have to get something that will enable the men to get out production without putting hands under the die."

One of the boys made this little automatic arrangement.

CHAIRMAN KUECHENMEISTER: Did that help your production?

MR. WALLMAN: It increased our production about 200 per cent.

CHAIRMAN KUECHENMEISTER: Will you send that to me also?

HAROLD MOORE: We used to use 75 pounds air pressure and we found that was not needed and we cut the pressure down to 25 pounds. The engineer and the mechanical division worked it out and the general manager told me the saving in air mounted to three thousand dollars a year as well as a saving in accidents.

ADJOURNMENT

October 4, 1928

J. W. HENNING, Chairman

Assistant Superintendent, Personnel and Operations, Automatic
Electric Company, Chicago

The fourth session of the Power Press Section was called to order at nine-thirty o'clock by the chairman, J. W. Henning.

CHAIRMAN HENNING: I want to call your attention to the *News Letter* which you will find on the chairs. I am going to ask you to take them home and read them. Vice-President Slaymaker has put a great deal of work into this and I think it would be appropriate to give him a vote of thanks for his work and I will now entertain such a motion.

J. B. GIBSON: (Western Electric Co., Chicago): I make such a motion, Mr. Chairman.

(The motion was seconded and adopted.)

CHAIRMAN HENNING: I want to take this opportunity of introducing to you our new chairman for the coming year. Mr. Gibson, please stand up.

(Mr. Gibson stood up and the members applauded.)

CHAIRMAN HENNING: I am going to make him do all of the work this morning, that is what he was elected for. I will now turn over the meeting to him.

(Mr. Gibson in the Chair.)

CHAIRMAN GIBSON: I would like to express my appreciation to the committees connected with the Section. I met the members of the committees during the past year and I anticipate much pleasure in working with them during the coming year.

In any successful accident prevention program the safety engineer has to rely to a very large degree upon the cooperation of the supervisory force if he expects to obtain the best results, and in safety work as well as other industrial problems, the human problem becomes most important.

In saving the most important thing to the last—the training and the teaching of the foreman—we are fortunate in having with us a speaker who is designated on the program—Mr. M. J. Kane—because of his experience which covers several years in training men, foremen and supervisors, as to their jobs.

At the present time Mr. Kane is associated with the American Telephone and Telegraph Company, as plant engineer in charge of training. It is with considerable personal pleasure that I present to you Mr. E. J. Kane.

Training the Foreman to Be a Teacher

By M. J. KANE

Engineer in Charge of Training, Plant Department, American Telephone & Telegraph Company, New York City

Training as it appears to me can be expressed as:—

"The *development* of an ability consisting of ideas and action which, when combined, result in doing that which is desired, in the way that it is best to do it."

The training of a foreman as a teacher is covering only one phase of foremanship where training would be profitable.

The foreman, of these days, should be trained in many things. I believe training him as a teacher will help other features of his work that are not seen at first glance, or connected with teaching as such.

Nearly any dictionary will define the word "teach" as follows:

"To impart knowledge to others by lessons; to give instruction to others; to

guide by precept or example; to train by practice or exercise; to impart skill or facility."

Synonyms for the word "teach" are found to be:

"Discipline," "drill," "enlighten," "inform," "train."

The same dictionary will define "teacher" rather tritely as "One who teaches, specifically, one whose occupation is to teach others."

If we say a teacher is one whose sole occupation it is to teach others, obviously we are not defining a foreman. If, however, we say that any one who has to teach, as the dictionary defined the word—whether it be his sole occupation or only part of the occupation—is a teacher, then we must admit that the foreman qualifies as one.

The synonyms for "teach" prove this. The foreman must drill, enlighten and inform the men who report to him. It is true that this is not the whole of his occupation and in some respects, not the most pressing part of his occupation. Whether a foreman will recognize it or not or whether the organization of which he is part, believes it or not, he is, of necessity, a teacher.

Teachers Can Be Developed

If the ability to teach was of the same inherent character as the color of eyes and the shade of hair, not capable of change to any marked degree, the selection of foremen would be limited to those people who are "born teachers." Fortunately, this is not true.

Teaching ability can be and has been built up and improved in individual cases. We do not wait for a man with *all* the qualifications required before appointing a supervisor, because some of these can be developed. Teaching ability is one which may not be in evidence prior to appointment to foremanship. However, there must be a certain level of proficiency in teaching which must be developed and maintained in the case of foremen. Before we condemn and throw out any foreman who apparently is not up to the required proficiency as a teacher, it is better economy to attempt to develop in him that particular art. It is usually only necessary to supplant wrong conceptions with right ones so far as the foreman as a teacher is concerned to make remarkable reformations.

How Can This Be Done?

The answer to this is quite simple and sound. It is to have one who is capable of developing a teacher work on the foreman in an attempt to develop this teaching ability. We know, that if it was thought necessary for a foreman to have first-hand knowledge of methods used by some other foreman, he would be sent personally to observe such methods in actual operation. If a particular practice has been modified in a process careful attention is given to getting this information into the hands of the foreman. We do make quite a considerable effort in a number of supervising activities to give the foreman at least an even break on matters which will affect his foremanship. It is not unreasonable to suppose that the same practice will be productive of good results if it is extended to include the field of teaching that the foreman covers.

There is one feature that will bear emphasis in this connection. We do not send a foreman to observe methods where there is uncertainty and unfamiliarity with these methods on the part of the man using them. When we issue new instructions, drawings and changed specifications to a foreman, we do not make use of an individual who is not familiar in every respect with the specifications and instructions. In each case we choose an expert for him to work with. To properly develop his teaching ability we should follow the same common-sense practice. In selecting

the individual who is to train the foreman-teacher we should look for ability and knowledge of the teaching art.

Good Teaching Saves Time

It is a mistake to believe that effective teaching takes longer, in point of time, than the usual or casual method of letting a man learn for himself or by simply telling him something in an off-hand way. The question is not so much whether telling constitutes teaching as it is one of how this telling is done. It is quite possible to learn by being told a thing. Many of us have personal evidence of this. It is also equally possible to be told things and not to learn that which was expected to have been conveyed.

We have personal evidence of this, too. It is in the actual certainty that definite pieces of information are really learned, that the teaching art bears fruit. It will take less time, to impart, train, instruct, etc., using sound teaching methods than it does to utterly disregard these and to place the full burden of self-teaching on the man who must know these things. The only extra equipment that will be required for the foreman to do effective teaching will be mental on the part of the foreman himself. The everyday work offers the best laboratory in which training can be done. The tools, material, equipment and condition being real are by the fact, the most effective. The mental equipment of the foreman will be an appreciation of the common-sense view of what teaching really is, and some drill in a different use of abilities he already possesses.

Definite Principles Underlie Good Teaching

The principles and fundamental practices of teaching are of such a nature and kind that it is fruitless to expect a foreman to acquire them without some attempt being made to aid him in his direction.

Just as was indicated in the case of the changed engineering practices, or the new methods, the need is for an expert thoroughly familiar with the practices. It is not good business to attempt to substitute enthusiasm and willingness for technique and ability as a trainer of teachers. We very definitely say in the training of people for a vocation that the first requirement made of one who qualifies to do the training is that he personally know the practices and the technical information of that branch of the vocation in which he professes to do training.

Naturally, if we apply this same thinking to the man who is going to train teachers, we will find that the first requirement is that the individual know teaching practices. He must know the fundamental teaching principles and have actual teaching experience enough to assure the people being trained a proper appreciation of these methods and their uses.

This particular teacher training technique cannot be acquired over night. The fact that the fundamentals are easily stated and because they are easy to comprehend, has misled many people to undertake to apply them without the background of their use which is the most essential part of any teacher training program.

In addition to the right selection of man to train foremen as teachers there are several other features to bear in mind when setting up this work.

The first error commonly made is the attempt to do this training work in too short a period of time and at odd intervals. As a concrete illustration, many attempts of the following nature have been tried:

A group of foremen meet with a leader who usually is without much teaching background himself, for one hour or possibly two hours, once a week. A conference method is attempted without a clear notion of its fundamental use.

It has been very definitely demonstrated that on a conference basis less than

eighty hours of training for a foreman as a teacher is almost wasted in point of effectiveness. It is not difficult to compute the length of time in months necessary to qualify the individual at the rate of one or two hours a week. A more practical way to equip the foreman to teach is to use an intensive full-time period for training. This gives the best results not only from the view of the quality of teacher training but, by equipping the foreman to *apply* the teaching ability during the time which is still devoted to preparing him on the one-hour-a-week basis a sound economy is achieved. The benefits of this are so apparent that no mention need be made of them.

In order to effectively train foremen as teachers, there are four steps to bear in mind.

First: Select as the one who is to make teachers of the foremen, a man who has taught, who knows the practices and principles of teaching and who has had experience in bringing others to a stage of perfection as teachers.

Second: Select a group of about twelve to whom teacher training is to be given on a basis of their having a definite need of it on their present job.

Third: Set the training up away from the regular work and isolate the group for a period of about four weeks, devoting full working-day time to their training as vocational teachers.

Fourth: After the group training period, some means of supervising the teaching done by the foreman in its actual application must be provided for.

How Far Should the Training of a Foreman Go?

Agreeing to prepare a foreman to do teaching opens the question of the extent to which the theory and detailed practices of teaching are to be introduced in his training course. The field of teaching being a broad one does cover more ground than will be called for on the part of a foreman in his activity. We only ask a foreman to impart knowledge affecting his product; this knowledge he now possesses. There will be little, if any need, for the consideration of the nicer points in pedagogy or the introduction of some phases of psychology and other studies which a candidate for the teaching profession must cover. A foreman will carry on teaching that is limited in that it applies to particular people in the work that he is responsible for. This is not the same problem as one whose sole occupation is to be that of teaching, faces. Such an individual must prepare to successfully meet with many situations which differ very widely from each other and deal with people of very wide range in mental abilities and possible future activity. A foreman covers a much more restricted field and has a more specific problem. A practical setup for the teacher training which could be given to a foreman is outlined in the following way:

Part a. *An appreciation section covering the determination of the need for training.*

- I. The evaluation of the present state of training.
- II. Conclusions on what must be supplied to make improvements.
- III. Realization of how this can be supplied under the present conditions.
- IV. His definite responsibility and need of aid in meeting it.

Part b. *An introduction to the teaching practices.*

- I. The teaching-learning process.
- II. Lesson planning.
- III. Discussion and appreciation of methods which must be used.

Part c. *The analysis of that which is to be taught.*

- I. Determining what *must* be taught.
- II. Set up a complete content of *required* and *related information* to be included.
- III. Determining the factors along which progress is expected.

- IV. Organizing a series of jobs in an order which will make for rapid progress along these factors.

Part d. *Drill on lesson planning.*

- I. Layout of the step which precedes or ties up the new ideas.
- II. Layout of the step which presents the new ideas.
- III. Layout of the step in which corrective criticism is carried on.
- IV. Layout of the step in which a definite test of the teaching is carried out.
- V. The utilization of lesson plans covering a complete assignment for a job requirements.

Part e. *Supervised practice in teaching.*

- I. The teaching of primary lessons, both group and individual.
- II. The teaching of secondary lessons, both group and individual.
- III. The preparation and effective use of lectures as such.
- IV. The use of conference fundamentals with a group.
- V. Carrying out a program of training on a particular job.

Part f. *Deals with records and reports.*

- I. Training records.
- II. Justification records which determine effectively the value of the training done.
- III. Individual or group reports.

This would equip a foreman with the essentials of the following:

What he is going to teach, *when* he is going to teach it and *how* he proposes to make certain that the man being taught has the ideas which it is desirable for him to have.

Some Faults Which Are Found in Training Programs

There is a tendency, once education and training have been accepted, to run ragged on the subject of teaching and on the things which it is felt desirable to teach. It is not unusual to find in a course two or three entirely different phases of training and education, combined to the detriment of each. The phases are more easily understood by considering the following:

Vocational Training means that ability and knowledge which is *essentially* part of a particular work activity. There may be little or no culture attached to that requirement.

General Training, which supplies a background that may ultimately aid the individual on his job or probably make him more appreciative of causes. Probably makes a man better for future work.

Technical Training, differing from the general phase in that it has a specific application and has a bearing on the vocation concerned. Differing from Vocational in that one can get along without it on a particular job.

The first one, Vocational, should be the one which is of interest to the foreman.

For Vocational Training then, let us first make sure that we have included in the course, those ideas and that practice which *will* make the individual a more capable worker on the job assigned him. Afterward, if there be time, we may add some of the general and technical features; but only as a supplement to the essentials. There is no profit in giving a supplement and expecting the individual to gather the essentials or fundamentals himself.

Training of foremen as teachers if properly done makes sure that the training course is one which covers the essential things. No one is in quite the same position to say what is required as is the foreman. Training him to organize this knowledge is productive of almost startling effects.

The question of where the actual teaching is to be done may lead to a discussion of Centralized vs. On the Job Training. Centralized training in schools,—on the job training,—out of hour training—all have inherent advantages under particular conditions. The teaching methods and practices apply equally to any of them. Train the foreman to teach and the place to teach in will soon be decided upon by local conditions.

Can the Foreman Do Teaching in Addition to His Regular Work?

This question is very often presented and at first glance by the foreman offers only one answer and that answer is "no." If an actual check is made of the items or details expected to be covered by the present-day foreman, it would be almost physically impossible to add a new one. This certainly is true—the foreman has plenty to occupy his time without attempting to add new activities to that burden.

This whole question dissipates itself when we consider that the foreman now has his teaching to do and now does it in some fashion or other. If a foreman does effective teaching, many of the activities which occupy the greater part of his personal time are eliminated. Where he can prevent errors which must be undone later he saves his own time and energy. One ounce of prevention is worth much more than several pounds of corrective methods which must be applied after the fact.

This does not only apply to his dealing with new men but presents itself numberless times with seasoned forces. If the foreman has a means for reviewing the probabilities of error and misunderstanding and he sees that enough informing or instructing is given to the man *as the work is assigned*, many regrettable, expensive, and irritating conditions will be avoided. This has a particular application to safe practices. Doing the work safely is just as much a part of the job requirement as doing it in conformance to technical specifications. Investigation in connection with accidents indicates plainly that most accidents that are attributed to unsafe conditions or practices could have been very easily avoided if somebody had only thought a little bit or had only planned a little more.

Most of the serious and fatal accidents do not occur on what is obviously hazardous work or under very apparent unsafe conditions. The very nature of a man working under such conditions causes him to be a much more careful person if the danger is quite apparent or if the conditions are particularly unsafe. The answer to the paradox of grossly unsafe conditions being safe is that when conditions are alarmingly out-of-line with safety, there is more attention paid to planning and more thought given to the performance of a given individual. It is with conditions, that have become very familiar to workers that unsafe practices or work habits are found. No one can deny that if a right-habit formation has been carried out, the normal performance will be much safer. Habit is the result of training—good training, good habits—poor training, poor habits.

The *best way* to do a particular piece of work which is the *safe way*, is invariably the *easiest way*. I do not mean that wrong habits cannot be made to appear easier than the right ones. A safe and correct method which insures quality and quantity thus making it the best way to do a job is by that very fact the easiest way to do it. There is no better medium for having the best way an habitual way than by beginning from a person's very first application on through the growing experience of a worker to definitely train in the use of that way. If this is done, then the best way will be the natural way and it will be exceptional when variation from safe practice presents itself.

We are not adding to a foreman's activity when we ask him to do some teaching in connection with training. We are handicapping him severely if we fail to equip him to do this teaching in a manner which makes it effective and economical in point of his time in achieving the end. It is unfair to ask him to equip himself

for this task; it is the management's definite province to equip the foreman to this end. Just as the organization cannot afford to allow the foreman to equip himself with a knowledge of methods, engineering practices, policies, etc., they cannot afford to have it rest with him to prepare himself to do this important part of his job.

Inasmuch as the requirements of the foreman's job call for ability in teaching, we cannot afford for an economic reason, if for no other, to wait until he, by his own effort, brings himself to a stage where the teaching he does, is as effective as he, personally, can make it.

On this basis, then, it is not a sound idea to expect him or even to demand of him that he put in his own time, out-of-hours, in an attempt to get this particular feature, the lack of which is handicapping his everyday performance. It needs only good, common sense, to realize the value of getting him to a stage of improved teaching as rapidly as can possibly be achieved. Some are deterred from this teacher training of a foreman on the basis of cost of training. It is a mistake to figure that the money saved in not training the foreman as a teacher, is a clear gain. Against this probable money saved must be checked the everyday cost and the losses which are directly attributable to his failure as a teacher.

Again, this is strikingly manifest, in considering safe practices. It is unfortunately, too late to do much of any instructing, after an employee has been seriously injured. No one knows when or where the lack of specific information or habit-perfection will cause a serious accident. If this be true—and it is—it is poor policy to neglect to equip a foreman to a point where he can effectively prevent accidents by taking action in advance of a situation which might through ignorance or wrong working habits cause one.

CHAIRMAN GIBSON: I am sure I am expressing the thoughts of this group when I extend to Mr. Kane our appreciation for the very complete and interesting paper which he has presented to us this morning. I am going to ask you to stand up and give Mr. Kane a rising vote of thanks.

Mr. Arthur L. Mann, Superintendent of Industrial Education, State Educational Department, Albany, N. Y., had agreed to lead the discussion on Mr. Kane's paper, but as Mr. Mann is not with us I will throw this subject open for a general discussion.

CHARLES H. FOUHY (Willys-Morrow Co., Elmira, N. Y.): I would like to take issue with Mr. Kane in regard to his statement about the conference method. I am rather sorry that Mr. Mann is not here because no doubt he could more ably cover this subject than I can, but I can't help thinking that Mr. Kane is telling us about the ideal foreman and the ideal situation in the conditions such as he has outlined.

I wonder how many men here have had just those conditions. As I look back on the history of my own plant and think of this matter of the training of foremen I find it is a difficult proposition because the majority of foremen have been away from school for a number of years; and to take a man out of industry and put him back into the schoolroom, ask him to prepare lessons, ask him to analyze certain materials and subjects for discussion is a difficult proposition.

I think you would fail for the reasons I have given. We have been conducting courses for the past three years. We have found that when we have asked a foreman to present some ideas, some explanations of a particular subject, when we have asked him to bring it before the group for discussion he is not only seriously embarrassed but at a loss to get together his thoughts, and present an argument that does justice to him; notwithstanding the fact that the foreman has the qualifications to do the work and a mechanical understanding of the matter;

but when he is asked to get up in the conference room or to prepare a lesson he is at a loss, you might as well ask him to swim over Niagara Falls.

There are very few men who are holding positions as foremen in the average industrial plant of the country who have the proper ideas of the policy of the company. The conference method gives you an opportunity of getting these policies properly before the men and we find the men are willing to answer questions that you put to them personally, or that you put to the group, that they will answer them much more readily than if you ask them to get up and prepare a paper on a certain subject. They will answer the questions and will give a logical, reasonable answer, but I can't conceive of a group of foremen working along the lines Mr. Kane has given us.

I think we have as high a type of foremen in our plant as in any plant in the country and I cannot conceive giving them an intensive course of training that Mr. Kane speaks of. I don't believe we have reached that stage as yet.

You could take the college and university graduates who are coming out this year and train them to be foremen, train them the way Mr. Kane suggests, and that may be done at some time in the future; but at the present time we are dealing with the foremen we have in the plant, we have to take the material we have right at hand and to try to give them an intensive three weeks' course I believe would be a failure.

I believe in the conference method, I have worked at it and we are training the foremen, the setup man and the assistant foreman. We have our meetings every week and we are getting results but I can't see how we could get results if we took those same men and put them through an intensive training course where they would have to respond to questions and prepare lessons, etc.

We have an ordinary conversational conference, they don't have to prepare lessons. This is my conviction and if it starts an argument that is the purpose of my being on my feet.

MR. KANE: I did not think there was anything in my speech to indicate that I did not advocate the conference method, and if I gave anyone that impression it is untrue. I don't know anything that will help you more in this work than well conducted conferences. There is this method of intensive instruction, as I outlined, but it was not my intention at all to discourage the conference method. You will remember I said to take a group of twelve people and isolate them and the training is to be given on the basis of their having a definite need of it on their present job. You would take the present situation and endeavor to improve it, give them a realization of their responsibilities. If that is not the subject of the conference method of handling the things, I don't know what is.

I was not thinking of an ideal foreman; I may have in mind an ideal course that we may sometime come to, but I am thinking of the garden variety of foreman, giving him this intensive three weeks' course, and you will find that it will not result disastrously but will give you excellent results as it has thousands of other groups.

It has been very effective in my own experience. I know of 1,200 foremen who went through with quite a measure of success. The one thing to consider about the conference method is that it needs a good leader, a man who knows how to handle the conference method. You can get certain activities in the conference that will look well, that will give the appearance of quite a constructive meeting, but when it is all sifted down you will find you are not getting the proper results. There is one specific feature I want to mention, you must consider whether you are training the foreman as a teacher or training him in the proper appreciation of foremanship which would include the policies and many of the other ramifications of foreman work that ought to be done in addition to training him as a teacher. Training him to be a teacher being a specific feature calls for a modified use of the conference method.

There is the informal conference where each man contributes to the general fund, where each draws from it what he needs. There is another type of conference, an adjusting conference where they are widely diversified and must be integrated. Because of these two types of conference it is difficult to hold discussion in one or the other that will interest all of the foremen who have to attend the conference, it is difficult to adjust the smoke and thunder and there is bound to be some hard feelings. It takes an expert in the conference method to handle it properly. If you could give this intensive training to the foreman in a cut and dried, academic lecture, it might work out, but if I gave any one that impression from my talk, I gave you the wrong impression.

You can't take twelve foremen of the ordinary variety and expect to get results unless you know how to handle this proposition, but if you do know that you can get results, because I have gotten them.

WILLIAM SHAPIRO (Syndicate Tavo Novelty Co., Newark, N. J.): The speaker passed over very lightly the point of vocational training. I have been working in a small plant for six years and my work has taught me the necessity of training the foreman. They have to be told the right way of handling the material and the correct method of operation. I have used my method successfully in foot press and power press work.

I have analyzed the work and find they do not use their hands right in order to keep them out of the danger zone. As I said before I am sorry Mr. Kane did not put more emphasis on the vocational method of training John Henry Foreman. I don't disagree with the things that Mr. Kane has said but I wish he had given this supplement to his talk, the vocational factor. I think there should be some one in the plant whose duty it would be to analyze the various jobs and learn the most effective way to do them. John Henry Foreman could find out the way his best operator does the work and then use that as an example.

MR. KANE: I certainly agree with you. John Henry Foreman knows, or should know the proper operation, and if he does not know he has got to have some one tell him. If you have a very good operator your foreman can watch him, as you have said, and teach his method to the others. I agree on that.

MR. SHAPIRO: I did not hear you say so in your talk.

H. H. TUKEY (Western Electric Company, New York City): I was interested in the comments of the first gentleman who opened the discussion and before entering into any further discussion of this paper I want to congratulate Mr. Kane. He has given one of the strongest, most spirited and most emphatic explanations of the fundamental principles of training the foreman as a teacher that I have ever listened to in my fifteen years' experience in this sort of work.

The question has been asked as to whether or not the average foreman can grasp this sort of thing. I have yet to find the average foreman who has not grasped it readily and utilized it and made it his job, and by so doing I have seen a remarkable saving in production and improvement in cost—I should have said improvement in production. There has been a marked improvement in the efficiency of the man, and to my mind the crux of the whole situation rests squarely upon the shoulders of the man who is leading the conference, training the foremen as teachers. This man must know his job, he must know what he is trying to put over and he must know how to put it over, he must be a super-teacher. Now that may sound somewhat academic but it is not intended so, for among the men that I know who are doing that sort of thing many of them have had a very broad background of industrial experience.

Some of them are former teachers who have come from the public school, but there are many who have had a practical background of industrial experience and they have acquired the knowledge of how to teach in industry. This fact Mr. Kane made very clear to you. I am sure that Mr. Kane does not think of an ideal foreman, but as he has said of an ideal course, but that course is not so

ideal as to be impractical. This work has been done many, many times, and I want to tell you from my own experience that we have trained a number of foremen and within a month we will start training some seventeen hundred and fifty or two thousand more.

We will put them through at least ten days of intensive work, full time. In the past we have had them as long as four or five weeks off the job. Then we reduced it to three weeks, and now by cutting out what appears to be frills, non-essentials, we have still further reduced it to two weeks or possibly ten days. Those foremen are not bored in that ten days or two weeks time, they are by no means inactive; their activity is very frequently so great that they do not wish to quit on time. There is a great deal of improvement during these conferences, as Mr. Kane has told you, it is truly remarkable, it is highly interesting to see how these men evolve from their job that they have been doing into a developed mental job.

These men learn to think, and to my mind one of the greatest features of this work is the developed mental feature. It does train these men to think, it makes the foreman a thinking foreman and that is what you want.

There is one other feature; we think of the foreman more and more as a personality and it also helps him to become a personnel man, and I don't know of any method that is better for training a personnel man.

If we look back to our younger days we will remember those from whom we learned most and best, those people who most strongly influenced us. We were attached to them, we liked them. Now the workman is attached to the company through the foreman and if the foreman is a good personnel man and a good teacher, this personal contact that he has with the workmen will be productive of good results.

J. A. MCCARTHY (Assistant for Industrial Education, Trenton, N. J.): Mr. Kane has presented a very able and forceful paper, one that I think should be of great interest to every one who is interested in the training of foremen. But I feel he is setting up an ideal situation with an ideal organization. It is not always possible to get that ideal situation. It has been our experience in the training of foremen that we have not found these ideal conditions, the foremen have not developed up to that point.

We would like to move the hands of the clock ahead and reach that stage. It will be reached eventually but I feel not at the present time. We must remember there are a number of small industries where there is a great deal of competition and I think it would be impossible for them to take twelve or fifteen foremen out of the plant at one time and give them this training for ten days or two weeks. The management realizes that it could not afford to do this, they could not afford to have the foreman away from the plant at all, and in those cases this work has to be handled in a different manner. I think we must consider that there are two distinct phases to this work. We have the conference work which Mr. Kane has explained. This particular type has to have a leader.

We have the situation where the contributions come from the group. The other type is more of an informal discussion. Mr. Kane emphasized the fact that you have to have a man who can readily impart information to others, he has to give them this informational matter. I think that is one thing we should bear in mind, that there is a great difference between the informal conference and the formal conference, where you are training the foremen to be teachers.

T. G. PATTERSON (New Jersey Manufacturers' Association, Trenton, N. J.): I would like to get Mr. Kane's ideas on the subject of the small plant. The talk here this morning has been generally about the large manufacturer, but when you get the small plants in New Jersey and near New York where they have to meet the New York competition it is very difficult to give this training.

I would like to ask Mr. Kane how it would be possible to go about this education

of the foremen in the small plant without any loss of time and without three or four weeks of preparation? Those are things that the small manufacturer cannot afford to pay for.

MR. KANE: You can handle the small group just as well as you can handle the large group. It is merely a question of getting the number of hours in. If the firm cannot afford because of economic conditions to give the full time intensive training, then you have got to take the next best proposition that would fit the needs of the company. I have tried out this proposition on nearly every basis that it could be tried on. We have had the lessons for one hour a week at night, but it takes a long time and there is a great deal of lost motion, but if that is the best you can do that is the thing for you to do. I have tried two hours a day twice a week, that is better than one hour a week at night. If the economic conditions make it necessary to do it in a way that takes so much longer, that is the way you will have to do it because any activity you carry out in this line is better than no activity at all. The course that I have outlined is an ideal one and if we cannot afford to have that then we must come as closely to the ideal as possible.

I would encourage anybody who is making an effort to put this thing on. If you do have a course you will find it is much better to give the man the intensive training, and while you may not be able to do this in the beginning, you will come to it eventually. It is a case of selling the proposition, it is largely a state of mind. This is not only true of the smaller plant but of the larger plant as well. I will simply give you these features, I think I stressed them in the paper, but I am going to repeat them. It is a pretty good selling device if there is any possibility of having this intensive training, and I think it is possible in all but the very small plants, it should be done.

This matter has been greatly over emphasized. They spare them for vacations, they spare them at certain periods when they are ill and they can spare them for this intensive training. This is a very good selling argument. You can tell them they can't afford to wait until some time later. They should do it now and collect for it later on.

I certainly would keep fighting for results, and these results will come as soon as this step is taken.

C. H. DAVEY (New York Telephone Company, New York City): There is one other point I wish to bring out. Mr. Kane, do you think the man with an industrial background, a practical background will get better results than the teacher?

MR. KANE: You are speaking of the qualifications, the background that is necessary for the man who is going to undertake this teaching?

MR. DAVEY: Yes, I mean the man who is training them.

MR. KANE: I think I can give you a pretty good picture of that. There are certain essentials and the first is teaching experience. You cannot know teaching methods without having used them. You want a practical teacher, one who has taught, not a theoretical one, one who has never done it. That answers your question I believe.

I think you should have one who has a successful background in industry if you can get him. Now what I mean by a successful background in industry is this. There fortunately are several—I might say a number of men who have demonstrated their ability as foremen, or workmen. There are men who have come to a point where they are particularly skillful, but perhaps he knows nothing about teaching, perhaps he knows nothing about how men react. You want a certain combination, a man who has taught, preferably in industry and a man with an industrial background who knows industry, who knows how men react. You want a man who is not so fixed in his views that he will not yield; you want a man who has breadth enough of vision to see that this foreman quite possibly is right in this particular instance. You do not want a dogmatic man.

You want a man with an industrial background and of that certain type of temperament who will draw men out and get them to unfold and who will not dogmatically force something on them. I don't know whether that answers the question as you wish it or not.

MR. DAVEY: Yes, thank you Mr. Kane. You believe in having a practical man?

MR. KANE: Yes, a practical man is the best, there is no question about it. When I spoke of vocational training, I emphasized the fact that the man must have actual experience. Now it is true we have found people who can teach without knowing how to do it but they are exceptional. It is also true that people will learn in spite of the teacher; that has happened a number of times.

You want to include some technical features that are desirable, but most of all you want a practical demonstration.

MR. TUKEY: I want to ask you about the follow-up, or supervision of this teaching work after the conferences are over, whether you think that is an important part. I think that has been advised in some of the small organizations. We have to consider this matter of the training of the foreman as a teacher and then the supervisory process, or advisory perhaps is better. To me it seems that that is very important. You can have your conference and the foreman is supposed to go on and teach the men, but if there is not some supervision you do not know whether he is doing so or not and I think that is a mistake. There must be a follow-up in order to get the best results.

CHAIRMAN GIBSON: Our time for adjournment has come. I think this has been a very successful session. I would like to express my appreciation to all who have contributed to the discussion and who have helped so well to round out Mr. Kane's paper. This is the last meeting of the Section for the present Congress. We have had the most interesting set of papers and the largest attendance that the Power Press Section has ever had, and I only look forward to meeting the same group somewhere, sometime, in the year 1929. I hope I may count on your support and cooperation in the months during which we will have to build up the program and during which I would appreciate it very much if you would let me have either suggestions for papers, as well as names of speakers, and anything else that you wish to bring up.

ADJOURNMENT

SEVENTEENTH ANNUAL SAFETY CONGRESS
NATIONAL SAFETY COUNCIL

Public Utilities Section

New Section Officers

- Chairman*—H. F. WEBB, The West Penn Electric Company, Pittsburgh, Pa.
Vice-Chairman in Charge of Electrical Interests—IVAN L. SCOTT, Electric Management & Engineering Corporation, Asbury Park, N. J.
Vice-Chairman in Charge of Gas Interests—E. S. BEAUMONT, Peoples Gas Light & Coke Company, Chicago, Ill.
Vice-Chairman in Charge of Telephone and Telegraph Interests—J. L. VANDERGRIFF, Chesapeake & Potomac Telephone Company, Washington, D. C.
Secretary—G. A. DOELLER, Dayton Power & Light Company, Dayton, Ohio.
Poster Committee Chairman—JOHN J. BARADA, The Laclede Gas Light Company, St. Louis, Mo.
Publicity Committee Chairman—E. J. KREH, Duquesne Light Company, Pittsburgh, Pa. (American Gas Association).
Film Slide Committee Chairman—ROY M. GODWIN, Philadelphia Sub-Counties Gas & Electric Company, Philadelphia, Pa.
Fire Protection and Prevention Committee Chairman—H. M. KELLER, Northern Indiana Public Service Company, Hammond, Ind.
Engineering Committee Chairman—H. B. HARMER, The Philadelphia Electric Company, Philadelphia, Pa.
Statistics Committee Chairman—C. P. RYAN, Northern Indiana Power Company, Indianapolis, Ind.
News Letter Editor—N. L. DEVENDORF, Consumers Power Company, Jackson, Mich.
Councillors:
C. J. RUTLAND, Texas Power & Light Company, Dallas, Texas.
B. B. McCULLOCH, Bureau of Safety, Chicago, Ill.
GEORGE C. A. OPP, The Detroit Edison Company, Detroit, Mich.
B. FRANK DAY, Philadelphia Electric Company, Philadelphia, Pa.
HARRY M. WEBBER, Illinois Bell Telephone Company, Chicago, Ill.
W. L. LOYD, Alabama Power Company, Birmingham, Ala.
C. R. BEARDSLEY, National Electric Light Association, c/o Brooklyn Edison Company, Brooklyn, N. Y.

Retiring Officers

- Chairman*, CARL J. RUTLAND, Texas Power and Light Company, Dallas, Texas;
Vice-Chairman in Charge of Electric Interests, W. R. LOYD, Alabama Power Company, Birmingham, Ala.; *Vice-Chairman in Charge of Gas Interests*, IVAN L. SCOTT, National Electric Power Company, Asbury Park, N. J.; *Vice-Chairman in Charge of Telephone and Telegraph Interests*, H. L. MEADE, Ohio Bell Telephone

Company, Cleveland, Ohio; *Vice-Chairman in Charge of Water Works Operations*, H. F. WEBB, West Penn Power Company, Pittsburgh, Pa.; *Secretary*, C. B. BOULET, Wisconsin Public Service Corporation, Milwaukee, Wis.; *Poster Committee Chairman*, E. S. BEAUMONT, The Peoples Gas Light and Coke Co., Chicago, Ill.; *Membership Committee Chairman*, F. S. ARMSTRONG, Central Illinois Public Service Company, Springfield, Ill.; *Slide Committee Chairman*, C. P. RYAN, Indiana Electric Corporation, Indianapolis, Ind.; *Fire Protection and Prevention Committee Chairman*, H. B. HARMER, The Philadelphia Electric Company, Philadelphia, Pa.; *Statistics Committee Chairman*, G. A. DOELLER, The Dayton Power and Light Co., Dayton, Ohio; *News Letter Editor*, N. L. DEVENDORF, Consumers Power Company, Jackson, Mich. *Councilors*: C. B. SCOTT, Bureau of Safety, Chicago, Ill.; GEORGE C. A. OPP, The Detroit Edison Company, Detroit, Mich.; H. W. MOSES, The Edison Electric Illuminating Company of Boston, Boston, Mass.; J. C. HUBBARD, The Western Union Telegraph Company, New York City; H. M. WEBBER, Illinois Bell Telephone Company, Chicago, Ill.; B. FRANK DAY, The Philadelphia Electric Company, Philadelphia, Pa.; HERMAN SPOEHRER, Union Electric Light & Power Company, St. Louis, Mo.; B. B. McCULLOCH, Bureau of Safety, Chicago, Ill.

October 2, 1928

C. J. RUTLAND, Chairman

Safety Engineer, Texas Power & Light Company, Dallas, Tex.

The first session of the Public Utilities Section at the Seventeenth Annual Safety Congress was called to order at nine thirty o'clock by the chairman, C. J. Rutland, Safety Engineer, Texas Power and Light Company, Dallas, Tex.

CHAIRMAN RUTLAND: Gentlemen, the Public Utilities Section of the National Safety Council has had what your Executive Committee feels is a very successful year. There has been a marked increase in the safety movement. Many companies are putting safety on the same plane of operation as any other department in that company. Safety is gaining ground and I don't know but what we should bow our heads in opening this meeting in memory of the 500 employees of the electric light, power, gas, telephone and telegraph, and water industries who have lost their lives by accidents, and thousands of others seriously injured. We should dedicate our work this coming year to a more concentrated action along the line of humanics in safety work. I think those who are giving closer study to accident prevention work year by year believe firmly that management has accomplished 80 per cent result of all that it could put forth in the carrying on of safety work.

There is a distinct need for safety men to provide the channel of soliciting safety cooperation from the employees themselves, and I hope, as we discuss these talks that are to be made to us these three mornings, that you will take them all to heart and feel keenly your responsibility in connection with accidents and deaths to employees in your respective companies. We have what we believe the best array of speakers for our sectional meetings that has ever been had at a Public Utility Section.

We have a number of new members this year. We extend a hearty welcome to new members, as your chairman and Executive Committee note with sincere interest the attendance of the new members. We are glad that so many are here, and we hope that you will get much good out of these programs. Before we begin I would like Mr. Brown, Mr. Oldfield and Mr. Thorn to collect the attendance cards.

The Executive Committee felt that your pulse strings needed to be touched in carrying on safety work. I don't know where the Executive Committee could

have gone to get speakers to fire the opening guns of this Congress better qualified than those gentlemen who will speak shortly. Dr. Grafflin, Religious Work Secretary, West Side Y. M. C. A., New York City, I suppose has spoken to hundreds of thousands of people in all walks of life, from highest to lowest. One man told me of meeting him at a meeting in North Carolina talking to some 400 or 500 people. He started late in the afternoon before the sun had gone down and people became so interested they forgot about the time, and it was long after the stars had come up that the meeting closed. I know he has that kind of message this morning.

First Principles

By DR. SAMUEL W. GRAFFLIN

Religious Work Secretary, West Side Y. M. C. A., New York City

When the historian writes of this age he will say several things. He will describe it as the age of the "Political Opportunist." He will call it the age of the "Decadent Home." Doubtless he will name it the age of the "Industrial Readjustment." He will criticize it as the period of the "Somnolent Church." Without question he will say that it is the age of the "Care of the Bodies of Men."

Never before in the history of the world was as much attention paid to the care, protection and preservation of the bodies of men, and never was this care more needed. I am not sure but that some of this is injurious to the race as a whole. Loving children and loving men as I do, I can see no reason for the preservation and care of the imbecile and the hopelessly unfit. We would not have been half as far as we are as a race if the primitive peoples had preserved their unfit.

Today we are facing a situation that calls for genuine interest, good judgment and rare technique in the saving of the thoroughly worthwhile in society, and I am here to speak for just a little while on "The First Principles of Progress" along any line of undertaking. I shall name seven.

The first is the **COURAGE TO PIONEER**. It takes real courage.

When Mr. Howe walked into that little meeting that day and announced that he was going to take the eye out of the stern of the needle and put it up in the bow and make the sewing machine he was promptly put in the hoosegow for observation. Men said, "For ten thousand years we have had the eye in the stern of the needle and here comes a nut who is going to put it up in the point. Lock him up!" And when Mr. Morse, America's greatest scenic artist, said that he was going to send a message around the City Hall in Baltimore, inasmuch as they could not lock such a great artist up they sent him to the city hospital for observation. It has taken *courage* to do what ever was worthwhile in the way of progress.

"Was the Mayflower launched by cowards,
Steered by men behind their time?
They were men of present valor,
Stalwart old iconoclasts,
Unconvinced by axe or gibbet
That all virtue was the past's.
But we make their truth our falsehood,
Thinking that hath made us free;
Hoarding it in moldy parchments,
While our tender spirits flee
The rude grasp of that great impulse
Which drove them 'cross the sea.

"Point those tracks toward past of future
That make Plymouth Rock sublime."

The second of these great First Principles is the **WILL TO INVESTIGATE.**

One of the hardest things in the world is to get people to look into new things. Recently the son of one of my oldtime friends, now deceased, was in financial straits. His little business was not paying. Thinking to help him out of the hole without seeming to do it I sent him a man, another friend, who had a mechanism to make that would have saved the situation as it would have fitted exactly into his machinery and methods. But he would not look into it and today is in the hands of the sheriff, where he should be.

When God got ready for the biggest single piece of enterprise in the history of the world, the bringing of the children of Israel out of Egypt, the first thing He did was to give a man forty years of education; then he gave him forty years of reflection under good leadership, and then set him a regent's examination. I hate to think what the Regents of the State of New York would have done with poor Moses. But all Jehovah did was to set a bush on fire off to one side of the desert. The other shepherds doubtless said, "Come on, sheep; don't get burnt!" But Moses said, "I will now turn aside and investigate why this bush burns and is not consumed." And God said, "Take it; you are ready. A man of eighty years who is still alert enough to investigate the interesting and unusual is ready to take charge."

But you say, "That is a Bible story. Don't tell any more." All right: hear the story of what I consider the most tragic thing in the history of the industrial world.

George Washington records in his diary: "While I was scouting in the valley of the Ohio I found a spring that apparently ran pure grease. I believe that stuff will burn." But not a pint of it did he retrieve. Not a can of it did he bring back.

At the very hour when George Washington turned his back on running petroleum that was not drilled for in Pennsylvania until one hundred years later, at the very hour when this young and alert soldier-scout left the great burning fluid to trickle down the mountain, Benjamin Franklin, the founder of this country, Benjamin Franklin the investigator, Benjamin Franklin who was rubbing pussy's back at the fireside and watching sparks jump from the fur, said: "All I have to do will be to have a big enough pussy and a fast enough hand and then I can make that stuff." If Mr. Washington had brought one pint of that petroleum to Mr. Franklin, saying: "Will it burn?" we should have had the internal combustion engine in 1800 instead of 1900; the industrial revolution would have centered in petroleum and not in coal (which should never be taken away from the mouth of the mine except as non-smoking coke) the oils, gases and power being piped and wired to the place of use right from the mine. If Mr. Washington had given it to Mr. Franklin the airplanes would have belted the world fifty years ago and much of the grime and grind of our last hundred years of industrial life would have been avoided. But all this was sacrificed because one man did not have the *will to investigate.*

The third of these underlying principles is **CAPACITY FOR NEW TRUTH.** The most of us have not capacity for old truth. Two of the great businesses of this country at the present minute have been able to buy out their competitors through the simple matter of looking into the absolutely new and apparently impossible phases of their business, in one instance the manager losing what he thought to be a lifetime position because he had turned down a young man who possessed a long-sought chemical formula that enabled them to eliminate one of the most costly elements in their business.

The fourth rung in this ladder of progress is a **TOLERANCE OF YOUNG MEN WITH RADICAL IDEAS** while we hold steady. I do not want any settled young man around me. May heaven save us from dissatisfied old men and satisfied

young ones. The young man that is down on the ground at twenty will never go up, and the old man that is up in the air at fifty will never come down.

In the fifth place, there must be a SENSE OF RESPONSIBILITY—responsibility for the thing that has been committed to our care, responsibility to society, responsibility to God, if you please.

In one of his rare sea tales Clarke Russell tells of a young mate of a sinking ship, to whose care the long boat with the women and children was committed. Said the captain: "I have two lanterns and two compasses. I am giving you the best of each and will take the smaller boats and the men with me. Take these women and children, this compass and lantern. One hundred and fifty miles due south of you there is a little island. On it there is food and water left there every three months by the British Government for shipwrecked men. If you miss that island there is nothing but open water for fifteen hundred miles and you will see these women and children shrivel up and die under your eye." And then he added with deep solemnity: "For God's sake, Madison, don't miss that island!"

And then the young mate tells the story of how all that late afternoon and all that night and the next day until three in the afternoon he sat with tight ropes and strained eyes trying to keep "due south," and how in the late afternoon a woman lying on the apron of the boat said: "Isn't that land ahead?"

Responsibility is a great thing when it is assumed in a great way. Most of us are like the father of the little boy who said, "Fader, der captain says der ship is going down." To which the father replied: "Vat iss dot to us, my son? It don't belong to us."

The Story of a Christmas

There is, as I said, a great responsibility to God, if you will, for, after all, responsibility is a moral question. Let me tell a story to illustrate what I mean.

It is the story of the first Christmas in which we were not broke; indeed, if I remember correctly, it was the last one. I had great difficulty in convincing my good wife of that fact because it is an unusual thing. I have always sympathized with Mr. Stanley Mitchell's famous story of the man who was dying, who sent for the minister to make the final arrangements for his funeral. "Who will you have for your pall-bearers?" inquired the dominie. "I guess the local bankers will do," was the reply. "They have been carrying me all my life anyhow. They might as well finish the job."

However, having convinced the good lady that we owed nothing and had a hundred and twenty-five dollars, we were promptly informed that she needed clothes. "That is what Eve said," was our answer. But we trimmed her out in fine style; then we asked our oldest daughter what she would have. She asked for a little set of books. We asked our second daughter, whose request was for fruit cake, sponge cake, pound cake, apples, oranges, doughnuts, candy and something to eat. Then we asked Don. Running true to form, (for he is one of the kind who, if he fell down a sewer, would come up with a gold watch in one hand and a diamond ring in the other) he said: "I want a little store with bins and things to sell. I want a little cash register and I want a little horse and wagon with which to deliver the goods."

Came Christmas morning, and after early church and breakfast the parlor was opened and the abundance of presents displayed. Everybody was happy; but it was not five minutes before the children were dashing back to inform me that Don was not giving them the goods. He was selling them. I knew that; and so I divided my small change, all that was left, equally among them and business began. Time and again he sold out the little stock, finally looting everyone's Christmas stocking and his mother's cooking jars. As the neighbors' children came in he sold the very cubes of sugar from the bags in the pantry.

About eight that evening there was a great quiet in the parlor,—a quiet that could be felt. We rose from where we were reading, my good wife and I, and walked to the portieres and parted them. I wish you could have seen the picture. Ruth in a big morris chair, her little shelf of books before her, head down, in the middle of Adam Bede, read out, all in. Dorothy flat on her back, sweating like an ice pitcher, full as a tick, but happy as a lord and sound asleep in the middle of the floor. Everything that she had, had perished with the using, but there was no question about her having had and having enjoyed it. And Don, the little horse in the stall, sold out, his arm around the store, his left hand literally leaking pennies, nickels and dimes.

We stood and looked at the picture for a few minutes and then I took Ruth's little set of books, set them back on one of the library shelves, carried her up stairs and her mother put her to bed. Then I carried Dorothy, eats and all, up and laid her on her bed and her mother put her to bed. Then I came back and took Don's little store and stood it in the corner, placed the horse in the stall, emptied his hand into mine, put the money in my pocket and carried him up and put him to bed.

When I returned, my good wife was seated by the student's lamp, not reading, but with moist eyes. "What is the matter, sweetheart?" "Nothing," she said. "Did you see that picture?" she asked. "Oh yes," I replied.

All life is just like that. God gives us books and banquets, stores, cash registers, nickels, dimes and pennies to play out this little thing which we call "Life." And some day we are going to fall asleep and the Great Father is going to come to the parlor door and look us over; and He will come pretty nearly knowing how we play the game by the way in which He finds us.

A Set of Great Convictions

And then there is a set of GREAT CONVICTIONS. Men do great and worthy things consistently, persistently from conviction, and conviction only. Men will do things occasionally because of their emotions: occasionally from hate; jealousy, irritation, for revenge; but there is only one reason why men do things persistently, and that is from *conviction* that those things are vital.

And in the last place, there must be a SACRIFICIAL PERSISTENCE.

Some time ago while delivering a commencement address in a Western city we heard this story that has gripped us as few stories have done. It seems that during the war, in one of the detention camps of continental Europe, there was a Y. M. C. A. secretary in charge of a group of Russians. Food was scarce, equipment lacking, but he had a boundless enthusiasm for baseball and a patriotic fervor that made such an impression upon his charges that when the Armistice was signed they "hopped to America" in a body. Twelve of them reached this middle Western town and went to work in one of the great industrial plants. They began to perfect their English and education in a night school and the teacher, a fine young Christian layman, asked them if they would not like an interview with one of the strong Christian business men of the town. They said, "Oh yes!" And he came, giving them a ten-minute talk that aroused their interest and apparently won their hearts.

"Now," said he, "would you like me to give you an hour some evening?"

"Oh yes."

"Where?"

"Your office."

"When?"

"Next Tuesday night."

"At what hour?"

"Six to seven o'clock."

He waited from six to seven. Not a Slav showed up. He went back to them.

"I missed you last Tuesday night."

"Oh yes, we will be there next Tuesday night."

He waited the next Tuesday night. Not a Russian came.

Ten more Tuesday nights he waited from six to seven and not a Russian came.

On the thirteenth night he saw one fellow peeping round the corner of the door, ran out and caught him, brought him in and gave him a wonderful hour. On the next Tuesday night there was another, a different one. And so week by week they came until each had had an hour with him alone. On the twenty-fifth night twelve young Russians dressed in their best, shaved, shoes shined, walked into his presence and said, "Here we are, sir. We have been here, all of us, every night. We were here, all of us, those first twelve nights. We have been here, all of us each of the other nights. We did not believe you on that first night when you said that you cared about us. We came from a land whose rulers were tyrants, whose priests were hypocrites and ignoramuses, and we did not believe in you or your God or your country. But now we believe,—we believe in your God and your country because of you."

The Result of a Personal Influence

And on the next Sunday he placed every one of those men in some Christian church. Each had applied for citizenship, each had accepted Jesus Christ,—and all because one Christian business man had given five and twenty-hours of Sacrificial Persistence in the interest of twelve men whose names he could not pronounce.

If in these days of dearth, unrest and low morale, we would carry forward to great achievement the cause and work of Jesus Christ we must have the COURAGE TO PIONEER, the WILL TO INVESTIGATE, CAPACITY FOR NEW TRUTH, a TOLERANCE OF RADICAL YOUTH, a SENSE OF RESPONSIBILITY TO ALMIGHTY GOD, a SET OF MORAL CONVICTIONS, crowning all these with a SACRIFICIAL PERSISTENCE.

"Greater things than these shall we do" because He has said so.

CHAIRMAN RUTLAND: It is characteristic of American people to need a shot in the arm every once in a while to awake them to action and I think we got it this morning. Sometimes we get in a rut. As safety men we think we need no new ideas of safety. On the other hand, if we check up, if we call our own conscience to account, we will find that we are responsible. The Doctor delivered a wonderful message for which we are duly thankful.

For the past two years, the Public Utilities Section has felt that some sort of visual education was helpful to safety men, foremen and others engaged in accident prevention work in getting over safety thoughts and messages to workmen. The Council has been making investigations in various ways in which this could be done. Mr. C. P. Ryan, Chairman of the Public Utilities Section's Film and Slide Committee and Safety Director of the Indiana Electric Corporation, Indianapolis, Ind., has developed a set of slides with an accompanying lecture which can in the future be secured from the Slide Committee or the Council, and if you don't feel like this particular subject will be applicable in the carrying out of your own problems, it will at least give you an idea of how it can be developed. Mr. Ryan will show you this set of slides this morning and in the future if you want to secure a set you have only to write him or the Council.

MR. RYAN: Owing to some impediment in my voice, not being used to this atmosphere, I have asked Mr. B. B. McCulloch, of the Bureau of Safety, Chicago, to present this matter with the assistance of Mr. Burns. Mr. McCulloch will read my paper.

The Use of Slides in Promoting Safe Operating Practices

By C. P. RYAN

Safety Director, Indiana Electric Corporation, Indianapolis, Ind.

It would probably be appropriate to first call your attention to what is meant by the subject of this paper—**FILM SLIDE SERVICE**. This service is now composed of individual pictures that may be shown to groups of employees through a stereopticon, which is supplied by the National Safety Council to all members at a very small cost, such pictures being devoted almost wholly to safe practices and supervision.

It is now proposed to enlarge on this service by creating film strips containing anywhere from 25 to 100 pictures, arranged progressively so that they will be educational to such groups and will offer a field for discussion as to ways and means, as shown by what others may do in other parts of the country under similar circumstances.

Let us assume that those assembled here are giving some thought to ways and means of preventing accidents in the various properties of the public utility industry and that they at intervals call employees or foremen, or both, together for the purpose of discussing safe practices where necessary hazards exist. What do we talk about? What interest do we inject into such meetings and how do we do it?

It may be said that we can not meet perpetually for the purpose of discussing care—being careful is one thing and knowing all about our job is another. One can not be charged with carelessness who does not know, or has had no opportunity to know, about the hazards involved.

Today it is thought that care among utility employees is much higher developed than the knowledge of operating practices and it naturally follows that those of us who seek new ways and means for the promotion of efficiency, which includes accident prevention, are anxious to know how our work is done elsewhere. Sometimes we read of these distant activities and gain the wrong impression and abandon any idea of change in our methods.

A few years ago we could depend on the transient workmen for this information and this type of workman was a God-send to our national industrial evolution. He carried from place to place a vivid description of new ways and means of operation and practically standardized effort in this country.

It is probably true that the industrial magazines assisted in this standardization scheme but these publications seldom reached the man in the field. The day of this transient workman is almost gone. Education has taught the employer and the employee that turnover in men and turnover in jobs is damaging to both. Employees are now realizing the importance of choosing a "life work" and clinging on until the day comes when promotion or pension is in order. He has found that the old adage that "a rolling stone gathers no moss" is true.

The employer has likewise learned that the constant turnover of employees has affected his efficiency and he realizes that occasionally in employing men, both the employee and the employer make mistakes and that there are some misfits but in the great majority of cases, an employment is a permanent tie between them.

Then comes the job of training. It has long since been evident to employers that training of employees is expensive. Such training covers a large field but training of men to use care and training them to know their jobs, is somewhat difficult unless special means are provided and with this thought in mind the National Safety Council is attempting to provide a means of carrying the latest ideas from one part of the country to the other on any subject of utility operation by the use of these film strips, so arranged that any phase of utility operation may be shown in a group of pictures on any particular subject.

It may be true that the pictures as shown may not be the last word in proper

operation, or in fact, these pictures may show incorrect methods but along with the film, it is proposed to point out such incorrect methods and also to call attention to the advanced methods in a lecture that would accompany each film.

Even this lecture may not be correct or might be improved upon. If so, the Council will request such information, as they may at all times keep such lectures, as nearly correct as possible, so that they will be beneficial to those interested in such subjects.

It may always be noticed that pictures illustrating the thought that an accompanying magazine article is intended to convey, receive the greatest attention of those concerned and the effect of them is to correct any idea obtained from the article itself.

Slide 2068—Two men loading poles on truck and trailer (rear view).

Our own institutions are careful to preserve by photograph the many new ways of doing things and usually such institutions will gladly furnish such information to others. If these photographs could be supplied to the Council for use in these film strips, they can be made of inestimable value to a great many institutions throughout the country.

If it would be true that, as some state, accident prevention depends 90 per cent on education and 10 per cent on mechanical correction, it is apparent that 90 per cent of our efforts should be made on educational matters. Such film strips are intended to be of educational value.

It is not difficult to realize the many different subjects that should be covered by such films when we realize that the various phases of the industry must be separated into their respective groups and that such films must be built up on the sub-divisions of these divisions, or, as we see it, the light and power, railways, telephone and telegraph, water, gas and ice industries, would each have their

respective groups of films and these films would be sub-divided into departmental films, in which event a film suitable for discussion before any group of men could be obtained from this library, together with such information as would be beneficial from the efficiency and accident prevention standpoints.

It should be understood that the National Safety Council can not provide the pictures from which such film strips would be made. These must be secured from the industries themselves.

This is a picture-taking nation and very few public utilities operate without occasionally being proud of some of their ideas or methods of construction, and as a consequence of this pride, they take pictures as a permanent record of their

Slide 2074—Tractor type—hole digger and pole setter.

achievements. It would be very simple and would be offering a contribution to mankind if a copy of such pictures could be sent to the Council with an explanation of the new idea or thing involved and these pictures could then be placed in these films for the education and information of other utilities.

The Film Slide Committee in this year has in a measure been successful in producing two films on two subjects of the light and power division, one being the "Pole Problem;" the other, "Distribution Line Maintenance," each with 30 pictures of the various phases of this work, which, as may be realized, could not completely cover either of the subjects but with the cooperation of the various utilities, that Committee hopes to build up these films to at least 100 pictures each, showing the many adequate and inadequate ways being used by various groups in the various parts of the country.

We have also been promised a full set of pictures by a Water Works Company

and in due time this series will be completed but as you understand, that series will show the method used by that company and it is hoped that other Water Works companies will also provide some pictures to be included in this film, which, as you understand, will give the various ideas from which we may all gain some knowledge.

There may be some doubt in the minds of some as to the value of such a scheme. We must admit that the idea is somewhat new and like all other new ideas, must prove itself but it is realized by those who advocate such a scheme that after a number of meetings of men have been held for the purpose of discussing safe practices, it becomes quite difficult to provide a program that will maintain that interest so necessary to success. It is the thought that these films may supply a want in this respect, in that they will elicit discussion of the various ways and

Slide 2080—First operation; setting pole with truck.

means. It is also thought that by this method standardization will be improved throughout the country as a whole.

With your permission we might demonstrate this matter somewhat by showing you the nucleus of the "Pole Problem" film, a subject that should in time, with your cooperation, show all of the latest practices as well as some practices that have been so disastrous in the past.

The contributors of the photographs included in this film are announced, however, it is presumed that in the future this policy can not be followed as it is hoped that the Council will receive photographs from so many sources that too much space would be taken up with announcements.

"The Pole Problem"—What a problem that has been to a great many of our institutions. It represents losses from injuries and damages to the extent that in every Light and Power Company, it is worthy of consideration. We have contended with everything from improper loading on railroad cars to improper use of pike poles, all representing losses. Improper loading is usually beyond our control and we must offset these hazards by extraordinary good judgment and care on our part.

Unloading poles from cars has resulted in a great number of fatalities and cripples scattered throughout the country. There was something wrong in nearly

every case, something overlooked, or some lack of knowledge of the job at hand and then some lack of care. So frequent and startling were these occurrences that some companies have made a study of this phase of the work for the purpose of stopping them.

Let us consider the result of the study by the Northern States Power Company. They have pictured the car loaded properly and conforming to railroad standards for loading, consequently we can not show you an improperly loaded car. We need several of these pictures so that this phase can be considered. This load

Slide 2082—Setting pole by hand.

stands erect or is not leaning, however, safeguards will be shown that will eliminate hazards where loads are leaning.

Ready to unload. The letters shown in circles represent an explanation of what we should find in connection with a properly loaded car and preparation for unloading, such as (A) blocking car to prevent moving, (C) skids properly supported to prevent breaking, (D) cables to support load after stakes and binding wires are cut, etc., all of which will be explained in a lecture accompanying the film.

There are other pictures in this film and others should be supplied which would show other conditions and means of efficiently unloading poles safely.

After unloading, poles must be moved to the place where they will be used. The following pictures show one way of handling them by two men. We all know that all companies do not have and can not afford such up-to-date equipment, yet they must move poles in various ways. Can we supply photographs of every known way of transporting them for the benefit of those who must occasionally

Slide 2083—Arriving on location. What's wrong here?

handle them and while doing so must combat the potential hazards accompanying each pole.

The erection of poles is another phase of the pole problem that in each year causes all of us more or less concern. This film at present contains only nine pictures bearing on this subject when all of us know that at least thirty-five might be shown to advantage.

Slide 2087—Raising transformer. What's wrong here?

Most of us here have in the past made some investigation of accidents of a more or less serious nature that have been caused by the handling of poles and after such investigation, our individual employees are encouraged to avoid similar occurrences in the future.

The Film Slide Committee are now requesting that photographs of conditions that existed at the time be provided for this film, together with an adequate description of the overlooked cause, so that this film may be built up to the extent that it will record every hazard experienced by all of us for the benefit of all of us, together with photographs of new ways and means of promoting efficiency in such matters.

Slide 2098—Soldering, with the second man in peril.

The other subject that has been partially prepared is "Distribution Line Maintenance"—a great subject. Many of us will aver that the maintenance of electrical distribution lines carries with it our greatest hazards and contributes more fatalities than all the other phases of effort in the Light and Power industry: What can we do about it? A great many things have already been done—standardization of equipment with their numerous provisions for clearances and location of conductors, guying, insulation, grounding and numerous other rules have been provided by engineers who have conformed generally to provisions laid down by the United States Bureau of Standards, all of which has tended to make this industry less hazardous to employees and the public.

Various companies have formed rules based on these standards but rules must be brief. A great deal of reading and studying required of some men is a decided shock to them and usually produces very little actual results and in a great many instances creates erroneous impressions unless the matter can be discussed with others.

Some might go so far as to advocate that all that is needed is to require the use of care in the handling of electricity and in case of a lack of care, a resort to penalties for failure to do so. Correct in some senses but let us suppose that I am to be employed as a lineman just as soon as I can, by some means, in the use of climbers, get to the top of a pole and return again to the ground with no injury to myself or anyone else. I am told to be careful as carelessness is penalized by my employer. What would I know about the many things that might injure me at the tops of those poles? What do I know about where I would, or should, find the higher voltages, neutrals and grounds? What would I know about con-

Slide 2107—Encouraging strains.

necting transformers, rubber protective devices and the thousand and one things that I should know before I can be careful?

It is for these reasons that we advocate the use of educational means for the purpose of eliminating the mysteries of electricity in the minds of those whose daily duties require them to come in contact with it. Will these pictures assist in this matter? If not, what can be done that will?

Let us look them over. It should be remembered that these pictures were posed for by an operating crew that is noted for complying with rules and they have very graciously attempted to show some of the common mistakes as well as correct methods.

What can be said of the first one? First, the truck is parked on the wrong side of the street, violating a law of some states and creating an unnecessary hazard to the public in all and in addition, shutting off free access to a fire plug.

Material has been unloaded for the work to be done on this pole and it is entirely incorrect to allow any material to encroach upon the rights of the public

without protecting against accident and injury to them. From the appearance, there was no occasion to lay these cross arms in this position and allow them to remain so without adequate protection.

Raising transformer with one man in a position that if something should break, this weighty object would seriously injure him.

Holding to arm braces has injured so many linemen that it is common among companies to make this act against the rules. If the habit is developed on new equipment, we will, of course, carry the habit to the old.

Two linemen ascending at the same time, one above the other, was a common occurrence until several of the lower ones were injured by the upper sliding down on them or some of their tools striking them. Against the rules now: The second man starts up when the first has secured himself with his safety and then usually on the opposite side of the pole.

These are just a few of the pictures in this film and we are briefly stating some of the things that might be said concerning them and the film covers only a small part of this subject. What would your line-foremen, linemen and groundmen say about these? Could a discussion be obtained in a meeting by presenting a film of 75 to 100 such pictures? If so, would this discussion be of value in clearing up some minds as to the reasons why we have some rules governing this work, which are sometimes considered a nuisance?

We think it should be remembered, as stated before, that our greatest effort should be made in promoting a greater knowledge of our duties rather than to attempt to correct our misfortunes by mechanical means and it should also be remembered that it is almost useless to attempt to improve our accident record by assuming that all accidents are the result of carelessness.

Lack of training and knowledge of the job at hand has been a more direct cause of accidents than all other causes combined.

In conclusion let us again beg of all branches of the industry that the Council be given some support in preparing these educational films for the use of those concerned. The expense and effort in providing photographs are of small consequence. The expense of the Council in reducing to film form is of considerable expense and trouble but if they will adequately serve those who are seeking information for improvement of their efficiency, the combined expense and trouble will be of little consideration as compared with results.

CHAIRMAN RUTLAND: This, I think, has been very practical. I wonder if there are any questions any one would like to ask?

MR. RYAN: It is proposed to have along with each of these films a lecture. I expect the 30 pictures would be sufficient for possibly an hour's discussion but there is not enough variety. What we are appealing for is pictures from other parts of the country. You will remember, these came from Wisconsin Power and Light Company. The Council needs photographs taken on distribution line maintenance, the pole problem, or gas operation. Send them in to the Council with your own story. I think you can go into the realm of supposition quite a bit by supposing that this or that would have occurred in your picture. That is what you want to do. You think those things out. It is too much to expect of the Council or any member that they can make the story. It is impossible for any man or group of men to become well posted on all lines of the Public Utility industry.

MR. DOUGLAS (Philadelphia, Pa.): We have used slides for years. We use several machines and we found we had to show them rapidly. Must this machine be shown rapidly, too?

CHAIRMAN RUTLAND: Mr. Burns will answer that.

G. E. BURNS (National Safety Council, Chicago, Ill.): If you will allow me just a few minutes I will tell you something of the construction of this machine. Inside here, we have the various lenses for condensing the light. We have a 200 watt lamp in what is known as a ray filter. You can hold that film there five minutes, five hours, or five weeks, as long as the lamp will last. Should the ray filter crack, it would scar your film. It meets all fire regulations. There is nothing flammable about it. As a matter of fact it only weighs four and one-half pounds. We did have a machine that had to be used rapidly, but you can hold this as long as you wish. There is no limit to the size of the picture but there is a certain volume you can get from the 200 watt lamp. Of course, the sharper your picture, the more detail you will get. This particular machine has a two and one-half inch lens. Now, it is possible to get a lens in any size. You could condense your focus but you would not have power enough with a 200 watt lamp. This is the largest made in the portable size. All the manufacturers have standardized on the 200 watt lamp. This machine sells for \$60 completely equipped, carrying case, extra lamp and slide containers. It has a simple slide attachment. All of the slides have individual carriers; you could carry 50 of them in your pocket. It is not any heavier than the film strip. There may be times when you don't want to show the entire pole problem and you can stock the slide catalog and select any one and we will send them free of charge—no cost whatever. If you don't care to purchase this outright you can rent it for one dollar a day and return it.

H. B. HARMER (Safety Engineer, Philadelphia Electric Company, Philadelphia, Pa.): What is the cost per film?

MR. BURNS: Fifty cents, roughly, which does not include the art work. We have to retouch every photograph we get to bring out the detail, but 50 to 60 cents is the rough figure for a frame.

The Council makes this proposition: If we have material submitted such as this in a series, we will share the expense with you fifty-fifty and put it in service so that other members can use it. We do that because some members have sent in a series of pictures and they are of no use to the section as a whole and they have to stand the entire expense, but, if you can send in a series of pictures, acceptable to your committee, we are willing to pay fifty per cent of the expenses.

H. A. MOTT (Illinois Bell Telephone Company, Chicago, Ill.): I would suggest that you go into the unloading of poles more thoroughly. Also, where people have joint poles, electric light on top and telephone beneath, show two men working on a pole, because some times you have what is known as a joint job where both companies have to be on the job at the same time; and it seems to me that a picture of that sort would be a good idea. Also where the high tension electric wires pass through trees, where a man has to get up to clear the telephone wires or electric light wires, etc. If they would take up the unloading of poles proposition, I would supply the picture of what I have described, the joint work and also the electric light and telephone wires going through the trees. Now, will the ordinary photograph answer?

MR. RYAN: A sharp photograph. It should be as sharp as possible. A photograph, anything five by seven or larger, will be all right. When they get down below five by seven they don't reproduce very good. Smaller pictures are not as good.

MR. MOTT: I will see that you are supplied with the pictures I spoke of. We had seven men killed this year while unloading poles.

CHAIRMAN RUTLAND: I would like to break in for a minute to have a report of the Nominating Committee of the officers and committee chairman for this Section for the ensuing year. Mr. Charles B. Scott, Bureau of Safety, Chicago, is chairman of that committee and the members of that committee have deliberated quite carefully in their selection of men for recommendation to you. I will ask Mr. Scott to read the report to you.

Report of the Nominating Committee

Chairman, H. F. Webb, The West Penn Electric Company, Pittsburgh, Pa.

Vice-Chairman in Charge of Electrical Interests, Ivan L. Scott, Electric Management & Engineering Corporation, Asbury Park, N. J.

Vice-Chairman in Charge of Gas Interests, E. S. Beaumont, Peoples Gas Light & Coke Company, Chicago, Ill.

Vice-Chairman in Charge of Telephone and Telegraph Interests, J. L. Vandergrift, Chesapeake & Potomac Telephone Company, Washington, D. C.

Secretary, G. A. Doeller, Dayton Power & Light Company, Dayton, Ohio.

Poster Committee Chairman, John J. Barada, The Laclede Gas Light Company, St. Louis, Mo.

Publicity Committee Chairman, E. J. Kreh, Duquesne Light Company, Pittsburgh, Pa. (American Gas Association).

Film Slide Committee Chairman, Roy M. Godwin, Philadelphia Sub-Counties Gas & Electric Company, Philadelphia, Pa.

Fire Protection and Prevention Committee Chairman, H. M. Keller, Northern Indiana Public Service Company, Hammond, Ind.

Engineering Committee Chairman, H. B. Harmer, The Philadelphia Electric Company, Philadelphia, Pa.

Statistics Committee Chairman, C. P. Ryan, Northern Indiana Power Company, Indianapolis, Ind.

News Letter Editor, N. L. Devendorf, Consumers Power Company, Jackson, Mich.

Councillors: C. J. Rutland, Texas Power & Light Company, Dallas, Texas; B. B. McCulloch, Bureau of Safety, Chicago, Ill.; George C. A. Opp, The Detroit Edison Company, Detroit, Mich.; B. Frank Day, Philadelphia Electric Company, Philadelphia, Pa.; Harry M. Webber, Illinois Bell Telephone Company, Chicago, Ill.; W. L. Loyd, Alabama Power Company, Birmingham, Ala.; and C. R. Beardsley, National Electric Light Association, c/o Brooklyn Edison Company, Brooklyn, N. Y.

CHAIRMAN RUTLAND: Mr. Webb, will you rise and face the audience? I want them to see who you are. Thank you, Mr. Webb.

Gentlemen, you have heard the report.

MR. HARMER: I move it be accepted and the secretary cast one ballot for unanimous election.

(The motion was seconded and carried.)

CHAIRMAN RUTLAND: First I want to call on Mr. Vincent Wakefield, of the City Ice Company, Kansas City, Mo., for an announcement regarding the Refrigeration Section.

VINCENT WAKEFIELD (Chairman, Refrigeration Section, National Safety Council, and Treasurer, City Ice Company of Kansas City, Kansas City, Mo.): Mr. Chairman, Gentlemen: Some of us have felt the need in the National Safety Council for means of studying refrigeration in exactly the same way and manner that you gentlemen are studying various problems that emanate from the utilities in which you are engaged. Most companies that I know of have become largely interested in ice properties; and feeling the neglect and lack of information relative to refrigeration and to the ice business and allied industries using refrigeration, some of us have organized a Refrigeration Section. With the courtesy of your chairman, I want to draw attention to the fact that this Section will meet at two o'clock this afternoon in Parlor 1 on this floor. I want to call attention also that the opening address will be made by one well loved by you and your own member, Mr.

Charles B. Scott. I would appreciate your taking occasion to attend our meeting if it is at all possible.

CHAIRMAN RUTLAND: Thank you, Mr. Wakefield.

At this time I want to ask Mr. Burns of the Council to tell you of the regional conferences held in the various parts of the United States during the past 12 months. He will tell you of their purpose and some features of these conferences which I think you will be interested in because they are trying to be located in certain sections where you can attend.

G. E. BURNS (National Safety Council, Chicago, Ill.): I don't know what I can say that you have not already said, Mr. Chairman. You told it all in a nutshell. In the past year, we have held 22 conferences throughout the states. As. Mr.

Rutland expressed it, the purpose is to reach the foremen and those interested, who because of time and expense cannot attend the National conferences; so we attempt to bring the conferences to them. Public Utilities as well as other Sections have cooperated more than 100 per cent, if that is possible not only in promoting these conferences but in contributing to the program and speakers. Our mutual friend, Carl Rutland,—well I should say we overworked him. I had him at New Orleans, I should not say "I"—the boys invited him, but I was responsible for his being there; also at Birmingham, and various other places such as Oshkosh. Those boys in Wisconsin try to outdo everybody else when it comes to regional conferences. They put on young congresses. We started out by having small, sectional meetings and gradually took in more territory and then it became a miniature congress and they have gained in such proportion that the city cannot accommodate them.

The one point I want to make is to ask the members of this Section to send their men in their particular territory, or canvass their men and get them to attend these regional conferences for your own good. In Wisconsin they have it so well organized, it is not a question of the staff or committee doing anything; they sent

their men out in various territories like Oshkosh and the Public Utility group there, and they knew exactly how many men they could expect on that particular day and they were all there. That was true of other industries, too, not only public Utility.

I am rather stumped about talking about regional conferences. I don't want to attempt to tell you how to run them. We have prepared a pamphlet on the "Why and How of Regional Conferences." There is one point, don't be frightened at the words "regional conferences." If you have a group in your city and wish to put on a miniature safety meeting, don't hesitate to write into Headquarters and we will send you the pamphlet and will even help you to get speakers. If

you want a certain speaker we will try to get him whether he comes 50 miles or 500. There is no expense involved in 99 cases out of 100.

CHAIRMAN RUTLAND: Gentlemen, we are very fortunate in having here, our beloved National Safety Council President, Mr. Homer Niesz, and I would like for him to say a few words.

HOMER NIESZ (Pres., National Safety Council): This is a real pleasure for me to be here and I feel most at home. This is my own business and I like to meet with the members of this Section. My duty as President, unfortunately, prevents me from being here long or taking part in your proceedings. I retain and always shall, the deepest interest in Public Utilities and wish you every success in the continued growth of this Section which has been so phenomenal.

CHAIRMAN RUTLAND: If there are no other questions to be asked regarding this slide practice, we will pass on, but I want to give you plenty of opportunity.

MR. DOUGLAS (Philadelphia, Pa.): I do want to say that I have in the Philadelphia Gas Works several hundreds of slides along the lines the committee seems to want to consider and copies of those slides will be gladly submitted or furnished and I hope they will be of some use.

CHAIRMAN RUTLAND: Thank you very kindly.

H. B. HARMER (Safety Engineer, Philadelphia Electric Company, Philadelphia, Pa.): So we won't go away with the idea that these are all the slides we have, will you ask Mr. McCulloch to tell us something about it.

CHAIRMAN RUTLAND: Will you tell us something about the slides available at the National Safety Council Headquarters?

MR. RYAN: Gentlemen, it is probable that all of you have received this catalog. If you have not received it, notify the Council. This contains a list of slides galore. You can order any number you want of what you find in this book; and in addition to that we expect to have, some time, a list of films to be placed in here, a library, in fact, all Sections analyzed into departments of the various utilities of industry. I am very glad that some of you have already made up your minds to help this Committee to develop these films, if they are going to be developed. If they should not be, now is the time to know it before we encourage the Council to spend a lot of time and money.

ADJOURNMENT

October 3, 1928

C. J. RUTLAND, Chairman**Safety Engineer, Texas Power & Light Company, Dallas, Tex.**

The second session was called to order at nine forty-five o'clock by the chairman, Carl J. Rutland.

CHAIRMAN RUTLAND: Gentlemen, our first speaker on this morning's program is William Johnston, Jr., Vice-President of the Twin States Gas and Electric Company, Boston. He has had considerable interest and activity in promoting safety work in his company and has produced some very marvelous results. I am happy to have him here from an executive standpoint to tell you what his good company has accomplished.

How I Accomplish Reduction of Accidents in My Company

By WILLIAM JOHNSTON, JR.**Vice-President, Twin States Gas and Electric Company, Boston, Mass.**

At the time my subject was assigned to me I had no idea that it was going to take the form of English that it has. From that subject you can readily deduct that there might creep in a sort of egotism and so I am going to switch that a bit and speak for the moment on why we have not reduced accidents of the company I represent. At the outset, I must inform you that you are not going to hear anything new. After all, there are just about so many rules affecting our every day conduct, so many rules affecting the governing of our every day life. One hundred odd years ago, a group compiled the Constitution of the United States. We all can attest to that document and the wonderful piece of work which they did. That document has stood the test of time and it has outlined the conduct, the path, which our Government has taken from that time on.

We have in the conduct of our social lives, ten commandments which were handed down and have stood the test of time. We know that adherence to those principles or precepts will keep us out of jail and will insure for us the benefits of our future well-being. And so in the question of safety we have certain rules which, if followed, we know will insure our keeping out of the hospital and similarly take care for our future lives.

We get back to fundamentals in all cases, and if in the company I represent we have had trouble back a few years ago in reducing accidents, it is because we did not know the fundamentals. True we have been operating under safety rules and holding safety meetings, but we did not have the fundamentals properly cared for.

I wonder if any of you folks have ever seen a football team that has gone stale—a football team at the middle of the season that has just seemed to have lost its edge? If so, you can readily see that it was of great importance to the coach and managers of that football team that they go back to the fundamentals, retrace their steps and pick up those things which they should have learned at the first of the season or at the start of their work.

I feel that the safety work in any organization, large or small, sometimes is in great danger of going stale. It used to be a sort of by-word of our companies that every safety meeting we had was the best safety meeting that had ever been held. Month after month, reports came in that it was the best safety meeting we ever had, and month after month there came in an evergrowing list of accidents and so we got back to the fundamentals. We began to read our ten commandments, if you

please; we began to feel that it was not a question of written English, that it was not a mere jumble of words, but that it was something of the nature of a heart-to-heart task. It was a question of getting close to the industrialists and not having them appear as automatons that just went through a mumble of certain words or motions.

Placing the Responsibility

What are the fundamentals from an executive standpoint? I think the most important fundamental is the question of placing the responsibility for accidents, the question of having some one responsible for the accident. I often think of that phrase and tie it up with the story of the gentleman who was a little under the weather who went into the bakery shop. He wanted some doughnuts. He went to the lady behind the counter and said, "I guess I'll have a dozen doughnuts." She took the doughnuts and put them in a bag and handed them to him. He sort of half turned at the door and saw some nice frosted cake in the glass case and it arrested his attention and he said: "No I don't want the doughnuts. I think I'll take that cake instead." So she tied up the cake in a package, handed the cake to him and he returned the bag of doughnuts. He turned to go out and the lady stopped him; "Sir, you have not paid me for the cake." "Well," he said, "I gave you the doughnuts for the cake." "But," she said, "you did not pay me for the doughnuts;" and his rejoinder was, "but I did not want the doughnuts."

Now comes the question of placing responsibility for accidents from the executive down to the man who has the accident. I firmly believe that if executives would realize that every accident which occurs on their property is one for which they are responsible, that we would soon see an improvement. The safety director, similarly, should feel the responsibility of accidents, the line foreman, the distribution superintendent and what not should take unto themselves the responsibility of accidents. The investigation of accidents, we found, is a fundamental issue. I sometimes feel that, when we investigate accidents, reports are received, filed and forgotten. I sometimes feel that as a result of accidents, there is quite a bit of sympathy due the man who might have been the cause of the accident. The injured man is forgotten and I feel there must be a more or less hardboiled attitude, tempered with mercy to be sure, but we must not overlook that some one has made a mistake and again might make a mistake if proper procedure is not followed.

The mental attitude toward accidents, I am sorry to say, in the part of the country I come from, is that "Accidents will happen anyway." It is an attitude that you are apt to get disgusted with. It is an attitude that in my estimation is one of the most deplorable things in this industry. We know that accidents don't happen. We know that in practically every accident you can put your finger on the cause and say that at this point something was done that should not have been done, or at this junction another method should have been used. And so we get down to the question of caring for the mental attitude toward accidents.

Careful Selection of Employees Important

The question of hiring new employees, of course, does not need to be touched upon at great length. Its importance is realized without any doubt at all. It has been our experience that minors under 21 had a very bad accident record. Their lack of experience in one case was the reason. Their unsettled frame of mind in another sphere accounted for it; and so I say we get back to the question of careful selection of employees.

The question of disciplinary measures we found to be one of importance. Discipline and the enforcement of safety rules, I firmly believe, must be cared for by executives of companies but I don't feel you can set any definite rule whereby men

will be punished. I feel that industrial cases warrant the passing of judgment, but I feel that there should be some discipline, some method of caring for careless workers, some method of caring for men who continually have accidents.

Five or six years ago, we considered safety—not a side show exactly—but we did not consider the importance of it, and the company, having some 600 odd employees, showed it. You see I am making a sort of a confessional to endeavor to throw out certain thoughts whereby a constructive program can be followed to cut down accidents. We, at that time, as I say, did not fully realize the responsibility of safety. The safety work was conducted by our merchandise manager. It received attention when the ranges were not going so good or when the vacuum cleaners were not selling, and we found that one of the most important things that we did was to put the safety situation on what I might call a real, honest to goodness basis by having a man devote his entire time to safety. I don't mean by having the safety man take care of claims. I don't mean, having him take care of industrial things like taxes or any other allied part of the functions of utility. The safety man's job is to take, think and act safety all the time. Perhaps you say, well, claims are part, you might say, of safety. It is an outcome of accidents to be sure, but I feel a man who has safety on his mind at all times is better fitted to carry through his program.

Perhaps you will say there is an economic reason for a combination. In response to that I would say we are always glad to state we don't consider the cost of these accidents. We don't like to think of dollars and cents when speaking of saving human lives and yet I venture to say we have a great many companies who were in the same predicament as the company I represent, and so I repeat that I don't think safety work is a combination of jobs and I feel that any company with 300 employees, or 200 employees, can find enough work for a safety man to keep him busy at all times.

I am strong in the opinion that the minute they put that man on safety work, the next minute they will see their safety work coming up to the standard it should. You get out of safety work just what you put in. That old adage was never truer and so I would leave with you this thought that we have got to get back to the fundamentals. Those of you who went through the service knew that every fourth week, every Monday morning, there were read certain articles of war, simply to bring home to you a certain gospel. I feel the same way about safety. We have got to go to that well and take from it safety knowledge, keeping it in mind and ever-dwelling on the thought that the fundamentals of safety are the things that we continually have to strive to stay with.

CHAIRMAN RUTLAND: Thank you, Mr. Johnston. I am sure the audience enjoyed your address.

I am glad to see so many present and when you think of the men who come from all over the country it is a remarkable attendance. An evidence of the continued growth of this Section is the expansion of its activities. The fundamental wish of industry in the accomplishment of safety work is to get down to the bottom rock. That means that the safety engineer must build up his prestige in his own organization without egotism or without the desire to obtain a lot of credit. He is after the answer, and if he can come in contact with the engineering organization of his own company to the extent where he has sold himself on safety rather than on personal desires, then, I think we will get much further ahead. Sometimes it looks as if the result some safety men should obtain, is to go out and counsel with the men themselves instead of going through the organization—go to the superintendent and the foreman, and sell them safety. That is one angle. Another is the contact this body of men represented here today should have with the Accident Prevention Committee of the National Electric Light Association and the American Gas Association, I am very glad this morning we have Mr. Beardsley and Mr.

Dobbin with us. Mr. Beardsley, will you tell some of the activities of the Accident Prevention Committee of the Electric Light Association?

It is unfortunate that some of the publications of this wonderful body do not ultimately get to you men. Sometimes these reports are included in the proceedings of the N. E. L. A. They contain a lot of valuable information. This morning we have Mr. Beardsley to tell of some of the reports his Committee has gotten, what they contemplate doing, and how his Committee can better cooperate with us in the future toward safety work. I take great pleasure in introducing Mr. Beardsley.

Address

By C. R. BEARDSLEY

Chairman Accident Prevention Committee, National Electric Light Association

Your chairman not only gave me permission to change my topic slightly but said I might take as much time as I wished, in his usual generous way. He has given me that opportunity and therefore instead of reading a set paper, I would like to talk on some of the aims of accident prevention and lead from there to where we may find an opportunity for close cooperation with the Public Utilities Section.

I remember in the days of real sport, in 1892 or 1893, the great joy that was occasioned in our neighborhood, when somebody undertook the building of a residence. It was an average neighborhood, an average town.

I presume the observation I make on the character of the boys I trained would represent largely what we get throughout the United States. When they started excavation, we started operation and the battles would begin, sand battles and then rock battles. We even dug trenches in open lots and we had some very effective mortars and catapults. We had quite exciting battles. Our fathers, in the difficulty of earning a living, did not give us as much time as they might, but as soon as we made a few direct hits we had attention good and plenty. I remember one poor lad who reached the stage of making a battleship and in his adventure-someness dropped two stories and paid with his life. That stopped us for a while but then boy nature asserted itself and we went back to the same old game.

The developments of the Y. M. C. A., the Boy Scouts and other organizations, have broken up the rock and sand battles, but boy nature has not changed since 1892. What is the difference between that boy and the man we all meet in our personnel in Public Utilities organizations? I think education and training and growth of experience, greater wisdom of years, have placed a veneer over that boy nature and the thing we have to deal with is the breaking of that veneer. It is nature to forget once in a while, just the same as boys forget their parental instructions. I commend Mr. Boyd Fisher's book on Mental Causes. I have read it and reread it.

Accident prevention work has taken the slant of a number of different methods of approach. We have the school which believes solely in the training of a man, the educating and habituating of him to better methods of work and better continuous caution. That is all to the good. It is the most fundamental thing we have. Then comes the man who wants to make rules and enforces rules by punishment, sometimes that punishment being vented on the poor fellow that is hurt. I don't hold with that method. Sometimes a repeater might have to get some kind of a suspension or a more effective lesson than simply a talking to. Some think it should be on the foreman or supervisor. The Union Pacific has the best record of all railroads and that is far better than we can boast of accord-

ing to the exposure and hazard in our industry. The steel industry, likewise, has done a lot better. The Union Pacific makes some pretty severe suspensions. They go pretty well up the line and a man who has a wreck or serious accident pays heavily. That method, I believe, is not so much used by public utilities as it might be.

Another method is the establishment of all kinds of mechanical safeguards. That is increasingly important. It stopped a lot of accidents and as engineering methods change that will become still more important. That is one of the lines that is being given considerable note. Fifteen years ago it was really crystallized in the formation of the Accident Prevention Committee of the National Electric Light Association. If I speak of the supposed shortcomings of that work I want it understood that it is in no sense criticism or lack of appreciation of the fine work those men did. I hope to say they were up against a good deal of difficulty which we are trying to break down at the present time.

In those days (Mr. Harmer, Mr. Van Brunt and Mr. McLane will correct me if I am wrong) I believe there were so many difficulties in design and operation and other phases of our work, developing some other phases that other fellows were having trouble with, that accident prevention was crowded out. The man who attempted to get his hearing was only a cry in the wilderness. What could he do? There was only one thing for him to do and that was to look to the individual, train him to such prevention as the industry could apply. That may have been unfortunate but it was quite fortunate too, and I think that is the fundamental point of accident prevention. They did a darn good job, if I may say that, and I have here some evidence of the amount of work put out, their operation for several years back and some later reports gotten out within the last two or three years.

Recently systems have become complex. They concern the engineering phase and the opinion has been given that the engineering phase has been over-emphasized. I don't know whether Chairman McKinnon and myself have been referred to. We have emphasized that in our own construction work. However, whether we were intended or not, I will take upon myself the answer of that point, that engineering is being over-emphasized.

How many of our companies continue to operate disconnect switches that are not in any way interlocked from being wrongly opened? How many cases do you know of in which two switches of one circuit and one of another have been left alive? I have heard a number of such accidents recently, serious ones too, where men have been hung up on all kinds of voltages because of no preventative measures; that is one of the things we can try to prevent by getting the foreman's activity more effectively, and we do find that men make the error of getting on the wrong circuit.

We might compare engineering devices somewhat to grade crossings. When there were nothing but horses the grade crossing was the rule rather than the exception; and when traffic became congested, gates were put in with a tender and that was effective in that stage of railroad and ordinary street traffic. When automobiles came in and we find human nature is not much of an improvement over horse nature; they ran into the gates and so they changed the gates to steel to prevent a fellow from passing; and then they made over and underpasses, but they were not designed with a view to present-day traffic and changes have been found necessary. I know of a place in Wallingford where a particular abutment caused many accidents so they changed the roadway so that the approach was not a sharp angle and made a large swing and that is being done in many cases. Underpasses are being straightened out so that cars coming in the opposite direction can be seen, and so that they can see each other under the pass.

The present cautions which our company has put in, in the matter of preventing men from getting hung up on circuits, involves the expenditure of money. I have

been sympathetic with this idea that we should approach accident prevention work without consideration of the dollar. It is a humanitarian matter before a dollar matter. After you get so far you must find out how many you can get by with. Furthermore, sooner or later, the Board will say, "What will you get for it?" You must say, "Accidents have been reduced, lives saved," and you may have to reinforce it by a statement of what the consequent damage may be. I have one particular accident in mind in which a man was seriously hurt on a short circuit of 2,700,000 volts. He came out and is all right. It was simply a burn case. He was well protected, but the consequent damage ran up into the \$20,000 figure. There is some reinforced argument we can use when we get on this border line of opinion to find out whether the added equipment is of profit or not, so I believe that engineering analysis of what these various pieces of equipment will do will be an increasingly important phase of our considerations.

There is one particular phase of our work this year that is of interest and that is the local hazards. In the Engineering Association Meeting, 203 cases were clipped from the newspapers in four months. I believe there will be an increasing exposure due to the use of cheap electric appliances, such as poor lamp cords and such causes which we should get after. We appointed a committee, headed by E. W. Gorry, a very effective man. He will look into it and we hope to have this improved by his doing a lot of educational work.

We have a big problem in getting people to understand that they must not use these defective appliances, the cheap toasters, etc. The second phase is how to prevent this stuff from getting on the market and how far we should go with that prevention. That is a big economic problem. You might say the Ford should be taken off the market because it is not as good as the Rolls-Royce, but the Ford car is very valuable to our motor transportation even though it is a cheap device. We must study to see whether these cheap devices can be improved, whether the money cost is a measure of their defectiveness, or whether they can be improved or controlled so that when they get on the market they will meet standards. That is a big problem. We ought not take a thing immediately off the market because it is cheap. We have different viewpoints in the N. E. L. A. which you possibly don't have to consider. I think you will agree that more elements of industry can be brought behind our work and if that is done the better it will be for the work we are trying to put across. If we go about our work without consideration of the other fellow's, he will not be ready to back us up as he would if we got his viewpoint, not as a criticism, but observation.

In public utility we have not done enough in the past. Mr. Johnston referred to it in getting the other group's interest. I don't think we should stop the educational work of safety men or employees but we should draw in executives and operating men. If they can be made accident prevention men and we can get their interest, our work will go ahead with great strides. I was told yesterday of one company that had not done a bit of accident work and one of the executives attended a committee meeting and became impressed and now they are doing great work. That is one of the main things of the committee, to get companies interested and to reach those who have not yet become interested in the work.

In Re Statistics

We had informal meetings to discuss this matter. The Public Utilities Section and the Accident Prevention Committee have parallel work, overlapping to a certain extent. We should prevent duplicating. We are trying to get together and make this work effective by an exchange of information. How, I don't know. A joint committee will be appointed and later we can report on that.

We had intended to have a sub-committee on refrigeration because many com-

panies operate refrigeration plants but we decided not to duplicate the effort when we found out there was one in the National Safety Council.

In the Matter of Posters

Mr. Johnston or Mr. Rutland referred to the fact that the publications of the National Electric Light Association had not possibly reached all you people. I may say that neither do the publications of the National Safety Council reach all our people and we could derive much benefit out of a greater exchange or circulation. After this meeting we will post on the board prepared for it, some of our information. I would like to suggest for your consideration and invite you to send your display down to the Accident Prevention Committee Meeting at Philadelphia so we can get it across there to the men who don't get it. If you approve of that I will be glad to appoint a committee to arrange it and see that it is done—a couple of fellows to do the dirty work, in other words.

As to the type of poster, circulation will reach far larger acceptance and extent if the information given is given a little restraint. I believe most people in the electrical industry would not be alarmed by a statement of the seriousness of electric shock; however, there is another viewpoint, the psychological viewpoint. Mr. Bennett told me that when he was in France observing action of men under fire they were instructed to do certain things and were told of the dangers of certain things, shrapnell for example, and they went back under fire. The psychology of prevention of accidents has caused people to think we should not play up to the terrible results of an accident but carefully stress the correct methods of doing things. We might give a slight degree of warning of what might happen but should not emphasize the accident. That would be more constructive on these posters. If that may be taken into consideration I think you will get a further use of your publications. The National Safety Council, through city channels, has access to a great many groups that can be approached, the Rotary Clubs, Kiwanis Clubs and Public Schools, which seem to me can be very much better attacked through the National Safety Council than through our activities.

Some 35 lines of publicity are open to us whereby people at large can be reached in an effective manner. We are not at liberty to give out the names or avenues of reaching the public but I think we may be able to exchange such news and have better effects.

I want to mention a few reports: The Accident Prevention Committee has had a Committee on Resuscitation. The Prone Pressure method of resuscitation has been under development; there have been discussions which culminated last year in the acceptance of this standard method by a number of different bodies of power. The American Gas Association, the Red Cross, the American Telephone and Telegraph Company, the Bethlehem Steel Company, the National Electric Light Association, the Safety Council, the U. S. Army, the U. S. Navy, and the U. S. Public Health, nine of them, have all given approval of the resuscitation method which is the basis of this pamphlet. The chairman of this committee got the approval of all these, even though there was some difference of opinion as to the best method. This pamphlet has reached a circulation of a quarter million, schools, firemen, policemen, as well as others.

There is an accident prevention case for lineman. One of the publications placed on the bulletin board will give an indication of the work for a number of years past. I commend to you the exchange of this information. We can gain by it.

In closing, I believe that while we possibly have reached a less rapid growth in our preventions, that is, diminishing accidents at a less rapid rate, there is still a great field for us, and certainly if we work together and put our shoulders to the wheel as that poster indicates, we can accomplish a lot and I feel that we will have a great advance and a great improvement in our records.

CHAIRMAN RUTLAND: Mr. Beardsley, I want to thank you on behalf of the membership here for the wonderful talk. I think there is a lot of room for improvement in our contact with your committee and I have just suggested to the new chairman that a consultation be had for an exchange of ideas. This is a good place where the Accident Prevention Committee can have direct contact with the men on the firing line. It is a wonderful opportunity for them to come in contact directly with you.

I will call on Mr. Dobbin, chairman of the Accident Prevention Committee of the American Gas Association. I don't know whether he will be the new chairman but at least he will cover the ground of the past year's work during his administration.

Address

By E. R. DOBBIN

Chairman, Accident Prevention Committee, American Gas Association

It is with a due sense of appreciation that I come before you this morning as Chairman of the Accident Prevention Committee of the American Gas Association to tell you of our activities and how the committee functions.

I am sorry that I cannot tell you in full of the past year's work, nor present the printed reports as promised in your program. This is due mostly to the fact that our annual Convention has not been held and issuing of reports previous to the Convention would be ill advised. However many of you will be with us in Atlantic City next week where full report will be made and printed copies available. Members of the Association will receive these in due course and I have no doubt but that Headquarters will gladly supply others of you who may concern.

Having been interested for some years in Accident Prevention work and having served, to the best of my humble ability, upon your council committees I have had exceptional opportunity to watch the growth of this Public Utility Section from a mere handful of enthusiasts to the wonderful gathering here at this session—everyone a willing worker eager to learn and to apply—all that preventable accidents in our great industries may be kept to a minimum both in number and severity. To this end it seems fitting that all organizations working with this in view should contribute their mite into this great melting pot—the National Safety Council—where the results of our labor can be used to such very great advantage.

It seems proper that this section should include, as it did this last year, the chairman of the American Gas Association and the National Electric Light Association Accident Prevention Committee among your councillors—thus establishing a direct point of contact—that I am sure will prove of service to all concerned.

During this last year the Natural Gas Association joined forces with the Manufactured Gas or American Gas Association. This meant added problems and added responsibilities—but it also brought to us a group of capable men anxious to learn and anxious to serve. Theirs was a very welcome addition and I am sure it will contribute much to our Accident Prevention program as a whole.

Our committee is drafted from the member companies of the Association and usually numbers 20 men from the four points of the compass skilled in their line and anxious to keep the Gas Industry in the front ranks as regards the prevention of accidents—not only to employees but to the public. The prevention of property damage—both plant and public—also comes in for a fair share of attention for we realize that property damage—especially in our industry—often carries with it its full toll in the matter of accidents to human beings.

Under the supervision of Headquarters and through a chairman—regular meet-

ings are held—and the general committee broken up into sub-committees each under its own chairman. Each sub-committee is assigned special work and accounts for its work in general committee session—where if satisfactory to the majority it is passed on through the Secretary to Headquarters and the Executive Committee for approval or disapproval, finally reaching the industry as a part of the General Committee report and printed in pamphlet form.

Now that you have a set up of the committee I will carry you along with me into sub-committee work—particularly this year's work.

The "Statistical" sub-committee gathers from the Association members data relative to number, class and cause of all accidents peculiar to the Industry as well as obtaining such special data as may be needed for special work. This is a progressive work added to year after year. It is both an indicator and a guide serving several important purposes.

The second sub-committee, "Safety and First-Aid Devices" examines, tests and renders a report on all devices, of the nature indicated in the title, which are referred to it. If the report is satisfactory to the General Committee—approval or disapproval is voted and this action becomes a matter of record for the guidance of any interested. Until lately this sub-committee has had to carry out tests where and how and as best it could. Now the Association Laboratory in Cleveland gives assistances and renders a report much more complete and final than we formerly could hope to secure. This enables us to pass judgment from the results of Laboratory tests as well as results from practical field tests.

The third sub-committee, "Bulletins" prepares and submits posters dealing with Gas Plant and Gas Distribution Hazards. After approval by the General Committee these are routed to the National Safety Council for printing and distribution. The report this year will show 22 such posters.

The fourth sub-committee, "Safety Practices in the Industry" has endeavored to utilize material gathered during previous years but finding itself faced with technical matters—has in joint session with a special committee from the Technical Section—confined itself to the solving of some few specific safety problems. It is pleasing, however, to build the foundation of a Safe Practice pamphlet which builded upon and added to for the next two or three years should prove a complete and trustworthy treatise on Safe Practices. Truly such a treatise is badly needed.

The fifth sub-committee, "Occupational and Catastrophe Hazard" is presenting a progress report in as much as it is impossible to complete an exhaustive report within the short time of one committee year.

The sixth sub-committee, "Safety Hints for Customers" prepares, as its name indicates material to be used as envelope stuffers or on the back of consumers bills in a continuous campaign to educate the consumer to use gas appliances efficiently, and in most cases efficiently used appliances means *safely* used appliances.

Sub-committee seven, "Medals," passes judgment on all applications for McCarter medals as well as recommends the award of the Addicks medal. This last is awarded to the employees performing a very outstanding heroic act and is known as the American Gas Association Meritorious Service Medal. Only one such medal can be awarded each year. The committee will recommend this year the award of 71 McCarter medals which is proof indeed that the adoption and teaching of the Prone Pressure Method of Resuscitation is bearing fruit. In 1924 only 5 applications were received—the number increasing each year up to this year's record number of 71.

In this convention I wish to let you know how elated we all are with the adoption by the many organizations concerned of the Prone Pressure Method of Resuscitation. For years the N. E. L. A. and the A. G. A. have *labored* and *loved* and all but *lost*. Now we are coming into our own—one method—broadcast to all the world. There may be some little variation in technique—and time may

bring a better method—but now—*right now* we are teaching and preaching *one* method. This with the McCarter medal in the Gas Industry, the Insull medal in the Electric and the President's medal taking care of those outside give us cause to rejoice. So let us be thankful and make the most of our opportunity.

I have given you only a brief outline of the work of this committee. I have not endeavored to give a report but have endeavored to show how our activities link in closely with yours and how willing we are to share with you the fruit of our labors and how so long as results are obtained we can go on happily each contributing to the other's welfare.

CHAIRMAN RUTLAND: Thank you, Mr. Dobbin and Mr. Beardsley. Now you gentlemen know how desirous these men are of your cooperation so I want to suggest that when Mr. Beardsley and Mr. Dobbin have arranged the booklet, that you take the names and write the committees direct for such reports as you desire; or, if any other questions arise from time to time, please feel free to write them direct and if it is handled diplomatically a safety engineer can build up his own prestige in his own organization, by getting a report such as this or some other report that has been gotten out on a like problem. It lets the engineer know that the safety man is coming to him for help or suggestions as the case may be.

Mr. Beardsley mentioned the voltage hazard and I am going to suggest to the incoming news editor that he consult with Mr. Beardsley as to how these leaflets may be procured and include that in the first *News Letter* or the next one, so you can in reading these *News Letters*, be acquainted with where you can get these leaflets and order a few of them and decide on whether you want to use them. The price can also be included in the *News Letter*.

Now, gentlemen, in industry today there is a very close tie between normal training and accident prevention work. The next speaker I am going to introduce to you is Mr. M. J. Kane, Engineer in Charge of Plant Training, American Telephone and Telegraph Company, New York City. Mr. Kane is closely associated with action of this kind and has been for some time. He has a national reputation as an authority on industrial training. He is now building within the telephone industry, a line of educational activities among men which will involve, when completed, more in the line of training than any university in the world. While Mr. Kane claims he is no teacher, those who know him know he is responsible for the tremendous amount of analytical training of hundreds and hundreds of men in the telephone industry. He is very competent and I am sure if you take some of his thoughts and put them in your own organizations that they will prove of decided advantage in safety work. I take great pleasure in introducing Mr. Kane.

The Foreman as a Trainer for Safe Practice

By M. J. KANE

Engineer in Charge of Plant Training, American Telephone & Telegraph Co.
New York City

I would like to tackle the subject in a manner a little different from its ordinary treatment. We have been talking a lot about foreman training. I would rather forget that now and begin at the beginning of our whole problem. Public Utilities, in particular, must find a special significance in safety matters that differs a little from other industries. It is always important in any industry, but particularly so in public utilities, and that applies to any sort whether communication, lighting, gas or transportation. Maybe I can point out some of its particularly impressive features that make it significant.

Effect of Public Opinion

One is your depending upon public opinion, and that can affect the success of your organization tremendously. Second: your men, or the working force, operating as a group. One man in a group out of line on safety measures can quite seriously affect the well-being of others in that group. A third feature is that your workers are almost invariably performing before an audience. The work is done in such fashion and under such conditions that the public is pretty much, at least in part, the audience viewing the work done. It may be small or large.

Another quite significant feature of safety, particularly the result of unsafe practices, is that the public is dependent upon you for the particular product that your public utility offers. They have seldom any choice. They are dependent upon the particular service you supply.

Let's take these as features. Let us see if there is any common denominator we might apply in accident prevention. I would like to make a distinction between accident prevention and safety work.

Accident prevention seems to me to indicate the rescue on the brink of the precipice. Safety seems to be something well worked out to prevent the dangers of coming to the precipice. Let me cite a few cases. These are taken at random, not applied to public utilities alone. Try to think what you would determine as the cause as they are being presented.

How Accidents Happen

In a fairly large manufacturing plant, large enough to require electric crane service to serve some of the heavy, mechanical work, the crane, while the operator was out of the cage, ran wild, got started down through the room, and a swinging lock on the take-up injured several people severely, not fatally, and wrecked a storeroom by getting caught and yanking it out. What do you think the cause of that was?

Another case, a little different, is this: A wireman, feeding in a pair of number six rubber covered wires through a wooden partition in the basement, did not know that on the other side was a power shaft and the end of the wire caught in the pulley, came through the partition hole much faster than he had planned, injuring him, destroying the partition and destroying the wire. That is another case you can decide for yourselves what the cause was.

Still a third I would like to present, which differs radically from the other two to this degree: There was a process used in a certain manufacturing establishment of treated fabric, I believe for airplane work but I am not certain now, but it required the use of a heavy, metal vacuum tank. The operator had the task of removing the heavy bolts which held the cover and operating a power crank for taking it off, taking the yards of fabric out afterward. Having worked at it successfully two or three months, he was rated as a good, careful worker. One day he attached the crank handle to the hook in the cover after having removed the bolts which held it at least partially, and without watching the vacuum tank, attempted to lift the cover up and pulled the whole outfit out by its roots. It did not hurt him or anybody else but it wrecked \$3,600 worth of equipment in the wink of an eye.

I am certain that if I could take a vote as to the cause of each there would be several varieties of causes, carelessness on the part of the man, negligence on the part of this, that or the other thing. Let's not think of causes. Let us see if there is a common source of control, which I think is a better way. Where could control have been applied in each of those cases so they could have been prevented and hence never have been entered in the books as an accident? Let us see whose job

it is to control situations so we do not have accidents, so we have safe conditions, keeping in mind the distinction I made between the two features formerly.

Active Supervision Necessary

I have a particular bias in my mind probably which gives me the answer so quickly that sometimes I am impatient if I don't get immediate agreement. I maintain the source of control is the supervisor, and I do not mean the supervisor who is in an office and gets out into the field only occasionally; I mean the line supervisor. I don't care what his title is, sub-foreman, line leader or what it is, but he is the source of control. I think it is commonplace to say to this group or any group that has thought much about industry in this connection that supervision, proper supervision, gives almost perfect control, not only of accidents, or rather of safe conditions, but of others, that it is surprising that we don't do more about it.

If you will bear with me a short time I will try to outline a thought for supervision that to my mind justifies getting a foreman equipped to supervise. If I were to ask you, as I have had the good fortune to ask many actively engaged in directing operations, what you supervise, when you supervise, I am quite certain I would get nearly the same answer at first. You supervise everything in general, of course. As a matter of fact, that is not true. You can't supervise everything in general. You must supervise something in particular. Either you do supervise this particular thing or you don't. If you do, it is taken care of. If you don't, it may come back as a boomerang. The things you do supervise, these particular features are small things, very insignificant details if viewed by themselves. I believe if you go back to the illustrations I used or any others parallel to them, you can see that, as one speaker indicated previously, there is a point where something went wrong. That is a point where supervision was not applied. You can always find some apparently trivial thing which is the cause.

I believe that the control is farther back than the cause. Let me see if I can make it a bit plainer. I am recalling in my own mind now some of the controversies and some of the arguments in properly setting forth the cause of an accident. In a particular instance it would be said that the man was negligent. All right. Maybe that was the cause. In another case it might be said that the man deliberately disobeyed instructions. That may be a cause too. In another case it might be said the foreman was busily engaged some place else and was not in a position to give instructions and the work was being carried on as well as it could be, and as a result something went wrong. Maybe that was the cause.

Probably you can take every cause set up, even to the mental conditions of the worker, and tie them up to the accident, but back of these causes there is or there should be a control. It may not be infallible. We know that accidents classify themselves generally under two heads, mechanical or material failures. I don't know whether we can get a clear cut distinction, a clear cut case. In any event, the number of that class in public utilities is small. We do have fairly good control of mechanical or material features. So that as a problem, that particular group can be quite easily isolated and quite definitely treated on an engineering or scientific basis. These mechanical improvements are easily handled when proper engineering attention is centered on them.

That is not true of human failures. The best safeguard of mechanical devices can be so handled by a human operator that the safeguarding features are nullified, and on the other hand very unsafe. Almost all extra-hazardous conditions can be taken care of if the human failure is eliminated. Probably that sounds a bit ambiguous. I mean, no matter how dangerous conditions are, if the industry working under those conditions cares to and is aware of the danger, it will avoid accidents. Most accidents are not on extremely hazardous conditions.

With that particular feature, thinking of the control, the source of control of accidents due to human failure,—I believe supervision is the most effective control.

Let me see what other devices there are to help get this control. I would like to be plainly understood in this connection as not finding fault with the devices I mentioned.

Effective Safety Devices

Now, some of the very effective devices used in safety practices are the use of posters, bulletin board material set up in poster fashion. We make quite an extensive use of that. Another device that is used is the practice of having, periodically, talks before groups who are engaged in the activities and having impressed on their minds the probabilities for accidents and mediums used for overcoming them. We have another feature of this nature. We have special safety men, full time safety men. We do use that and quite effectively, too. In addition, we use a little closer tie to actual productive work and I don't like to be misunderstood in that either—a tie in activity only and that is a special methods man. He is a little different type of individual than the purely safety man. He devises means to be used in getting out safety work and a safety man gets the organization of the field in such a fashion that results are as expected. All of these are good.

Everyone has a particular place in a safety program. My own opinion is that all of these are simply nullified if the proper first line supervision is not applied. I don't care how good your safety man is, your methods man is, how effective the speakers are that give the inspiration of talks or how striking the posters, if you do not get the first-line supervisor to control those conditions, you will continue to have bad accidents.

That may seem as though the supervisor was the universal panacea. The ideal supervisor, I think, would be. We are not dealing with idealisms. We have to face practical features. Let us try to look at this improved supervision on a practical basis. Can the first-line supervisor by himself take this activity under his wing and carry it through successfully? No, he can't do it. Behind the first and second (mind you I am counting backward now) the third line supervisor is the man on the firing line. The second and third and fourth are backing up toward the general manager or the plant executive or whatever title is assigned to the highest supervisor. The first and second can't do that but maybe the first, second and third in conjunction can do something but you will get better results if the whole line is working toward that end. Each one has a functional part. Each one is responsible.

When I say supervision I mean the whole line functioning in the particular sphere that the responsibility assigned them calls for. That simply makes a preface for a statement that while it is true it is sad news in many sections of the industry. The foreman just cannot equip himself to do anywhere near this idealized supervising. Somebody within the organization must help him so he can do the sort of supervising that will avoid hazardous conditions resulting in accident.

Helping the Foreman

That simply brings us to a point of consideration of what can be done to help this foreman. He is expected to supervise details, whatever agency is made use of or whatever devices are inflicted upon him. It ought to make him more aware of the significance of details and particular application of these details to safe practices. He must realize that doing a job safely is of as much importance and in some cases of more importance than doing it economically or in conformance with standard specifications. That is a new thought to a lot of first line supervisors. He is not to blame for it being a new thought. The evolution of our

practice plainly traces the evolution of those higher in the organization so that many of them are just orienting themselves into that real thought.

Safety is not a fad. Accident prevention is not a beautiful suggestion. The beautiful feature of that situation is this: The safe way to do work is always the best way and the easiest way to do it. This is the first premise, I believe, in the mind of the foreman. He is not pleasing a safety man or a personnel organization when he gives occasional thought to safe practices. He is taking care of an important assignment on his own job and if he does not take care in the march of progress he will be eliminated.

Now, having gotten that particular conception in his mind, it is not fair to leave him there. You don't gain anything by saying to the foreman, "You must do this work safely. It is part of your job." He is definitely entitled and is perfectly within his rights when he says to his superiors or his supervisor, "Well, how am I going to do it? In what fashion can I control these conditions?" The organization must be in such a position that some device which he can use immediately is placed in his hands. Again, fortunately, that is not a difficult thing to do.

The Importance of Analysis

The detail that I spoke of which is the sum total when you consider the whole feature of supervision simply indicates that foremen should be given a device which will let them know those details. It is only a step from that to the conclusion that analysis, much as we hate that word (most of us) is the answer. Now analysis has been worked to death as a term. We all like to talk about analysis but none of us like to analyze. It is hard, gruelling work.

The first line supervisor is not a bit different from ourselves. Among the devices to help him in this analysis should be one in which he can overcome the natural reluctance he has to analyze on a basis which is more or less selfish in its motive. I would not analyze just for the sake of analyzing, nor would you, but I would analyze if it were going to make my work particularly easy. If I could find a way to save time that is so valuable to a first line supervisor, I would listen eagerly and go through some grief to get the benefit of it. I believe that particular feature in the training of a foreman in safe practices is a worthwhile venture.

This is a simple attack on analysis which isolates and emphasizes small features in each of these various operations where there is a possibility of accident for one feature. Now, supervision can be definite in a sort of grand sense this way: to know what is being done in detail; to know what the limiting features are that might cause failure; to set up a plan which eliminates as nearly as they can be eliminated those limiting features; and then to give it attention to see that no deviations are creeping in. That is an ideal supervisor.

Sometimes we ask a first line supervisor to do one or the other of these but seldom ask them to apply all of them. We say, "You should have seen that in advance." That is true. "You should have had some plan to avoid that." That is true. But, as a medium of helping him you must have a device to cover all four.

Now, as a medium of analysis, it is a common sense one which applies the analysis or analytical thought for the particular progress for which the first line foreman is responsible. If he pulls it apart to minute details he can plan to offset the limiting features and he can plan to take care of that particular activity subsequently so deviation does not creep in. That in itself is the essence, the backbone of any training of a supervisor in promoting safety practice. If you do that, you can trust the foreman to apply the pretty good common sense that he must possess to get the job in the first place, so results will be fairly satisfactory and increasingly so as he becomes more familiar with the practice of analyzing and has the background of experience in eliminating these features.

I want to express again, first get in his mind a realization that doing the work safely is of much importance, and sometimes more than doing it economically and in conformance with specifications. If he believes that, you have a good start. If he does not you won't get far with that premise. Give him training in analyzing the particular job so he can build up a plan which anticipates conditions and prevents their occurring rather than waiting until an accident has occurred and then after discovery try to remedy the fact.

CHAIRMAN RUTLAND: Mr. Kane has led us down a very interesting highway in discussing this problem. It is fundamental in our business.

I want to ask Mr. George Opp to make an announcement to you in reference to one or two requests in regard to holding conventions in other cities.

CHAIRMAN RUTLAND: Gentlemen, we still have a few minutes, the luncheon does not begin until 12:30, so I would like to introduce to you the members of the Executive Committee and have them make brief reports of their activities during the past year.

Mr. Ivan L. Scott with the National Electric Power Company, New Jersey, will make a report as Vice-Chairman in charge of Gas Interests.

IVAN L. SCOTT (Vice-Chairman, Gas Interests and Safety Director, National Electric Power Company, Asbury Park, N. J.): Mr. Chairman: As Vice-Chairman in charge of Gas Interests during the past year, there are only two accomplishments really made by this office. One of the things was to secure a paper written by Ralph Gilman of the U. G. I. Company on the subject of the human side of the gas business. It was turned over to our Publicity Committee and was published in the *National Safety News* and other publications.

The Vice-Chairman in charge of Gas Interests also was successful in securing *The Gas Age Record* of New York to donate a trophy to the winner of the gas group sponsored by the Public Utilities Section, and that will be awarded at the joint luncheon this afternoon. As chairman of a committee to prepare an exhibit of safety rule books, various accident report forms and other literature, I want to take this opportunity to thank the companies who so willingly submitted that material to us. We have what we think is a very good display, and I think a good deal of commendation and credit is due to the New York Edison Company for the manner in which the material was prepared. I hope you will all take an opportunity to look over the material. There are some things of value to everybody. I believe that is all that was accomplished by myself as Vice-Chairman during the past year.

CHAIRMAN RUTLAND: These men are all rather modest. They won't tell you of the hundreds of details they have accomplished during the year.

Next I will call on Mr. H. F. Webb, West Penn Power Company, Pittsburgh.

H. F. WEBB (Vice-Chairman, Water Works, General Safety Division, West Penn Power Company, Pittsburgh, Pa.): I will read the report of the Publicity Committee.

Report of the Publicity Committee

Following a precedent set during the previous active years, your Publicity Committee has consistently secured worthwhile manuscripts all of which were accepted for publication in both safety and Association journals. Altogether seven manuscripts were received, all of which have been published in such Journals as the *National Safety News*, *N. E. L. A. Bulletin*, *American Gas Association Monthly*, *Safety Engineering*, and *The Literary Digest*.

The work of securing articles for publication proved rather difficult in the past, since it was frequently necessary to write a large number of safety advocates before locating one who would be willing to devote the time necessary to the fabrication of a suitable article. However, your Committee hit upon a new plan

of action during this past year which produced results with little or no effort on the part of the Chairman.

In brief, a selected subject was assigned one of our Executive Committee members who in turn farmed it out to either someone in his own organization or one known to him as having ability along this particular line. In this manner we were able to provide the above named publications with seven excellent articles as follows:

SUBJECT	CONTRIBUTOR	PUBLICATION
The Lineman's Best Friends.....	R. V. Pickett, Constr. Supt., West Penn Power Co.....	National Safety News
The Human Side of the R. V. Inman, United Gas Gas Industry.....	Improvement Company.....	National Safety News
Training Men for Industry.....	J. L. Vandergrift, General Plant Employment Supervi- sor The Chesapeake & Po- tomac Telephone Co.....	National Safety News
Stopping the Accident Leaks in Water Works Opera- tion	A. F. Porzelius, Supt. City Water Co. of Chattanooga.....	National Safety News
Standardization for Safety.....	Stanley Green, Meter Engr., Indiana Electric Corpora- tion	National Safety News
Executive Interest in Acci- dent Prevention.....	Fred W. Bagnall, Asst. Supt., The Detroit Edison Com- pany	National Safety News
How to Keep From Getting Hurt	O. O. Paugh, Northern Indi- ana Power Company.....	Safety Engineering The Literary Digest

Your committee would like to express its appreciation of the cooperation on the part of the author contributors listed in this report as well as that of our fellow committee members, Messrs. Ivan L. Scott, H. L. Meade, C. P. Ryan, and Geo. C. A. Opp, and recommend the continuance of the Publicity Committee as a definite part of the Sectional activities.

CHAIRMAN RUTLAND: Mr. Webb worked hard in his activity during the past year and we appreciated his untiring efforts. We will now have the report of the Chairman of the Poster Committee, by E. S. Beaumont!

E. S. BEAUMONT (Chairman, Poster Committee, Public Utilities Section, National Safety Council): I don't like to listen to long reports any more than you do so I will apply the Golden Rule.

Report of the Poster Committee

The work of the Poster Committee for the past year has been split into sections and handled by groups representing each of the several utilities.

Mr. W. E. Hughes, Rochester Gas and Electric Corporation, headed the Gas Division. With the assistance of Mr. M. B. Hile of the Citizens Gas Company, Indianapolis, and the Poster Committee of the American Gas Association, of which he was chairman. Mr. Hughes submitted material for thirty posters. Most of these were found useful by the Poster Staff.

Mr. Robert N. Klinge, of the Alabama Power Company at Birmingham, headed the Electric Division. He was assisted by Mr. C. W. Chiles of the C. I. P. S. Company, Mr. Johnson of the Tennessee Electric Power Company at Chattanooga, and Mr. F. B. Stiver of the Union Electric Light and Power Company at St. Louis. This group also turned in a great deal of useful material.

Others who rendered great assistance are Mr. H. F. Webb of the West Penn Power Company at Pittsburgh; Mr. H. L. Meade of the Ohio Bell Telephone Company at Cleveland; Mr. H. M. Kellar of the Northern Indiana Public Service Company at Hammond; Mr. E. J. Kreh of the Equitable Gas Company at Pittsburgh; Mr. A. R. Gray of the Peoples Natural Gas Company at Pittsburgh; Mr. J. F. McCurdy of the New England Telephone and Telegraph Company at Boston; Mr. H. L. Brown of the Northern States Power Company and yourself.

In all, more than a hundred poster ideas have been submitted. A few could not be effectively used and some have not been used because we have been unable to get suitable pictures or sketches to accompany them.

The excellent cooperation of all those named and any whom I may have by chance overlooked was greatly appreciated and made this rather dreaded job an easy one.

CHAIRMAN RUTLAND: Thank you, Mr. Beaumont, for your untiring efforts.

The next man I want to introduce is Mr. N. L. Devendorf, Consumers Power Company, a man to whom a lot of thanks is due for his work this year in editing our *News Letters*. He spent a lot of time in getting the material together, and he received a letter a short time ago from Mr. Cameron and Mr. Keefer advising him that in their opinion the *News Letter* as published was the very best of any Council Section and I take great pleasure in introducing Mr. Devendorf.

N. L. DEVENDORF (Consumers Power Company, Jackson, Mich): I have a very brief report to make. Instead of the 12 letters scheduled I have been able to get out eight. There was plenty of material and I had excellent cooperation during the year. They have gone out as fast I could get them, in connection with the work I was obliged to do. This is one point I would like to bring up. I want more material from the Gas, Water Works and Telephone and Telegraph Companies because letters this year have been heavily burdened with electric light and power. If we can get more material the letters will be well worth while this coming year.

ADJOURNMENT

October 4, 1928

C. J. RUTLAND, Chairman

Safety Engineer, Texas Power & Light Company, Dallas, Tex.

The third session was called to order by the chairman, C. J. Rutland.

CHAIRMAN RUTLAND: I take great pleasure in introducing to you Mr. H. B. Harmer, Safety Engineer of the Philadelphia Electric Company, who will address you.

Housekeeping for Power Houses, Substations, Storehouses and Other Public Utility Properties

By H. B. HARMER

Safety Engineer, Philadelphia Electric Company, Philadelphia

Housekeeping for power houses, substations, storehouses and utility properties in general, embraces many and varied elements that cover a surprisingly large field of activities. The importance of this subject cannot be too strongly emphasized. Good housekeeping is fundamental to maintaining continuity of service and is essential to successful and economic operation of utility properties.

There are two outstanding features of good housekeeping—orderliness and cleanliness. These are never accidental but are the results of planning, system and supervision. Then comes the most important element—inspection. Intelligent, earnest study of inspection methods plus hard conscientious work by every person in the organization is necessary to secure the best results. A system of inspections should be started and maintained.

Written plant inspection reports covering buildings, equipment and contents should be carefully made, kept and checked until any hazardous conditions have been corrected. These reports should cover fire hazards, maintenance of fire fighting equipment, installation of equipment and apparatus, storage conditions, cleanliness of buildings, cleanliness and upkeep of yards and adjoining properties. This routine should have a tendency to develop a sense of good housekeeping among the employees and should result in better cooperation of the working force.

Buildings, grounds and outdoor structures require constant supervision to maintain them in a proper state of repair and in satisfactory condition. Without this constant supervision unhealthy conditions of the physical properties will arise. Prolonged neglect will surely result in such dilapidation as to require replacements in many cases when comparatively simple and inexpensive repairs made at the proper time might have prevented deterioration. Both the inside and outside of building structures should be rigidly inspected and any defect, no matter how small, should be given immediate attention. This attention to detail insures that the structure is thus maintained in a creditable condition, and produces a favorable reaction in the mind of the operating force and tends to a better spirit of cooperation among the entire personnel of the organization which is particularly desirable.

All outside structures, in general, should be painted alike but even this rule need not stand in the way of making some particular structure conform in appearance to its surroundings, if, for some reason this course seems desirable. Modern generating plants, substations and relative buildings, however, are as a rule fire resistive, but many other buildings are not. Therefore, the question of painting enters very little into the exterior appearance of modern structures.

The interiors, and this applies to structures and apparatus, should be kept well painted, and floors and walls should be looked after in this respect. The color

scheme should be agreeable, cheerful and well blended in order to contribute its share toward a proper frame of mind, and if such tint and consistency as will produce the largest quantity of reflected light possible from such surfaces. Inside structures and apparatus should be painted chiefly because of utilitarian reasons, but even these should be so colored that they will blend nicely with the building colors and not produce sharp contrasts.

The grounds surrounding the buildings, both operative and inoperative, should be kept clean and neat and, if possible, should be cultivated so as to present a pleasing aspect. Well-kept lawns, a generous supply of shrubs and, where practicable, a few trees, selected and placed with care, will add materially to the general appearance. Where personal supervision can be given by the operating force, flower beds with well-chosen combinations can well be made a part of the landscape gardening. The grounds of outdoor stations generally are covered with crushed rock and do not lend themselves to decorative effect, but even these structures can be so maintained as to blend well with the surroundings.

The careless and untidy storing of materials in storerooms and plants may occasion both fire and accident hazards. Often when a shipment of material arrives the cases are opened and allowed to remain unpacked for several days, and the excelsior, sawdust or paper packing constitutes a very serious fire hazard. Special care should be exercised that material piled near aisles and passageways is not likely to fall, or to be knocked over; the piles should not be too high; neither should parts extend into the passage or roadway where passing men or trucks may strike against them.

Proper provision should be made for the storing and handling of miscellaneous oils, paints, etc., and when small quantities are withdrawn for use, any portion left over from the day's supply should be returned to storage. The practice of storing materials in operating rooms of power houses, substations, etc., constitutes a serious fire hazard and should not be permitted.

The lighting and ventilation systems should be maintained in good operating condition. A well designed artificial lighting layout is an essential upon which too much stress cannot be laid and this applies equally as well to ventilating by natural or artificial means. Poor ventilation and bad lighting result in physical and mental reactions which are detrimental to service and cause diminution of alertness.

Although the modern building housing electrical apparatus and equipment is constructed in conformity with the best engineering standards for fire resistive qualities, nevertheless some electrical apparatus and equipment necessarily contain materials of a combustible nature. A fire hazard therefore exists but such fires are easily kept under control. In order to place the combating of such fires on an efficient basis, each building should be equipped with a full complement of fire extinguishing devices carefully selected for the building in question and located in conspicuous and accessible places. The proper selection of extinguishing devices for each particular building necessitates a thorough knowledge of each and all items in the building, electrical and otherwise, from the standpoint of possible fire hazard, and the selection should be made on the basis of efficiency of each extinguishing device in combating each class of fire.

Extinguishing devices have certain rather definite characteristics and applications. Because of such differences certain devices have come to be recognized as particularly adaptable for certain classes of fire and this tends to simplify the investigators' task in selecting the proper extinguishing equipment. It is advisable to submit proposed installations to a check by the engineers of the insurance rating bureaus. This will also facilitate securing proper credit in the insurance premium.

Closely associated with the fighting of fires is the danger from fumes of some extinguishing agents and from suffocation due to smoke. To protect the employees against these hazards, gas masks of an approved type should be supplied in confined areas where the ventilation is insufficient to remove the fumes or gas. These masks

Standard mountings of Fire Gun, Fire Extinguisher, Sand Pail and Markers.
(Station construction department, Vje Philadelphia Electric Co.)

should be conveniently located so as to be instantly available. Definite instructions and frequent practice in the use of these masks should be given to those concerned.

Great stress should be placed on the absolute necessity for frequent and periodic inspection, care and maintenance and instructions in use of all fire extinguishing apparatus and gas masks to insure 100 per cent utility. It is desirable to locate extinguishers on a specifically marked background. Through constant association employees become familiar with the different locations of fire fighting devices and it becomes second nature for them to make the proper selection.

The desirability of cleanliness in and about stations and buildings is so unquestionable that no particular argument need be advanced in support of it, but even so it frequently happens that too little attention is given to attain this end.

The necessary cleaning supplies such as tools, brooms, dust pans, mops, mop pails, sponges, etc., should be furnished unstintingly. In the larger stations it has become recognized as economy to install modern labor saving appliances for the use of the clean-up crew. Having provided the necessary equipment and clearly defined the standards of cleanliness in and about the buildings, steps should be taken to see that the established standards are maintained.

It is sometimes difficult to prevent accumulations of litter and dirt, particularly in basements, at the bottom of elevator shafts, under piles of materials and other out-of-the-way places. Such conditions, however, can be prevented if proper measures are taken. Extreme care should be given the storage of rubbish and useless material, and prompt removal from premises should be the rule. Wooden boxes should never be used for temporary disposition of these materials.

Greasy and oily waste is subject to spontaneous ignition and the greatest care should be taken in its disposition. Unless it is immediately burned after use, waste should be deposited in standard metal waste cans. The construction of the waste can is of vital importance, and non-standard cans are of but little value. The old-style wooden closets, lockers and enclosures are sometimes used as a catch-all for discarded and greasy garments all of which increases the fire hazard. Substantially constructed and properly ventilated metal lockers for employees' clothes should be installed.

Cleanliness of machines and other equipment, such as transformers and oil switches is another housekeeping requirement that is particularly important. Machines covered with grease and oil are dangerous for operators and repairmen to work around. Where oil and grease are allowed to collect on a machine, the floor usually becomes soaked, thus increasing both fire and accident hazards.

The education of the operating force along these lines and the gradual attainment of these standards is no light task and requires both energy and tact in no small degree, but once this mental attitude of good housekeeping is developed it is a comparatively simple matter to maintain it. Constant and rigid supervision, however, is necessary. One of the best means to accomplish this is to provide well defined and explicit inspection forms and an established practice of reporting and supervising.

The foregoing statements as to what should be done to maintain desirable housekeeping conditions very naturally gives rise to the question, how can all this be accomplished? There are many ways in which this can be done, but the best results may be obtained with the smallest expenditure of time by close cooperation between those charged with the supervision of such matters and the operating force.

Quite frequently meritorious reports are forgotten, due to the fact that specific attention is not called to them. Attention is directed to the splendid reports of the Accident Prevention Committee, N. E. L. A., particularly:

FIRE ALARM IN GOOD ORDER?.....

IS WATCHMAN TOUR OF PREMISES SATISFACTORY?.....

REMARKS.....

For the greater safety of all employees, and the protection of Company's property, each extinguisher, fire bucket, hose, hose outlet, fire pump, chemical engine, must be examined individually and thoroughly. Only thru the co-operation of all can we expect the highest degree of protection from fire.

Fire hose and spanners must be kept in their proper place and ready for immediate use. Each hose connection inspected separately, each length of hose run off of the rack at least once every two months and tested with pressure at least every six months. All valves on fire line outlets kept in such a condition that they are easily opened. All hose thoroughly dried after water is run thru and carefully rehung or wound on the reels.

Chemical Extinguishers contain a solution of water, bicarbonate of soda and sulphuric acid. Foamite Extinguishers come under this same heading, and contain a solution of bicarbonate of soda and foam producing agents dissolved in water in the outer compartment and aluminum sulphate dissolved in water in the inner chamber. The hose nozzle must be kept clean and free of obstructions caused by seepage. The couplings and hose kept in perfect condition. A tag must be kept on these extinguishers showing the date that they were charged. They should be charged once every year, both the tank and the hose thoroughly cleaned and washed before recharging. To keep from freezing they should not be left in an exposed location or an unheated building.

Fire Doors—Must be arranged to close easily, kept clear of all obstruction, the fusible link examined and all hardware kept in good repair.

Fire Pails—If containing sand must be examined for any dirt, and kept filled with sand within two inches of the top of the pail; if containing water the water should be within two inches of the top of the pail and clear of all dirt.

Tetrachloride Extinguishers—Must be tested by turning the handle, seeing that the pump works freely and from time to time oiling the plunger to prevent sticking. Fire Guns, J. M. Fyr Fyter, Pyrene and all extinguishers containing a non-conducting fluid and for use where there is electrical current contain tetrachloride liquid. There must be kept on hand a sufficient amount of liquid to keep these extinguishers charged to their full capacity.

Inflammable Liquids—All inflammable liquids must be kept in special approved containers and at that point set aside for this purpose exclusively.

Oily waste, rags, etc., must be kept in approved containers with gravity closing lids.

SUGGESTIONS FOR REDUCING FIRE RISK AND INCREASING PROTECTION

Signed.....

Position.....

EVERY LINE MUST BE FILLED IN OR CHECKED.

Remember that these inspections are very important. The Safety of this property from fire is largely up to YOU.

Give attention to every question on this blank. If the question does not apply to this plant draw a line through the space left for the answer. In this way you can be sure that you have not overlooked anything.

Under the heading of (Condition of Fire Appliances) the word GOOD or BAD should be used. The balance of the questions answered YES or NO or more fully if necessary.

shown on previous page.*

Inspection and Maintenance of Fire Fighting Equipment." Report G1-22, May 16, 1922.

Detail Report—"Fire Extinguishing Devices and Liquids." Report, Accident Prevention Committee, 1924-1925.

"Good Housekeeping" should be a slogan constantly in mind and rigid adherence to its basic principles will result in continuity of service.

ETHELBERT STEWART (Washington, D. C.): I am Commissioner of Labor Statistics and have been trying to get some line on the amount of loss from fire both of property and of life. I am told by the National Fire Protection Association and the other associations, that the only figures that are reported are where there is insurance. That means that nobody knows what proportion of the fires are reported or what proportion of accidents are reported. The day before I left Washington, in Forest Glen, a small town just out from Washington, a woman took her five-year-old and her seven-year-old child to the station to meet some one. She left two younger children in the house. When she came back only ashes remained of everything they had—children and all. The fire insurance had lapsed about five days before. Those things we don't get. Is there any way that this organization can give me assistance in getting the report of the actual number of fires and losses and injuries and deaths from fire? I am thoroughly convinced that I don't know what per cent of properties are outside of insurance. I am convinced it is a very large percentage and that our figures are rather deceptive.

CHAIRMAN RUTLAND: I am sorry I did not recognize you, Mr. Stewart. I don't know if there is a body that accumulates statistics on losses. The insurance companies do where they have risk covered and in cities where there are fire departments well established. Of course, the Fire Chief or someone delegated by him makes a proper report and they summarize it each year. Whether there is a national body that checks those statistics irrespective of whether or not insurance is carried, I don't know. I think it is a proper question. I think it is a problem for our benefit at least from a standpoint of gas and electric fires, and incidentally the gas and electric industry is charged with many fires due to defective wiring and gas leaks, and mostly where they should not be. Our committee might take that under advisement, consult with the National Fire Protection Association and see what can be worked out. I think you will be interested each year in knowing of this loss and injuries because of fires and particularly interested in those fires caused from electricity or alleged to have been caused from electricity or gas, so we thank you for the suggestion.

MR. STEWART: When you get fire insurance figures you have gotten, after all, the cream of the American people—I mean the 127,000,000 that comprise the population. The people who are not insured are in my judgment a vast majority. I am not going into the industrial side, but owing to the fact that they have no one at home to look after things, the percentage of loss of life in those fires would be greater in proportion to the dollars invested than in the other; I have been trying for a year to get some line on how to get at that figure. It does seem to me that if we put our shoulders to the wheel, all of us, we could get some line on the real fire loss and the real loss from fire.

CHAIRMAN RUTLAND: I promise you we will take this up with the National Council Headquarters' staff and see what they have in the line of suggestions and see what can be done; and I will suggest to Mr. Keller that whatever he finds out in the immediate future that he communicate with Mr. Stewart and advise him of what progress is being made.

H. B. HARMER (Safety Engineer, Philadelphia Electric Co., Philadelphia): There is wonderful ground being laid by public utilities in gathering that information. We expect to have, without any doubt whatever, every fire loss with resultant

loss of life together with causes that happened on utility property in the United States in full operation before the end of the next year.

MR. STEWART: Do you mean the fires in the homes?

MR. HARMER: I said "utility." Now take the next step. We, as members of the Fire Prevention Committee, expect to get in touch with the Chambers of Commerce or those organizations that primarily have fire prevention as part of their activity, and gather information together. I feel, as Mr. Stewart does, that it has been overlooked to a certain degree. Fire prevention has been given too much engineering thought and not enough human.

MR. STEWART: I am interested in the home that burns down as well.

H. L. MOTT (Bell Telephone Company, Chicago, Ill.): Generally speaking, insurance people pay no attention to fires except when insured. The majority of large cities have what is known in the Fire Department as a Bureau of Statistics which gives the approximate loss of fires in a record book whether insured or not, the number of people insured, loss of life, I think you can get that from the books of the Bureau of Statistics of the Fire Departments. Furthermore, I might say that when the Chief or Battalion Chief arrives at a fire his first guess may be it was crossed wires. His report covers whether it was lamp exposure, crossed wires or fireworks or whatever it might be.

ROBERT STEWART (Interstate Public Service, Indianapolis, Ind.): Some states have state fire houses and they are supposed to get a report of all fires in the state. Now, through them, Mr. Stewart might be able to get the information or some of the information he desires.

CHAIRMAN RUTLAND: Thank you.

I think nearly all of you attended the joint luncheon and witnessed the trophies given to the different gas and electric and combination gas and electric companies who won those trophies and are really appreciative of the accomplishment of those companies in accident prevention work. It is hoped that next year will witness a great number of contestants in this contest so that next year instead of having 115 we will have possibly 215. We did not call on Mr. Doeller, Chairman of the Contest Committee, yesterday to make his report for the specific reason that we wanted him to make it after the luncheon which was held yesterday so I will call on Mr. Doeller to make his report now.

Report of Statistics Committee

By G. A. DOELLER, Chairman

This report covers the two principal activities of the Committee. The first refers to the simplification of the Accident Report Form, together with a study of combining the report forms of the N. S. C.—A. G. A. and N. E. L. A.

The second part pertains to the Accident Prevention Contest, sponsored by the Public Utilities Section.

I.—Report Forms

At the St. Louis meeting of the Executive Committee of this Section on December 5, 1927, the subject of simplified and combined forms was discussed. Immediately following the Safety Congress in Chicago last September, a meeting was called by Mr. MacKinnon, then Chairman of the Accident Prevention Committee, N. E. L. A. This meeting was attended by many of the subchairmen of the geographic sections who were in Chicago at the time. The question of duplication of effort was discussed and Mr. MacKinnon sent a letter to Chairman C. J. Rutland of the Public Utilities Section, N. S. C., in which it was suggested that the collection of

statistics on accidents be made one of the functions of the National and of the Geographic Committees of N. E. L. A. Copy of the data thus collected would then be submitted to the N. S. C. for its further study.

The chairman of the Statistics Committee drew up a form which was a combination of the forms used by the N. E. L. A. and N. S. C. Copies of this were submitted to Mr. MacKinnon and Mr. Rutland.

Considerable correspondence was exchanged and finally at the time of the annual convention of N. E. L. A. at Atlantic City, Mr. Wm. Loyd called a meeting which was attended by Messrs. Van Brunt and W. Dean Keefer. This group discussed the matter of combination forms and seemed to be in agreement relative to the procedure of collecting the data, that is, by having the N. E. L. A. do the work as outlined in the previous paragraph. Official approval, however, has not yet been obtained and so the matter rests at this point.

The committee therefore recommends that the chairman of the Accident Prevention Committees of N. E. L. A. and A. G. A. take the necessary steps to procure the official approval of their respective organizations on the plan outlined at the Atlantic City Conference.

II.—Contest

By far the greater portion of the actual work of "Putting On" the contest was done by Mr. Burns and his assistants of the Headquarter's Staff. The idea of a contest such as this is not new. Other sections of the Council have been conducting similar contests for several years and the efforts required have been justified in every case. Our own contest was not started as early as we had hoped and for that reason only six months have been included in the first contest. A complete report covering the relative standing and the experience of the various companies, together with the announcement of the winners will be made at some other time during the present Congress.

The committee wishes to acknowledge its great obligation to Mr. Burns and his assistants in compiling the reports and computing the standing of the various companies.

The committee wishes to make the following suggestions for the guidance of the new committee which will serve the coming year:

A—Effort should be made to enroll a much larger number of companies in the next contest.

B—The monthly results as compiled by Headquarters should be made available as soon after the end of the month as possible. A special letter to the managers or safety directors of the companies in the contest would perhaps make this information available more readily.

C—In computing the relative standing of the companies, we believe that the severity factor should in some way be included in the computation. In our first contest the only factor used for rating was that of frequency. Some of the contestants have raised the question as to why it was necessary to report severity each month when this figure was not used for computation.

D—During the last few months of the contest it was noticeable that several contestants in each group failed to submit reports. The inference is that the record was perhaps so poor that the company was ashamed of the record and therefore would not submit it. Since the identity of the contestants is known only to a few people at Headquarters Staff, we see no reason why the contestants should not submit their experience each month, even though it is unfavorable.

In conclusion, the committee wishes to acknowledge with thanks the help received from Messrs. K. R. MacKinnon, George C. A. Opp, W. Dean Keefer, and G. E. Burns.

CHAIRMAN RUTLAND: Thank you, Mr. Doeller.

Ladies and Gentlemen: We have a real treat in store for us. Mr. R. O. Bentley, Superintendent, Public Service Electric Light and Gas Company, Newark, N. J., has consented to put on a playlet entitled "Cloud and Sunshine," which portrays to a very great extent, fundamental causes of some accidents. I know you will enjoy it.

(Telephone rings)

SECRETARY: Mr. Bentley's office. Yes, this is the superintendent's office. No, he is not in now. All right. Thank you.

(Telephone rings)

SECRETARY: Mr. Bentley's office. That is service order 10039 to set meter at No. 140 Broad Street, isn't it? Mr. Bentley told you this morning that meter would be set today, didn't he? Well, then it will be!

SECRETARY: *(Calls)* Mitchell 6070 please. Yes, that's right, 6070. Mr. Rosseland please. Is this Mr. Rosseland? This is Mr. Bentley's office, Public Service. Will it be convenient for Mr. Bentley to see you at your office tomorrow at two o'clock? Thank you, Mr. Rosseland. Good bye.

SECRETARY: *(Looks at calendar on Superintendent's desk, calls)* Market 126. I would like to speak with Mr. Snyder, please. Is this Commissioner Snyder? This is Mr. Bentley's office, Public Service. I called to tell you that Mr. Bentley can meet you tomorrow at eleven o'clock at the City Hall. Will that hour be convenient for you? Thank you, Mr. Snyder. Good bye.

(Enter Superintendent's Son)

SUPERINTENDENT'S SON: Hello, Dorothy! Where's the Governor?

SECRETARY: Hello, Bill! Out; I think he will be here in a few minutes.

SUPERINTENDENT'S SON: How long before you are going home?

SECRETARY: When your father gets here.

SUPERINTENDENT'S SON: I don't know about that. He usually gets busy when it's time to quit.

SECRETARY: That's better than not getting busy at all, isn't it?

SUPERINTENDENT'S SON: Yep, I've been busy all day. Where did you get the pretty flowers?

SECRETARY: Your father brought those in. You know he is very fond of flowers.

SUPERINTENDENT'S SON: Have you an engagement for tonight?

SECRETARY: I'm not sure, why?

SUPERINTENDENT'S SON: Want to go to the movies? There's a good show at the—

(Enter Superintendent)

SUPERINTENDENT: *(Takes off overcoat and hat)* My, it's a nice day. I hated to come in. The sunshine is beautiful. There's not a cloud in the sky. Wouldn't it be wonderful to have our lives like that, with never a cloud of sorrow or adversity. Then they would be filled with sunshine and happiness. Tears would be replaced with smiles and each day would bring new hopes, new joys, new ideals and new inspirations. Wouldn't that be wonderful?

SECRETARY: That would be heavenly.

SUPERINTENDENT: Yes, I guess it would. Well, now, after that burst of eloquence, I think we will come back to earth.

SECRETARY: Yeh, your necktie is untied.

SUPERINTENDENT: So it is; so it is.

SUPERINTENDENT: Any calls for me?

SECRETARY: A few, I took care of them. A cable splicer who said he used to work for you in Hackensack called.

SUPERINTENDENT: *(Busy at desk)* Yes, what did he want?

SECRETARY: A job.

SUPERINTENDENT: What did you say to him?

SECRETARY: I asked him if he was working in Hackensack.

SUPERINTENDENT: Yes, what did he say?

SECRETARY: He said "no." I asked him why not and he said he got in a jam with his foreman.

SUPERINTENDENT: Yes, what did you tell him?

SECRETARY: I told him if he would get a letter of recommendation from his superintendent, we might take him on.

SUPERINTENDENT: Yeh, what did he say?

SECRETARY: He said there was a fat chance for that.

SUPERINTENDENT: Yes, what did you say?

SECRETARY: I told him that without that letter, his chances of getting a job here were just about as fat.

SUPERINTENDENT: So that's what you told him, eh? Well, I guess that was all right. Anything else?

SECRETARY: That Mr. Fussy called to see you.

SUPERINTENDENT: He did, eh? Has he had a haircut since the last time he was here, or is it still growing over his coat collar?

SECRETARY: It's still growing over his collar.

SUPERINTENDENT: What did he want?

SECRETARY: He wanted to see if he could interest you in an electric egg beater he is working upon.

SUPERINTENDENT: An electric egg beater? Good Lord! I am glad I wasn't here. He would have been good for an hour at least. How he can talk and his false teeth don't fit. They are always clattering around in his mouth until I am fearful every moment he will spill them in his lap or mine.

SECRETARY: Well, you have some false teeth, haven't you?

SUPERINTENDENT: Yes, but mine fit.

SECRETARY: *(Types, then slams desk drawer)* Ouch, darn it, ouch!

SUPERINTENDENT: What's the matter now?

SECRETARY: I just broke my finger nail.

SUPERINTENDENT: Oh, my gracious, thought you'd broken your arm.
SECRETARY: *(Starts filing nail)* Do you file your nails, Mr. Bentley?
SUPERINTENDENT: No, I just cut them off and throw them away. Call Mr. Rosseland of the Newark Safety Council and ask him if it will be convenient for me to see him in his office tomorrow at two o'clock.
SECRETARY: I did and he said that it will be convenient.
SUPERINTENDENT: Oh, you did?
SUPERINTENDENT: *(Looking at calendar)* Call Commissioner Snyder and tell him I'll meet him tomorrow at 11:00 o'clock at the City Hall to go over that street lighting matter.
SECRETARY: I did and he said that would be satisfactory.
SUPERINTENDENT: These lighters are handy little things. I could not get along without this one. I think a lot of it.
SECRETARY: Was it a present?
SUPERINTENDENT: Yes, an agent for life savers gave it to me.
SECRETARY: It is handy, isn't it?
SUPERINTENDENT: Yes, very, just about as useful as the hole in the center of a life saver.
SECRETARY: *(Strikes match and lights cigarette for him which he has been trying to light with cigarette lighter.)*
(Enter Office Boy with card which he hands to Superintendent)
SUPERINTENDENT: Tell Montgomery to come in, Frank. I want to see him, too.
(Enter Lineman)
SUPERINTENDENT: Hello, Tom. How are you coming along? Sit down.
LINEMAN: I guess I'm coming along all right. I came down to get my pay and I thought I'd just stop in, say hello.
SUPERINTENDENT: Tom, I'm awfully sorry you were injured, and at the same time, I haven't much sympathy for you, either.
LINEMAN: You haven't? Gee, boss, my getting hurt was just hard luck.
SUPERINTENDENT: Maybe I did not get all the facts in the case. Tell us about it.
LINEMAN: Well, I came into the storeroom to get a reel of No. 4 wire and the storeroom man asked me to come up on the next floor and help him with it and when I was going up the stairs, I stubbed my toe and in trying to catch myself, I stuck my spur in there, clear to the bone. Oh boy, it is sore.
SUPERINTENDENT: So am I. You didn't have to put your spurs on to climb up the stairs, did you?
LINEMAN: No sir, but I didn't stop to take them off when I came in from the job. I wish I had now. There wasn't any sense in keeping them on and after I did hurt myself, I didn't do anything about it until two days later.
SUPERINTENDENT: That was bad. It only takes about a half minute to put a pair of spurs on or take them off, and when it is not necessary to wear them, a man should take them off, then he will not injure himself or anyone else. You should have had that wound treated at once. There is a medicine kit right in the storeroom.
LINEMAN: Yes, I guess that's right.
SUPERINTENDENT: When does the doctor think you'll be able to get back on the job?
LINEMAN: In about ten days. I would have been back before, but the wound became infected and my leg swelled up like a balloon. It's coming along all right now, though.
SUPERINTENDENT: Well, I hope so. How is your wife and the children?
LINEMAN: They are all right, but my wife was sure worried about that leg. Well, I guess I'll be going now so as to get a bus home ahead of the crowd.
SUPERINTENDENT: All right, Tom. I am glad you came in. Is there anything we can do for you?

LINEMAN: No, thank you. Good bye. Did you ever walk on crutches?

SUPERINTENDENT: Not yet.

LINEMAN: Well, don't try it. They sure are hell on your arm pits if you ain't used to them.

SUPERINTENDENT: Now can you beat that? There is a man who actually fell down and stepped on himself. I'll bet we won't have to tell him to take his spurs off when there is no climbing to be done.
(Airplane heard—Secretary goes to window)

SECRETARY: (Returning to desk) My, he was up high, wasn't he? I wouldn't want to be away up there with that little thing.

SUPERINTENDENT: You wouldn't, eh? Well, I wouldn't want to be way up there without it.

SECRETARY: What made that airplane snap and bang like that every once in a while? I never heard one do that before.

SUPERINTENDENT: Why, the engine was missing.

SECRETARY: The engine was missing! What did all the roaring and made all the noise if the engine was missing?

SUPERINTENDENT: Why the engine, of course.

SECRETARY: Yes, but you said it was missing.

SUPERINTENDENT: I didn't say there was no engine. There was an engine but it was missing.

SECRETARY: How could there be an engine if it was missing?

SUPERINTENDENT: The engine was there, but it was not functioning properly.

SECRETARY: Oh well, why didn't you say so.
(Enter Assistant Superintendent)

SUPERINTENDENT: Hello, Bernie, how is everything?

ASSISTANT SUPERINTENDENT: Everything is fine now.

SUPERINTENDENT: Where did you find the fault on that Montclair cable?

ASSISTANT SUPERINTENDENT: Up on Bloomfield Avenue at Lake Street.

SUPERINTENDENT: Did you have to pull in a new section?

ASSISTANT SUPERINTENDENT: No, trouble was in a manhole in a joint. We made up a new joint and turned it back at 2:30.

SUPERINTENDENT: Did you stop in the hospital to see how Smith is getting along?

ASSISTANT SUPERINTENDENT: Yes, he is doing very well, expects to go home Saturday.

SUPERINTENDENT: I'm glad to hear that. Let me see, he is the last man we have in the hospital, isn't he?

ASSISTANT SUPERINTENDENT: Yes, he's the last one.

SUPERINTENDENT: (Picks up accident report) Miss Burkner, see if Splicer Flynn is in. I want to see him. (To Assistant Superintendent) Bernie, here is a report of an accident that occurred yesterday. I want to read it to you.

ACCIDENT REPORT

While lowering a pot of hot solder into the manhole, Splicer Joseph Flynn bumped the pot against the side of the manhole and spilled hot solder down the back of Carl Pierson's neck. Pierson was treated from the emergency kit and taken to the company doctor. A woman who was passing just as Pierson came out of the manhole said she was going to report him for using improper language. His language under the circumstances sounded proper to me. I didn't see anything wrong with it. It seemed just right for the occasion. He didn't leave anything out.

(Signed) EDWARD STALEY,
Foreman.

(When Superintendent finishes reading report, Secretary returns with Splicer Flynn)

SUPERINTENDENT: Hello, Flynn. Sit down. Flynn, how did you come to spill hot solder on Carl Pierson yesterday?

CABLE SPLICER: I don't know. Everything went wrong yesterday.

SUPERINTENDENT: How is that?

CABLE SPLICER: Oh, I got off to a bad start in the morning.

SUPERINTENDENT: What happened?

CABLE SPLICER: Well to start with, I was out late the night before and overslept in the morning. Then, the kids left a ball bat on the top step of the front porch and I stepped on it and fell down the stairs and near busted myself open.

SUPERINTENDENT: That was bad. What else happened?

CABLE SPLICER: Then the foreman bawled me out for not getting to work on time.

SUPERINTENDENT: Well, you don't blame the foreman for that, do you?

CABLE SPLICER: No, I suppose not, but I ain't late often; there wasn't no use of him being so damned nasty about it.

SUPERINTENDENT: What else happened?

CABLE SPLICER: Then I burnt my hand when I lit the gasoline furnace and that was hurtin' all day.

SUPERINTENDENT: *(Gets up to get a drink of water)* My gracious, you were out of luck, weren't you?

CABLE SPLICER: I sure was.

SUPERINTENDENT: Have a drink, Flynn?

CABLE SPLICER: I don't mind, what you got?

SUPERINTENDENT: Water.

CABLE SPLICER: Naw, I don't want water.

SUPERINTENDENT: Why not, water never hurt anyone.

CABLE SPLICER: Don't you believe it. I once heard of a guy who died with water on the brain.

SUPERINTENDENT: Poor man, I'll bet he wasn't a cable splicer.

CABLE SPLICER: Naw, he was a superintendent.

SUPERINTENDENT: Now, if you had said he died from nervous prostration, I would not be surprised, but water on the brain, that's terrible. Well, Flynn, you must buck up, get here on time in the morning and replace that grouch with a smile. Pierson's getting hurt was due to your carelessness and I am sorry for him.

CABLE SPLICER: So am I and I am going to turn over a new leaf, Mr. Bentley. I won't cause any more trouble from now on; believe me. I am going to be careful. I've learned my lesson and I ain't a damned bit proud of myself.

SUPERINTENDENT: That's the way to talk, Flynn. Now I believe you have come to your senses. I think that's all, thank you for coming in. Now do be careful. So long.

SUPERINTENDENT: Bernie, I want to read some accident reports to you. Miss Barker got them out for me this morning. I think you will agree with me that they were all due to carelessness and thoughtlessness.

ACCIDENT REPORT

While driving Dodge car, Company number E-74 south on Walnut St., Newark, I was run into by taxicab number 0973-T. E-74 had the running board smashed, front wheel broken and mudguard badly bent. The headlights on the taxi were broken. I was driving at about four miles per hour. There were no personal injuries.

(Signed) WALTER MEYERS.

ASSISTANT SUPERINTENDENT: What did you do with him?

SUPERINTENDENT: I discharged him for two reasons. In the first place I think he

was untruthful when he said he was only going four miles an hour. Why that is about as fast as a live person walks and we do not want anybody in our employ who does not tell the truth. In the second place, if he *was* going but 4 miles an hour, we don't want him around here either. He would be too damned slow to keep up with the rest of the outfit.

SUPERINTENDENT: Here is one by Isaac M. Wiser, the Troubleman.

ACCIDENT REPORT

I went to No. 295 Fifth Avenue on a trouble call. I went down in the basement. The Janitor was taking hot ashes out of the furnace and throwing them on the floor. The main switch and fuses were near the furnace. Everything looked all right so I put my fingers across the main switch to feel for current. I landed on the pile of ashes. I got right up again. I was burned where I touched the switch and I was burned where I sat on the ashes. I decided not to test for current with my fingers no more.

(Signed) I. M. WISER.

ASSISTANT SUPERINTENDENT: He should be.

SUPERINTENDENT: Some people would think that is funny. It isn't. That man might have been seriously injured.

ACCIDENT REPORT

While driving down Mt. Pleasant Avenue at 4:30 in the afternoon with truck E-89, I run over a brindle bull dog near Clark Street. It was the dog's own fault. If he had been up on the sidewalk and not in the street, he wouldn't have been runned over.

(Signed) MICHAEL BRENNAN.

ASSISTANT SUPERINTENDENT: Even dogs become careless.

SUPERINTENDENT: Yes, they have a bad example set for them by their owners.

SUPERINTENDENT: Bernie, do you know we are having a regular epidemic of accidents again? When I think of the large number of accidents we have had during the last six months and of the very serious one that cost Parker his life, well, to say the least, I am worried all the time. I sit up nights to devise ways and means to prevent accidents, and when I go to sleep I dream of "Safety" lectures, artificial respiration, prone pressure and everything imaginable about accidents and their prevention. I'll swear it's getting on my nerves.

ASSISTANT SUPERINTENDENT: Yes, I worry about them, too. I do not believe men as a whole are as careful as they used to be.

SUPERINTENDENT: Well, perhaps they are not. If they are not, it is up to us to be more vigilant. We have got to get it into the heads of the foremen that they must watch their men more carefully to see that they do not make foolish moves. Now, take that case of Parker's. If he had covered up the exposed parts around him while he was making that connection, he would be here today. He knew what to do. He covered up some of them and left others exposed. He took an unnecessary chance and that does not pay. He was a good man and a good workman and he left a nice wife and little boy. It's going to be hard for them. It is true they have a little money that they saved and they also have his insurance, but that will not last forever. It sure is hell when you think of it, and damn it, there is no excuse for it.

ASSISTANT SUPERINTENDENT: None whatever.

SECRETARY: (Takes report from typewriter which she has just written) Here is a report of one that occurred this morning.

SUPERINTENDENT: WHAT! (*Secretary hands him report which he reads*)

SUPERINTENDENT: I would like to know more about this. Bernie, step out in the linemen's room and see if any of the men that were in that gang are in.

(*Assistant Superintendent returns with Mickey, the Truck Driver*)

SUPERINTENDENT: Hello, Mickey. How are you today? Sit down.

TRUCK DRIVER: Fine, sure I'm feelin' fine.

SUPERINTENDENT: How is Mrs. Mickey and all the little Mickies?

TRUCK DRIVER: Sure they are fine.

SUPERINTENDENT: You have five children, haven't you, Mickey?

TRUCK DRIVER: No, I have six.

SUPERINTENDENT: Is that so, I thought you had five.

TRUCK DRIVER: No, there's six o' them.

SUPERINTENDENT: Michael is the older, isn't he?

TRUCK DRIVER: No, Patrick is the oldest. Now here's the way they are. Patrick is one, Michael is two, the twins is three, Mamie is four and the baby is five.

SUPERINTENDENT: I thought you had but five.

TRUCK DRIVER: No, wait a minute, wait a minute, what the hell is wrong here? (*Counting on fingers*) Patrick is one, Michael is two, the twins is three, Mamie is four and the baby is five.

SUPERINTENDENT: All right Mickey, I was sure there were five.

TRUCK DRIVER: There's six o' them, I'm tellin' ye, don't you suppose I know how many kids I've got?

SUPERINTENDENT: Well, you should know.

TRUCK DRIVER: Yes and I do know, too. Now here's the way they are. Patrick is one,—

SUPERINTENDENT: Never mind, never mind, I won't quarrel with you about a child or two more or less. You were driving for Cobb's gang this morning when an accident occurred, were you not?

TRUCK DRIVER: Sure, I was there.

SUPERINTENDENT: Then you know about the accident?

TRUCK DRIVER: Sure, I know all about it.

SUPERINTENDENT: That's fine. Now, Mickey, tell me in your own way all about it and just what you saw and did.

TRUCK DRIVER: Well, I had just gone over to me truck with a hand full of old tie wires to throw them in when I heard a lineman yellin' to beat hell. I looked up where Sweeney was working and saw him drop over like and hang there in his belt. I started to run over there and when I got about half way there, I thought, when they get him down they will want to take him away in a hurry, so I runs back to the truck, turns the switch, gives her a crank and she just gives a little sputter and stops. Then I gives her another crank, but she don't start. Then I runs back to make sure I had turned the switch, then I runs around front again and gives her a good crank. Nothing doing. Then I lifts up the engine hood and tickles the carburetor.

SUPERINTENDENT: You did what?

TRUCK DRIVER: I lifts up the engine hood and tickles the carburetor, then I cranks her again but she don't start.

SUPERINTENDENT: Then what did you do?

TRUCK DRIVER: Then I started to cuss. First I used the kind that we are all used to using. Then I cranked her again and she wouldn't start. Then I used some that you don't hear every day. Then I tried her again, then I invented some. I've done some cussin' in my day but I never did any that I was as proud of after, as the cussin' I done this morning.

SUPERINTENDENT: That's fine Mickey, I always knew you were capable. Then what did you do?

TRUCK DRIVER: Then I went over to see how Sweeney was gettin' along, but by that time they'd taken him off in the ambulance.

SUPERINTENDENT: Oh, I see. Well, what was wrong with the truck Mickey?

TRUCK DRIVER: There was a little leak in my gas pipe and when I stopped there in the morning, I turned the gas off at the valve so it wouldn't be leakin' all the time and in the excitement, I forgot all about the damned thing.

SUPERINTENDENT: All right Mickey, thank you, that's a great help. I'm glad you came in. *(As Mickey starts out, counting on fingers)* Say Mickey, after this, be careful how you run around with your gas pipe out of order.

TRUCK DRIVER: Yes sir, thank you, the same to you sir.

SUPERINTENDENT: That's a big help. We know a lot about that accident now. See if the foreman is in, will you Bernie?

(Assistant Superintendent goes out, returns with Foreman Cobb)

SUPERINTENDENT: Hello Cobb, how are you? Sit down.

FOREMAN: Not so good.

SUPERINTENDENT: Cobb, I have read the report upon the accident of Lineman Sweeney and I do not understand how he got crossed up. You say he was wearing his gloves at the time. How did he get it?

FOREMAN: Well he had changed the crossarm on the pole and was just tying the three phase primary. He had three of the wires tied in and he was reaching out to toe the wire on the end pin. He had his safety around the pole and as he could not reach the wire very well in the position in which he was standing, he kicked one spur loose and let his leg hang down and that's when he got it for his leg went right into the telegraph wires below.

SUPERINTENDENT: But I don't understand yet how he got it if he had his gloves on.

FOREMAN: Why he was lying right across the opposite phase wire and the juice went through the insulation and his shirt. That's how he got it.

SUPERINTENDENT: Oh, I see. Didn't he have any of those wires around him covered with blankets or hose?

FOREMAN: No sir.

SUPERINTENDENT: Well, don't you think it would have been much safer if they were covered?

FOREMAN: Yes, I suppose so, but that was an easy job. He had no business getting crossed up.

SUPERINTENDENT: Yes, but he got crossed up just the same, didn't he? I do not understand why you did not have him throw a blanket over those telegraph wires or put a hose on that phase wire that he had to reach over. You had plenty of them on the truck, didn't you?

FOREMAN: Not today.

SUPERINTENDENT: How did that happen?

FOREMAN: Well, we cleaned the truck out this morning and we took all that stuff off with the rest of the junk.

SUPERINTENDENT: You don't call these protective devices that we furnish to keep you fellows from getting hurt, junk, do you?

FOREMAN: No, not any more. Believe me Mr. Bentley, I learned my lesson this morning. I never had such a scare in my life. That man being hurt was just damned foolishness and from now on there will be no more chances taken by the men in my gang. I hope Sweeney will come through all right for he is a fine chap and a good lineman. We all think a lot of him.

SUPERINTENDENT: All right Cobb, do your best, don't get careless, and help me to run this job in a safe way. We must do everything possible to avoid accidents and to prevent carelessness. Thank you for coming in.

SUPERINTENDENT: I thought after Parker was killed by not using the protective devices, the men would be more careful and not take chances, but it seems I was mistaken.

(Enter Office Boy with card which he hands to Superintendent)

SUPERINTENDENT: All right, tell them to come in Frank.

(Enter Lineman and Truck Driver)

SUPERINTENDENT: Well for the love of Mike, now they are coming in pairs. Hello fellows, you are looking fine. How are you feeling? Sit down.

LINEMAN: We came down to get our pay and we thought we'd drop in for a minute.

SUPERINTENDENT: Well, that was nice of you. Haven't tried to knock any more street cars off the track lately, have you?

LINEMAN: Not lately.

SUPERINTENDENT: When I first heard about your accident, I was that mad that I could have beaten up both of you. My first inclination was to fire you and I am not sure that I have changed my mind. Have you fellows got a book of rules?

LINEMAN: Yes sir.

SUPERINTENDENT: Did you ever read it?

LINEMAN: Yes sir.

SUPERINTENDENT: Did you ever read the rule that says when trailing another vehicle you shall stay at least 20 feet back of it?

LINEMAN: Yes sir.

SUPERINTENDENT: By the looks of you two men and the front end of your truck you didn't stay 20 feet behind the street car, did you?

LINEMAN: I'll say we didn't, but boss, you should have seen the way that street car stopped. It was rolling right along about 18 miles per hour and next thing we knew, bang, she had stopped.

SUPERINTENDENT: Yes and the next thing you knew, bang, your head was through the windshield and bang, Bill's arm was broken where it jammed in the steering wheel. You were driving on the track, I suppose.

LINEMAN: Yes sir.

SUPERINTENDENT: And it had just started to rain.

LINEMAN: Yes sir.

SUPERINTENDENT: And you were trailing the car pretty closely and chinning, I suppose.

LINEMAN: Yes sir.

SUPERINTENDENT: Never thinking of an accident.

LINEMAN: No sir.

SUPERINTENDENT: And you had one.

LINEMAN: We sure did.

SUPERINTENDENT: Well; I am glad it was not more serious. It is bad enough as it is. Two good men and a truck "busted" up simply because you were careless. It was carelessness, wasn't it? Come now, be honest.

LINEMAN: Yes, I guess it was and Mr. Bentley, you don't know how sorry I feel for poor Bill with his broken arm and then he says his wife keeps giving him hell all the time and says she'll bet he was looking at some little chicken and not paying attention to his business.

SUPERINTENDENT: Some of them are good to look at, aren't they Bill? But see here, when you get over your injuries and come back to work, do be careful. Don't have accidents and help me to guard against them. I am doing everything I can to handle this job in the safest possible manner, but I cannot do

it alone and you and every other employee must help and then accidents will be avoided.

LINEMAN: All right, Mr. Bentley, we'll help. We are very sorry this happened and I guess it was all our own fault. Bill was too close to the car in front and I didn't have sense enough to tell him to stay back. Well, I guess we'll be going. Good bye.

SUPERINTENDENT: Good bye, remember your good resolutions, take care of yourselves and get back on the job as soon as possible for we miss you.

Bernie, they are two nice boys, It's a pity they had that foolish accident. They have been here a long time and have a good record.

ASSISTANT SUPERINTENDENT: Yes, they are nice boys.

SUPERINTENDENT: Now, something is going to be done. Miss Burkner, the first thing tomorrow morning, I want you to notify those in charge of accident prevention that there will be a meeting in this office at 4 o'clock Thursday afternoon, and do not confine your notices to our own department. Get men from other departments and companies. Call the Safety Director and he will give you their names and Bernie, you select some of our foremen and have them here and we will see if we cannot do something that will arouse interest and enthusiasm in the work of accident prevention. We must do more than we are doing. Now, as there are no more cripples coming in, I think we will call it a day.

(Enter Office Boy with card which he hands to Superintendent)

SUPERINTENDENT: All right Frank, tell Mrs. Parker to come in.

ASSISTANT SUPERINTENDENT: How do you do Mrs. Parker.

SUPERINTENDENT: How do you do Mrs. Parker. I am glad to see you. How are you getting along?

WIDOW: Quite well, thank you.

SUPERINTENDENT: Have you moved yet Mrs. Parker?

WIDOW: Yes, we are living with my sister now and it is very pleasant, but it is not like our own little home.

SUPERINTENDENT: No, I suppose not. How is the little boy?

WIDOW: He is well, but he misses his father very much.

SUPERINTENDENT: Yes, I suppose so, I am very sorry for you both. What are your plans, Mrs. Parker?

WIDOW: Well, I will have to find employment. That is what I came to talk to you about. The money that I have will not last long if there is none coming in.

SUPERINTENDENT: That is so. Have you any idea what kind of employment you would like to have?

WIDOW: I would like a position in an office.

SUPERINTENDENT: Have you had experience in office work?

WIDOW: Oh yes, before we were married, I held the position of secretary to the manager of the electric light company in Pennsylvania where Mr. Parker was employed. That is where I met him. I would like to get a position of that kind if I can.

SUPERINTENDENT: Are you a stenographer?

WIDOW: Yes sir.

SUPERINTENDENT: Well you came to just the right place. There will be a vacancy here the first of the week. One of our young ladies is leaving. She is to be married.

WIDOW: Do you mean that I will be employed here?

SUPERINTENDENT: Right here.

WIDOW: In this building? Right here with all of these nice Public Service people who have been so kind to me?

SUPERINTENDENT: Yes, right in the next office.

WIDOW: Oh, Mr. Bentley, thank you, that's wonderful. When shall I come?

SUPERINTENDENT: Tomorrow morning if you want to. I would like you to be here for a few days before the other lady leaves.

WIDOW: Oh, thank you, so much. Oh, Mr. Bentley, I don't know what to say. You have no idea how I was worried. It just seemed that the sun would never shine again and now it is shining.

SUPERINTENDENT: Now never mind, never mind, of course it is shining. You are going to get along fine here and we are all going to do everything possible to make you happy.

WIDOW: Thank you. I will go now.

SUPERINTENDENT: Wait a minute, Mr. Reilly is going your way and he will take you home. Here, take this to your little boy and give him my love. *(Takes apple from desk drawer and gives it to Mrs. Parker)* Keep your eye on the road Bernie. Good night.

Mrs. Parker seems like a very nice lady.

SECRETARY: Yes, she is exceptionally nice.

SUPERINTENDENT: She is pretty too. It must be nice to be young and good looking.

SECRETARY: It is.

SUPERINTENDENT: Yeh, it must be. *(Takes mirror out and looks in it)* My, I am getting old and gray and homely.

SECRETARY: No, you're not. If you would dress up and take care of yourself as you used to a couple of years ago you would not look a day over 40.

SUPERINTENDENT: You don't say so. Let me see, Miss Barker, What are your wages now?

SECRETARY: Thirty-five dollars a week.

SUPERINTENDENT: I thought so, you know I've been thinking for quite some time you were underpaid. Beginning the first of the week your wages will be forty dollars.

SECRETARY: Thank you.

SUPERINTENDENT: Do you know Mrs. Parker's new address?

SECRETARY: Yes sir.

SUPERINTENDENT: Just make a memorandum of it for me. I may want to use it some time. You might forget it.

SECRETARY: No, I won't.

SUPERINTENDENT: Well, you might.

(Secretary makes note of address and hands it to Superintendent)

You may as well run along now Miss Barker, there is nothing more today. I'm tired and I guess you are. Miss Barker, on your way out, stop in the Street Lamp Dept. and tell the Foreman the lamp right in front of my house was out at half past one last night when I came in. No, don't say that. Say it was not burning at half past one.

SECRETARY: *(Aside)* That's bad. *(To Superintendent)* You didn't have any trouble finding the house did you?

SUPERINTENDENT: No, I made it the first time.

Sorry I kept you so late. It's getting dark too. I should have told Bill to take you home. Good night, Miss Barker, be careful, don't get hurt.

CHAIRMAN RUTLAND: Gentlemen, I am sure you enjoyed this part of the program.

Next I have the honor of presenting Mr. W. H. Olschewsky, Jr., Supervisor, Western Union Telegraph Company, New York City, who will address you on typical pole accidents.

Pole Accidents

By W. H. OLSCHESKY, JR.

Supervisor Western Union Telegraph Company, New York City

Under the classification of pole accidents we find many different classes of accidents, among the more serious class being those resulting from poles falling, and it is the prevention of this class of accident which we will give consideration at this time.

While the number of accidents from poles falling according to the Western Union Telegraph Company's experience is relatively small, it is generally the case

Slide No. 1. Pike pole method of testing the pole.

that such accidents result in serious personal injury, involving considerable suffering and long periods of disability.
